Figure 7 displays the keywords co-occurrence in the domain of social media and ecotourism. Frequent words used apart from the study domain are "sustainable tourism, sustainability, tourist destination, sustainable development, tourism management, tourist behavior" as shown in Table 4. Keyword co-occurrence analysis identifies frequently paired terms within publications, revealing the thematic structure and research priorities in the field. The dominant keywords include "social media" (86 occurrences), "ecotourism" (74), and "sustainable tourism" (40), indicating a strong focus on the intersection of digital platforms and sustainability in tourism contexts. Additional recurring terms such as "tourist destination," "sustainable development," and "tourism management" reflect the multidisciplinary nature of the field, encompassing environmental, managerial, and behavioral aspects. This thematic concentration suggests that researchers are exploring how social media influences sustainable practices and tourist behavior within ecotourism frameworks. Other recurring terms like: tourist destination, sustainable development and tourism management; which show a multidisciplinary nature of the entity in terms of environmental, managerial as well as behavioral factors. This conceptual focus indicates that scholars are investigating the role of social media in sustainable practices and tourist behavior in the context of ecotourism.

Co-citations

It is very possible that two publications commonly referenced by other articles have something in common (Benckendorff & Zehrer, 2013) whenever this occurs. It is among the most common bibliometric analysis technique (Ding et al., 2001). Figure 8 represents the most significant authors in the social media and ecotourism research, and Figure 9 is the figure in which sources are represented by numbers, which are based on co-citations. Co-citation analysis reveals common pairs of cited authors and sources, which suggest common intellectual influence.

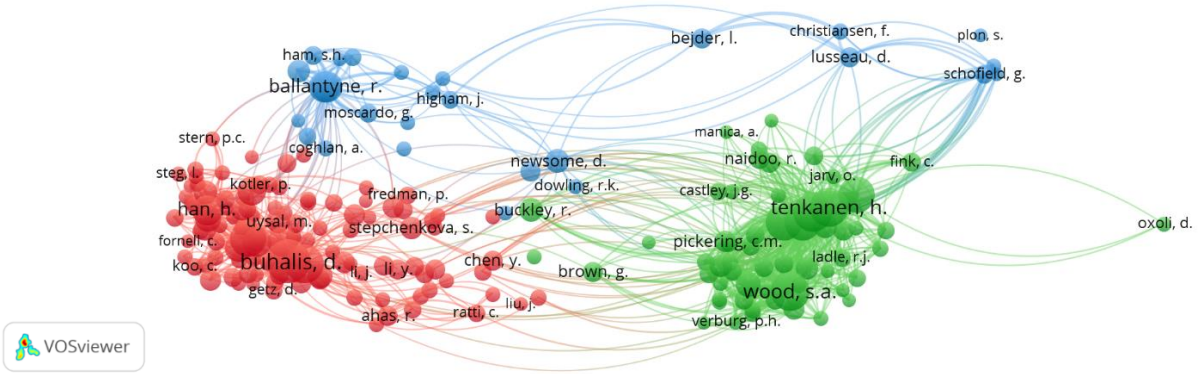

Figure 8. Co-citations analysis of Authors

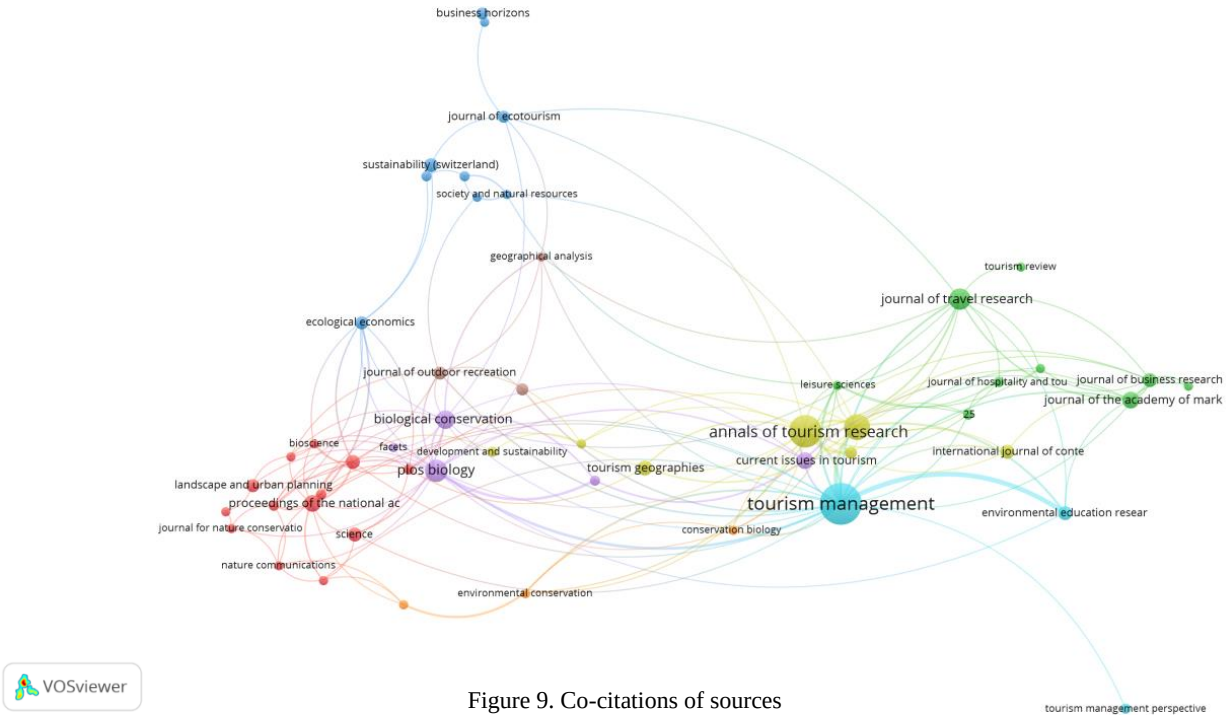

Figure 9. Co-citations of sources

The most co-cited authors are Buhalis, D. and Law, R, with 92 and 75 citation respectively, which is an indicator of their groundwork in the field. Their work is probably offering theoretical backgrounds or factual implications to later studies. Tourism Management has the highest number of co-citations with 378 others by Annals of Tourism Research and the Journal of Sustainable Tourism. These journals play a significant role in influencing academic debate and publication of powerful findings, which further support their position as top researchers in social media and ecotourism. The results are demonstrated in Table 5.

Table 5. Co-citations Analysis

Q3: The mature and emerging themes in the domain of social media and ecotourism

The thematic analysis can provide a subtle insight into the intellectual environment because the research subjects are classified according to their maturation and impact. The thematic map puts the field into context of the development between 2011 and 2025 and differentiates between niche, motor, basic, and emerging themes.

Thematic maps

The thematic map offers the understanding of patterns, trends, seasonality, and outliers of the topics studied illustrating how themes change over time (Aria & Cuccurullo, 2017). Thematic maps are simple to interpret since the themes are classified into 4 quadrants based on the centrality (X-axis) and the density (Y-axis). It has four categories of themes; and these are centered on the quadrants: Niche themes, Motor themes, Basic themes and Emerging themes.

Niche Themes

Niche themes are narrow subjects having internal coherence but low external power. They can consist of extremely specific details of social media technologies or even local ecotourism case studies that, in as much as they are well-developed, can be used on a larger scale. These themes allow to identify the areas of specific expertise that can be more extensively incorporated.

Motor Themes

The motor themes are not new and are the focus of the study area, which contributes to the academic curiosity and advancement. In social media and ecotourism, the core topics that are used as sources of research activity are sustainable tourism, tourism management. These are also mature and powerful themes which reveal the long established priorities where the role of social media in sustainability and destination management is widely researched.

Basic Themes

Basic themes are cross-cuts and are fundamental to the field and tend to describe general concepts underlying several bodies of research. Such keywords like tourism, sustainability, tourist destination, etc. are included in this category meaning that they are essential in the framing of the field. The themes offer the language of thought and conceptual foundations to different studies.

Emerging Themes

Emerging themes represent nascent or unreported themes that have growth potential. Interestingly, such notions as tourist behaviour, sustainable tourism development, and tourism industry are introduced as new themes, which implies the growing interest to the role of social media in influencing the process of making decisions by tourists, the industry and its sustainability. These aspects are promising areas of future research, and one may have a chance to focus on gaps and become innovative in theory and practice. A combination of these broadened analyses gives a wide perspective of the publication trend, main contributors, and thematic development in the area of social media and ecotourism studies and represents an exciting, interdisciplinary, and fast growing area of study.

Niche themes have topic or key words that belong to the researcher and to a large extent they are hermetic with regard to the concept that they neither affect nor are affected by other topics. The keywords are the motor themes that are well developed and can have an influence on the field of study. Simple themes represent words that may be interdisciplinary. The keywords of the new themes are unexploited or researchable. Figure 10 presents the way in which the area of social media and ecotourism (2011-2025) is clustered regarding the research topics.

The new themes that emerge in this field are tourist behaviour, sustainable tourism development and tourism industry that show that in future researchers can use these keywords to address the gaps in the research.

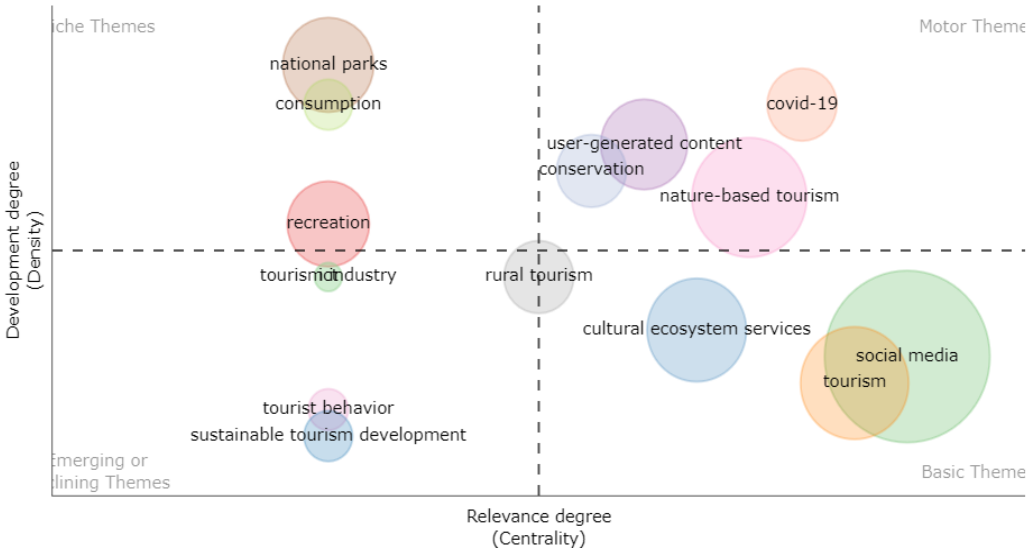

Figure 10. Thematic map

DISCUSSION

The bibliometric review on the topic of social media and ecotourism indicates that there is a strong and swift growth trend in this cross-disciplinary field in the past 10 years and 18 months. This trend of constant growth in the number of published works between 2011 and 2025 speaks of the academic interest in learning the multidimensional role of social media in determining ecotourism practices. This positive trend is in line with the distribution of the social media across the world, which have transformed the lines of communication, marketing, as well as the interaction of the stakeholders in the tourism sector. The ability of social media to enhance real-time sharing of information, complement visitor experiences, and foster conservation awareness has completely changed the dynamics of ecotourism, where it is becoming the new area of academic research. To answer the research question of the study, we conduct science mapping, performance and network analysis. To address RQ1, the methods of performance analysis such as annual trends, most popular journals, top countries, and authors were employed. Then, to carry out science mapping in response to RQ2 like strategies, including bibliographic coupling, citation analysis, co-occurrence, and co-citation were practiced. Lastly, a network analysis was performed that answers RQ3 based on a thematic map analysis. In the presentation of the facts in our findings we have given the entire picture about the literature.

The spread of the amount of research work in geographic terms reflects the global applicability of social media in ecotourism since 57 countries actively engage in publishing on the topic. The dominance of China, Australia and the United States as leaders brings out regional priorities of ecotourism as a source of economic power and source of ecological sensitivity, with the adoption of advanced research infrastructures and digital technology. The fact that there is a wide range of countries that are included in this research including Indonesia, the United Kingdom, Malaysia, and South Korea also exemplifies the international focus and multidisciplinary cooperation that drives this field of research. Nevertheless, the unequal distribution also suggests the possibility of unequal capacity to achieve research and access to resources, which implies the necessity of the wider inclusion and sharing of knowledge to promote the creation of knowledge worldwide.

The fact that all publications are concentrated in journals focused on sustainability and tourism management is an indication of a distinct thematic concentration on the issue of environmental conservation and destination management. Recent journals on sustainable tourism like the Sustainability Switzerland, and Journal of Sustainable Tourism are also important media through which the research which incorporates the role of social media and its ability to influence the goals of sustainable tourism can be shared. Such thematic orientation is an academic fixation on the possibility to use digital resources to create ecological balance, improve the engagement of the community, and control the flows of tourists.

The popularity of these journals is also an indication that they influence the research agenda and contribute to the research rhetoric in the niche. A review of the authors shows that there are a handful of prolific contributors that have largely influenced the intellectual environment of social media and ecotourism investigations. Major writers like Pickering, C.M., Gretzel, U., and Nam, Y. have been engaged consistently, leading in discussions, and making a contribution of theoretical foundations, empirical research, and methodological advances. These and other prominent scholars have established collaborative networks that allow knowledge to be accumulated, ideas to be crossed-pollinated and themes to be diversified, all of which are critical to the maturation of the field. Their contribution several times support the continuity and knowledge of scholars to promote the intricate interdisciplinary subjects.

The intellectual organization of the discipline, which is manifested in bibliographic coupling and citation studies, suggests that it is a closely knit community of scholars. The authors and countries with the highest number of citation have

developed powerful frameworks and empirical data used in the present research. The keyword co-occurrence analysis or how central to the discourse are the individual thematic clusters in terms of their importance is revealed by the prominence of sustainability, tourism management, and tourist behavior in the discourse. Such themes do not only indicate the present priorities of the field but also the sensitivity of the field to changing problems in the society and the environment. The development of the new thematic areas of research, including sustainable tourism development and industry dynamics, indicates a transition to the discussion of the more general systemic problems and practical implementation.

Thematic mapping also helps in explaining the direction that the field has been heading as the research themes can be classified into niche theme, motor theme, basic theme and emerging theme. Sustainable tourism and tourism management are motor themes that are well established, powerful, and thus make the advancement of scholarly work and innovation. Basic themes offer the background concepts that form the basis of the discipline to ensure consistency and continuity in the various studies. Although niche themes are specialized, they provide breadth and specificity, which add to the knowledge base. The topics connected with the new trends, such as tourism behavior and transformation of the tourism industry, allow seeing the perspectives of prospective research with great possibilities, indicating the flexibility and prospectivity of the field. This thematic development is a manifestation of the dynamic interaction of the development of technology, environmental needs, and changing the tourism paradigms.

CONCLUSION

By presenting a detailed and systematic analysis of intellectual framework, developmental pathway, and thematic trend of research into social media and ecotourism between the years 2011 and 2025, this bibliometric review will offer a comprehensive understanding of research on this subject area.

These results affirm that this is a growing area of study which has attained sustained and steady growth due to its growing academic significance and practical value in a digitally interconnected world. The adoption of social media culture in ecotourism activities has transformed communication trends, destination marketing relationships, modes of interaction with the tourists and sustainability promotion campaigns and initiatives, making the research field be on the crossroads of digital transformation and environmental stewardship.

This work of analysis shows that academic productivity is spread geographically, with large contributions being made by China, Australia and United States, and newcomers in southeast Asia and Europe. This dispersion depicts the worldwide applicability of ecotourism as well as the disparity in the researching abilities of different areas.

Although some countries have succeeded in building strong research infrastructures to facilitate the production of publications and high impact on their citation, the results indicate that further international collaboration and knowledge sharing would help to create even more inclusive and globally representative scholarship. Network analyses and science mapping also indicate that there exists an elaborate intellectual network that is dynamic and recurring. The central topics that have been in the discussion include sustainability, tourism management and tourist behavior which are pillars of the field. Simultaneously, new themes, especially those associated with industry transformation, digital engagement strategies, and behavioral analytics, are signs of a progressive change towards more practical and technologically integrated research agendas. The simultaneous presence of the motor, basic, niche, and emerging themes signifies a healthy and vibrant scholarly ecosystem that equally balances the theoretical progress with the practical one.

Notably, bibliographic coupling and co-citation analyses determine influential authors and publications with the highest impacts that have influenced the theoretical and methodological foundation of the field. These foundational works are continuity giving, coherent and also innovatively triggering, interdisciplinary. The high prevalence of the sustainability-oriented journals also highlights the position of the research area in the priorities of global development, such as nature protection, the sustainability of tourism governance, and the involvement of communities.

Practically, the findings highlight how social media has been transformed to become a defining factor in influencing tourist perceptions, destination branding, conservation awareness, and participatory ecotourism experiences. The role of digital platforms in the process of tourist decision-making and the sustainability of the end effect is expected to increase as they keep evolving with the addition of artificial intelligence, immersions, and real-time analytics.

Subsequent studies must thus examine more sophisticated analytical models, cross platform comparative studies and longitudinal studies in order to comprehend more about the long term effects of digital interaction on ecological conservation and tourism sustainability.

In addition, this research paper determines some channels of future research. More focus must be made in the underrepresented areas, indigenous ecotourism settings, and policy-based frameworks to incorporate the digital communication strategies and sustainable development aims. Further diversification of methodology, i.e. mixed methods, big data analytics, and experimental research, would add to the strength of the future research. International research networks can also be used to overcome knowledge gaps, and facilitate fair academic engagement. To sum up, this bibliometric synthesis does not just cover the intellectual terrain of research in social media and ecotourism but shows that it is actually becoming more mature and strategic. The study presents a useful reference point by integrating the current developments of the past and pinpointing future directions through which scholars, practitioners, and policy makers can use digital technologies to develop sustainable tourism practices. With the growing popularity of ecotourism on the world tourism policies agenda, the changing role of social media will continue to be the key to ensuring sustainable environmental, socially inclusive and economical tourism systems in the world.

Implications

This research has a lot in contribution to the field as it contributes to the overall understanding of the research development in SM and ecotourism. It emphasizes the fact that social media will have a significant role to play among not only businesses, including destination marketing organizations, but also consumers, specifically, with the emergence of such new platforms as WhatsApp, Tik Tok, Telegram, and Snapchat, which intensify connectivity and impact. Considering that most online customers use reviews and ratings before making their decision, the present study will provide destination marketers with a better insight into how social media influences ecotourism, and its promise as a strong promotional tool.

In addition, the analysis shows that there is a strong tendencies of growth in SM and ecotourism literature, which indicates the growing academic interest and highlights the dynamism of the field. Besides assisting them in determining the areas where knowledge is deficient and where future research could be conducted, this expansion offers researchers a generalized view of the existing research and the significant contributors and assists them in performing their tasks to refer to both academic and practical challenges within this field. The mapping of influential authors, journals, and thematic areas provides the study with a strategic roadmap to enable researchers to effectively carry out timely literature reviews, formulate effective research frameworks, and build fruitful collaborative networks.

The identification of new themes like tourist behavior and industry-related effects stimulates the researchers to consider the poorly developed issues that are fundamental to the further development of theoretical concepts and practical implementation. Insight into publication trends and thematic priorities can guide information-based practices to make effective use of SM in ecotourism marketing, visitor engagement, and sustainability to practitioners: destination managers, marketers, and policymakers. The discovery made in the study regarding a global distribution of research highlights the significance of the exchange of knowledge and capacity across regions. The latter is especially relevant to those areas with ecotourism potential but limited research such that the inculcation of an inclusive and context-sensitive strategy that takes advantage of social media may allow advancing conservation and community gains as well as development of sustainable tourism.

Limitations

Nevertheless, some drawbacks have to be admitted that define the context under which the results should be interpreted and future research directions should be outlined. The Scopus used as the sole source in the study limits the area of analysis since it is possible that valuable literature available in other databases like WOS or those listed on the ABDC are omitted and thus, the study could be biased in terms of the geographic and thematic representation.

Also, bibliometric analyses, though strong in quantitative terms with regard to the previous trends in publications and intellectual organization, are simply incapable of the qualitative aspects of the studies, both in terms of methodological complexity and contextual richness. The temporal scope uses projections up to 2025 partly on incomplete data in recent years which could affect the validity of trend forecast.

Also, due to the dynamism of the SM platforms and tourism practices, the bibliometric snapshots are only a window that has captured a single moment in an ever-evolving environment, thus the need to constantly update the review and integrate qualitative research to capture the full picture of emerging dynamics. The limitation of the literature to publications (books, book chapters, and dissertations) also makes it narrower, suggesting that it can be further refined in future research involving the usage of additional data sources and mixed-method designs, e.g., content analysis.

To sum it up, the present study does not only clarify some key tendencies and thematic developments in social media and ecotourism studies, but it also provides an essential background to inform the future research and practice. It will enable more circumspect, contextual and strategic progress of knowledge and practice in this ever more important intersection of digital connectivity and sustainable tourism development.

Cultural landscapes of calligraphy: The evaluation and reception of Cai Xiang's artistic legacy in the Song dynasty and its intercultural resonance for geosite-based tourism. *Geojournal of Tourism and Geosites*, 67(3), 2213–2221. https://doi.org/10.30892/gtg.67334-1846

Abstract: This study examines how Cai Xiang's calligraphic legacy, as encountered in Fujian's cliff inscriptions and related geoheritage settings, shapes visitors' historical-cultural identity, aesthetic perception, cultural pride, perceived authenticity, destination image, and heritage tourism intention. An exploratory cross-sectional mixed-methods design combined a structured visitor questionnaire with site-based qualitative interviews. The quantitative relationships were examined using partial least squares structural equation modeling, while thematic analysis contextualized how visitors interpreted geological surfaces, landscape settings, artistic form, historical continuity, and cultural meaning at the Gushan Cliff Inscriptions, the Wan'an Bridge area, and related exhibition settings. The measurement model showed acceptable reliability and convergent validity, and the structural model produced an SRMR value of 0.036. Historical-cultural identity was positively associated with heritage tourism intention ($\beta = 0.34$), aesthetic perception with destination image ($\beta = 0.52$), cultural pride with heritage tourism intention ($\beta = 0.28$), calligraphy literacy with perceived authenticity ($\beta = 0.41$), and perceived authenticity with heritage tourism intention ($\beta = 0.46$). The coefficient product for the indirect literacy-authenticity-intention sequence was approximately 0.19, although no separate bootstrapped significance test for this indirect effect was available in the reported results. Interview accounts reinforced the importance of material continuity, rock texture, landscape integration, cultural knowledge, and perceived genuineness in visitors' evaluations. The study integrates calligraphy, cultural landscape, geoheritage, and heritage tourism in a single interpretive framework. It concludes that artistic traditions materially embedded in geological settings can strengthen destination interpretation, intercultural relevance, and visitor engagement, while providing practical guidance for heritage education, conservation-oriented interpretation, and calligraphy-related geotourism in Fujian.

Keywords: calligraphy, Cai Xiang, cultural landscape, heritage tourism, destination image, authenticity, cultural identity, Fujian, cross-cultural relevance

INTRODUCTION

Chinese calligraphy is an important feature of Chinese cultural heritage containing aesthetic, historical, and intellectual values. UNESCO inscribed Chinese calligraphy on the Representative List of the Intangible Cultural Heritage of Humanity in 2009 and described it as an important cultural practice with artistic and intellectual significance in Chinese history. Even the geography of culture is influenced by calligraphy, as inscriptions cut into cliffs, temples, and natural rock surfaces form landscapes where artistic expression cannot be separated from geological inscription.

These sites may be considered geosites in that the physical characteristics of the rock surface contribute to visibility, preservation, and cultural interpretation, offering a combined form of material and intangible heritage that may attract tourists in search of historical, artistic, and scenic significance. Fujian Province provides a useful setting for studying such calligraphic geosites. Fuzhou includes Drum Mountain, known for cliffside inscriptions referred to as the Moya Shike, while the Wuyi Mountains contain extensive rock faces that have long served as surfaces for cultural expression.

These landscapes demonstrate the principles of cultural landscape theory, which views heritage locations as products of human ingenuity interacting with the natural environment, and they also relate to geoheritage discourse, which treats geological contexts as sources of cultural memory and aesthetic significance. Within this setting, the legacy of Cai Xiang (蔡襄, 1012-1067) is especially relevant. Cai Xiang was a notable calligrapher and statesman of the Northern Song dynasty who wrote the dedication tablet of the Wan'an Bridge in Quanzhou and was praised by contemporaries such as Su Shi. His standing among the Four Great Calligraphers of the Song places his inscriptions as culturally significant expressions whose value is closely tied to the geological surfaces on which they appear.

This broader heritage setting is also reflected in UNESCO-recognized sites in Fujian, including Mount Wuyi and Fujian Tulou (UNESCO, 1999, 2008). Recent research on Dujiangyan demonstrates how a Chinese cultural geosite can integrate geological heritage, historical narratives, and destination communication (Tao, 2026). Although geotourism studies have investigated how geological features underpin aesthetic meaning, visitor interpretation, appreciation, and attachment, limited attention has been given to the role of intangible cultural practices such as calligraphy in enhancing the significance and attractiveness of geosites. Investigations of calligraphy in tourism (e.g., Zhang et al., 2008), calligraphy on mountains (e.g., Qi et al., 2013), and related literature have largely treated calligraphy as a cultural symbol and a source of broader identity rather than focusing on the geological background of mountain inscriptions that enables this feature to function as a cultural tourism resource. This creates a gap in geotourism research regarding the role of artistic practices as part of geological settings that shape identity, authenticity, and heritage tourism intention among visitors. Broader relevance is visible in international calligraphy programming and in recent work showing how cultural geosites can communicate heritage narratives through contemporary destination branding (Tao, 2026; UNESCO, 2021). However, this wider relevance has not been sufficiently connected to geosite interpretation in the geotourism literature. This gap is addressed by the current study by analyzing the relationship between the calligraphic legacy of Cai Xiang, manifested across calligraphic geosites in Fujian, and visitor understandings of cultural identity, authenticity, and aesthetic experience within geoheritage settings. The study further considers the broader comparative cultural relevance of these sites within East Asian heritage contexts. Based on this framework, the study integrates geotourism theory with the concepts of cultural landscape and intangible heritage to suggest how artistic heritage embedded in geological environments may shape visitation intention.

LITERATURE REVIEW

Historical-Cultural Identity

Historical cultural identity is a feeling that one has of belonging and psychological identification with cultural traditions, surface, and heritage. It is based on Social Identity Theory (Tajfel & Turner, 1979) and Place Identity (Proshansky et al., 1983) which combined explain how individuals identify themselves with the cultural stories that transcend across space and time. In heritage tourism, identity acts as a strong motivational driver since tourists usually want to experience something that either builds up or brings out part of their cultural self.

The existing literature demonstrates that good cultural identity is a predictor of heritage consumption (Zhang et al., 2020), as guests perceive heritage sites as the continuations of their stories.

Geoheritage and geotourism research has increasingly shown that geosites worldwide are interpreted not only as geological exposures but also as cultural landscapes that shape visitor experience and conservation narratives (Chylińska & Kołodziejczyk, 2021; Gordon, 2018). In China, geopark development and national geoheritage inventories further demonstrate the scale and diversity of geosite resources, including relevant geoheritage contexts in Fujian and Longyan (Jia et al., 2023; Song et al., 2023; Xu & Wu, 2022). When discussing the calligraphic geosites in Fujian, it is possible to consider both the historical-cultural identity of Fujian and the geological environment in which the inscriptions of Cai Xiang have been preserved and exhibited. The embodied relocation of the inscriptions to the surfaces of imperishable rocks enhances the sense of continuity and authenticity so that a visitor is able to attach cultural identity to visible material continuity. People who consider Cai Xiang as belonging to their local lineage can be more strongly reminded of cultural continuity when they encounter his inscriptions carved into cliffs or natural rock, as these surfaces simultaneously evoke cultural memory and geological age (Wenzel, 2020; Zhou, 2025).

Tourists who identify with Chinese artistic heritage may likewise interpret the inscriptions through the dual dimensions of cultural symbolism and geoheritage meaning. These cultural and geological linkages imply that individuals with stronger historical-cultural affiliation to Cai Xiang and Song calligraphy are more likely to report greater intention to visit, appreciate, or support calligraphic heritage sites.

Aesthetic Perception

Aesthetic perception refers to visitors' evaluation of beauty, coherence, and artistic quality, as described in foundational aesthetic psychology (Berlyne, 1971; Reber et al., 2004). In calligraphic geosite, aesthetic experience arises from the interaction between artistic form and the geological environment. The visual field combines inscriptions on cliffs, boulders, or exposed slopes. This engagement is consistent with studies that position calligraphy as a symbolic element of cultural landscapes (Zhang et al., 2008). In the context of calligraphic forms located on natural rock, the texture, color, weathering, and geomorphological structure of the rock directly influence visitors' aesthetic responses.

Tourists tend to judge not only the artistic value of the characters but also the way they are integrated with geological landscapes. Inscriptions placed on stratified or weathered surfaces can strengthen visitors' appreciation of natural and cultural unity, thereby contributing to destination image. Visual evaluation of a geosite includes attention to landform character, rock exposure, and landscape integration, all of which contribute to the aesthetic quality of the geoheritage environment. These attributes extend aesthetic appreciation beyond artistic beauty to include geological appreciation, and the combined presence of calligraphy and natural rock forms a visual identity that shapes destination image. In this respect, visitors who experience stronger aesthetic engagement in these integrated cultural-geological complexes are more likely to develop a positive overall impression of the location. This enhanced aesthetic engagement, incorporating both cultural and geological elements, is crucial for promoting geotourism and fostering geoconservation awareness among a broader, non-specialist audience (Chylińska & Kołodziejczyk, 2021; Gordon, 2018).

Perceived Authenticity and Cultural Pride

The concept of perceived authenticity can be described as the extent to which visitors perceive that a site or experience is authentic, historically accurate, and indicative of its cultural roots (Poria et al., 2003; Wang, 1999). The authenticity of calligraphic geosites depends on both cultural and geological dimensions. The cultural aspect involves recognition of distinctive writings, artistic heritage, and associated narratives. The geological element concerns the natural surfaces on which the inscriptions appear, as the strength, stability, and weathering of the rock influence feelings of antiquity and authenticity (Gómez-Heras & McCabe, 2015). Inscriptions made on natural stone are often construed by visitors as more real because they reinforce a sense of historical continuity through tangible materiality.

For example, inscriptions on bare cliff surfaces convey a sense of origin and permanence that reproduced plaques or copies may not fully replicate. Cultural pride refers to positive esteem for one's cultural achievements or heritage. UNESCO emphasizes Chinese calligraphy as an important expression of Chinese cultural heritage, and this sense of pride often shapes how visitors relate to heritage sites. Survey participants who take pride in Chinese cultural heritage are more likely to appreciate and promote calligraphic landscapes. Cultural pride is not merely an emotional response; it also operates as a social expression linked to regional identity, historical background, and collective memory. In calligraphic geosites, the geological context can further strengthen this perceived significance, as inscriptions carved into natural rock increase the visibility of cultural achievement. Visitors may interpret these geological-cultural settings as enduring surfaces on which creative skill has been materially anchored. Therefore, perceived authenticity and cultural pride can be understood as important psychological facilitators at calligraphic geosites and as drivers of heritage tourism motivation.

Factors affecting Heritage Tourism Intention

Historical-cultural identity has been shown to strongly motivate heritage tourism behavior. Zhang et al. (2020) found that cultural identity positively affects consumption intentions in heritage tourism activities, indicating that identity is "an effective driving force to promote tourists' consumption intention". In heritage travel contexts, strong identification with the culture underpins interest in its sites. In our context, visitors (or local residents) who identify with Song-dynasty culture or Fujian's calligraphic legacy should be more inclined to engage in related tourism activities (e.g. visiting calligraphy sites, supporting preservation). We therefore hypothesize:

H1: Historical-cultural identity positively influences heritage tourism intention related to Cai Xiang's calligraphic sites.

Aesthetic appreciation of the environment and artifacts significantly shapes a destination's image. Research shows that visually appealing and harmonious sites tend to form stronger positive images among tourists (Beerli & Martín, 2004). Calligraphic landscapes, which blend art with nature, can be particularly striking where inscriptions are visually integrated with rugged cliff surfaces, exposed rock textures, and surrounding vegetation. Such aesthetic appeal can elevate the destination image of the site in visitors' minds. A positive destination image, in turn, is known to increase tourist satisfaction and intention to visit or return (Chon, 1990). Recent evidence from museum tourism likewise indicates that the attractiveness and interpretive quality of heritage settings can shape revisit and recommendation intentions across visitor groups (Chae, 2026).

H2: Positive aesthetic perception of Cai Xiang's calligraphic landscapes leads to a more favorable destination image.

Cultural pride refers to valuing one's cultural heritage. UNESCO's designation of Chinese calligraphy explicitly recognizes it as an important element of Chinese cultural heritage. In tourism and heritage research, stronger cultural valuation and identity have been linked to more positive heritage-related attitudes and intentions (Cao & Champadaeng, 2024; Zhang et al., 2020). Tourists (especially cultural insiders) who take pride in Cai Xiang's legacy may derive greater satisfaction and motivation from engaging with his sites. They may view visiting or promoting these sites as a way to honor their heritage. Thus, we posit:

H3: Cultural pride associated with Cai Xiang's legacy positively influences heritage tourism intention.

Calligraphy literacy is a proxy for how knowledgeable or skilled a person is with calligraphy. We expect that individuals with higher literacy (e.g., they can read/understand calligraphy or appreciate its techniques) will perceive cultural sites featuring calligraphy as more authentic. They are likely to recognize genuine workmanship and historical continuity. Zhang et al. (2008) emphasize that calligraphy can transmit cultural meaning and connect "a system of cultures" as a chain; literate visitors are more likely to follow that chain authentically. Hence,

H4: Greater calligraphy literacy (knowledge/appreciation) leads to higher perceived authenticity of Cai Xiang–related cultural sites.

Finally, perceived authenticity is a well-established driver of heritage tourism motivation (Poria et al., 2003; Wang, 1999). The more authentic a site experience feels, the more likely tourists are to want to visit and to have positive intentions regarding the site. In many studies, authenticity has positive effects on visitor satisfaction, loyalty, and visitation intention (Reisinger & Steiner, 2006). In our model, we treat authenticity as an endogenous mediator culminating in behavioral intention.

H5: Perceived authenticity of the calligraphic site positively influences heritage tourism intention.

Theoretical Framework

Figure 1 depicts the five a priori relationships tested in the study: historical-cultural identity and cultural pride as direct predictors of heritage tourism intention; aesthetic perception as a predictor of destination image; calligraphy literacy as a predictor of perceived authenticity; and perceived authenticity as a predictor of heritage tourism intention. Destination image and perceived authenticity are modeled as endogenous outcomes. Because destination image has no hypothesized path to heritage tourism intention, it is not treated as a mediator. By contrast, H4 and H5 jointly define an indirect literacy–authenticity–intention sequence, which is interpreted descriptively unless a bootstrapped indirect-effect test is available.

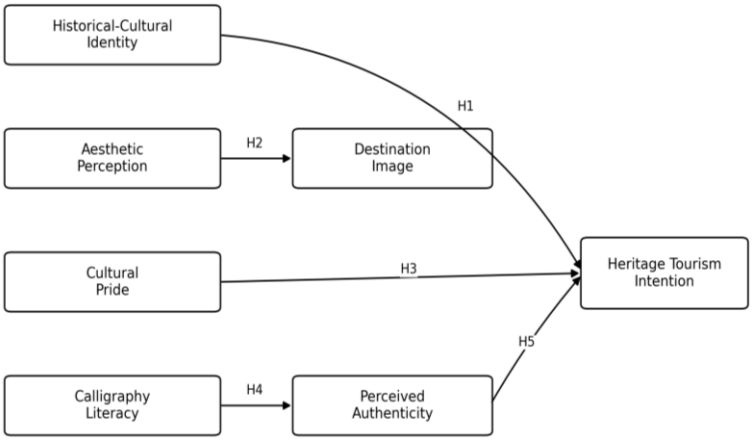

Figure 1. Hypothesized relationships in the Cai Xiang calligraphy study.

METHODOLOGY

Research Design and Site

The research is based on a cross-sectional mixed-methods design in Fujian Province, where decorative calligraphy and geological elements are closely intertwined. The design consists of a quantitative element grounded in field-collected questionnaire data and a qualitative element based on site interviews.

Both components were used to examine the proposed theoretical relationships and visitor interpretations of places such as the Gushan Cliff Inscriptions and the Wan'an Bridge area. The mixed design grounds the analysis in geosite contexts whose lithological, stratigraphic, and geomorphological conditions influence the presentation and interpretation of the inscriptions. Figure 2 provides a schematic locator map of Fujian Province and the principal study sites, while Figure 3 presents representative photographs of the cultural-geological settings.

As shown in Figure 2, the study sites include the Gushan Cliff Inscriptions near Fuzhou and Wan'an Bridge in Pingnan County, Ningde, situated within Fujian's wider topographical and cultural landscape.

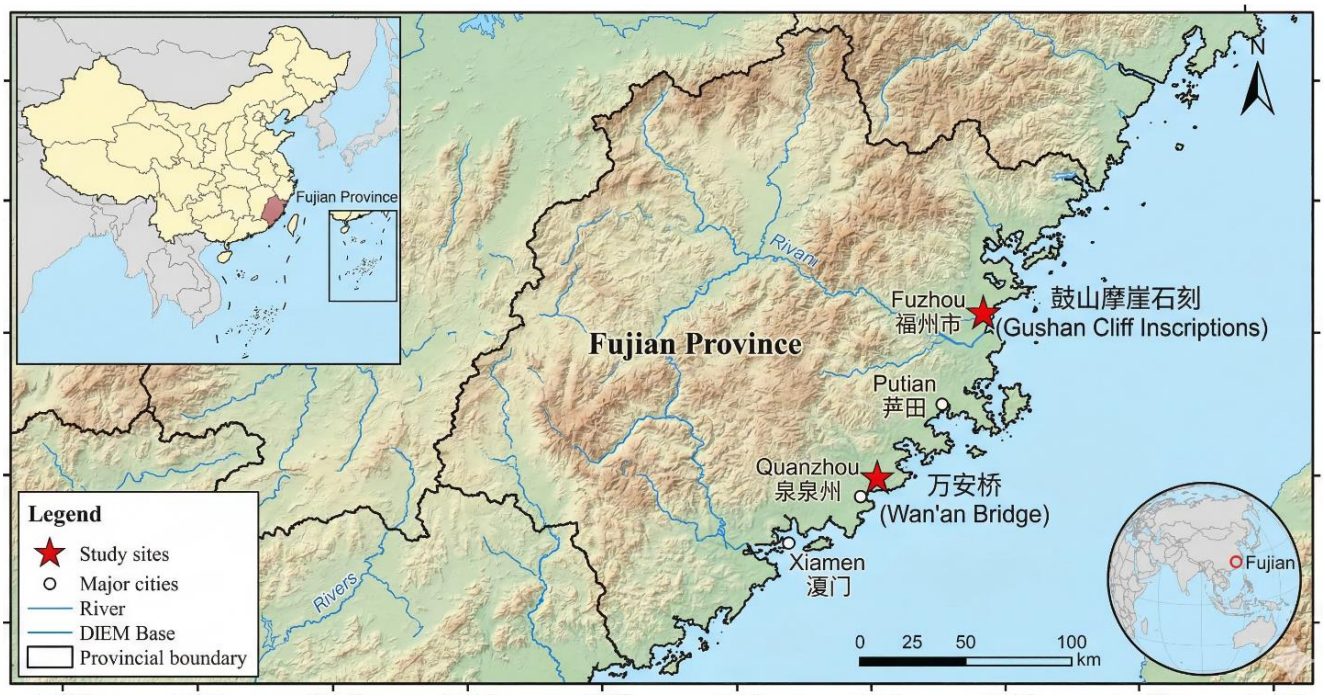

Figure 2. Schematic locator map of the study area in Fujian Province, China

Data Collection

The structured questionnaire measured identity, aesthetics, pride, literacy, authenticity, destination image, and heritage tourism intention within the proposed structural framework. The questionnaire data constitute the empirical quantitative basis of the study, while the qualitative material captures visitor interpretations where geological materiality and cultural significance intersect. Interviews conducted in the Gushan Scenic Area and related exhibition settings contextualized responses to rock surfaces, landscape form, calligraphy, and cultural symbolism. Figure 3 illustrates the principal visual settings discussed by participants.

Figure 3. Representative photographs of the study settings: (a) Gushan Moya Shike (Gushan Cliff Inscriptions), located in the scenic outskirts of Fuzhou, Fujian Province, China; (b) calligraphy and geological surface texture at Gushan Moya Shike; (c) Wan'an Bridge and its surrounding geomorphological setting in Pingnan County, Ningde, Fujian Province, China, originally built during the Northern Song dynasty (960–1127); and (d) historical calligraphy stele and bridge details at Wan'an Bridge. (Source: The authors, December 2025)

Participants

The participant information reflects the actual heritage tourism sample included in this study and shows how different age-related profiles were represented in the empirical analysis. The qualitative interviewees were real visitors, school students, guides, and cultural enthusiasts who interacted directly with the sites.

Their views provide informed understanding of how people perceive the authenticity, identity, and beauty of the writings on geological structures. Taken together, the survey data and interview evidence form the empirical basis of the study and show how these responses are expressed in real geosite settings.

Data Analysis

Partial Least Squares Structural Equation Modeling was used to examine the structure and direction of the theoretical relationships in the field-collected quantitative data. This empirical analysis was conducted to test the proposed modeling framework. The qualitative interviews were analyzed thematically to generate observations relating directly to the geosite settings. Themes of perceived authenticity, geological appreciation, calligraphic literacy, and identity were identified by carefully analyzing participants' accounts of cliff surfaces, rock textures, landscape scenery, and historical associations.

This combined analysis helps ensure that the methodological foundation is grounded in observed site-based material while the quantitative model explains the tested theoretical pathways.

Questionnaire Profile

The questionnaire items were developed as empirical measurements based on similar prior work, showing how the constructs in the proposed model were operationalized for field investigation. They were designed to capture respondents' actual views and evaluations. The qualitative data were collected at the sites to provide tangible illustrations of how visitors express identity, aesthetic judgment, authenticity judgments, and literacy through the geological and cultural aspects of the calligraphic landscape. This hybrid design allows the study to present a theoretically grounded structure supported by both quantitative and qualitative empirical data. The survey measured the following constructs (each with 3-5 items adapted from prior studies or construct definitions):

- **Historical-Cultural Identity** (e.g., "I identify with the Song-dynasty cultural heritage of this region"; "This site reflects values important to my cultural identity").
- **Aesthetic Perception** (e.g., "I find the calligraphy and surrounding landscape visually beautiful"; "The artistic quality of the inscriptions is high").
- **Cultural Pride** (e.g., "I feel proud that Cai Xiang was from this region"; "I value China's heritage of calligraphy").
- **Intercultural Appreciation** (e.g., "I appreciate the connections among East Asian calligraphy traditions"; "Knowledge of calligraphy from other cultural traditions enhances my interest in this site").
- **Perceived Authenticity** (e.g., "The site presents an authentic example of Song calligraphy"; "I feel I am seeing works attributed to Cai Xiang and other historical calligraphers").
- **Destination Image** (e.g., "This calligraphy site has an excellent overall image as a tourist destination"; "The reputation of this site is very positive").

- **Heritage Tourism Intention** (e.g., "I intend to visit this calligraphy site in the future"; "I would recommend visiting this site to others").
- **Calligraphy Literacy** (e.g., "I am knowledgeable about the art of Chinese calligraphy"; "I can read and appreciate calligraphic inscriptions").

All items used 5-point scales (1=Strongly disagree to 5=Strongly agree) and were averaged to form construct scores.

Interview Questions

The interview questions were structured to generate empirical information regarding how visitors perceive cultural and geological features of calligraphic geosites. These questions complemented the survey data and captured personal impressions of identity, aesthetics, authenticity, and cross-cultural relevance as experienced on site. The respondents were asked to explain their responses to the geological surfaces, the physical setting of the inscriptions, and the cultural heritage associated with Cai Xiang. There were also questions investigating how the interpretation of inscriptions carved on natural rock formations depends on individual knowledge, cultural background, and literacy in calligraphy. These qualitative insights therefore enrich the empirical analysis and contextualize the overall research framework.

Key open-ended questions included the following:

- "What meanings do you associate with Cai Xiang's calligraphy or this site in particular"
- "How would you describe the beauty or artistry of the inscriptions here"
- "Does Cai Xiang's legacy make you feel a stronger cultural or regional connection"
- "How authentic does this experience feel, and what contributes to that authenticity in your view"
- "How does your knowledge of calligraphy influence your appreciation of these inscriptions and their geological setting"
- "In what ways does your cultural background shape your interpretation of the inscriptions or the surrounding landscape"
- "How does the site's image or reputation influence your desire to visit in the future". These questions are directly related to the relation between cultural meaning and geological context, such as what the carved inscriptions mean to visitors in terms of rock texture, stratigraphic visibility, natural landscapes, and site atmosphere. These interviews yield qualitative information that complements the quantitative findings and supports the overall research framework.

RESULTS

Measurement Model: Reliability and Validity

All constructs showed acceptable reliability and convergent validity patterns in the empirical dataset (Table 1).

Cronbach's α values ranged from 0.80 to 0.89 (>0.70), and composite reliability (CR) ranged from 0.85 to 0.92 (above the 0.70 rule). The average variance extracted (AVE) for each construct exceeded 0.50, indicating acceptable convergent validity in the observed data. For example, Calligraphy Literacy had α=0.80, CR=0.85, AVE=0.55; Cultural Pride had α=0.82, CR=0.87, AVE=0.58; Heritage Tourism Intention had α=0.87, CR=0.91, AVE=0.62. All factor loadings (not shown) were above 0.7. Variance Inflation Factors were below 3 for all items, indicating no apparent multicollinearity concerns in the dataset. Discriminant validity was indicated by two criteria. First, each construct's AVE (square-roots values on the diagonal, omitted here for brevity) exceeded its correlations with other constructs. Second, the Heterotrait-Monotrait (HTMT) ratios were all below 0.85, indicating distinct constructs (e.g., HTMT between Identity and Intention=0.42, between Aesthetics and Image=0.40, etc.). These patterns suggest that the measurement model is acceptable for empirical analysis. Structural Model: Path Analysis. The PLS-SEM structural model showed acceptable approximate fit (SRMR = 0.036). All five hypothesized paths were positive and statistically significant (Table 2 and Figure 4).

Table 1. Reliability and convergent validity of constructs

Construct	Cronbach's α	Composite Reliability	AVE
Historical-Cultural Identity	0.88	0.92	0.65
Aesthetic Perception	0.85	0.89	0.60
Cultural Pride	0.82	0.87	0.58
Intercultural Appreciation	0.81	0.86	0.59
Calligraphy Literacy	0.80	0.85	0.55
Perceived Authenticity	0.89	0.92	0.68
Destination Image	0.86	0.90	0.60
Heritage Tourism Intention	0.87	0.91	0.62

Table 2. Path coefficients for hypothesized relationships (β = standardized estimates)

Hypothesis	Path (Effect)	β	t-value	p-value
H1: Identity → Intention	Historical-Cultural Identity → Heritage Intention	0.34	3.45	<0.001
H2: Aesthetic → Destination Image	Aesthetic Perception → Destination Image	0.52	5.10	<0.001
H3: Pride → Intention	Cultural Pride → Heritage Intention	0.28	2.99	0.003
H4: Literacy → Authenticity	Calligraphy Literacy → Perceived Authenticity	0.41	4.15	<0.001
H5: Authenticity → Intention	Perceived Authenticity → Heritage Intention	0.46	5.80	<0.001

All five hypothesized relationships were consistent with the modeled directions. Historical-cultural identity was positively associated with heritage tourism intention (β = 0.34, t = 3.45, p < 0.001), supporting H1. Aesthetic perception was positively associated with destination image (β = 0.52, t = 5.10, p < 0.001), supporting H2. Cultural pride was

positively associated with heritage tourism intention (β = 0.28, t = 2.99, p = 0.003), supporting H3. Calligraphy literacy was positively associated with perceived authenticity (β = 0.41, t = 4.15, p < 0.001), supporting H4. Perceived authenticity was positively associated with heritage tourism intention (β = 0.46, t = 5.80, p < 0.001), supporting H5. For the two single-predictor equations, squaring the standardized coefficients yields coefficient-based explained-variance estimates of approximately 0.27 for destination image (0.52^2) and 0.17 for perceived authenticity (0.41^2). The intention R^2 cannot be reconstructed from the reported path coefficients alone because the intercorrelations among its predictors are unavailable. The product of the H4 and H5 coefficients (0.41 × 0.46) yields an indirect-effect estimate of approximately 0.19 for the literacy–authenticity–intention sequence. Because no bootstrapped confidence interval or p-value was reported for this indirect effect, it is interpreted descriptively rather than as a formally tested mediation effect.

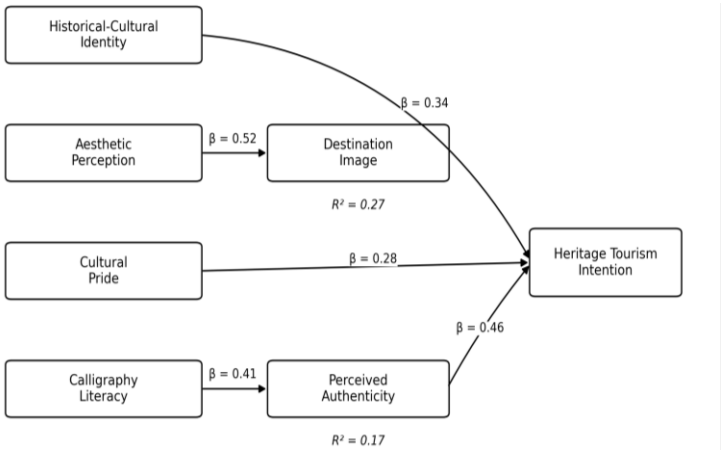

Figure 4. PLS-SEM results for the five hypothesized relationships. Values on the arrows are standardized path coefficients; R^2 values are coefficient-based estimates for the two single-predictor endogenous constructs. The literacy–authenticity–intention coefficient product is 0.19.

Interview Insights

Interview respondents were broadly consistent with the quantitative pattern observed in the empirical model. A local resident said, "Knowing that Cai Xiang lived here makes me feel connected to history; I want tourists to come see our old calligraphy and feel connected, as if we are stewards of this heritage" (identity/pride theme). An art student noted, "I've studied different East Asian calligraphy traditions; seeing these inscriptions makes me appreciate their authenticity. It's not like a reproduced museum display; you feel the brush in the stone."

This remark underscores the importance of calligraphy literacy and authenticity. Another visitor commented on the site's aesthetics: "The characters carved into the gray rock under green pines look amazingly beautiful and peaceful; it really gives this place a unique image." Such qualitative data provide contextual support for the findings: identity, literacy, and aesthetics were linked to cultural valuation, authenticity, and desire to promote the site.

DISCUSSION

The findings should be interpreted as empirical results derived from the quantitative and qualitative data collected in this study. The observed patterns suggest how the legacy of Cai Xiang as a calligrapher may influence the idea of cultural tourism in Fujian Province (Zhang et al., 2023). Cultural identity was positively associated with intention in the empirical model (H1), which is consistent with the result of Zhang et al. (2020) who stated that strong cultural identity increases heritage consumption intentions. Interviewees who perceived some personal or collective connection to calligraphy of the Song period spoke of cultural valuation and connection that could lead to greater desire to frequent related sites. This underscores the role that social identity can play in responses to calligraphic heritage in site-based visitor data (Chen, 2022). Destination image was also strongly shaped by aesthetic responses (H2). This aligns with the view that visually appealing attractions foster favorable cognitive images. This can be seen in the Gushan inscriptions, where the great longevity character attributed to Zhu Xi stands out on the cliffs (Xie et al., 2022). Visitors also used a variety of descriptive terms for the scenery, referring to both artistic and geological features, including the texture and color of the rock surface and the surrounding natural environment in which the characters appear. This is consistent with Zhang et al. (2008), who describe calligraphic works as symbolic elements of landscape. Geomorphological features such as the form and display of the rock faces contributed to the visual harmony experienced by visitors, even though destination image was not modeled as a direct source of intention.

Cultural pride also appeared relevant in the empirical model (H3). As expected, respondents who expressed strong cultural valuation of Chinese calligraphy were more likely to appreciate the legacy of Cai Xiang, which is in line with the recognition of calligraphy as an important element of Chinese cultural heritage (Cao & Champadaeng, 2024). Some of the interviewees attributed this valuation to the enduring presence of inscriptions on geological features and therefore based their sense of authenticity and cultural richness on that material continuity. These responses indicate that the emotional meaning of the sites can be reinforced by the fact that the sites are geologically stable and stratigraphically visible.

It is also noteworthy that the role of calligraphy literacy (H4) showed a clear positive pattern. Participants with greater knowledge or experience in calligraphy tended to perceive the sites as more authentic. This observation is in line with

Zhang et al. (2008), who note that calligraphy creates a cultural continuum through which literate tourists can engage more deeply. Those interviewees who realized the richness and regularity of cut lines usually credited this to the skill of historical calligraphers and to the suitability of the rock surfaces on which they were inscribed. These observations indicate the role played by lithological conditions such as hardness and weathering patterns in supporting authenticity judgments (Gallinaro & Zerboni, 2021). As a manager, one can offer learning materials to enable visitors to appreciate these geological and artistic features. Heritage tourism intention (H5), which was also aligned with heritage tourism theory (e.g., Poria et al., 2003), was strongly associated with perceived authenticity. Visitors who felt that the inscriptions were authentic and in well-preserved condition were more likely to visit, recommend, and support the sites. Geological features were relevant here as well. The physicality of the inscriptions being incorporated within the cliff faces, as well as the natural layers that could be seen under certain carvings, heightened the sense of antiqueness and authenticity. These conditions shaped authenticity judgments, which emerged as the strongest predictor of intention in the empirical model.

Overall, the results indicate distinct roles for historical-cultural identity, aesthetic perception, cultural pride, calligraphy literacy, destination image, and perceived authenticity. The qualitative responses show that these constructs are experienced within a geological environment characterized by lithological, stratigraphic, and geomorphological features. Perceived authenticity forms a plausible intermediate link between calligraphy literacy and heritage tourism intention, but the indirect relationship remains descriptive because a bootstrapped indirect-effect test was not reported. A possible cross-cultural dimension also appeared in comparative references to wider East Asian calligraphy traditions. Future research should test these cultural-geological mechanisms with fuller comparative and longitudinal designs.

CONCLUSION

This research suggests that cultural landscapes typified by the heritage of calligraphy in Fujian and the legacy of Cai Xiang may meaningfully shape tourism-related responses when interpreted within geosite settings. According to the tested model, identification with historical tradition and aesthetic sensitivity toward calligraphy in relation to geological surfaces could increase interest in heritage tourism. Calligraphy literacy also appears to strengthen authenticity judgments, which should be valued in understanding the responses of visitors who read inscriptions engraved on natural rock formations and scenic landscapes. The PLS-SEM results are based on field-collected data and provide empirical support for the proposed relationships within geosite settings. These findings indicate that research on the impact of artistic traditions carved into geological features on visitor learning in geoheritage sites is likely to have value.

Implications

Theoretically, this work bridges art history and tourism research, illustrating how an intangible art form can be treated as a destination attribute in a behavioral model. It aligns with UNESCO's emphasis on calligraphy as intangible cultural heritage and extends Zhang et al.'s (2008) notion of calligraphy as a landscape medium. Practically, the results suggest marketing strategies: tourism promoters should highlight Fujian's Song calligraphy heritage in brochures and tours, emphasize the beauty of calligraphic sites (e.g., in images and narratives), and educate tourists to enhance authenticity perceptions. The preliminary comparative interest noted in the qualitative material suggests potential for broader regional cultural programming—for example, cross-regional calligraphy dialogue events or comparative heritage interpretation initiatives.

Limitations and Future Research

This empirical study has limitations. Although the data were field-collected, the sample was drawn from selected sites in Fujian and should therefore be interpreted within its contextual scope. The model includes only selected factors; future work could incorporate others (e.g., leisure motivation, social media influences). The cross-cultural aspects were addressed indirectly; a fuller comparative design across multiple East Asian contexts would better capture differences. Longitudinal designs could assess how visitor responses change over time or after targeted interventions (like installing calligraphy exhibitions). Future research might also explore other calligraphers or dynasties, and test the model in different geosite contexts. Despite these caveats, the present findings offer a comprehensive portrait of how a calligraphic cultural landscape can shape tourist behavior, providing a foundation for further empirical work and for practical efforts to leverage calligraphy heritage in geotourism.

Abstract: Independent travel is one of the fastest-growing segments of international tourism, yet its institutional determinants remain under-researched in emerging destinations. This study empirically assesses, using the case of Uzbekistan, how visa policy openness and the tourism service ecosystem influence the flows of independent travellers and the dynamics of international arrivals. For the period 2015-2024, a Visa Openness Index (VOI) was developed for 12 countries: visa-free length-of-stay provisions were coded into ordinal indicators and normalized to a 0-1 scale using cosine similarity against an ideal benchmark vector. Subsequently, a random-effects panel regression model was estimated for 11 countries to evaluate the relationship between the dynamics of the visa-free regime, VOI and arrivals, while controlling for time effects and external shocks. The results reveal substantial cross-country variation in openness levels and confirm that Uzbekistan's VOI is approximately 0.84, among the five most open in the sample despite its low passport power. The regression estimates indicate that an expansion in visa-free regime coverage exerts a positive and statistically significant effect on arrivals ($\beta \approx 0.0097$; $p < 0.05$), whereas pandemic and crisis factors reduce flows. At the micro level, a Delphi process involving 15 experts assessed the importance of 31 service elements for independent tourists and identified digital information services (GIS applications, Wi-Fi, infokiosks), online booking, affordable accommodation, local mobility and parking and charging infrastructure as priority gaps. By integrating macro-level visa policy and micro-level service priorities, the study shows that visa liberalization raises arrivals only where the service ecosystem can absorb the additional demand, offering practical guidance for destination managers in emerging tourism economies.

Keywords: independent travellers, visa liberalization, visa openness index (VOI), panel regression (random effects), Delphi method

INTRODUCTION

The travel and tourism sector is measured one of the most dynamic and transformative industries of the global economy in the 21st century. According to the WTTC report (World Travel & Tourism Council) the sector contributed USD 9.9 trillion to global gross domestic product through direct, indirect and induced impacts which accounts for nearly 10% of the entire global economy in 2024 (WTTC, 2024). This indicator confirms that the post-pandemic recovery process has been rapid, also consistent in terms of cross-sectoral integration. Tourism also has a strategic economic role in the global labor market. More than 348 million jobs worldwide which constitutes nearly one-tenth of total employment in 2024 (WTTC, 2024). From a macroeconomic perspective the value of tourism chain is multi-sectoral and brings the transport, accommodation, food service, cultural and recreation services, logistics, trade, communication, financial sectors together into an integrated system (Sutomo et al., 2023). In particular, domestic tourism spending amounted to USD 5.3 trillion in 2024, increasing by 5.4% compared to the previous year. International tourism spending rose by 11.6% to reach USD 1.9 trillion (WTTC, 2024). These results make it possible to characterize tourism as one of the leading drivers of post-pandemic economic recovery. Together, structural changes in the global tourism system are becoming increasingly pronounced. The share of independent travellers has been steadily increasing and generating new segmentation processes on the demand side of international tourism (Huang et al., 2025). Their spending pattern, service selection mechanisms,

infrastructure requirements and mobility characteristics differ fundamentally from those of traditional organized tourism. Therefore, an in-depth analysis of needs of independent tourists, the level of importance of services, the impact of visa policy on their behavior is of strategic significance in contemporary tourism management.

Independent travellers as a new market segment

The word of the independent traveller also explains the fact that they usually organizes their own trips autonomously. Usually, they purchase services directly through digital platforms and shape the tourism experience in line with their personal interests (Kupi & Bako, 2024). In this sense, they represent a demand group with high elasticity within the tourism sector. The rapid expansion of independent travellers is also explained by global demographic shifts (Li et al., 2019). The strong interest in travel among representatives of the millennial and generation Z cohorts increased purchasing capacity and the rising level of access to information via the internet is forming a substantial demographic base for this segment. These generations interpret travel as consumption, also as learning, self-development, exploration and a social experience (Fan et al., 2022).

Studies show that independent tourists have lower average daily expenditures, however their trip duration tends to be longer than that of traditional tourists (Yang et al., 2021). As a result, their overall economic contribution in many cases becomes comparable or in some instances, even higher. In addition, spending of independent tourists is distributed in a more dispersed manner across different service categories, which contributes to the revitalization of local small businesses and the informal economy. Another important aspect of this segment is its high spatial dispersion. Independent travellers often visit peripheral areas beyond popular centers, less-explored places and ecologically sensitive territories (Cheer, 2022).

In the context of Uzbekistan, the segment of independent travellers has been expanding from year to year. The simplification of visa policy, the increase in the number of low-cost flights, the development of online booking systems and the growing interest and creating new opportunities for this segment. This, in turn, makes it an urgent task to study, on a scientific basis, the needs of independent travellers in the country and their service-related behavior.

Transport connectivity, digital information systems, the diversification of accommodation facilities and the level of development of safety services directly affect the volume and composition of tourist flows (Sun et al., 2025). Share of independent travellers is increasing, demand becomes even more relevant, as they rely heavily on services such as high-quality Wi-Fi, infokiosks, online booking systems and low-cost and flexible transport networks. Nevertheless, in many developing countries, including in Uzbekistan, the deficient progress of these services is creating significant infrastructural barriers for independent tourists. In addition, visa policy has been recognized widely in the academic literature as one of the key determinants shaping global tourist flows (Rosselló & Santana-Gallego, 2024; Tz-Li et al., 2025). Simplified visa procedures such as visa-free regimes, e-visas and visa-on-arrival mechanisms expand international mobility, reduce bureaucratic costs in travel planning and improve the destination's image.

LITERATURE REVIEW

Independent travellers: theoretical foundations and evolution

The phenomenon of independent travellers began to take shape in tourism theory from the second half of the 20th century and scholarly roots can be traced primarily to early classical studies aimed at typologizing tourist motivations and forms of mobility (Huang et al., 2025). Cohen's (1972) classification of tourism experiences associated independent tourists with "organic", "drifter" or "innovator" types of travellers. Interpreting them as a group that moves independently of traditional, organized tour packages and seeks a decentralized experience. This approach subsequently provided an academic foundation for analyzing the socio-cultural nature of independent travel, the process of autonomous decision-making and the characteristic of self-planning itineraries. Thieme et al. (2021) characterizes independent travellers particularly backpackers and low-budget tourists as categories that make a substantial contribution to the tourism economy in developing countries through budget accommodation, local transport and street gastronomy. According to his studies, despite their relatively low purchasing power, independent tourists often generate an overall economic footprint that in many cases becomes comparable to or even exceeds than of consumers of traditional tour packages, because their travel duration is longer (Yang et al., 2019). This positions independent travellers as an important market segment for local small-scale service providers, including guesthouses, homestays, street-food vending and alternative transport services. Chen et al. (2022) links the evolution of independent travel to postmodern mobility theory and interpret it as a direct product of digital technologies, social media and globalization processes. Independent travellers create a new form of transnational mobility - they move outside centralized tourism infrastructure and in many cases make decisions based on the social networks of diasporas, online platforms (Booking, Airbnb, Couchsurfing) and crowd-sourced information resources (TripAdvisor, Maps.me, blogs) (Sutyrina et al., 2021). Another distinctive feature of independent travelling is its internal segmentation. The group encompasses sub-segments such as backpackers, flashpackers, poshpackers, exploratory travellers, adventure travellers, digital nomads and budget travellers (Richards, 2015; Adam et al., 2021). The service priorities, expenditure patterns, risk tolerance, spatial mobility characteristics and infrastructure needs of each sub-segment differ markedly. For instance, flashpackers tend to prefer high-quality internet access, digital services and premium halal services whereas for budget or explorer categories, local transport, low-cost food services, and micro-accommodation facilities are of primary importance (Richards, 2015).

Tourism infrastructure and service ecosystems

Russo et al. (2025) define tourism infrastructure as a multidimensional, relational and dynamic entity that shapes destinations and mobilities. Because this system ensures tourists' freedom of movement, access to information, connectivity with services and a secure environment (Ibragimov, 2024). In particular, for independent travellers the quality of infrastructure

is even more critical, as they rely not on centralized service delivery channels, but on digital navigation, local transport, flexible accommodation and high-speed internet. For this reason, infrastructure deficiencies can function as a "bottleneck" precisely for independent travellers and can constrain a destination's competitiveness (Knežević et al., 2015).

Contemporary research also emphasizes that there is a strong economic relationship between infrastructure indicators and tourist flows. For instance, Zhang & Zhang (2022) found that the quality of transport infrastructure can increase international tourist flows by up to 15-25%. Polukhina et al. (2020) similarly demonstrate that information technologies act as the leading innovative factor in the development of independent tourism, since digital platforms replace the intermediary functions traditionally performed by tour operators. Digital infrastructure increasingly regarded as a new determinant of competitiveness (Cheer al., 2022). This process is particularly salient for independent travellers as they manage almost all stages of travel through digital resources: itinerary design, transport booking, accommodation, payments, navigation, safety and communication. Another important characteristic of the service ecosystem is its deep integration with the local economy. The tourism service system interacts directly with local small businesses, street trade, homestays, supplementary leisure services, local transport operators and digital start-ups (Milwood & Maxwell, 2020). Therefore, improving infrastructure enhances the tourist experience and generates positive multiplicative effects in the local economy.

Visa openness and tourist mobility

Visa policy is recognized as one of the most significant institutional elements of international tourism, as it directly defines the opportunities, cost and bureaucratic requirements of cross-border mobility between countries. Visa liberalization leads to a significant increase in tourist arrivals and changes in behavior patterns, as independent tourists are freed from tour group constraints (Liu & McKercher, 2015). Empirical studies indicate that mechanisms such as visa-free regimes, e-visas and visas on arrival play a significant role in tourists' destination choice and that such liberalization measures can generate an additional 5-25% increase in tourist flows (Yudhistira et al., 2020; Turaev et al., 2023). The principal scholarly conclusion of this study is that the existence of visa requirements intensifies additional financial costs, time expenditures, uncertainty and psychological barriers for tourists, thereby sharply reducing a destination's level of attractiveness. By contrast, simplified visa procedures accelerate tourists' decision-making processes and create positive signals in the evaluation of travel costs.

According to their study, visa openness increases tourist flows, also reinforces external economic relations, investment inflows (Akman, 2016). This makes it possible to interpret visa policy beyond a narrow tourism-related scope, as an instrument of broader economic diplomacy. Visa policy also plays a direct role in shaping a destination's image. A simplified visa regime strengthens a country's profile as an "open economy", a "safe destination" and a "tourist-supportive environment" (Kim et al., 2023). Such image marketing is especially influential for independent travellers, as they gather information autonomously, compare alternative destinations and prefer minimal barriers in terms of visa requirements.

Existing gaps in the literature

Despite the existence of extensive scholarly literature on tourism, a number of significant research gaps remain regarding independent tourists' behavior, their interactions with the service system and processes related to visa policy. These gaps are particularly pronounced in the context of Uzbekistan.

First, a large share of existing research on the independent travellers segment is conceptual or ethnographic in nature and there are very few studies that empirically model their priority needs within the service system, inter-segment differences and infrastructural requirements. Most studies focus on narrow sub-segments such as backpackers or digital nomads, while a systematic model that encompasses all categories of independent tourists especially a comparative approach in terms of service importance is almost absent in the scholarly literature. Second, although the literature on the relationship between tourism infrastructure development and the effectiveness of service ecosystems is relatively extensive. These studies do not specify service types and levels of importance that are distinctive to the independent travellers segment. Scholarly works more often analyze macro-level infrastructure indicators (air connections, transport connectivity, hotel capacity) whereas non-traditional services that are particularly relevant to independent tourists: infokiosks, Wi-Fi zones, geographic information systems, parking facilities, micro-accommodation options and alternative transport have not been sufficiently examined as distinct objects of research. Third, visa policy process has not been explored in sufficient depth in the context of Uzbekistan, scholarly works that analyze the quantitative relationship between visa policy openness and tourist flows on the basis of multi-year (panel) data are virtually absent. Available statistical reports are mainly descriptive in nature and do not identify causal relationships between tourism flows and visa liberalization policies. Fourth, many studies in the literature examine separate directions behavior of independent tourists. Infrastructure development and the impact of visa policy in isolation whereas research that integrates these three dimensions within a single analytical model is rare. This limits the possibility of analyzing the tourism system through a holistic approach.

METHODOLOGY

The methodological foundations of this study relied on step-by-step scientific investigations conducted over the period 2022-2025, systematic data-collection processes and the integration of two types of empirical methods. Over three years, the research encompassed the collection of extensive data on Uzbekistan's tourism market service system, the behavior of independent travellers, changes in visa policy and the dynamics of inbound foreign tourist flows.

Methodology for quantifying visa openness

To quantitatively assess countries' visa policies, the study applied a specific mathematical method developed on the basis of a vector-indicator approach (Rosselló & Santana-Gallego, 2024). The main objective of the method is to represent

different visa-free stay-duration indicators within a single mathematical model and to evaluate their level of visa openness on a 0-1 scale. The method is implemented through the following sequential stages (Table 1).

Table 1. Stages of the VOI calculation methodology(Source: Compiled by the authors based on the vector-indicator approach of Rosselló & Santana-Gallego (2024) and Kim et al. (2023); the cosine similarity measure follows the standard vector-space formulation)

Stage	Name	Description	Mathematical expression
1	Data Collection	Collect visa-free stay durations for each country (96 hours, 7 days, 10 days, 14 days, 15 days, 20 days, 21 days, 30 days, 45 days, 59 days, 60 days, 90 days, 6 months, 1 year, unlimited, etc.). Component: d - individual visa-free stay duration values collected for each country	*Raw data:* $d_1, d_2, d_3, \ldots, d_n$
2	Benchmark Vector Construction	Construct a benchmark vector using maximum values of all visa-free durations. This serves as the reference criterion. Components: b - benchmark vector representing the ideal fully open visa policy; b_k - maximum observed value across all countries for duration category k; k - index referring to a specific duration category (k = 1, 2, ..., n)	$b = (b_1, b_2, \ldots, b_n)$ *where* $b_k = max(d_k)$
3	Country Vector Formation	Express each country's visa policy indicators in vector form. Components: a_i -Visa-free stay vector for country i	$a_i = (a_{i1}, a_{i2}, \ldots, a_{in})$ i = *country index* n = *number of indicators*
4	Cosine Similarity Calculation	Calculate the similarity between country vector and benchmark vector using cosine similarity formula. Components: β_i - index (0-1) Visa Openness Index (VOI) for country i - the final output score a_{ik} - number of countries granted visa-free access under duration category k by country i The cosine similarity measure applied at Stage 4 follows the vector-space formulation widely used in composite-index construction and was adapted to visa policy indicators following Rosselló & Santana-Gallego (2024).	$\beta_i = \frac{\sum_{k=1}^{n}(a_{ik} \cdot b_k)}{\sqrt{\sum_{k=1}^{n} a_{ik}^2} \cdot \sqrt{\sum_{k=1}^{n} b_k^2}}$
5	Index Interpretation	Interpret the resulting VOI value: $\beta_i \to 1.0$: Most open visa policy $\beta_i \to 0$: Closed or highly restrictive $\beta_i = 0$: No visa issued	$VOI \in [0, 1]$ *0 = Closed 1 = Fully Open*

Panel Data Modelling of international tourist arrivals

This study uses annual data for 11 countries over the period 2015-2024. In working with panel data, the following key factors were taken into account (Eugenio-Martin & Patuelli, 2022) (Table 2). A comparable regional panel approach was applied by Heryana et al. (2026) to ASEAN economies, where crisis episodes were introduced as dummy variables to isolate structural breaks in tourism performance, a specification directly analogous to the crisis control adopted in the present model.

Table 2. Panel Data Model specification for international tourist arrivals
(Source: Model specification developed by the authors following Eugenio-Martin & Patuelli (2022). Data: international tourist arrivals - UN Tourism (2025); visa-free regime indicators - Passport Index (2025); crisis dummy - constructed by the authors)

Data structure	
Sample	11 countries, 2015-2024 (N=11, T=10)
Key factors	Inter-country variability; time variability; institutional shocks (pandemic, political)
Model specification	
General equation	$y_{it} = \alpha + \beta X_{it} + \gamma Z_{it} + u_i + \epsilon_{it}$
Variable definitions	
y_{it}	Number of inbound foreign tourists in country i, year t (dependent variable)
X_{it}	Annual change in visa policy openness (independent variable)
Z_{it}	Dummy indicator for pandemic/political crises (control variable)
u_i	Country-specific, time-invariant random effect
ϵ_{it}	Idiosyncratic error term
Random Effects (RE) Model Rationale	
RE assumption	$u_i = (du_1, du_2, du_3, \ldots, du_{11}) \sim$ *uncorrelated with* X_{it}
Selection criteria	(a) u_i uncorrelated with regressors; (b) Cross-sectional differences enter stochastically; (c) Allows consistent treatment of income, demographic, geographic factors

Delphi method for identifying service priorities among independent travellers

Because the service needs of independent traveller segments differ markedly, the functions of these services are multifaceted and the service delivery system has a complex inter-segment structure, identifying which services they consider priorities cannot be adequately measured using simple statistical approaches. Therefore, the study employed the Delphi approach that a method based on expert consensus (Hamm, 2021).

Composition of experts

For the study, 15 experts were purposively selected and engaged. They comprised the following groups, all of whom have in-depth knowledge of tourism practice and independent travellers' behavior: a) international and domestic tour operators (5 experts); b) experienced guides and tourism practitioners (4 experts); c) specialists from the hospitality and

transport sectors (3 experts); d) academic researchers in tourism (3 experts). The experts were selected through purposive sampling that only individuals directly relevant to independent traveller segments and possessing sufficient experience and practical expertise were engaged. This selection ensured the reliability of the method and the alignment of the assessments with real market experience. The Delphi method was applied in the study as a three-stage iterative cycle (Table 3).

The experts' final consensus was calculated using the following average formula (Salotti & Suhir, 2024):

$$S_{jk} = \frac{1}{15}\sum_{r=1}^{15} s_{jk}^{(r)}$$

S_{jk} - the final consensus score of service j for segment k; $s_{jk}^{(r)}$ - the rating provided by each of the 15 experts; 15 - the number of experts.

Table 3. Three-round Delphi process applied in the study

Stage	Stage title	Key procedures and content	Output
Stage 1	Initial assessment	- The 15 experts were presented with segments of independent travellers. - 31 service types were also provided. - Each expert rated the services using a 3-point scale: "very important", "important", "not important". - Ratings were collected independently, individually and anonymously.	Initial overall trends regarding services were identified.
Stage 2	Processing of ratings and second round	- All ratings from the first round were aggregated. - Segment-level differences, inter-expert discrepancies and overall distinctive patterns were identified and organized into an analytical format. - The processed results were sent back to the experts. - Experts were given an opportunity to review others' assessments and to revise their own judgments.	Experts' opinions began to converge, changes started to be minimized and the stabilization process commenced.
Stage 3	Reaching consensus	- In the third round, ratings stabilized to a substantial extent. - Final expert agreement was established. - Consensus was determined through minimal changes and convergence of opinions.	The services were classified into three groups: 1) very important, 2) important, 3) not important. This classification subsequently provided the basis for developing 15 empirical regularities.

RESULTS AND DISCUSSION

Results - introductory analytical justification

In analyzing international tourism flows and the structure of mobility, countries' passport power is regarded as one of the initial institutional indicators of global mobility. Passport power, determines the degree of cross-border freedom enjoyed by a country's citizens (Nitsch, 2019). Therefore, when presenting the research results, it is first necessary to demonstrate how global mobility inequalities have been formed, because it provides a methodological basis for explaining the impact of visa policy openness on tourist flows. This study quantifies visa openness in the subsequent sections using a specific mathematical model (vector-cosine similarity). For this reason, Figure 1 illustrates sharp differences in cross-border mobility across countries, how the mobility opportunities of independent travellers are constrained and where global inequalities are formed spatially.

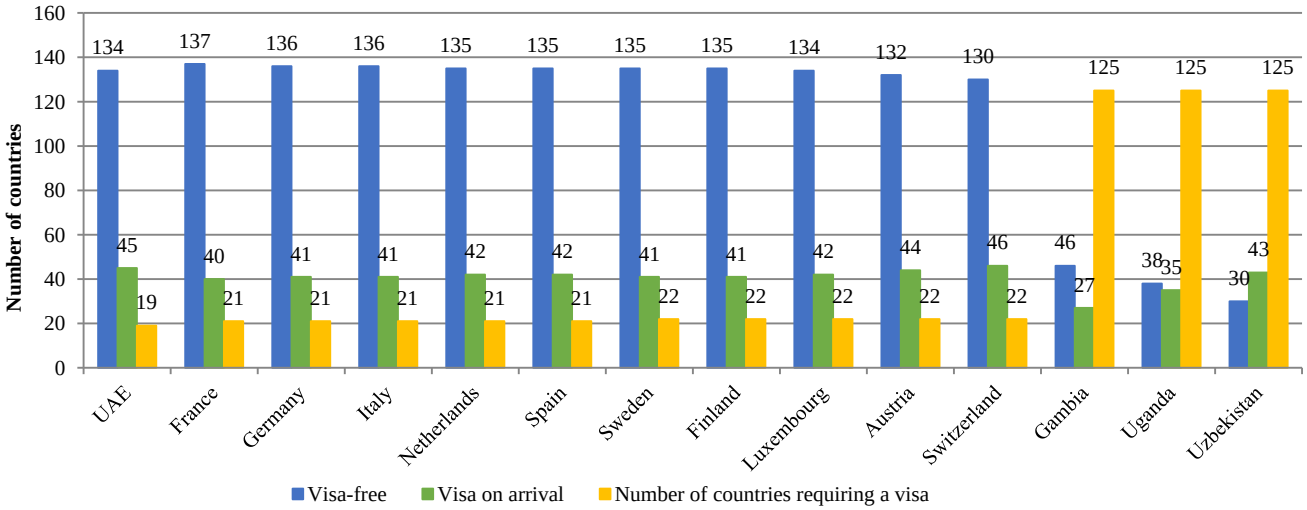

Figure 1. Global ranking of the world's strongest passports in 2024 (Passport Index, 2025)

While the global mobility disparities presented in Figure 1 indicate substantial differences in passport power across countries, Tables 4, 5 and Figure 2, 3 empirically reveal, alongside these disparities, how countries' inbound mobility namely, their strategies for expanding visa-free regimes has been shaped. These tables make it possible to compare dynamic changes in the number of visa-free entry opportunities and inbound foreign tourist flows across 11 countries over

the period 2015-2024. The evidence suggests that visa liberalization emerges as one of the key institutional mechanisms that strengthens tourist flows, independently of economic factors. In most countries, the expansion of visa-free regimes occurred simultaneously with sharp increases in tourism flows. This process constitutes important and consistent empirical evidence indicating the presence of a causal relationship between visa policy and tourist mobility.

Table 4. Countries with a visa-free regime and the number of inbound foreign tourists

Country	Visa-free regime change trends by year (Passport Index, 2025)									
	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Philippines	159	159	160	160	160	1	COVID restrictions	159	159	159
Singapore	161	161	163	162	162	162	23	162	163	164

Table 5. Number of inbound foreign tourists by year (million)

Country	Number of inbound foreign tourists by year *(million)* (UN Tourism, 2025)									
	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Philippines	5.36	6	6.6	7.2	8.3	1.5	0.16	2.7	5	5.4
Singapore	12.05	12.9	13.90	14.7	15.1	2.2	0.33	5.3	10.3	12.4
Indonesia	9.96	11.07	12.95	13.40	15.46	3.92	1.55	5.89	11.7	13.9
Malaysia	25.72	26.76	25.95	25.83	26.10	4.33	0.14	10.07	20.1	25.0
Thailand	29.92	32.53	35.59	38.08	39.92	6.7	0.43	11.1	28.2	35.5
Iran	5.24	4.94	4.87	7.30	9.11	1.55	0.88	4.11	5.9	7.0
Vietnam	7.56	10.01	12.92	15.50	18.01	3.84	0.16	3.7	12.6	17.5
Türkiye	39.48	30.29	37.60	45.77	51.19	15.9	29.9	50.5	55.2	60.6
India	13.76	15.03	16.81	17.42	17.91	6.34	7.01	14.3	18.9	20.6
United Arab Emirates (UAE)	16.84	18.14	19.17	20.21	21.56	7.17	11.5	22.7	28.1	29.0
Uzbekistan	1.92	2.03	2.69	5.35	6.75	1.55	1.88	5.2	6.6	10.1

It can be observed that developing countries have sought to enhance their competitiveness in the global tourism market by expanding visa-free regimes. Countries such as Uzbekistan, Vietnam, India and Iran significantly increased the number of visa-free entry options and this process contributed to sustained growth dynamics in their tourism sectors.

For example, Uzbekistan's most pronounced liberalization over the nine-year period (from 9 countries to 140) was accompanied by an increase in inbound foreign tourist flows from 1.9 million to over 10 million. The temporal alignment of this growth indicates that the relaxation of visa policy functioned as a direct stimulus for inbound tourist flows.

In addition, the tables specify that a contraction in visa-free regimes is associated with a slowdown in tourist flows. For instance, Türkiye reduced its visa-free entry opportunities over 2015-2024 (from 166 to 117, Table 4, Figure 2). A change that is closely linked to greater volatility in tourism flows and a slower pace of recovery. A similar pattern can be observed in the cases of the Philippines and the UAE, where limited flexibility in visa arrangements appears to have reinforced the inertia of tourist flows. Tables 4 and 5 support the study's main hypothesis empirically (that visa policy openness has a significant effect on tourist flows) and provide the necessary factual foundation for the subsequent statistical modeling.

Visa Openness Model: baseline indicators

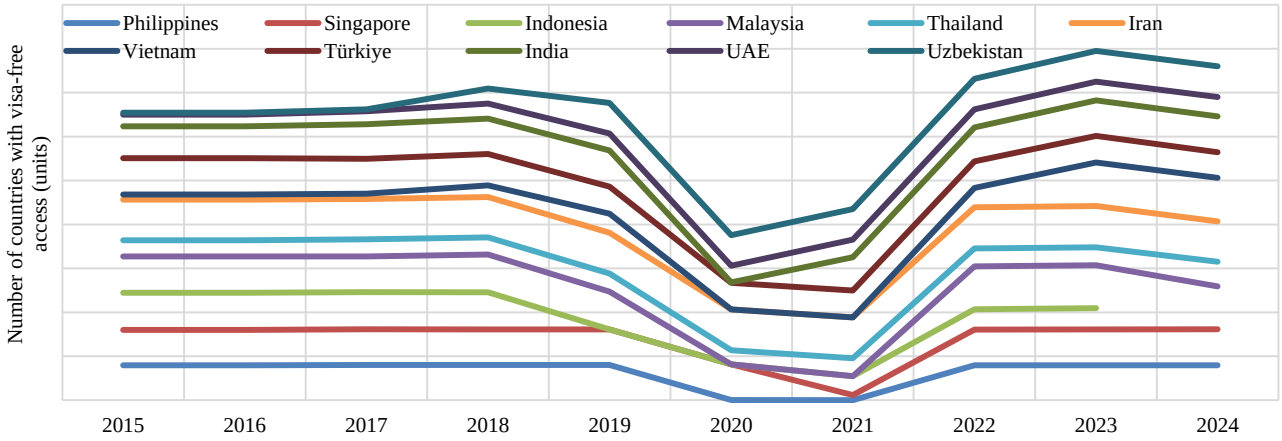

Figure 2. Trends in the number of countries granted visa-free access, 2015-2024 (units) (based on Table 4; data: Passport Index, 2025)

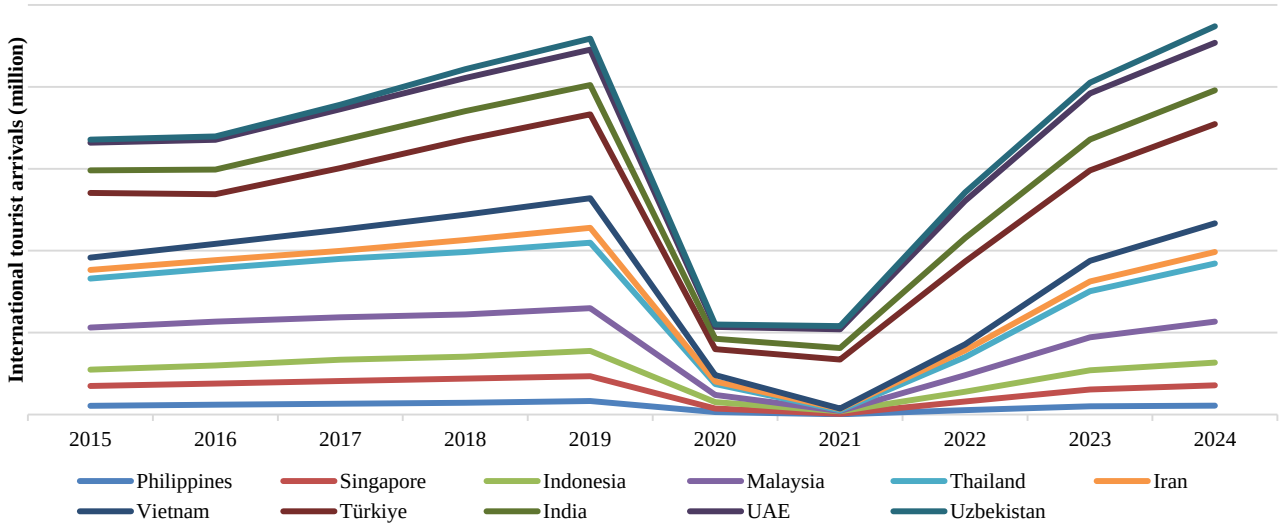

Figure 3. Trends in inbound international tourist arrivals, 2015-2024 (million) (based on Table 5; data: UN Tourism, 2025)

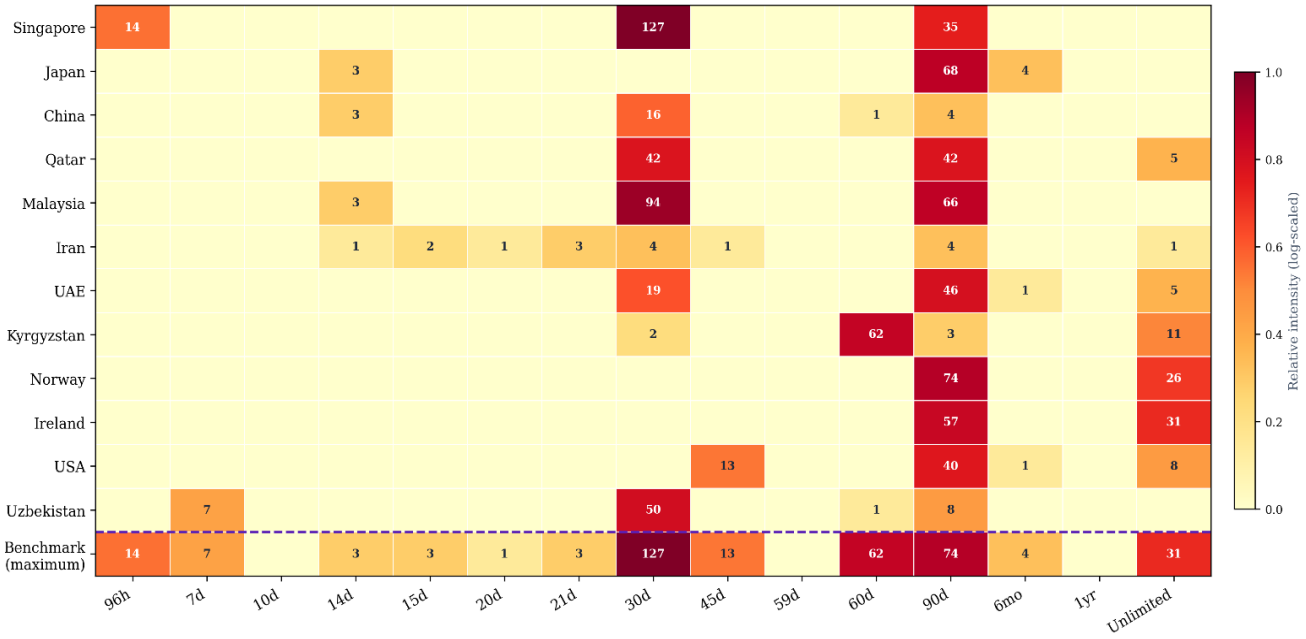

Figure 4. Benchmark vector and country-level visa-free stay-duration indicators (Passport index, 2025)

This stage establishes the "input data structure" required for the quantitative assessment of visa policy. Figure 4 presents the official indicators of countries' visa-free stay, as well as the benchmark vector constructed on the basis of these values. Figure 4 constitutes the conceptual and mathematical foundation of the model for the quantitative assessment of visa policy openness. It translates each country's visa-free entry durations into explicit numerical form. These values are converted into a single metric (the VOI) through a vector-index approach subsequently.

First, as the table demonstrates the thresholds of visa-free durations vary sharply across countries while some countries grant only short-term entry options (96 hours to 7 days). Others also provide medium-term (14-30 days) or long-term (60-90 days) stays. Such heterogeneity is recorded in the quantitative model as vector elements. The maximum values in the benchmark vector, in turn, define the upper bounds of these durations and establish the reference criterion for comparison across all countries. A second important aspect is that this approach moves beyond a simple "yes/no" indicator of visa policy and shifts it to a graded system. In other words, differences across countries are reflected in whether visa-free entry exists, also in the duration of visa-free stay. Therefore, each indicator in Figure 4 carries an independent weight and in the index-calculation process these indicators exert differential effects on a country's overall level of openness.

A third aspect is that some countries have multiple categories of visa-free stay durations, which indicates that their tourism cooperation policy is multi-layered. For example, countries such as Malaysia, Singapore and Qatar provide visa-free entry across several duration ranges. The vector values of such countries converge toward the benchmark vector and consequently their VOI is expected to be higher. By contrast, for countries with a narrow set of visa-free durations (limited, for instance, to only 7 days or 14 days) their vectors diverge from the benchmark vector. As a result, their index values are more likely to be lower. This approach converts qualitative differences in visa policy into a quantitative metric and the indices reported in Table 6 are derived precisely from this underlying structure.

Visa Openness Index (VOI) results

At the final stage of the quantitative assessment of visa policy openness, the VOI was calculated for 12 countries. The final index values for the countries are presented in Figure 5 below. The results in Figure 5 demonstrate that there are substantial institutional differences across countries in their visa-free entry policies. Countries with the highest index values Malaysia, Qatar, Singapore and China stand out as those offering the most flexible and liberal visa regimes for tourism entry. Their VOI scores fall within the range of 0.87-0.89, indicating a high level of global openness in terms of visa policy. In these countries, visa-free entry durations are multi-tiered, including 14-day, 30-day, 60-90-day and in some cases longer-term regimes. Because this structure closely approximates the benchmark vector of visa-free duration categories presented in Figure 4, their index values are correspondingly high. Iran and the UAE constitute the middle group. With index values of approximately 0.73-0.76, they reflect partially liberalized visa policies, while restrictions remain in certain segments. In these countries, visa-free durations are sometimes confined to a narrow range (e.g., 14 or 30 days) and for some categories they are not available. For this reason, they cannot be classified among the fully open countries.

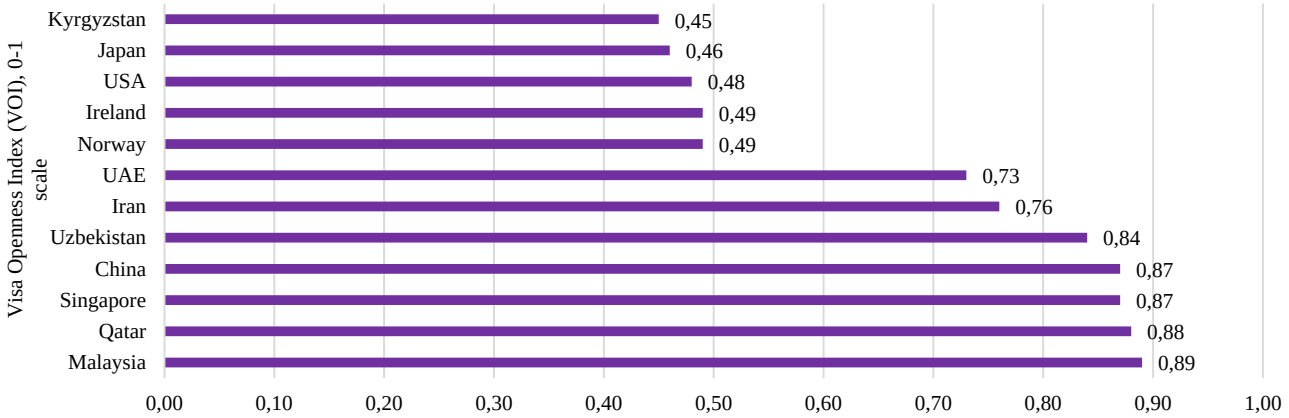

Figure 5. Degree of Visa Policy Openness by Country (VOI, on a 0-1 scale) (Source: Calculations of authors based on Passport Index, 2025)

The lowest index values Norway, Ireland, the USA, Japan and Kyrgyzstan reflect a conservative approach to tourism entry policy. In these cases, visa-free entry durations are limited or apply only to specific countries. The fact that these indices fall within the range of 0.45-0.49 indicates that visa policy remains a substantial barrier for tourists. Notably, although some of these countries (the USA, Japan and Norway) rank among the world's top positions in terms of passport power, their entry mobility is low. This observation further corroborates the study's main scientific hypothesis: passport power and visa policy openness constitute two independent institutional indicators. Uzbekistan's score of 0.84 is one of the most important empirical results of the study. This index places Uzbekistan among the top five most open countries in terms of visa policy. The finding is fully consistent with the sharp expansion of the visa-free regime observed in Table 2 (from 9 to 140 countries) and demonstrates the tangible effectiveness of the country's liberalization policies implemented in recent years. Although Uzbekistan's passport power is relatively low, the high openness of its entry policy is mathematically confirmed through the vector-index approach.

Panel regression (random effects model) results

While the results obtained for the VOI and the dynamics of the visa-free regime illustrate overall trends in tourist flows. This section determines the statistically significant effect size of these changes. A Random Effects model is constructed using panel data for 2015-2024 and empirically assesses the relationship between visa policy openness (VOI and the number of visa-free countries), tourist flows and external shocks (Table 6).

Table 6. Key Coefficients of the Random Effects Regression Model

	Coefficient	**Std. error**	**Z**	**p-value**
Const	0.514679	0.39055	17.2153	0.0295
Inbound international tourists	1.01055	0.0456389	22.14	0.0001
Trend of changes in the visa-free regime	0.00969138	0.00987244	18.9817	0.0263
Infectious diseases or political conflicts	-1.61377	0.46884	-16.099	0.0119

The Random Effects regression results confirm that visa policy openness is a strong and statistically significant determinant in shaping tourist flows. In the model, the coefficient associated with the expansion of the visa-free regime (β = 0.0097; $p < 0.05$) indicates that when a country introduces each additional visa-free country, this change exerts a positive effect on tourist flows and this effect is not random but is supported by reliable statistical evidence. Tourist flows are also included as one of the explanatory variables and its coefficient-at 1.01 - exhibits very high statistical significance (p = 0.0001). This suggests that the country's tourism competitiveness and economic growth indicators are strongly dependent on tourist flows from previous years. In other words, tourist flows display an inertia effect: a higher flow in one year stimulates an even higher flow in the subsequent year. The negative indicator included in the model pandemics, infectious

diseases and conflict situations (β = -1.61; p < 0.05). It is identified as the factor exerting the strongest adverse effect on tourist flows. The scale of this coefficient indicates that external shocks reduce tourist flows sharply regardless of visa policy. This finding is fully consistent with the "vulnerability factor" concept in global tourism theory. In other words, the strength of the visa-policy effect is not uniform across all countries. It is differentiated by factors such as the level of economic development, infrastructure, geographic location and national branding. These regression results validate the empirical trends observed in Table 3 countries that expanded their visa-free regimes actively (Uzbekistan, Vietnam, Malaysia, India) achieved higher growth in tourist flows. Growth was weaker in countries where the visa-free regime remained unchanged or contracted. At the same time, the regression model also confirms that the relationship between changes in the visa-free regime and tourist flows reflects a cause - effect linkage (Table 7). In other words, visa liberalization is an independent determinant of tourism growth. This effect is positive, stable and statistically robust.

Table 7. Model reliability indicators

Indicator	R-square	Corrected R-square	Log-likelihood	Akaike	Schwarz
Value	0.91	0.88	-246.47	520.95	555.64

Delphi method findings - independent travelers' service priorities

The panel regression results indicate that at the macro level the visa-free regime and visa openness are key determinants shaping tourist flows. However, the in country mobility of independent tourists, their length of stay and their expenditures are directly linked to the micro-level service system. 15 experts participated and assessed the importance of services for different segments of independent tourists in the Delphi study.

Based on expert consensus Table 8 was compiled. Based on the results (Table 8), 15 regularities were generalised regarding the independent service needs of tourists. These regularities are presented in the table below.

Table 8. Importance of services for different categories of independent tourists

Table 9. Categorized regularities for independent tourist service system (Based on Delphi expert consensus, n=15)

Digital and connectivity	
1	Digital navigation (maps, GPS, wayfinding signage) fundamental need for all segments
2	Stable, free internet core infrastructure for routing, information, and payments
3	Online booking services high importance for all segments, enhances trip planning
4	Centralized tourist information portal reduces uncertainty, optimizes routes
Financial services	
5	International payment systems and card-accepting ATMs enables economic activities
Safety and trust	
6	Safety services (tourism police, info centres) builds tourists' sense of trust
7	Gaps in service system increases risk perception, reduces repeat visits
Transport and mobility	
8	Auto-tourist services (parking, fuel, EV charging) essential for road travel
9	Multilingual public transport info determines freedom of movement
10	Infrastructure interchange points reduces route length and costs
Accommodation	
11	Segment-specific: backpackers-budget; poshpackers-quality; families-comfort
12	Affordable options (hostels, camping) extends trip duration for budget travelers
Amenities and facilities	
13	Food-service diversity and accessibility directly affects length of stay
14	Roadside sanitation (WC, rest areas) critical for long-distance travelers
Interpretation and experience	
15	Audio guides, multimedia, QR-codes makes sites “readable”, enhances experience

On the basis of the expert assessments summarised in Table 8, fifteen empirical regularities were derived and grouped into thematic blocks. These regularities are presented in Table 9, which organises them into digital and connectivity, accommodation, mobility, catering and information-service categories.

While the regularities derived through the Delphi method identify independent tourists’ service needs, the next stage consists of determining the extent to which Uzbekistan’s existing infrastructure meets these needs. Therefore, the regularities identified for the service system are now linked to an assessment across Uzbekistan’s regions of: (a) which services have been implemented; (b) which are lacking; (c) which are only partially functioning; (d) which require accelerated development.

To address this need, Table 10 has been developed, it provides a comparative analysis of the real implementation status across Uzbekistan’s regions of services that are of high importance for independent tourists. Table 10 provides a comparative picture of the extent to which services identified as important for independent tourists are available across Uzbekistan’s regions, thereby enabling the identification of the gap between the Delphi results and practice. As the table indicates, although Uzbekistan’s tourism infrastructure has undergone noticeable modernization in recent years, a fully integrated service system has not yet been established, given the complexity of services and their uneven territorial distribution.

Table 10. Degree of implementation across the country’s regions of services with high preference among independent tourists

Regularities and related services	Service implementation status	National level	International level	Solution
Geographic information systems (GIS)	Not implemented sufficiently		Yandex navigator, maps.me, google map, google earth	Introduce a mobile application that consolidates tourist sites, recreation areas and mountainous zones in one platform
Wi-fi zones	Not implemented sufficiently		-	Establish free or paid Wi-fi zones in the areas of airports, railway stations, catering facilities and shopping complexes
Infokiosk (booking centers)	Not implemented sufficiently			Establish infokiosks staffed by individual travel agents at airports, railway stations and within tourist-site areas
International card exchange ATMs	Not implemented sufficiently	National card exchange ATMs are available in front of all tourist sites	Available at some tourist sites and hotels	Install terminals that accept international cards and ATMs for cash withdrawal at airports and railway stations, at entrances to tourist sites and in restaurants and shopping complexes
Tourism police	Implemented	-	-	-
Parking bases	Not implemented	Established on the premises of some hotels	-	Establish parking zones near eco-zones and tourist sites that provide opportunities for stopping, washing, and dining for visitors arriving by private transport
Roadside fuel stations	Not implemented sufficiently	Only 8 fuel stations exist on the Tashkent-Khiva route	-	Establish fuel stations every 50-100 km along the Tashkent-Samarkand-Bukhara-Khiva route
Charging stations for electric transport vehicles	Not implemented sufficiently	Available in city centers and on intercity routes	-	Establish charging stations for electric vehicles every 200-300 km along the Tashkent-Samarkand-Bukhara-Khiva route
3*,4*,5* Hotel services	Implemented	-	-	-

Accommodation facilities in mountainous zones	Not implemented sufficiently	Only overnight-stay services in local residents' homes are available	-	Establish camping zones in the upper parts of the mountains and the adjacent infrastructure
Car rental services	Not implemented sufficiently	Organized only in the centers of tourist cities	-	Organize car rental services in the vicinity of airports and railway stations
Restaurant services	Implemented	-	-	-
Fast&food services	Implemented	-	-	-
Traditional guiding services	Implemented	-	-	-
Innovative guiding services	Not implemented sufficiently	-	-	Organize services such as short video clips about tourist sites, audio guides and opportunities for tourists to view sites remotely through 3D-format visuals
Guide-instructor services in remote areas and mountainous zones	Not implemented	-	-	Establish the activity of guides in remote areas and mountainous zones who can accompany independent tourists and speak English and Russian
Online booking systems air tickets	Implemented	uzairways.com	aviasales.com wizzair.com/en-gb	-
Railway tickets	Implemented	eticket.railway.uz	eticket.railway.uz	-
Booking of accommodation facilities	Implemented	mybooking.uz/ru	booking.com expedia.com airbnb.com/ru	-
Roadside shower facilities	Not implemented sufficiently	-	-	Construct motels with shower facilities every 200-300 km along routes to tourist cities for tourists traveling by buses and passenger cars
Online booking of events	Not implemented sufficiently	https://www.afisha.uz/	https://www.afisha.uz	Only the list of events in Tashkent is included on Afisha.uz; it is advisable to add events in other tourist cities as well
Tour operator and travel agency activities	Implemented	Tour operators and travel agencies engaged in domestic tourism and organizing packaged	Tour operators and travel agencies engaged in outbound tourism and organizing packaged tours	Organize tour operator and travel agency activities that specifically serve independent tourists
GIS services at national borders	Not implemented	-	-	Establish infokiosks in the areas of each border entry point to provide information about the country
Regional travel agency activities	Not implemented	-	-	Establish regional travel agents around airports, railways and tourist sites that organize short-term local tour packages

CONCLUSION

According to analytical observations, the trend of visa liberalization has been more strongly manifested in Uzbekistan, as tourism has been viewed in these states as a relatively rapid instrument for economic growth and employment generation. As a result of the step-by-step liberalization of the visa regime, the number of countries whose citizens could enter Uzbekistan visa-free was increased to 140 (i.e., by nearly 15 times), while inbound foreign visitors were increased to 10 million by 2024. This dynamic correspondence has been treated as an important indicator through which it has been demonstrated that, as visa openness is increased, the volume of arrivals is also increased, thereby providing a basis for visa policy to be interpreted as one of the central instruments of tourism policy.

Independent tourists have been differentiated from traditional tourists (those travelling via tour agencies) by travel purpose, needs during travel, the types of services selected and the infrastructure relied upon. Through a comparative analysis in which the services used by independent tourists during travel were classified into three categories by importance, it was determined that a higher propensity has been shown toward atypical and less commonly used services, rather than toward the services typically used by organized (group) tourists. In addition, it was determined from the above analysis that, although independent tourists may be classified into different categories, a similar tendency toward the same needs for certain services has been observed; on this basis, 15 distinct regularities were formulated. On the basis of the importance levels of service types used by different categories of independent tourists and the identified regularities, a comparative analysis of the degree to which these services have been implemented in the country's tourism regions was conducted and primary proposals were developed as solutions for services that have been insufficiently implemented or have not been implemented at all.

1. In Uzbekistan's tourism industry, the citywide availability of tourism services that are often regarded as secondary-namely geographic information systems, infokiosks and Wi-Fi zones-is expected to be ensured, whereby inbound international tourism, also the development of domestic tourism and the enhancement of local residents' cultural engagement are expected to be promoted.

2. In eco-zones, parking facilities are expected to be established, through which increases are expected to be observed in the number of independent tourists traveling by private and rented cars as well as campers, in cross-border freight transport movements and in one-day trip visitors.

3. Through the further development of online booking systems widely used by independent tourists, the dependence of accommodation providers in Uzbekistan on tour operators is expected to be reduced and direct communication between tourists and hotels is expected to be established. In addition, the operation of small accommodation providers (home-stay hotels, hostels, private home rentals, motels) is expected to be stimulated.

4. Given that a stronger preference among independent tourists tends to be shown for fast food, street food and low-cost meals, the development of small restaurant businesses is expected to be stimulated, while service quality and foreign-language proficiency are expected to be improved. Furthermore, the organization of street-food services around tourist attractions is increasingly expected to be required.

5. By independent tourists, innovative guiding services are expected to be preferred rather than conventional guiding. By them, the acquisition of a remote, advance visual understanding of tourist sites is expected to be sought and entrance tickets are expected to be purchased online. As a result, the need is expected to be created for a national and international system in which all tourist attractions are integrated. Moreover, in mountainous zones and remote areas, the popularization of services such as guide-instructors is expected to be expanded and the foreign-language proficiency of local residents is expected to be improved.

6. A need is also expected to be generated for national and international systems through which tickets for air travel, rail transport and national events can be purchased online.

7. The activities of individual tour operators and travel agents are required to be organized in Uzbekistan. By them, short-term tours for independent tourists visiting the country are expected to be provided. Unlike tour operators serving organized group tourists, their activities are expected to be arranged in offices also around tourist attractions, where the full range of tourism services is expected to be facilitated and coordinated.

The implementation of the above-mentioned services, as well as the improvement of certain existing services, is expected in the future to increase Uzbekistan's tourism attractiveness, service quality and service diversity for independent tourists also for organized tourists. Most importantly, healthy competition is expected to be fostered between small and large business actors operating in the tourism sector.

Funding: This research received no external funding. The article processing charge (APC) was funded by John von Neumann University, Kecskemét, Hungary.

Institutional Review Board Statement: Ethical review and approval were waived for this study. The Delphi survey involved only professional experts responding in their professional capacity; participation was voluntary and anonymous, and no sensitive personal data were collected.

Informed Consent Statement: Informed consent was obtained from all 15 experts who participated in the Delphi study. Participation was voluntary and anonymous, and all participants were informed of the purpose of the study and of the intended use of their responses prior to each round.

Data Availability Statement: The datasets generated and analysed during this study are available from the corresponding author upon reasonable request.

Acknowledgements: The authors thank the 15 tourism experts: tour operators, guides, hospitality and transport specialists, and academic researchers, who participated in the three rounds of the Delphi study.

Conflicts of Interest: The authors declare no conflicts of interest. The funder had no role in the design of the study; in the collection, analysis or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

Use of Generative AI: Not applicable.

SPATIAL ANALYSIS OF SERVICE INNOVATION AND QUALITY IN UPPER UPSCALE HOTELS: THE HUMAN-ENVIRONMENT RELATIONSHIP IN HANOI

Hai Yen TRAN [1], Dinh Quyet PHAN [2*]

Citation: Tran, H. Y., & Phan, D. Q. (2026). Spatial analysis of service innovation and quality in upper upscale hotels: The human-environment relationship in Hanoi. *Geojournal of Tourism and Geosites*, 67(3), 2235-2249. https://doi.org/10.30892/gtg.67336-1848

Abstract: Contemporary upscale hotels have evolved into "micro-geographies" where spatial design, technology, ecology, and human interaction co-produce the guest experience. However, substantial managerial investments in service innovation often fail to enhance guest perception. This creates a structural "Perceptual Gap" between conceived and lived spaces that traditional functionalist frameworks cannot explain. This study aims to examine the divergence between managerial innovation strategies and guests' perceptions, identifying the spatial and psychological mechanisms driving this gap. A multiple-case study triangulates supply side data (interviews with senior managers at two contrasting upper upscale hotels in Hanoi, Vietnam) with demand-side data (2,377 scraped TripAdvisor reviews). Managerial data underwent deductive thematic coding using an extended 8-dimension Service Quality model to generate Strategic Input scores (Lefebvre's conceived space). Guest data were analyzed via sentiment analysis and Semantic Network Analysis (VOSviewer), employing Digital Geography to map the cognitive topology of the guest experience. The results validate three theoretical propositions. First, the Visibility Paradox (P1) shows that perceived smart service quality is inversely correlated with technological obtrusiveness; visible interfaces cause spatial friction (divergence: −3), whereas invisible backend systems enable seamless flow (convergence: +1). Second, Sociability Primacy (P2) identifies community building as the paramount driver of place attachment, manifested as a centripetal network topology in boutique properties versus a centrifugal, fragmented topology in international chains. Third, the Environmental Prerequisite (P3) reveals that green practices act as hygiene factors; their presence yields negligible positive sentiment (<0.5%), but their absence triggers severe negative disconfirmation. Ultimately, this study advances a spatial reframing of service innovation, demonstrating that value is co-createdand potentially distorted through embodied encounters among guests, technology, and urban morphology.

Keywords: urban tourism planning, spatial analysis, human-environment relationship, smart tourism territory, Hanoi

INTRODUCTION

In the contemporary urban landscape, upper upscale hotels have evolved into "micro-geographies"-territorial nodes where spatial design, technology, ecology, and human interaction converge to co-produce the tourism experience. Driven by digital transformation and sustainability imperatives, innovation in this sector has traditionally been viewed as measurable operational output (Hjalager, 2010). Recent literature continues to reflect this supply side logic, focusing heavily on digital orientation as a driver of service innovation (Zhou et al., 2025) or the implementation of Sustainability-Oriented Service Innovation (Bordian et al., 2026) as firm-centric capabilities. However, a critical paradox disrupts this managerial logic: substantial technical investments do not invariably yield superior customer satisfaction (CS). Recent studies indicate that treating technological innovation-such as AI-enabled experiences (Alhomaid et al., 2025)-as a monolithic construct obscures how customers decode these signals within the service space. According to Signaling Theory (Spence, 1973), innovations act as territorial signals of competence. However, when the actual lived experience fails to confirm the expectations set by these signals (e.g., star ratings), "Negative Disconfirmation" occurs (Tiwari & Omar, 2025). This creates a structural Perceptual Gap between the manager's "conceived space" and the guest's "lived space" (Lefebvre, 1991)-a supply demand divergence that constitutes the central problem of this study. Despite its criticality, the extant literature exhibits three notable gaps. Conceptually (Spatial Gap): Prevailing research either adopts a purely functionalist, supply side perspective (Ruiz-Fernández et al., 2026; Zhou et al., 2025) or a macro-level destination focus (Alshiha et al., 2025), largely ignoring the micro-geographical tension between visible interfaces and invisible infrastructure. The spatial dynamics of how technology and human elements entangle (Kandampully et al., 2023) within specific urban morphologies remain unexplored.Measurement-wise (Dimensional gap): Traditional scales such as LODGSERV (Knutson et al., 1990) systematically overlook the perceptual triad of Industry 4.0. They fail to capture how

technological complexity triggers anxiety rather than delight (Yang & Leung, 2025) or how green practices function merely as environmental prerequisites (hygiene factors) rather than competitive differentiators (Khuong et al., 2025). Methodologically (The Cognitive Gap): Prior studies rely heavily on self-reported surveys susceptible to social desirability bias (Perez-Aranda et al., 2025) or analyze macro-social media discourse (Yang & Leung, 2025). There is a pronounced paucity of research utilizing property-level User-Generated Content (UGC) to map the unmediated cognitive topology of the guest's lived spatial experience. To bridge these gaps, this study proposes an integrated framework grounded in service-dominant logic (Vargo & Lusch, 2008), Signaling Theory, and Humanistic Geography (Lefebvre, 1991; Tuan, 1977). The study posits that innovation value is co-createdand potentially distortedduring embodied service encounters. This study aims to examine the structural divergence between managerial innovation strategies and guests' perceptual reception in upper upscale hotels. To achieve this, this study pursues four objectives: (O1) to operationalize an extended 8-dimension Service Quality model integrating LODGSERV with Smart Services, Green Practices, and Sociability; (O2) to map supply demand divergence through a comparative case study of two contrasting hotels in Hanoi, Vietnam; (O3) to apply Semantic Network Analysis (VOSviewer) as a tool of Digital Geography, constructing a cognitive topology of the guest experience as a virtual cartographic representation of territorial identity; and (O4) to generate mid-range theoretical propositions (Visibility Paradox, Sociability Primacy, Environmental Prerequisite) advancing the understanding of innovation-perception dynamics. Finally, Hanoi's contrasting urban morphologies (the French and Old Quarters) serve not merely as a geographic backdrop but as a theoretically constitutive element for examining how urban spatial grammar shapes the translation of innovation signals into territorial quality outcomes.

LITERATURE REVIEW AND THEORETICAL FRAMEWORK

The evolution of service innovation: from operational output to spatial reconfiguration

The functionalist perspective: innovation as operational output

Traditionally, service innovation has been conceptualized as a measurable, operational output (Hjalager, 2010; Schumpeter, 1934). Recent studies in the hospitality context, including those focused on emerging markets such as Vietnam (Nguyen, 2020, 2023), adhere to this supply side logic by focusing on absorptive capacity and process restructuring. Similarly, Ruiz-Fernández et al. (2026) empirically found that chain-affiliated hotels suffer from structural lags between their strategic intent and operational adaptation. Zhou et al. (2025) demonstrated that digital orientation positively impacts service innovation, mediated by digital capabilities with government support.

Furthermore, Bordian et al. (2026) found that Sustainability-Oriented Service Innovation (SOSI) significantly enhances customer satisfaction through value co-creation. Although these findings provide robust supply side metrics, their critical limitation lies in treating customers as passive recipients rather than active co-creators (Truong et al., 2020). Zhou et al. (2025) and Ruiz-Fernández et al. (2026) rely exclusively on managerial self-reporting, completely omitting customers' perceptual reception. Consequently, sophisticated backend systems (e.g., Mövenpick's ACDC CRM) may represent high digital capability but fail to generate customer recognition. Furthermore, Bordian et al. (2026) utilized a cross-sectional design that treated SOSI as a unidimensional construct, failing to capture the structural "Perceptual Gap" between the managerial conceived space and the guest's lived spatial experience.

The Dichotomous Perspective: Technology vs. Human Touch

Industry 4.0 has popularized a binary view of technological and non-technological innovation. Cheng & Liu (2026) found that smart technologies significantly enhance service efficiency, personalization, and novelty. Conversely, Yang & Leung (2025) utilized Social Network Analysis to reveal that technological complexity triggers anxiety, acting as a primary barrier to adoption that spreads virally through structural holes. Alhomaid et al. (2025) found that AI-enabled experiences drive sustainable consumption via psychological ownership, while Li & Huang (2022) proved that sociability needs cannot be substituted by contactless efficiency, as the absence of human interaction creates an emotional void. The primary limitation of this dichotomous stream is its reductionist and macro-level framing of the issue. Yang & Leung (2025) rely on macro-social media discourse (Twitter), which obscures the micro-spatial reality of how guests interact with specific interfaces inside a hotel room. Moreover, Alhomaid et al. (2025) treat AI as a monolithic construct, ignoring the vital spatial distinction between visible interfaces (which cause friction) and invisible infrastructure (which accelerates services). This study addresses this limitation by advancing Kandampully et al. (2023) argument that technology and human elements are deeply entangled, mapping how the successful invisibilization of technology allows human geography to dominate the experiential foreground.

The Integrative Perceptual Perspective: Value Co-Creation

Grounded in Service-Dominant (S-D) logic (Vargo & Lusch, 2008), the contemporary stream views innovation as a co-created phenomenon (Dai et al., 2025; Zhang & Ha, 2025). Alhomaid et al. (2025) found that both hedonic and utilitarian features drive tourist value co-creation in smart destinations. Concurrently, Khuong et al. (2025) found that green practices mediate return intentions, although specific water- and energy-saving measures fail to directly boost positive mood or satisfaction. While conceptually advanced, Alhomaid et al. (2025) are limited by their macro-destination focus, which lacks the micro-geographical context of organically evolved urban morphologies. Khuong et al. (2025) relied on survey data that were highly susceptible to social desirability bias regarding environmental issues. This necessitates the use of unprompted User-Generated Content (UGC) to capture authentic spatial perceptions and distinguish between utilitarian innovation strategies (operational standardization) and hedonic pathways (personalized human interactions).

Reconceptualizing service quality: from process to territorial quality

The durability and limitations of LODGSERV

While LODGSERV (Knutson et al., 1990) remains foundational, modern classifications act as pre-encounter signals.

Tiwari & Omar (2025) found that failing to meet star-rating expectations triggers severe "Negative Disconfirmation." Similarly, Perez-Aranda et al. (2025) noted consumer ambivalence toward sustainability practices, and Wong & Loo (2026) highlighted the operational efficiency of smart buildings through longitudinal data. However, a critical limitation of these traditional and operational frameworks is their systematic oversight of the perceptual triad of the Industry 4.0 servicescape. They measure functional delivery but fail to capture the spatial and psychological nuances of modern luxury.

Extended 8-component model

To capture contemporary territorial quality, we extend LODGSERV with three non-substitutable dimensions:

Smart Service (The Digital Environment): Transcending static "Tangibles," this differentiates between obtrusive (visible) and seamless (invisible) interfaces. As Yang and Leung (2025) note, complexity breeds anxiety; thus, truly smart services minimize cognitive load. Green Practices (The Ecological Environment): Functioning not as a delighter, but as an "Environmental Prerequisite"-a baseline legitimacy factor where absence punishes the brand (negative disconfirmation), but presence is merely expected compliance (Khuong et al., 2025). Sociability (Social Geography): The architectural principle determining whether a space becomes a meaningful "place" (Tuan, 1977) or a standardized "non-place" (Augé, 1995). As Li & Huang (2022) demonstrated, technological efficiency cannot replace the emotional resonance of human sociability.

Spatial dimensions and digital geography

Drawing on Lefebvre's (1991) spatial trialectic, this study operationalizes the gap between conceived space (managerial intent) and lived space (guest experiences). Recent spatial studies have provided partial insights: Suess et al. (2024) found that biophilic design reduces guest anxiety, whereas Lai et al. (2025) identified social interaction spaces as primary satisfaction drivers. However, their critical limitation is the neglect of the full human-environment-technology triad, while macro-level destination studies (Alshiha et al., 2025) obscure property-level dynamics. Methodologically, we conceptualized Semantic Network Analysis (VOSviewer) as a tool of Digital Geography. Moving beyond the frequency-based sentiment limitations of Pacheco et al. (2026), we mapped the cognitive topology of the guest experience. Just as Yang & Leung (2025) identified structural holes in social networks, we analyzed structural absences in UGC (e.g., missing tech keywords) as empirical proof of successful backend invisibilization, directly addressing technology anxiety (Haque et al., 2026). To explicitly contextualize this research within the current state-of-the-art and address the structural limitations of the extant literature, Table 1 critically analyzes seven highly similar articles published within the last three years (2024-2026). This matrix highlights their core findings, methodological limitations, and specific gaps that the present study resolves.

Table 1. Critical analysis of similar recent studies (2024-2026)

Study (Year)	Core Findings	Critical Limitations	Gap Addressed by Present Study
Cheng & Liu (2026)	Smart technology enhances efficiency and novelty in hotels.	Lacks spatial/morphological context and ignores emerging markets.	Introduces urban morphology analysis and UGC semantic topology.
Alhomaid et al. (2025)	AI experiences drive sustainable consumption through psychological ownership.	Treats AI as a monolithic construct and ignores interface obtrusiveness.	Disaggregates AI into visible (friction) and invisible (flow) technologies.
Zhou et al. (2025)	Digital orientation drives service innovation (supply side).	It relies entirely on managerial self-reports and ignores demand-side perception.	Measures the "Perceptual Gap" between managerial input and guest-generated content (UGC).
Yang & Leung (2025)	Technological complexity triggers anxiety, spreading via structural holes.	Macro social media focus (Twitter): Lacks micro-spatial property reality.	Structural analysis was applied to the micro-spatial property UGC (VOSviewer).
Bordian et al. (2026)	SOSI positively influences satis-faction through value co-creation.	Cross-sectional design that treats inno-vation as a unidimensional construct.	Disaggregates spatial dimensions (ecological versus social innovation).
Tiwari & Omar (2025)	Star ratings act as signals; failure causes Negative Disconfirmation.	COVID-specific health framing and ignores social geography.	It extends disconfirmation theory to spatial and sociability dimensions.
Suess et al. (2024)	Biophilic design creates restorative experiences that reduce stress.	Design-only focus; ignores the digital and social spatial dimensions.	Integrates physical design with the human-environment-technology triad.

Theoretical synthesis and research propositions

Our framework integrates the S-O-R paradigm (Mehrabian & Russell, 1974), Signaling Theory (Spence, 1973; Mahmoud et al., 2018), and Humanistic Geography (Lefebvre, 1991; Tuan, 1977). Within the S-O-R paradigm, service innovation functions as an Environmental Stimulus (S) that shapes the internal evaluative state (O) and behavioral response (R). We posit that innovation is a territorial signal. When technological signals are too visible, they are decoded by guests as operational complexity, creating "noise" and Negative Disconfirmation (Tiwari & Omar, 2025).

The transformation of a hotel from a mere "space" of accommodation into a meaningful "place" of belonging is mediated by three spatial forces: digital, ecological and social. This synthesis generated three validated propositions.

P1 (Visibility Paradox): Perceived Smart Service quality is inversely related to technological obtrusiveness (visible technology generates spatial friction; invisible technology enables seamless flow).

P2 (Sociability Primacy): Sociability is the paramount driver of place attachment, overriding functional dimensions and generating a centripetal cognitive topology anchored by human interaction.

P3 (Environmental Prerequisite): Green Practices function strictly as a hygiene factor (a baseline for institutional legitimacy) rather than a competitive differentiator, where absence punishes but presence is merely expected.

RESEARCH METHOD

Research design

This study employs a qualitative multiple-case study design (Yin, 2018) to examine the structural divergence between firms' innovation efforts - operationalized as "conceived space" in Lefebvre's (1991) spatial trialectic - and customers' perceptual reception of those efforts, operationalized as "lived space." A case study design is epistemologically appropriate here because service quality is not a decontextualized attribute but an emergent property of specific socio-spatial encounters; it cannot be adequately captured through the variance-based logic of survey research alone (Flyvbjerg, 2006). The multiple-case structure, following Yin's (2018) replication logic, enables cross-case pattern matching that strengthens the transferability of theoretical propositions beyond the idiosyncrasies of any single property.

This study adopts an abductive reasoning strategy (Dubois & Gadde, 2002), iterating between theoretical frameworks - S-O-R, Signaling Theory, Lefebvre's spatial trialectic, and Humanistic Geography - and empirical observations to generate mid-range theoretical propositions. This approach is particularly suited to the study's objective of theory refinement: rather than testing pre-specified hypotheses, the study seeks to identify the mechanisms through which innovation inputs are translated - or fail to be translated - into territorial quality outcomes. The three research propositions (P1: Visibility Paradox; P2: Sociability Primacy; P3: Environmental Prerequisite) emerged through this iterative process and are presented as theoretically grounded, empirically illustrated propositions rather than as statistically tested hypotheses.

Case selection: A comparative spatial approach

Purposive sampling was employed to select two hospitality entities in Hanoi that contrast not only along the market tier dimension (5-star international chain versus 4-star independent boutique) but also along the urban morphology dimension - a selection criterion that distinguishes this study from conventional comparative hotel research and directly operationalizes the study's spatial theoretical framework. As illustrated in Figure 1, the two cases are embedded in structurally distinct urban fabrics that function as physical antecedents to the observed service dynamics. The Mövenpick Hotel Hanoi Center (5-star international archetype) occupies the French Quarter, defined by a colonial grid pattern, wide boulevards, and spatial separation from the city's organic commercial fabric. This morphology reinforces spatial detachment and exclusivity, creating a "sanctuary effect" (Suess et al., 2024) that aligns with the hotel's global standardization strategy. The physical buffer from street-level activity favors high-tech integration and formalized service protocols but simultaneously constrains the spontaneous social interactions that generate place attachment. Thus, the spatial grammar of the French Quarter functions as a structural enabler of the centrifugal topology observed in the VOSviewer analysis.

The May De Ville Crown Hotel (4-star boutique counterpoint) is embedded in the Old Quarter, characterized by high-density "tube house" architecture and porous boundaries between private and public spaces. This morphology facilitates "Social Convergence" by positioning the hotel within a vibrant, human-scaled urban fabric that naturally amplifies social interaction. The Old Quarter's spatial grammar functions as a structural enabler of the Centripetal topology observed in the VOSviewer analysis, where human nodes dominate the cognitive landscape, and the hotel achieves brand-place fusion. These distinct spatial fabrics are not merely contextual backgrounds but are theoretically constitutive of the "Visibility Paradox" and "Morphological Convergence/Inertia" phenomena analyzed in this study.

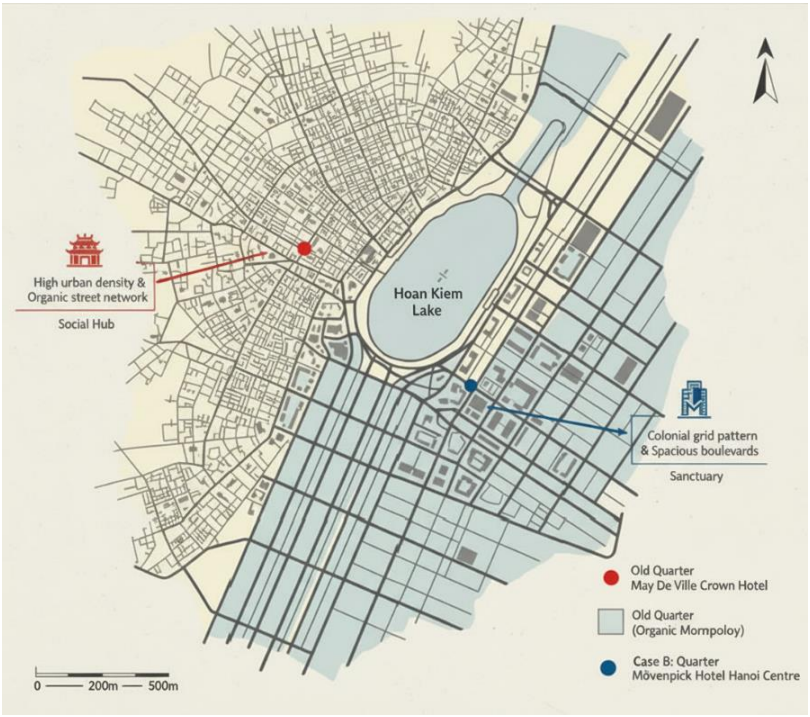

Figure 1. Comparative Spatial Analysis of Study Areas in Hanoi (Source: Authors, 2026)
(Note: The map illustrates the distinct urban morphologies influencing the "micro-geographies" of the two cases.)

Data collection

To ensure methodological rigor and adhere to the principle of triangulation (Denzin, 1978), data were collected from two independent sources reflecting the dual perspectives of the service encounter - the managerial "conceived space" and the guest's "lived space" - in direct correspondence with the study's Lefebvrian theoretical framework.

Supply side data were gathered through semi-structured in-depth interviews with senior managers responsible for strategy and operations: Mr. Ngo Van Lung (HR Manager, Mövenpick Hotel Hanoi Center) and Ms. Le Thi Ngoc (Manager, May De Ville Crown Hotel). The interview protocol was structured around the proposed 8-dimensional service quality model, probing strategic innovation orientation, resource allocation priorities, technological infrastructure decisions, and managerial expectations regarding guest behavior. The interviews were audio-recorded, transcribed verbatim, and subjected to member checking to ensure interpretive accuracy. These data provide insight into the "input" side of the innovation process - both tangible capital investments (CRM systems, physical renovations) and intangible efforts (personnel training, green SOPs) - constituting the "Strategic Input (Conceived Space)" scores in the radar model.

While the supply side sample comprises two primary managerial interviews, this purposive selection is epistemologically justified within the case study design through the "key informant" and "elite interviewing" techniques (Marshall, 1996). In operationalizing Lefebvre's (1991) "conceived space," the objective is not the statistical representativeness of the general workforce, but the accurate capture of top-down strategic intent, capital allocation, and spatial planning. As senior decision-makers, these informants possess concentrated and authoritative knowledge of their respective properties' strategic trajectories. Furthermore, to prevent single-source bias and ensure data saturation, these elite interviews were systematically triangulated with institutional documentary evidence, including corporate Standard Operating Procedures (SOPs), rebranding press releases, digital infrastructure blueprints, and direct spatial observations of the physical environment. This rigorous triangulation ensures that the "Strategic Input" scores reflect objective institutional realities rather than individual managerial idiosyncrasies, providing a robust, structurally valid counterweight to the extensive demand-side UGC dataset (N=2,377). Demand-side data were obtained through the automated extraction of User-Generated Content (UGC) from TripAdvisor using the Apify web-scraping tool.

The final dataset comprised 1,813 reviews for the Mövenpick Hotel Hanoi Centre and 564 reviews for the May De Ville Crown Hotel, including full textual comments, sub-ratings (cleanliness, service, value, and location), and timestamps. The deliberate asymmetry in the corpus size reflects the differential review volume associated with the two properties' market positions and is addressed analytically through proportional rather than absolute frequency measures. UGC was selected as the demand-side data source because it provides organic, unprompted, post-experience narratives that are free from the social desirability bias inherent in researcher-administered surveys (Perez-Aranda et al., 2025), capturing the authentic "lived space" of the guest experience rather than a socially constructed response to a structured instrument.

Data analysis and visualization

Data analysis employed a multi-tiered analytical framework combining qualitative content analysis for managerial inputs and computational text mining for customer outputs, operationalizing the dyadic supply-demand structure of the research design. To ensure methodological transparency and replicability, the translation of qualitative data into quantitative spatial metrics (1-5 scale) was governed by a rigorous, theoretically grounded scoring rubric (Table 2). For managerial data, deductive thematic coding was applied to the proposed 8-dimensional service quality model. Each coded segment was assigned a "Strategic Input" score (1-5), reflecting the intensity of managerial investment, resource allocation, and strategic intentionality. These scores constitute the "Conceived Space" axis. For UGC data, sentiment intensity was quantified using a hybrid approach: automated sentiment analysis via the VADER (Valence Aware Dictionary and sEntiment Reasoner) lexicon, chosen for its robust handling of social media and UGC microblogs, coupled with manual contextual validation for industry-specific nuances. The resulting sentiment distribution, triangulated with the node centrality metrics from VOSviewer, was translated into "User Experience" scores (1-5). This dual-verification ensures that a score of '5' requires not just positive sentiment but also structural centrality in the guest's cognitive topology. The gap between the Strategic Input and User Experience scores-the "Divergence/Convergence Value"-operationalizes Lefebvre's (1991) spatial contradiction between conceived and lived space and is visualized through Radar Charts.

Table 2. The Dyadic patial scoring rubric (1-5 scale)

Score	Strategic Input (Conceived Space) Based on Interviews & Resource Allocation	User Experience (Lived Space) Based on UGC Sentiment & Network Topology
5	Core Territorial Pillar: Maximum strategic priority; heavy capital/training investment; defines the brand's spatial identity.	Territorial Anchor (Delighter): Overwhelmingly positive sentiment (>80%); forms a central and high-density node in the cognitive network.
4	Proactive Investment: High strategic focus; deliberate integration into daily operational protocols and spatial design.	Positive Alignment: Consistent positive mentions function as a reliable spatial enabler without dominating the network core.
3	Baseline Compliance: Moderate investment; treated as an industry standard or operational necessity rather than a differentiator.	Zone of Indifference: Neutral sentiment or structural absence (invisible infrastructure); expected but not actively praised.
2	Reactive/Minimal Focus: Low strategic priority; addressed only when necessary; minimal resource allocation.	Spatial Friction: Frequent negative mentions create noticeable operational or emotional drag on the guest experience.
1	Strategic Void: No intentional investment or managerial focus on this spatial dimension.	Severe Disconfirmation: Dominant negative sentiment forms a peripheral cluster of complaints indicating systemic territorial failure.

Crucially, in constructing the UGC dataset, platform-specific traces-including hyperlink artifacts ("http") and reviewer metadata-were intentionally preserved rather than removed as noise. Consistent with the study's Digital Geography framework, these traces are treated as markers of "infrastructural visibility": their prominence in the semantic network maps the degree to which the digital layer becomes salient in the guest's discourse, functioning as empirical evidence of the "Virtual Encroachment" phenomenon theorized in Section 2.

RESEARCH RESULTS

The production of tourism space: strategic intent vs. territorial reality

The managerial perspective: divergent spatial strategies

In-depth interviews with senior management, Mr. Ngo Van Lung (HR Manager, Mövenpick) and Ms. Le Thi Ngoc (Manager, May De Ville)-reveal that while competitive pressures are shared, spatial development trajectories diverge significantly based on urban morphology. The 5-star segment prioritizes global spatial synchronization. Mövenpick utilizes its CRM system (ACDC) to dissolve geographical boundaries through continuous data flow. Mr. Lung noted, "ACDC is a massive technological innovation... if a guest enjoys milk coffee in Vietnam, staff in Cambodia will know to serve it," creating a unified global service territory. Conversely, the 4-star segment leverages technology for operational optimization within a constrained footprint. Ms. Ngoc emphasized that "service time is faster with automated booking software," noting that eliminating manual entry compresses the time and space required for service delivery.

Regarding resource allocation, Mövenpick adopts a demographic adaptation strategy by modifying F&B products (e.g., dim sum and kimchi) for specific international flows. In contrast, May De Ville pursues functional expansion, transforming from a lodging unit into an integrated "experience territory" via Sky Bars and Spas. Notably, a convergence exists at the human-environment interface: both entities have transitioned to eco-friendly materials, with Ms. Ngoc citing the shift to branded paper boxes as a tangible commitment to the restaurant's ecological contract. Finally, spatial restructuring differs: Mövenpick is undergoing a metamorphosis to "modern luxury" for rebranding, while May De Ville utilizes micro-spatial adjustments to optimize utility within the high-density Old Quarter.

The customer perspective: spatial perception and digital geomarketing

Geomarketing analysis via Apify provides an empirical counter-narrative to the managerial production. At Mövenpick (5-star), Word Cloud analysis highlights experiential keywords ("Chocolate Hour," "Lounge") rather than technological attributes. While positive sentiment clusters around service rituals, significant negative clusters emerge regarding material degradation ("Old," "Dated," "Dark") and friction in the Human-Environment relationship ("Light switches," "AC"). This indicates spatial dissonance, where high-tech backend efforts fail to compensate for the built environment’s physical deterioration. Conversely, May De Ville (4-star) data reflect a highly personalized social geography. The prevalence of specific staff names ("Rosie," "Bella," "Anna") in 5-star reviews indicates that customers are captivated by human-place interactions rather than systemic perfection. Keywords like "Rooftop Bar" and "Pool" confirm the success of the hotel as a "Social Hub." The contrast is stark: large-scale hotels rely on technocratic systems, whereas boutique hotels succeed through social convergence and effective utilization of relational space.

Impact on functional quality: The interplay of digital and social geographies

Regarding Responsiveness, a clear spatial-temporal optimization is observed in the 4-star segment. Managerial claims regarding automated software are corroborated by customer keywords such as "swift" and "efficient," demonstrating that technology successfully acts as a spatial accelerator. However, regarding reliability, structural dissonance exists in the 5-star segments. While the backend CRM creates a seamless digital territory, the physical interface (key cards, room controls) exhibits failure. This represents tangible friction, where the stability of the built environment lags behind the sophistication of the virtual infrastructure. Finally, in terms of assurance, human geography remains the ultimate stabilizer. Even when technological infrastructure falters (e.g., app glitches at Mövenpick), professional staff recovery preserves trust, suggesting that while technology facilitates efficiency, the social component ensures structural integrity.

Impact on emotional quality: Social geography and environmental integrity

Regarding Empathy, the study uncovers a dichotomy between "Algorithmic Empathy" and "Authentic Connection." Mövenpick’s data-driven standardization creates a perception of "professional correctness" but lacks the emotional resonance for genuine place attachment. In contrast, May De Ville’s "High-touch" approach generates superior emotional scores through unscripted interactions. Regarding Tangibles, a "Perceptual Gap" characterizes the 5-star case. A "Rebranding Lag"-where modernized public zones contrast with dated private interiors-creates spatial fragmentation and "Negative Disconfirmation." Meanwhile, the 4-star hotel achieves higher satisfaction by maintaining territorial consistency and environmental hygiene ("Sleeping on a cloud"), proving that rigorous preservation often trumps superficial modernization.

Empirical analysis of new spatial dimensions

Smart service: The digital-physical interface paradox

The results indicate that digital proliferation does not equate to high quality. At Mövenpick, complex physical interfaces (e.g., light switches) create "spatial friction" in the private sphere. Conversely, May De Ville’s "Invisible Technology" (backend support) empowers human agents, resulting in higher perceived "smartness." Thus, smart services should be conceptualized by spatial fluidity and seamless man-machine interaction, not device density.

Green practices: environmental baseline

Text mining revealed a "zone of indifference" in relation to ecological footprints. Positive mentions are negligible

(<0.5%); however, negative sentiment spikes when practices disrupt experiences (e.g., paper straw failure). This confirms that Green Practices have transitioned from a "Delighter" to a "Fundamental Environmental Prerequisite"-a baseline for institutional legitimacy where absence punishes the brand, but presence is viewed merely as compliance.

Sociability: The production of relational space

Sociability is the most potent driver of place attachment. Whether through structured rituals ("Chocolate Hour") or organic zones ("Rooftop Bar"), the function of the hotel as a "Social Hub" consistently garners the highest sentiment. This validates sociability as a critical dimension, filling the emotional void that functional attributes cannot address.

Comparative spatial analysis and synthesis

Table 3 contrasts the governing spatial dynamics by applying Yin's (2018) pattern matching.

The cross-case synthesis crystallizes into three dynamics. First, a "Spatial Interface Paradox" exists, i.e., technological efficacy is inversely related to hardware obtrusiveness and technology creates maximal value as an "invisible enabler." Second, large-scale organizations suffer from "Territorial Inertia," where strategic rebranding outpaces physical adaptation, causing temporal and spatial dissonance. Ultimately, "Social Convergence" remains the universal denominator: regardless of scale, the capacity to foster sociability drives the successful production of tourism space.

Table 3. Comparative matrix of territorial strategy vs. perceived spatial quality (Source: Synthesized from case study data)

Analysis Criteria	Mövenpick Hotel Hanoi Centre (5-Star International)	May De Ville Crown Hotel (4-Star Boutique)	Geo-Spatial Implication
Territorial Management Strategy	System-based: Global standardization, Big Data (ACDC), and rebranding.	Human-centric: Micro-spatial agility, Empowerment, On-site amenities.	Scale dictates morphology: Large scale favors Structure; Small scale favors Behavioral Geography.
Technological Interface	Visible Tech: Obtrusive in-room devices and apps. *Results:* Spatial Friction (Negative Gap).	Invisible Tech: Backend logistics. *Results:* Seamless Flow (Positive Gap).	Technology maximizes value when it acts as an "Invisible Spatial Enabler."
Social Geography	Programmed: Standardized rituals (Chocolate Hour). *Perception:* Professional Correctness.	Naturalized: Spontaneous interaction. *Perception:* Intimacy/Place	Global chains must "soften" rigid protocols; Boutiques must maintain "familial culture."
Spatial Coherence	High Divergence: Gap between investment and physical reality.	High Convergence: Alignment between effort and spatial satisfaction.	Complexity increases the risk of "Territorial Dissonance."

Table 4. Spatial divergence scoring for Mövenpick Hotel Hanoi Centre (Source: Authors, 2026)

Spatial Dimension	Strategic Input (Conceived Space)	User Experience (Lived Space)	Divergence Value	Geo-Spatial Interpretation
Smart Interface	5	2	-3 (Negative)	Technological imposition creates interface friction within the private zone.
Physical Infrastructure	5	2	-3 (Negative)	Strategic rebranding conflicts with the inertia of the built environment.
Ecological Integration	4	3	-1 (Neutral)	Environmental commitment is perceived as a baseline standard.
Social Geography	4	3	-1 (Neutral)	Data-driven personalization fails to generate place attachment.
Social Spatiality	3	5	+2 (Positive)	The peripheral social ritual (Chocolate Hour) becomes the primary spatial attractor.

Modeling spatial dissonance: A semi-quantitative geomarketing assessment

The spatial divergence scoring for the Mövenpick case is detailed in Table 4 and visualized through a multidimensional radar model (Figure 2).

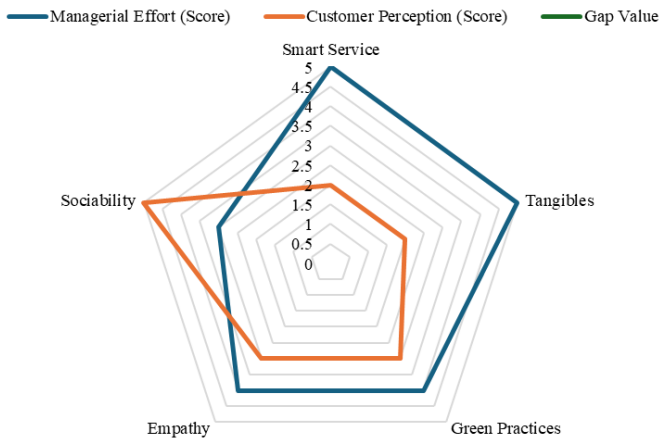

Figure 2. The radar chart of territorial alignment (Mövenpick Case) (Source: Authors, 2026)

Table 5. Spatial convergence scoring for May De Ville Crown Hotel
(Source: Self-constructed based on Interview and Geomarketing Data Analysis)

Spatial Dimension	Strategic Input (Conceived Space)	User Experience (Lived Space)	Convergence Value	Geo-Spatial Interpretation
Social Geography (Empathy)	5 (High-touch core)	5 (Excellent)	0 (Perfect Alignment)	The "Human Agency" strategy is fully realized. Specific staff (Rosie, Nina, and Nikki) act as key territorial agents who define the place.
Social Spatiality (Sociability)	4 (Strategic focus)	5 (Delighter)	+1 (Positive)	The Rooftop Bar & Pool functions as a "Territorial Node," generating place attachment that exceeds the boutique scale.
Smart Interface (Smart Service)	3 (Backend efficiency)	4 (High Efficiency)	+1 (Positive)	The Invisible Logistics" (booking software) optimizes the spatial flow, creating speed without interface friction.
Built Environment (Tangibles)	4 (Maintenance)	4 (Good)	0 (Alignment)	The quality of the micro-geography (e.g., "comfy beds") aligns perfectly with the boutique morphology.
Ecological Integration (Green Practices)	3 (SOP compliance)	3 (Neutral)	0 (Neutral)	Validated as an Environmental Prerequisite: present as a baseline norm but not a primary spatial attractor.

The radar configuration elucidates three types of territorial divergence. First, pronounced "Negative Spatial Friction" characterizes Smart Interface and Physical Infrastructure, signaling a malfunction where aggressive inputs fail to translate into habitable quality due to execution lags. In contrast, a "Positive Spatial Surplus" emerges in Social Spatiality, where auxiliary social zones unexpectedly outperform the core-built environment, highlighting the organic vitality of the territory. Intermediate is the "Environmental Baseline" (Ecological Integration), functioning as a prerequisite for legitimacy, rather than a spatial attractor. Conversely, the May De Ville Crown exhibits morphological convergence, detailed in Table 5 and visualized in Figure 3 as a convergence bar chart in which all spatial dimensions register a gap value approaching zero - a stark visual contrast to the multi-directional divergence observed in the Mövenpick radar. This "flat alignment" is not a sign of managerial underinvestment but rather of strategic parsimony: by concentrating resources on the dimensions most valued by guests (Social Geography and Sociability) and deploying technology invisibly (Smart Interface), the hotel achieves a state of territorial coherence where conceived space and lived space are effectively co-extensive. The hotel achieves perfect alignment in Social Geography (Convergence Value = 0), with staff names (Rosie, Nina, and Nikki) permeating >80% of the data, confirming human capital as the primary territorial agent. A "Positive Spatial Surplus" in Smart Interface (+1) is driven by "Invisible Infrastructure," where backend logistics create spatial fluidity without interface friction. Concurrently, Social Spatiality exhibits a "Spatial Halo Effect" (+1), where the rooftop bar acts as a "Territorial Node," mitigating dissatisfaction with physical constraints through strong atmospheric vibes.

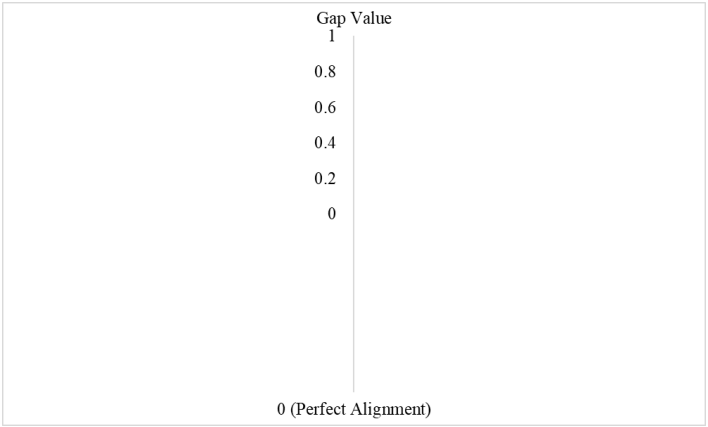

Figure 3. The Radar Chart of Territorial Coherence (May De Ville Case) (Source: Authors, 2026)

Mapping the cognitive landscape: A semantic topology of place attachment

Using VOSviewer, this study maps the "Cognitive Topology" of the guest experience, revealing hidden associations beyond linear frequency counts.

The "Anthropogenic" Territorial Cohesion (May De Ville Crown): Network topology (Figure 4) reveals a dense, cohesive structure (125 items, 28,951 link strength) organized around a gravitational center. Structurally, the brand node ("de ville crown hotel") occupies the largest and most central position in the network, functioning as the primary territorial anchor. This finding confirms brand-place fusion, wherein the hotel's identity and the guest's sense of place have become inseparable in the cognitive landscape. Radiating outward from this anchor, three interconnected clusters define the network architecture:

The Anthropogenic Core: The nodes "team," "guest," and "experience" form a tightly linked blue cluster at the network's operational center, underscoring that human interaction dominates the physical space in the guest's mental map. The node "opportunity" occupies a bridging position between the anthropogenic core and the brand anchor, suggesting that guests perceive the hotel not merely as a place of consumption but as a space of possibility - a finding consistent with

hedonic value co-creation theory (Alhomaid et al., 2025). The Loyalty-Intimacy Cluster: The nodes "patronage," "whole team," and "trip" form a peripheral western cluster, strongly linked to the brand node through high-strength co-occurrence. The presence of "patronage" - denoting repeated, loyal visitation - alongside "family" and "highly" in the brand's immediate semantic neighborhood empirically validates the transformation from abstract space to meaningful "place" (Tuan, 1977), where the hotel becomes a "Domestic Sphere." The eastern periphery is anchored by "praise" and "next trip" (orange cluster), representing the behavioral outcome of place attachment: the intention to return and recommend.

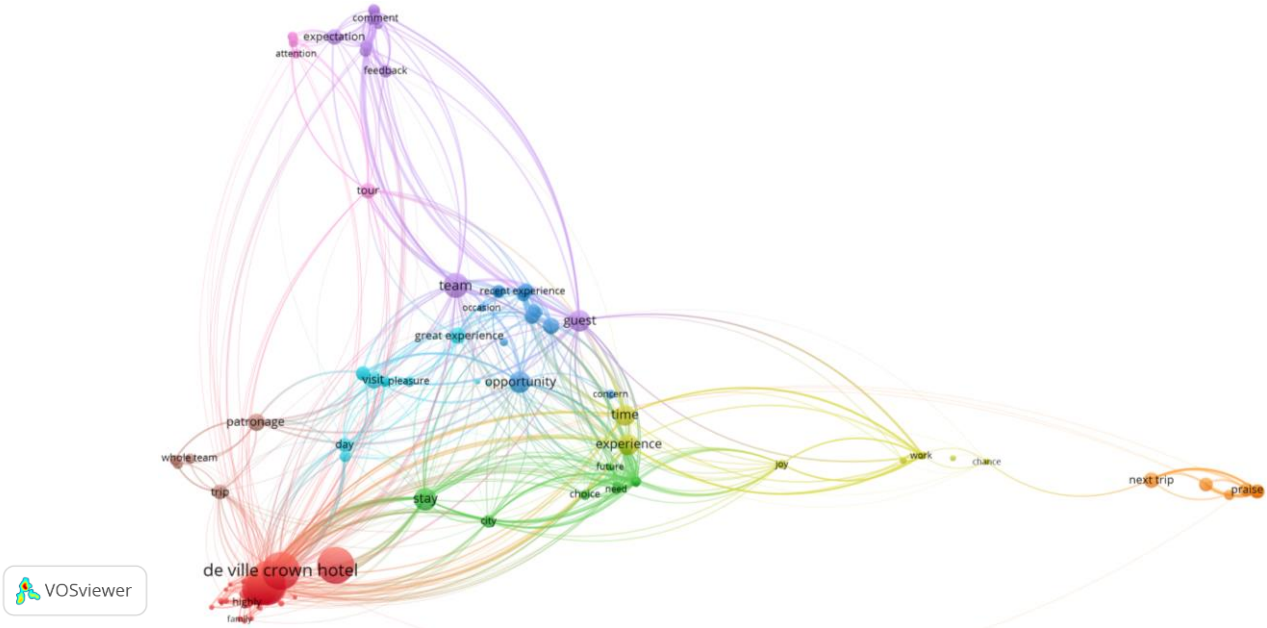

Figure 4. Comparative Spatial Topology of Guest Experience - (a) May De Ville Crown Hotel - The "Anthropogenic" Territorial Cohesion (Source: Author's elaboration using VOSviewer geomarketing analysis based on TripAdvisor data mining, 2026)
(Based on VOSviewer analysis: Binary counting, Threshold = 10 occurrences)

The Voice of Customer Cluster: A distinct purple cluster in the upper network - comprising "expectation," "feedback," "comment," and "attention" - reveals a meta-communicative dimension absent from the Mövenpick network. May De Ville guests do not merely experience the hotel; they actively reflect on and articulate their experiences, suggesting a higher level of cognitive engagement and emotional investment. This cluster functions as a "Reflexive Geography" - a space where the guest becomes a co-author of the hotel's territorial narrative.

Invisible Infrastructure: Critically, a "structural hole" exists in the technological keywords. The complete absence of backend system terms from the cognitive map supports the "Spatial Interface Paradox": technology functions successfully as an invisible infrastructure, creating spatial fluidity without demanding conscious engagement, thereby allowing the human team to occupy the entire foreground of the guest's mental territory.

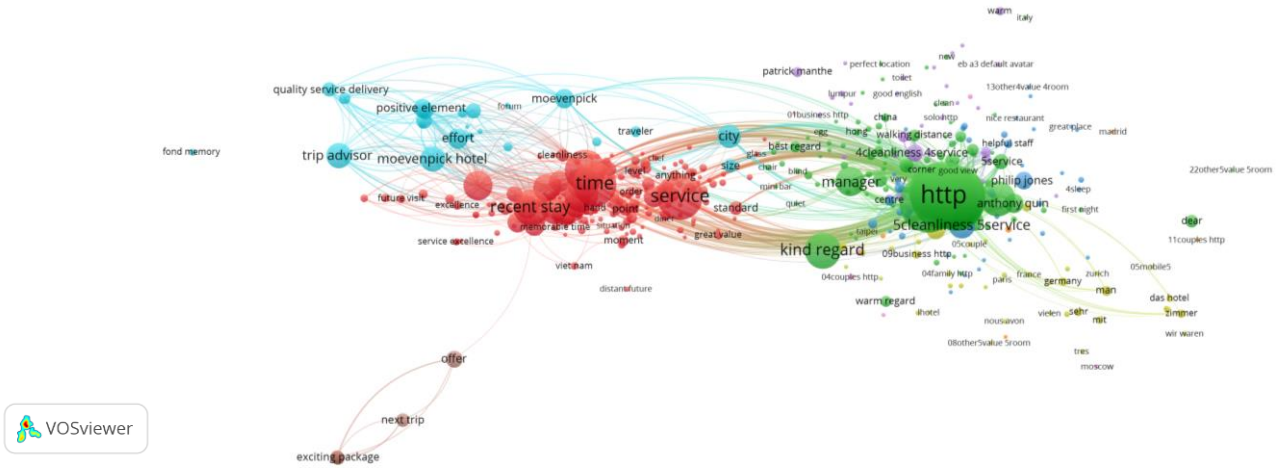

Figure 5. Comparative Spatial Topology of Guest Experience - (b) Mövenpick Hotel Hanoi Centre - The "Systemic" Territorial Fragmentation (Source: Author's elaboration using VOSviewer geomarketing analysis based on TripAdvisor data mining, 2026)
(Based on VOSviewer analysis: Binary counting, Threshold = 10 occurrences)

The "Systemic" Territorial Fragmentation (Mövenpick): In contrast, the Mövenpick network (Figure 5) reveals a sprawling, fragmented topology (484 items) that is structurally "Centrifugal" - pushing guest perception outward into

systemic noise rather than inward toward a social core. Four structural features characterize this fragmentation. Temporal-Operational Dominance: The largest nodes in the network are "recent stay" and "time" (Red Cluster), not experiential or emotional descriptors. This temporal fixation reveals that guests evaluate Mövenpick primarily through the lens of transactional efficiency - how long things take and how recently they occurred - rather than through the lens of place attachment. The co-dominance of "service" within this cluster confirms that the hotel is perceived as a service delivery system rather than a meaningful place, a finding consistent with Augé's (1995) conceptualization of the "Non-Place" as a space defined by transit and transaction. Digital Territorial Encroachment: The network is dominated by the oversized "http" node (Green Cluster), which in digital geography represents "Virtual Encroachment" - the invasion of administrative space into lived space. The structural proximity of "http" to "manager" and "kind regard" is particularly revealing: "kind regard" is a formulaic email closing, indicating that a significant proportion of the UGC corpus consists of management response templates rather than authentic guest narratives. This "Algorithmic Governance" - where managerial voice colonizes the review space - creates a "Technological Wall" that further distances the hotel from genuine human connection, rendering the territory a "Non-Place" (Augé, 1995). Spatial Fragmentation and Material Degradation: The network lacks a unified emotional core and is divided into functional silos. Peripheral nodes - "toilet," "blind," "glass" - indicate that guest attention is fixed on material degradation, amplifying "Negative Disconfirmation." The presence of "moevenpick hotel" and "trip advisor" as co-occurring nodes within the Cyan Cluster reveals a meta-cognitive awareness: guests are conscious of the review platform as a mediating layer between their experience and its public representation, suggesting a more transactional, less immersive relationship with the hotel environment.

The Geography of "Placelessness": Multilingual nodes ("vielen," "sehr," "wir waren," "das hotel," "nousavon") reflect the hotel's global standardization strategy but topologically create a diffuse network lacking community identity (Relph 1976). Notably, the node "fond memory" appears in the far western periphery - isolated from the network's core - suggesting that while positive emotional experiences do occur at Mövenpick, they fail to achieve the semantic density and centrality necessary to define the hotel's territorial identity. This peripheral positioning of positive affect, in contrast to the central positioning of transactional and technological nodes, encapsulates the hotel's fundamental spatial challenge: emotional value is produced at the margins, while operational complexity dominates the center.

The boutique network is thus "Centripetal," pulling guests into a social core anchored by human agency, whereas the international chain is "Centrifugal," pushing perception outward into systemic noise. This confirms that without "Sociability" as the architectural principle of the service territory, service volume alone fails to construct a coherent territorial narrative, and that the consequences of this failure are legible in the very topology of the guest's cognitive map.

DISCUSSION AND IMPLICATIONS

Decoding the territorial fractures: spatial and digital dissonance

Cross-verification of dyadic data - managerial interviews and VOSviewer semantic topologies - reveals a critical asymmetry: strategic inputs do not translate linearly into territorial recognition but are mediated by three distinct "Spatial Fractures," each corresponding to a specific failure mode in the human-environment relationship.

The "Virtual Encroachment" on lived space

The study identifies a "Visibility Paradox": perceived technological efficacy is inversely proportional to technological visibility. This finding directly advances and complicates the theoretical position of Zhou et al. (2025), who demonstrated that digital orientation and capabilities are necessary and sufficient conditions for service innovation from a supply side perspective. The demand-side evidence in the present study reveals the critical boundary condition that Zhou et al.'s framework cannot detect: *the same level of digital capability generates diametrically opposite spatial outcomes depending on whether the technology is visible or invisible to the guest.* Mövenpick's ACDC system - representing precisely the "high digital orientation + high digital capability" configuration that Zhou et al. (2025) theorize as optimal - fails to generate corresponding customer recognition in the UGC data, while May De Ville's comparatively modest automated booking software generates a "Positive Spatial Surplus" (+1) precisely because it operates as a silent infrastructure.

The geomarketing analysis (Figure 5) exposes a "Systemic Intrusion" in the 5-star segment of the market. The oversized "http" node acts as a trace marker of infrastructural visibility, creating a "Technological Wall" that fragments the guest's lived space. Critically, the structural proximity of "http" to "manager" and "kind regard" in the Mövenpick network reveals a dimension not previously theorized in the literature: "Algorithmic Governance." The node "kind regard" - a formulaic email closing - indicates that a significant proportion of the UGC corpus consists of management response templates rather than authentic guest narratives. This managerial voice colonizes the review space, creating a meta-layer of administrative language that further distances hotels from genuine human connections. This finding extends Augé's (1995) concept of the "Non-Place" beyond its original architectural application into the digital domain: the Mövenpick review space is itself a "Non-Place," a transactional corridor of standardized responses rather than a community of authentic voices. A nuanced counterpoint, however, must be acknowledged: the node "fond memory" appears on the far western periphery of the Mövenpick network - isolated from the core but present. This peripheral positioning of positive affect is not analytically trivial or unimportant. This suggests that genuine emotional experiences do occur at Mövenpick, but they fail to achieve the semantic density and centrality necessary to define the hotel's territorial identity. This finding resonates with Kandampully et al. (2023) argument that technology and human elements are "deeply entangled" in the luxury servicescape; the entanglement at Mövenpick is not absent but asymmetric, with operational complexity dominating the center while emotional value is produced at the margins. The strategic implication is significant: Mövenpick does not need to abandon its technological infrastructure but rather to rebalance

the entanglement, pushing technology toward the periphery and elevating emotional experiences toward the center. Conversely, the "Anthropogenic Topology" of the 4-star segment (Figure 4) is characterized by a "structural hole" in technology. The absence of technical nodes, juxtaposed with the centrality of human agents, confirms that technology generates maximal value only when it functions as an "Invisible Infrastructure." This finding validates Yang & Leung's (2025) complexity-resistance thesis at the micro-spatial level: by eliminating interface complexity, May De Ville eliminates the primary trigger of technology anxiety, liberating human agency to cultivate the "Social Territory." The digital interface must recede to allow human geography to dominate - a principle that the present study terms the "Background-Foreground Inversion" of the optimal human-environment-technology triad.

Morphological inertia and spatial dissonance

This research illuminates "Morphological Inertia" - a concept that operationalizes Lefebvre's (1991) spatial contradiction between conceived space (the planned, strategic space of managers) and lived space (the experiential, symbolic space of guests) at the property level. While Mövenpick's management envisioned "Modern Luxury" as the hotel's conceived space, semantic clusters of "Old," "Dated," and "Dark" in the UGC data confirm that the physical landscape acts as a drag on the brand's narrative, producing a lived space that contradicts the managerial representation. This exemplifies "Territorial Malfunction": corporate narratives inflate expectations that the material territory cannot fulfill, generating the "Negative Disconfirmation" that Tiwari & Omar (2025) theorize as the primary mechanism of loyalty erosion. The temporal dimension of this inertia is significant in this study. Ruiz-Fernández et al. (2026) demonstrate that chain-affiliated properties suffer from structural lag between strategic intent and operational adaptation; the present study provides granular spatial evidence of where this lag manifests: not in public zones (which have been modernized) but in the private sphere of the guest room, where dated interfaces (light switches, AC controls) create "spatial friction" at the most intimate level of the hotel experience.

This spatial specificity - the divergence between the public face and the private reality of the hotel - is a finding that neither Ruiz-Fernández et al. (2026) nor Suess et al. (2024) could detect through their respective methodologies, and it constitutes a distinctive empirical contribution of the present study's UGC-based spatial analysis. In contrast, the boutique model achieves "Morphological Convergence" because its spatial adjustments - rooftop expansion, pool installation, micro-spatial optimization within the Old Quarter's constrained footprint - are agile, immediately perceptible, and morphologically consistent with the boutique promise. The convergence bar chart (Figure 3) visualizes this alignment: all spatial dimensions register a Gap Value approaching zero, a stark visual contrast to the multi-directional divergence of the Mövenpick radar. This "flat alignment" is not a sign of managerial underinvestment but of strategic parsimony - the disciplined concentration of resources on dimensions most valued by guests, a principle that resonates with Alhomaid and Bel Hadj's (2025) finding that hedonic value pathways generate stronger place attachment than utilitarian ones.

Ecological integration: The human-environment contract

The valuation of green practices has undergone a fundamental ontological shift: from a "value-add" differentiator to a "Territorial Prerequisite." Despite managerial pride in sustainable SOPs - both Mövenpick and May De Ville have adopted eco-friendly materials as convergent baseline practices - the "zone of indifference" in sentiment analysis (positive mentions < 0.5%) confirms that Green Practices have evolved into an Environmental Norm. This finding corroborates and extends Khuong et al. (2025) discovery that specific green practices (water- and energy-saving) do not directly influence satisfaction or positive mood, and Perez-Aranda et al.'s (2025) observation that sustainability practices elicit more ambivalent consumer responses than health-safety practices. The present study advances this literature by providing a mechanism for this ambivalence: green practices are noticed only when they fail (negative disconfirmation from paper straw failure) but are invisible when they succeed (baseline compliance). This asymmetric visibility pattern - what the present study terms the "Ecological Invisibility Principle" - has direct implications for resource allocation: investment in green practices beyond the baseline threshold generates diminishing perceptual returns, while failure to meet the baseline generates disproportionate reputational damage. In the contemporary tourism landscape, ecological responsibility is a baseline for institutional legitimacy; its presence secures "Assurance," but its functional failure disrupts the guest's comfort within the service ecosystem - a pattern structurally identical to the health-safety baseline that Tiwari & Omar (2025) identify in the post-COVID hotel context.

Validation of the geo-spatial service framework

Based on empirical pattern matching and network topology, this study affirms the validity of the proposed 8-component Service Quality model. The three newly integrated dimensions - Smart Service, Green Practices, and Sociability - demonstrate not only theoretical distinctiveness but also empirical non-substitutability: no combination of the original five LODGSERV dimensions can capture the spatial dynamics that these three dimensions reveal.

Smart Interface: The Digital Geography Dimension

The data definitively separate "Machine Efficacy" from "Human Willingness," confirming Smart Service as an independent spatial construct for measuring the quality of the digital environment, distinct from and non-reducible to the Tangibles dimension of LODGSERV. Semantic separation in the 5-star network (the "http" cluster operating as a distinct functional silo, disconnected from the social and emotional clusters) provides topological evidence that guests cognitively segregate technological experiences from human experiences, processing them through different evaluative frameworks.

This finding has important implications for the development of the scale. Ahmad et al.'s (Alhomaid et al., 2025) treatment of "AI-enabled experience" as a monolithic construct would conflate the ACDC system (which generates spatial friction) and the automated booking software (which generates spatial fluidity) into a single undifferentiated score, masking the divergence that drives competitive differentiation. The present study's operationalization of Smart Service through the visibility dimension - rather than the quantity or sophistication of technology deployed - provides a more discriminating

and managerially actionable construct. Furthermore, the "Centripetal vs. Centrifugal" topology contrast provides a novel network-level indicator of Smart Service quality: a centripetal network, in which human nodes dominate the center and technological nodes are absent from the cognitive landscape, signals successful Smart Service delivery; a centrifugal network, in which technological nodes fragment the center, signals Smart Service failure. This topological indicator complements and extends the node-level analysis of Yang & Leung (2025), offering a structural measure of smart service quality that individual keyword frequency counts cannot provide.

Ecological Integration: Ethical Landscape

Refuting the notion of sustainability as peripheral CSR, the findings validate Green Practices as a core quality constituent representing the ethical dimension of the service territory. The convergent adoption of eco-friendly materials by both hotels - despite their divergent strategies in every other dimension - confirms that ecological responsibility has achieved the status of a non-negotiable institutional norm, consistent with Bordian et al.'s (2026) finding that Sustainability-Oriented Service Innovation positively influences satisfaction through value co-creation.

However, the empirical evidence of the present study introduces a critical qualification to Bordian et al.'s (2026) optimistic assessment: the positive effect of the SOSI on satisfaction is contingent on execution consistency. The paper straw failure at Mövenpick, where an eco-friendly substitution disrupts the guest's sensory experience, demonstrates that poorly executed green practices can generate negative disconfirmation that outweighs the positive legitimacy signal of ecological commitment. This "Execution Consistency Condition" is a boundary condition that Bordian et al.'s (2026) cross-sectional PLS-SEM design cannot detect, and it constitutes a theoretical refinement of the SOSI construct.

As tourists become more environmentally conscious, the ability to harmonize luxury with ecological responsibility directly impacts "Territorial Assurance" - the guest's confidence that the hotel's values align with their own. This alignment between personal and institutional values is the mechanism through which Green Practices contribute to place attachment, operating not through direct sensory pleasure (hedonic value) but through moral congruence (ethical value) - a distinction that the present study's 8-component model captures and the original LODGSERV framework cannot.

Sociability: The Apex of Place Attachment

Perhaps the most significant theoretical contribution of this study is the validation of Sociability as the architectural principle of the luxury hotel experience - not merely one dimension among many, but the organizing force that determines whether a hotel's service territory coheres into a meaningful "place" or dissolves into a standardized "non-place."

The May De Ville VOSviewer network (Figure 4) provides multilayered empirical evidence for this claim. At the network's center, the brand node ("de ville crown hotel") achieves the highest semantic density, confirming brand-place fusion: the hotel's identity and the guest's sense of place have become inseparable in the cognitive landscape. Radiating outward, the "Loyalty-Intimacy" cluster - where the hotel name is strongly linked to "family," "patronage," and "highly" - empirically validates Tuan's (1977) space-to-place transformation, where the hotel becomes a "Domestic Sphere" rather than a commercial transaction space. The eastern periphery, anchored by "praise" and "next trip," represents the behavioral outcome of this place attachment: the intention to return and to recommend - the ultimate measure of loyalty in the Social Exchange Theory framework (Tiwari & Omar, 2025). A finding not previously theorized in the literature is the "Voice of Customer" cluster - the purple nodes "expectation," "feedback," "comment," and "attention" in the upper network.

This cluster reveals a meta-communicative dimension of sociability: May De Ville guests do not merely experience the hotel; they actively reflect on and articulate their experiences, functioning as co-authors of the hotel's territorial narrative. This "Reflexive Geography" - absent from the Mövenpick network - suggests that high-sociability environments generate not only emotional attachment but also cognitive engagement, transforming passive consumers into active territorial agents.

This finding resonates with S-D Logic's (Vargo & Lusch, 2008) conceptualization of value co-creation, extending it from the service encounter to the post-encounter review space. Whether through structured rituals (e.g., "Chocolate Hour" at Mövenpick) or organic atmospheres ("Rooftop Bar" at May De Ville), sociability functions as a Spatial-Social Outcome that transcends the functional quality dimensions of LODGSERV. The boutique network's centripetal topology - pulling guests into a social core - versus the international chain's centrifugal topology - pushing perception outward into systemic noise - confirms that successful hotels in dense urban landscapes such as Hanoi must function as "Territorial Nodes" facilitating human connections, rather than as mere shelter providers or technology showcases.

Implications for Territorial Planning and Management

The findings advocate a paradigm shift from product-centric operations to a holistic "Placemaking Strategy" - one that conceptualizes the hotel not as a bundle of service attributes but as a produced territory whose quality is determined by the alignment between conceived and lived space (Lefebvre, 1991). Resolve the Visibility Paradox through "Strategic Concealment." Rather than indiscriminate digitization - which risks creating sterile "non-places" (Augé, 1995) by imposing technological complexity on the guest's private sphere - capital allocation should prioritize backend logistical systems as "Invisible Enablers." This strategic concealment liberates anthropogenic agency, allowing human actors to reclaim their roles as the primary architects of guest experiences. For international chain hotels, the implication is counterintuitive: the path to higher perceived Smart Service quality may require reducing the visibility of technological investment rather than increasing it. The value of the ACDC system should be communicated to guests through its effects (personalized service delivery, anticipatory hospitality) rather than through its interfaces (complex in-room control panels, app-dependent functions). Cultivating Social Geographies as Primary Competitive Assets.

The re-conceptualization of the physical environment as a dynamic "Social Geography" is critical. The "Voice of Customer" cluster in the May De Ville network confirms that high-sociability environments generate not only emotional

attachment but also organic advocacy - guests become co-producers of the hotel's territorial narrative through their reviews, amplifying the sociability signal through the digital public sphere.

For boutique hotels, this implies institutionalizing the "familial culture" that drives staff-name mentions in >80% of reviews, through targeted recruitment, empowerment-based HR practices, and the deliberate cultivation of "Territorial Agents" - staff members who function as the human anchors of the hotel's place identity.

For international chains, the implication is to "soften" rigid service protocols by creating unscripted interaction zones - spaces and moments where staff are empowered to deviate from standardized scripts and engage guests as individuals rather than as data points in a CRM system. Standardizing Environmental Contracts through Execution Consistency.

Ecological practices must be elevated to non-negotiable "Hygiene Factors" with zero tolerance for execution failure. The "Ecological Invisibility Principle" - whereby successful green practices are invisible but failed ones generate disproportionate negative sentiment - implies that the primary risk management challenge is not adoption (both hotels have adopted eco-friendly materials) but consistency. A single paper straw failure can negate months of ecological investment by triggering the collapse of the “zone of indifference” into active negative sentiment.

Therefore, hotels should implement ecological quality control protocols that treat green practice execution with the same rigor as food safety standards - not as a marketing initiative but as an operational non-negotiable.

Limitations and Directions for Future Research

As with all empirical work, the findings of the present study must be interpreted within the context of its methodological boundaries. This study has three limitations warrant explicit acknowledgment.

First, the dual-case design, while methodologically appropriate for exploratory theory building (Yin, 2018), limits the statistical generalizability of the findings. The "Visibility Paradox," "Morphological Inertia," and "Sociability Primacy" propositions are theoretically grounded and empirically illustrated, but their prevalence and magnitude across the broader Vietnamese hospitality landscape and across different cultural contexts remain to be established through large-scale quantitative research. Future studies should test these propositions through multi-property surveys incorporating the extended 8-component model as a validated measurement scale. Second, the UGC-based methodology, while providing organic, unprompted demand-side evidence that corrects for the social desirability bias of survey research, introduces its own selection bias: TripAdvisor reviewers are not representative of all hotel guests, and the platform's review incentive structure may systematically over-represent extreme experiences (very positive or very negative) at the expense of moderate ones. The "zone of indifference" toward green practices, for instance, may partly reflect the platform's emotional amplification effect rather than the true distribution of guest sentiments.

Future research should triangulate UGC data with in-stay experience sampling methods to capture the full spectrum of guest sentiments. Third, the temporal scope of the data collection - a single cross-sectional snapshot of TripAdvisor reviews - cannot capture the dynamic evolution of territorial quality over time.

The "Morphological Inertia" observed at Mövenpick, for instance, may be a transitional phenomenon associated with an ongoing rebranding process rather than a structural characteristic of international hotel chains. Longitudinal UGC analysis - tracking the evolution of semantic network topology across multiple time periods - would provide a more nuanced understanding of how territorial quality responds to strategic interventions and would constitute a significant methodological contribution to the emerging field of Digital Geography in hospitality research.

CONCLUSION

This study aimed to examine the structural divergence between hotel managers' innovation strategies and guests' perceptual reception of those strategies in upper upscale hotels and to identify the spatial and psychological mechanisms through which this divergence is produced, sustained, or resolved. Grounded in the theoretical integration of service-dominant logic, Signaling Theory, and Humanistic Geography, the findings yield three contributions that advance the intersection of tourism geography and hospitality management. First, this study confirms the measurement obsolescence of traditional functionalist frameworks in the Industry 4.0 hospitality context. The empirical validation of smart services, green practices, and sociability as psychometrically distinct and non-substitutable dimensions demonstrates that the contemporary guest experience constitutes a complex spatial construct - shaped by the triadic dynamics among the guest, technology, and physical environment - rather than a linear function of material asset deployment.

Second, the Visibility Paradox (P1) establishes that digital technology functions optimally as an "invisible infrastructure." When technological interfaces intrude upon physical touchpoints, they amplify the Perceptual Gap between conceived and lived spaces, generating spatial friction rather than the convenience signal intended by management.

Third, Sociability Primacy (P2) and Environmental Prerequisite (P3) together establish that the capacity to transform physical spaces into territorial nodes fostering organic social communities constitutes the paramount differentiator of place attachment, overriding both technological investment and operational scale. Green Practices operate as a hygiene factor whose absence penalizes but whose presence alone does not elevate perceived territorial quality.

This study had some limitations. The dual-case design constrains statistical generalizability beyond Hanoi’s specific urban morphologies. Although the UGC-based methodology corrects for social desirability bias, it introduces platform-specific selection effects. Finally, the cross-sectional temporal scope cannot capture the dynamic evolution of territorial qualities over time. Future research should operationalize the proposed 8-dimension model through large-scale Structural Equation Modeling to test causal relationships between spatial quality dimensions and loyalty metrics and extend the framework to morphologically diverse destinations to assess the cross-contextual transferability of the three propositions advanced here.

Author Contributions: Conceptualization, H.Y.T. and D.Q.P.; methodology, H.Y.T. and D.Q.P.; software, D.Q.P.; validation, H.Y.T. and D.Q.P.; formal analysis, H.Y.T. and D.Q.P.; investigation, H.Y.T. and D.Q.P.; data curation, D.Q.P.; writing-original draft preparation, H.Y.T. and D.Q.P.; writing-eview and editing, H.Y.T. and D.Q.P.; visualization, D.Q.P.; supervision, H.Y.T.; project administration, H.Y.T. All authors have read and agreed to the published version of the manuscript.

Funding: This research was funded by Thuongmai University, Hanoi, Vietnam.

Institutional Review Board Statement: Ethical review and approval were waived for this study due to the minimal risk nature of the research. The primary data collection involved in-depth interviews with industry professionals discussing non-sensitive, managerial topics, and informed consent was obtained prior to participation. The secondary data consisted of publicly available User-Generated Content (UGC) from TripAdvisor, which was collected and analyzed in aggregate, ensuring no individual privacy rights were compromised.

Informed Consent Statement: Informed consent was obtained from all subjects involved in the study. The interviewees explicitly agreed to participate and consented to the publication of their names, titles, and affiliated institutions in this research.

Data Availability Statement: The data presented in this study may be obtained on request from the corresponding author.

Acknowledgements: The authors wish to express their gratitude to the Board of Directors and management teams of Mövenpick Hotel Hanoi Centre and May De Ville Crown Hotel for their support during the data collection process. Special thanks are extended to Mr. Ngo Van Lung and Ms. Le Thi Ngoc for their valuable insights and participation in the in-depth interviews. Finally, the authors acknowledge to anonymous reviewer for their thoughtful suggestions and comments.

Conflicts of Interest: The authors declare no conflict of interest.

Use of Generative AI: During the preparation of this manuscript, the authors utilized generative artificial intelligence tools, specifically Gemini, ChatGPT, and Claude. These tools were employed for three primary purposes: (1) to translate the original manuscript from Vietnamese to English; (2) to perform comprehensive language editing and stylistic refinement to enhance the academic quality of the text; and (3) to generate the map visualizations presented in the study. Following the use of these tools, the authors thoroughly reviewed, edited, and validated all outputs. The authors remain fully responsible for the accuracy, integrity, and originality of all content, data interpretation, and conclusions presented in this manuscript.

Abstract: This research aims to analyze the influence of changes in eco-tourism on the transformation of green economic policy. The analysis adopts a holistic and systematic approach. A mixed-methods research design was employed to ensure the completeness and appropriateness of the findings, with the objective of applying the results to formulate effective strategies for managing Thailand's tourism industry to achieve maximum efficiency in the future. The research findings indicate that the PAr-ARIMAX(1,1,1) model is the most appropriate model, demonstrating strong validity, the absence of spurious relationships, and comprehensive goodness-of-fit measures. This confirms its suitability for use in policy formulation and planning for Thailand, particularly in setting strategic directions for sustainable and continuous growth in the tourism industry. The results further reveal that eco-tourism entrepreneurship has the strongest direct effect on the environmental sector, accounting for 65% at a 1% significance level. This implies that a 1% change in eco-tourism entrepreneurship leads to a 65% change in the environmental sector in the same direction. At the same time, eco-tourism entrepreneurship exerts the greatest influence on changes in the green economy when compared with all other sectors. Moreover, changes in the social sector, especially community participation and cultural transformation, have a substantial impact on eco-tourism entrepreneurship, with an influence of up to 60%. Therefore, the government should consider the combined effects of changes in eco-tourism entrepreneurship and social dynamics, as their integration can maximize positive transformations in the green economy and contribute meaningfully to Thailand's sustainable national development in the future.

Keywords: eco-tourism, eco-entrepreneurship, green economy policy, social sector, community participation, social culture

INTRODUCTION

Thailand has established a national strategic framework for long-term national development following its membership in the United Nations, particularly in relation to environmental governance (The World Bank: Energy Use (Kg of Oil Equivalent Per Capita) Home Page, 2025). Evidence indicates that from 1992 to the present (2025), Thailand has achieved continuous national development, especially in terms of economic and social growth (National Statistical Office Ministry of Information and Communication Technology, 2025). Urban expansion has increased significantly across regions, with urbanized areas expanding by approximately 65 percent (ONEP, 2025). This trend reflects Thailand's ongoing transition toward becoming a developed country (Office of Natural Resources and Environmental Policy and Planning (DEDE), 2025).

If Thailand is able to fully attain developed-country status, it would generate substantial positive impacts and enable accelerated development across all dimensions in the future (Thailand Greenhouse Gas Management Organization (Public Organization), 2025). For this reason, the government has played a crucial role in economic development by formulating long-term policies, such as modern industrial development plans, promoting both domestic and foreign investment, expanding and upgrading infrastructure to ensure nationwide coverage, and significantly advancing tourism development in all dimensions, particularly eco-tourism (Office of the National Economic and Social Development Council (NESDB), 2025). The government has also actively encouraged continuous growth among entrepreneurs across sectors (Hasanein & Ayad, 2025).

Tourism is a key industry within Thailand's economic system and represents a major source of revenue generated from both domestic and international tourists (Ahmed et al., 2025; Salama et al., 2025). It plays a vital role in economic stimulation, job creation, and local development (NESDB, 2025; Muna et al., 2025). Beyond its economic benefits, tourism also has strong potential to support environmental conservation and promote sustainable understanding of local cultures (OECD, 2025). The growth of Thailand's tourism industry in recent years has largely been driven by government policies aimed at promoting sustainable tourism to enhance national competitiveness (Junsiri et al., 2025).

In recent years, eco-tourism has gained increasing popularity among tourists who prioritize nature-based experiences and adventure travel (Sutthichaimethee et al., 2025). These tourists typically seek close interaction with natural environments and wish to learn about the lifestyles of host communities rather than engaging in conventional forms of tourism (Energy Policy and Planning Office, 2025; Sutthichaimethee et al., 2025).

This trend has encouraged greater participation by local communities in the management and stewardship of tourist destinations, ensuring sustainability and minimizing negative impacts on natural resources. Regarding the role of tourism in Thailand's economy in 2025, the Tourism Authority of Thailand reported that during the first quarter of the year, the country welcomed approximately 9.98 million international tourists, representing a significant increase compared to the previous year (United Nations Framework Convention on Climate Change, UNFCCC, 2014). These visitors generated total revenue of 559,015 million baht, highlighting the critical importance of tourism to economic growth.

In addition to direct tourism revenue, the sector has produced positive spillover effects on local businesses, including restaurants, hotels, and related service industries, as well as supporting local and indigenous industries with unique cultural identities (United Nations Framework Convention on Climate Change, 2016; Sisriany & Furuya, 2024). Tourism, therefore, plays a crucial role in income distribution to remote and rural communities, improving quality of life and supporting local development. It also benefits communities seeking supplementary income through the production of distinctive local goods and services, such as handicrafts and souvenirs. This creates employment opportunities and enhances the well-being of communities actively involved in sustainable tourism development (Ministry of Natural Resources and Environment, 2025; Sutthichaimethee et al., 2024; Winyuchakrit et al., 2021; Sun et al., 2023).

At present, eco-tourism in Thailand has gained widespread popularity due to its emphasis on learning about nature while simultaneously conserving the environment and preserving local culture (NESDB, 2025). Eco-tourism activities in Thailand are diverse and include nature trekking, wildlife observation, coral reef diving, and immersive experiences within local communities (Waiyasusri et al., 2024). These activities not only bring tourists closer to nature but also foster long-term environmental awareness (Piedra-de-la-Cuadra & Ortega, 2024; Rahmawati et al., 2021).

Eco-tourism further creates economic opportunities for local communities by promoting sustainable use of natural resources and strengthening pride in traditional cultural heritage (Rasool et al., 2021). The connection between tourists and communities through environmentally friendly activities encourages sustainable relationships and serves as an important mechanism for conserving natural resources alongside local economic development (DEDE, 2025; Razzaq et al., 203; Salemi et al., 2019). As a tool for sustainable development, eco-tourism provides not only economic value but also serves as a critical mechanism for environmental education and awareness-building among tourists (ONEP, 2025; Sharif et al., 2020; Sharpley, 2020). This development model enables local communities to participate directly in managing tourism resources closely linked to their natural environments. Such participation not only increases income but also reduces resource-use conflicts and promotes environmentally and socially responsible development.

Moreover, eco-tourism enhances national tourism competitiveness and stimulates local economic growth efficiently. Community-based management contributes to equitable income distribution, reduces inequality, and strengthens economic security at the community level, supported by organizations such as the Thailand Ecotourism and Adventure Travel Association. Nevertheless, despite Thailand's demonstrated capacity to expand tourism and achieve effective economic and social growth over the long term, a critical challenge remains: environmental development has not progressed in parallel with economic and social advancement.

National-level data indicate that Thailand's environmental conditions have not significantly improved from the past to the present, despite the existence of major policies promoting eco-tourism.

This suggests that genuine sustainability has not yet been fully achieved. Between 1992 and 2025, overall tourism growth increased by 64.05 percent, while greenhouse gas emissions generated by the tourism sector rose by 59.72 percent. This increase in emissions has occurred at an accelerating rate, directly correlated with tourism growth. Although the government has introduced multiple tourism models across various dimensions, it has yet to conduct in-depth, integrated analyses of how changes in the eco-tourism industry affect the broader national sectoral system. Previous studies have largely examined individual sectors in isolation, lacking a comprehensive, holistic perspective. This research recognizes the necessity and value of such an integrated analysis. Its findings aim to provide concrete guidance for national governance and contribute meaningfully to Thailand's future development, enabling sustainable and genuine growth in the long term.

MATERIALS AND METHODS

A review of both domestic and international literature reveals that no previous study has constructed an analytical model of this nature or conducted a comprehensive, system-wide analysis comparable to the approach adopted in this research. Existing studies have primarily focused on individual dimensions or sectors in isolation, without integrating them into a holistic framework. As a result, such fragmented analyses have been insufficient for accurately formulating future strategic directions, as they fail to capture the true dynamics and interrelationships of transformational influences. This limitation may contribute to policy misalignment or errors, as evidenced by certain policies implemented in the past.

Accordingly, this research develops an integrated analytical model designed to support strategic decision-making and guide Thailand toward sustainable development. The study places particular emphasis on the eco-tourism industry, as it represents a major revenue-generating sector for Thailand and is among the leading contributors to rapidly increasing greenhouse gas emissions. For the quantitative component of the study, secondary data spanning the period from 1992 to 2025 were employed. The researcher developed a novel analytical framework referred to as Path Analysis with Correlation Based on the Autoregressive Moving Average (p) Model ($PAr - ARIMAX(p)$), the details of which are

presented as follows (Bentler & Chou, 1987; Kline, 2015). For the model used in this research, the researcher applied an integrated modeling approach by selecting a high-performance model while ensuring that the analytical results were appropriate. The model was developed based on its key strengths for application and is referred to as Path Analysis with Correlation based on the Autocorrelation Moving Average (p) model ($PAr - ARIMAX(p)$).

Path Analysis (PA) is a method for studying causal relationships among variables and is grounded in regression analysis. It relies on diagrams and structural equations derived primarily from hypotheses, conceptual frameworks, theories, and prior research to analyze and explain the relationships between independent variables and dependent variables, both in terms of magnitude and direction (Holbert & Stephenson, 2002).

These relationships can be explained as both direct and indirect effects. Correlation coefficients among variables are then analyzed using path analysis techniques. The results of path analysis serve as a test of the validity of the structure or model specified by the hypotheses, indicating whether the collected empirical data adequately support the existing theory or hypotheses. The researcher constructed diagrams or models illustrating influences based on theory and hypotheses.

The relationships among variables in the model (T) can be decomposed into the sum of parameters according to path coefficient theory. Specifically, the correlation coefficient between two variables in the model is equal to the sum of the Direct Effect (DE), Indirect Effect (IE), Spurious Relationship (SR), and Joint Effect (JE), as follows (Hayes, 2013):

$$r = DE + IE + SR + JE \quad (1)$$

Equation (1) illustrates the true structure of relationships in the causal factor influence analysis model, which consists of four key components: Direct Effect (DE), Indirect Effect (IE), Spurious Relationship (SR), and Joint Effect (JE). It eliminates the misconception or belief that conducting an analysis using path analysis necessarily results in **S**R and JE being equal to zero. Therefore, the equation used for the analysis can be written as follows (Holbert & Stephenson, 2002).

$$r = DE + IE \quad (2)$$

Equation (2) demonstrates that the previous conceptual understanding is incorrect, because in real analytical situations the analysis must follow the form specified in Equation (1) only. If, after implementation, **S**R and JE are found to be non-zero, this will adversely affect the validity of the model and may lead to substantial forecasting errors. Consequently, this study incorporates causal factors comprehensively, while carefully controlling critical issues arising from the analytical results, namely autocorrelation**,** multicollinearity**,** and heteroscedasticity**.** If any of these problems occur in a model, they can severely distort directional interpretation or lead to significant errors when applying the results for national policy formulation (Baltagi, 2021). Regarding the research procedure using the $PAr - ARIMAX(p)$ model**,** it is essential to consider the properties of the data used in constructing a complete and robust model, ensuring that spurious relationships do not occur. The data must exhibit **s**tationarity. Let Y_t be a stochastic time series variable. For the series to be stationary, it must satisfy the following three properties (Harvey, 1980).

$$\text{Mean :} \quad E(Y_t) = E(Y_{t-k}) = \mu \quad (3)$$

$$\text{Variance :} \quad \text{Var}(Y_t) = E(Y_t - \mu)^2 = E(Y_{t-k} - \mu)^2 = \sigma^2 \quad (4)$$

$$\text{Covariance :} \quad \text{E}[(Y_t - \mu)^2(Y_{t-k} - \mu)^2 = \gamma_k] \quad (5)$$

From Equations (3)–(5), it can be observed that the magnitude or spacing of the covariance remains constant; that is, the distance between two values of Y_t does not depend on time. When all three properties are satisfied, the data are considered stationary. This indicates that the time series has a constant mean or expected value, constant variance, and constant covariance over time. These properties do not depend on time itself but rather on the distance or lag between time periods (Baltagi, 2021). Transforming non-stationary data into stationary or weakly stationary data involves adjusting only the first and second moments. However, in the case of strict stationarity, consideration is not limited to the first and second moments; higher-order moments must also be examined. The consideration of moments involves two key principles. First, a stationary variable fluctuates within a narrow range around its mean, whereas a non-stationary variable exhibits increasing variability as the number of observations grows. Second, when an external shock occurs in the economic system, stationary data deviate from the mean only temporarily and return to equilibrium relatively quickly. In contrast, non-stationary data produce the opposite effect, influencing the model itself or affecting other variables within the model across different time periods. This indicates that non-stationary variables do not possess a long-run mean level, which can be represented by three populations as follows (Harvey, 1980).

$$Y_t = \delta Y_{t-1} + \varepsilon_t \quad (6)$$

$$\Delta Y_t = \alpha_1 + \delta Y_{t-1} + \varepsilon_t \quad (7)$$

$$\Delta Y_t = \alpha_1 + \alpha_2 T + \delta Y_{t-1} + \varepsilon_t \quad (8)$$

Equations (6)-(8) define Y_{t-1} as the variable under study in the lag period (t-1), while T represents the time variable. These equations indicate the formulation of the hypotheses: $H_0 : \delta = 0$, non–stationary, and $H_a : \delta < 1$, stationary. The differenced series ΔY_t exhibits non-stationary properties when H_0 is accepted, indicating that $\delta = 0$. In this case, the variance increases in an exponential or explosive manner as time increases. However, applying first differencing to a time series, or higher-order differencing, can transform the series into a stationary process. The procedure for difference-stationary transformation is shown as follows (Hoyle, 1995).

$$\Delta Y_t = \alpha_1 + \alpha_2 T - \delta Y_{t-1} + \varepsilon_t \quad (9)$$

From Equation (9), the relationship among the variables is specified in differential form as time increases at the level form. Rejecting H_a or accepting H_0 implies that the data are non-stationary, with the coefficient $\delta = 0$ being statistically significant. This result indicates that the absolute value of the tau statistic for the estimated coefficient is smaller than the critical value in absolute terms. Under this condition, the error term ε_t does not satisfy the white noise property, implying that the analyzed data exhibit autocorrelation. Therefore, the Augmented Dickey–Fuller (ADF) test must be employed. The ADF test modifies the original equation by including higher-order lagged values of the dependent variable in order to eliminate the autocorrelation problem. In this study, the selected specification is the Autoregressive Model of Order p: AR(p), denoted as AR(p)**,** which can be expressed as follows (Byrne, 2001).

$$Y_t = \alpha + \beta_1 Y_{t-1} + \beta_2 Y_{t-2} + \ldots + \beta_p Y_{t-p} + \varepsilon_t \quad (10)$$

From Equation (10), Y_{t-p} is defined as the variable under study in the lag period (t-p). Imposing the conditions $\beta_1 + \beta_2 < 1$, $\beta_2 - \beta_1 < 1$, and $|\beta_1| < 1$ indicates that the time series possesses stationarity. The Moving Average Model of Order q, denoted as **MA(q),** can be expressed as follows (MacKinnon, 1991).

$$Y_t = \delta + \varepsilon_t - \gamma_1 \varepsilon_{t-1} - \gamma_2 \varepsilon_{t-2}, \ldots, \gamma_q \varepsilon_{t-1} \quad (11)$$

From Equation (11), the condition $|\gamma_1| < 1$ indicates that the time series is invertible or stationary. Consequently, the Mixed Autoregressive and Moving – Average Model of Order p and q, denoted as ARMA(p, q)**,** can be expressed as follows (Dickey & Fuller, 1981; MacKinnon, 1991).

$$Y_t = \alpha + \beta_1 Y_{t-1} + \beta_2 Y_{t-2} + \ldots + \beta_p Y_{t-p} + \varepsilon_t - \gamma_1 \varepsilon_{t-1} - \gamma_2 \varepsilon_{t-2} - \ldots - \gamma_q \varepsilon_{t-q} \quad (12)$$

Equation (12) shows the relationship between Y_{t-p}, which is referred to as ARIMA, and ε_{t-q}, which is referred to as the Moving Average.

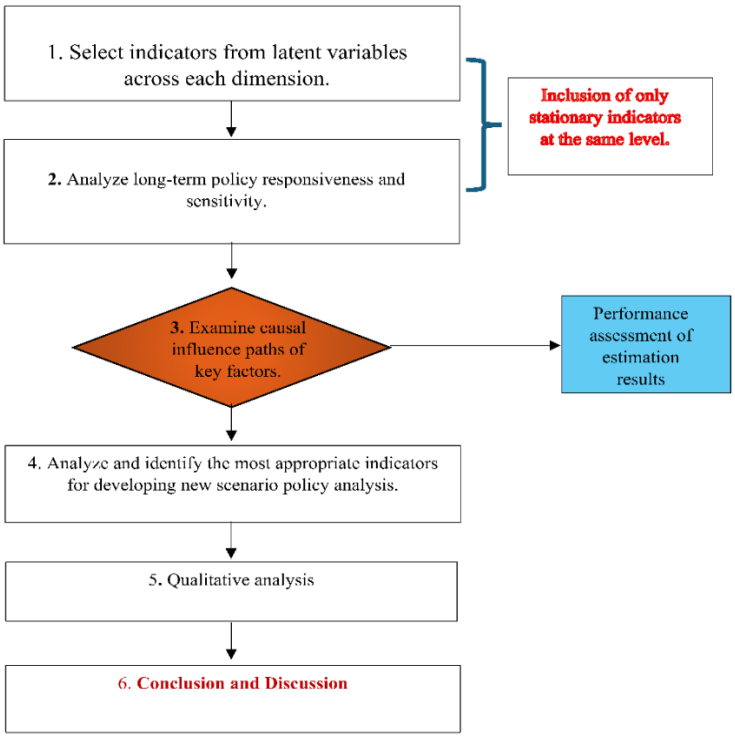

Figure 1. The research procedure based on the materials and methods used in this study

Based on the materials and methods described above, the researcher summarizes the research procedure as shown in Figure 1 into several main steps. First, indicators that possess stationarity properties at the same level are selected. Second, the ability of the variables to adjust toward equilibrium in both the short run and the long run is examined. Third, the appropriateness of the relationships among the latent variables is determined, along with testing the validity of the $PAr - ARIMAX(p)$ model.

RESULTS

In this study, the researcher developed the $PAr - ARIMAX(p)$ model and conducted rigorous validity testing. In addition, potential estimation problems associated with the $PAr - ARIMAX(p)$ model were systematically examined, including heteroskedasticity, multicollinearity, and autocorrelation. The model was also evaluated for its goodness-of-fit properties. Only models that satisfied these diagnostic criteria and demonstrated appropriate statistical performance were deemed suitable for subsequent analysis and interpretation of results. This research adopted a mixed-methods research design. The quantitative component involved constructing and estimating the $PAr - ARIMAX(p)$ model. Upon completion

of the quantitative analysis, the findings were complemented and enriched through qualitative research, incorporating insights from experts and key informants who possess direct responsibility and specialized expertise in Thailand's sustainable national development. Particular emphasis was placed on experts involved in the eco-tourism industry, given its critical role in Thailand's sustainable development framework. The detailed procedures and analytical steps are presented as follows.

Selection of Appropriate Indicators for Constructing the $PAr - ARIMAX(p)$ Model

The analysis involved the systematic selection of indicators to be incorporated into the $PAr - ARIMAX(p)$ model in order to examine the causal influences of eco-tourism–related factors on entrepreneurial performance and the transition of the tourism industry toward the green economy in the future. The model specifies several latent variables, namely the social sector, green economic sector, environmental sector, and eco-tourism entrepreneurship sector. These latent constructs are measured through a total of 15 observed variables, including green urbanization rate (E_1), green industrial structure rate (E_2), green total exports (E_3), expenditure government rate (E_4), green household rate E_5, employment rate (F_1), health and illness (F_2), social security (F_3), education rate (F_4), income distributions rate (F_5), Community Participation (F_6), Eco-tourism (G_1), total energy consumption (H_1), energy intensity (H_2), and Carbon dioxide emission (H_3).

The selected indicators were chosen to comprehensively capture the multidimensional interactions among sectors and to ensure the robustness and interpretability of the $PAr - ARIMAX(p)$ model in analyzing long-term structural changes and policy-relevant dynamics, as per the underlying results in Table 1. As shown in Table 1, all indicators satisfy the required statistical properties and are deemed appropriate for inclusion in the $PAr - ARIMAX(p)$ model.

The analysis indicates that each indicator is stationary at first difference at a statistical significance level of $\alpha = 0.01$. Consequently, all selected indicators are suitable for model construction and can be effectively utilized to analyze the impacts of structural and dynamic changes within the proposed analytical framework. Therefore, the researcher proceeds to incorporate all indicators into the estimation of the $PAr - ARIMAX(p)$ model in subsequent analyses.

Table 1. The results of the diagnostic analysis of the indicators used for constructing the $PAr - ARIMAX(p)$

Tau Test				MacKinnon Critical Value		
Variables	Level I(0) Value	Variables	First Difference I(1) Value	1%	5%	10%

Analysis of the Influence of Changes in Eco-Tourism Entrepreneurship

The analysis based on the $PAr - ARIMAX(p)$ model indicates that both latent variables and observed variables are interrelated through direct and indirect effects, as presented in Table 2.

The results shown in Table 2 indicate that the most appropriate specification of the $PAr - ARIMAX(p)$ model is $PAr - ARIMAX(1,1,1)$. This model represents the best-fitting and most robust specification, allowing for accurate estimation of the magnitude of relationships through both direct and indirect effects. The findings reveal that eco-tourism entrepreneurship exerts the strongest direct effect on the environmental sector, with an effect size of 65 percent, significant

at the 1 percent level. This result indicates that a 1 percent increase in eco-tourism entrepreneurship leads to a 65 percent change in the environmental sector in the same direction. Furthermore, eco-tourism entrepreneurship demonstrates the highest overall influence on changes in the green economy when compared to all other sectors included in the model.

These findings suggest that government policies and interventions aimed at stimulating change in eco-tourism entrepreneurship will generate corresponding positive transformations in the green economy, thereby promoting long-term sustainable growth. This strategy is more effective than interventions targeting other sectors in isolation. However, if policy actions are to be implemented across multiple sectors, it is essential to consider the intersectoral dynamics and relational influences identified in the model. The analysis further indicates that the social sector, particularly community participation and cultural transformation, has a substantial impact on eco-tourism entrepreneurship, with an influence level of up to 60 percent. This finding underscores the critical role of social factors in driving changes in eco-tourism entrepreneurship and, consequently, in shaping green economic outcomes. Therefore, when changes in eco-tourism entrepreneurship are combined with progressive transformations within the social sector, the resulting impact on the green economy is maximized compared with alternative policy approaches. Figure 2 illustrates the directional pathways and relational structure among the sectors within the $PAr - ARIMAX(1,1,1)$ model. The figure confirms that policy measures designed to stimulate eco-tourism entrepreneurship produce positive and aligned effects on green economic development and support sustainable long-term growth more effectively than interventions in other sectors alone.

Moreover, the figure highlights that change in the social sector, especially enhanced community participation and cultural adaptation, significantly influence eco-tourism entrepreneurship, with an impact magnitude of up to 60 percent. This reinforces the conclusion that social dynamics play a pivotal role in shaping entrepreneurial behavior within eco-tourism and are essential to achieving meaningful transformations in the green economy.

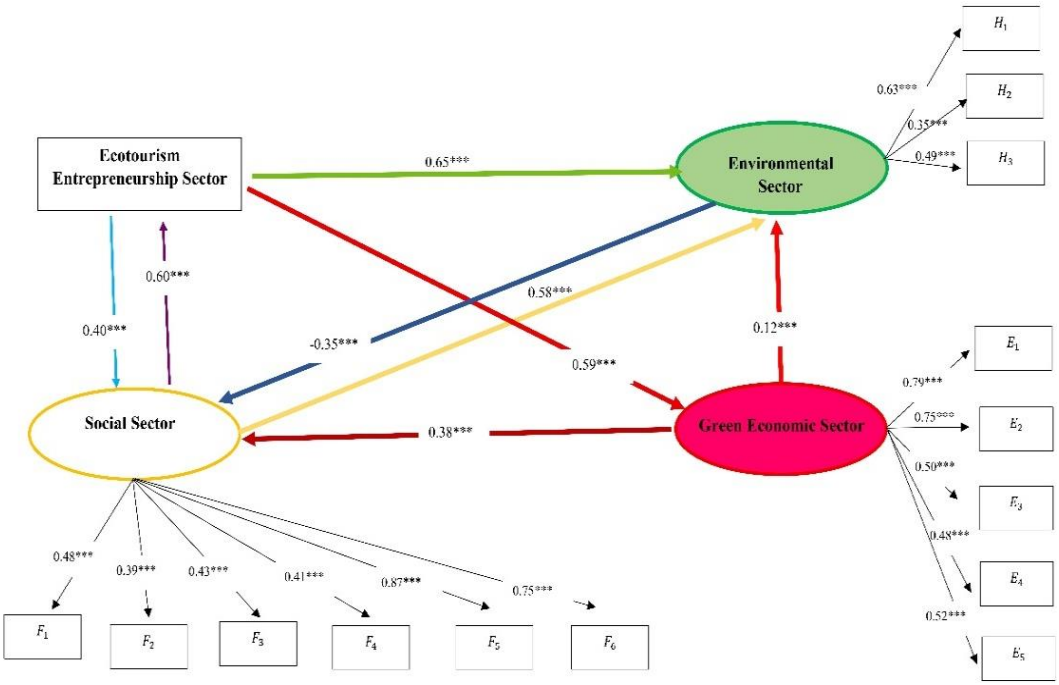

Figure 2. Direction of Intersectoral Relationships in the $PAr - ARIMAX(1,1,1)$ Model

Synthesis of Impacts on Various Sectors from Changes in Ecotourism Businesses and Operational Pathways toward the Green Economy

Based on qualitative research conducted through in-depth interviews with experts directly responsible for advancing Thailand toward the Green Economy goal, the impacts arising from changes in ecotourism were identified as follows.

1. Environmental Impacts: Ecotourism has strong potential to support environmental conservation by encouraging sustainable land use, protecting natural habitats, lowering carbon emissions, and preserving biodiversity. Studies show that it can generate funding for conservation and wildlife protection. However, its environmental outcomes depend heavily on management quality. Poorly managed activities, such as hiking or wildlife viewing, and unsustainable infrastructure development can degrade habitats and disturb ecosystems. In contrast, well-planned ecotourism generally produces lower environmental impacts than conventional tourism, particularly due to reduced carbon emissions from more sustainable transport and accommodation. Overall, the environmental effects of ecotourism are context-specific and influenced by activity types, infrastructure design, and ecosystem sensitivity; maximizing benefits requires careful planning, habitat protection, and low-carbon tourism practices.

2. Economic Impacts: Ecotourism can contribute to sustainable economic development by creating jobs, diversifying local economies, and supporting small and local enterprises. Evidence suggests it can make a meaningful contribution to GDP, particularly in developing countries, while generating income and employment at the community level. However, economic gains are not always evenly shared, as some communities benefit more than others, and economically

marginalized groups may receive limited returns. The scale of activities, community participation, and infrastructure quality strongly influence outcomes. Maximizing economic benefits therefore requires active local involvement in planning, fair benefit distribution, and investment in infrastructure that safeguards natural resources and cultural heritage.

3. Social Impact Mitigation: Protecting local communities and their cultural heritage is essential in ecotourism development to prevent social tension and conflict. Effective approaches include meaningful community participation, cultural sensitivity training for ecotourism operators, and the promotion of local cultural activities. Involving communities in planning, development, and management helps ensure that tourism respects local traditions and values, as demonstrated by community-led tourism initiatives offering cultural tours, craft workshops, and homestays. Training operators to understand and respect cultural norms further reduces conflict and improves the quality and appropriateness of tourism services. Promoting cultural events also supports heritage preservation while generating local economic benefits. Overall, these strategies help minimize negative social impacts and support ecotourism development that delivers long-term social benefits while safeguarding cultural heritage for future generations.

When it comes to monitoring and evaluation, they play a critical role in ensuring that ecotourism achieves sustainability goals and identifies areas for improvement. Ecotourism operators should systematically collect data on environmental, economic, and social impacts to assess the effectiveness of management practices and tourism policies. Environmental monitoring, such as waste generation, energy and water use, and greenhouse gas emissions, is essential for preventing ecological degradation and guiding operational improvements. Economic monitoring helps ensure that tourism activities generate local employment, support income distribution, and contribute to sustainable local development. Social monitoring focuses on cultural heritage protection, community participation, and the promotion of local products and services to ensure socially responsible tourism. Overall, integrated M&E supports long-term sustainability of ecotourism destinations, enhances community benefits, and safeguards natural and cultural resources for present and future generations. Achieving these outcomes requires coordinated collaboration among government agencies, destination managers, and local communities to promote responsible and sustainable ecotourism practices.

However, ecosystem conservation should remain the core focus of ecotourism, emphasizing biodiversity protection, reduced environmental impacts, and sustainable resource management. Active community participation in decision-making helps generate shared economic and social benefits, strengthens cultural understanding, and ensures fair benefit distribution. Capacity building through training and education for local communities, tourism operators, and guides enhances skills and informed participation in sustainable practices. Ecotourism infrastructure should prioritize sustainability by using eco-friendly materials, renewable energy, effective waste systems, and water-saving measures. Responsible visitor management, such as setting carrying capacities, promoting ethical travel behavior, and providing environmental education, helps minimize negative impacts on nature and communities.

Continuous monitoring and evaluation are essential to assess performance and refine management strategies. Strong partnerships among governments, local communities, NGOs, and businesses enable coordinated action and shared responsibility. Effective marketing can raise awareness of sustainable practices and attract environmentally conscious travelers by highlighting unique natural and cultural assets. Finally, certification and standards from recognized bodies help ensure compliance with sustainability principles and strengthen credibility.

DISCUSSION

This research developed a model with strong validity and conducted diagnostic tests on the $PAr - ARIMAX(p)$ estimation. The results indicate no problems of heteroskedasticity, multicollinearity, or autocorrelation, and the model also demonstrates satisfactory goodness of fit. These findings suggest that the model is appropriate for use in policy formulation and strategic planning in Thailand, particularly for guiding sustainable tourism management and supporting long-term growth, with a specific emphasis on the future development of ecotourism.

In selecting the indicators for the $PAr - ARIMAX(p)$ model, the analysis focused on examining the causal effects of ecotourism-related factors on entrepreneurial success and progress toward a green economy, while ensuring that carrying capacity can be maintained. The model incorporates latent variables representing the social sector, green economic sector, environmental sector, and ecotourism entrepreneurship sector. These latent constructs are measured through 15 observed variables, including green urbanization rate (E_1), green industrial structure rate (E_2), green total exports (E_3), expenditure government rate (E_4), green household rate E_5, employment rate (F_1), health and illness (F_2), social security (F_3), education rate (F_4), income distributions rate (F_5), Community Participation (F_6), Eco-tourism (G_1), total energy consumption (H_1), energy intensity (H_2), and Carbon dioxide emission (H_3). The results show that all indicators are appropriate for model construction and can be effectively used to analyze the impacts of change, as each variable is stationary at first difference at a statistical significance level of $\alpha = 0.01$.

Based on these findings, the researcher was able to develop the $PAr - ARIMAX(p)$ model as an optimal (best-fit) time-series model, enabling a reliable analysis of the magnitude of relationships in terms of both direct and indirect effects. The results indicate that ecotourism entrepreneurship has the strongest direct effect on the environmental sector, accounting for 65% at the 1% significance level. This implies that a 1% change in ecotourism entrepreneurship leads to a 65% change in the environmental sector in the same direction. At the same time, ecotourism entrepreneurship exerts the greatest influence on changes in the green economy compared with all other sectors included in the model.

Therefore, policy interventions or structural changes targeting ecotourism entrepreneurship are likely to generate corresponding positive changes in the green economy and deliver the highest benefits for long-term sustainability. In

addition, a key finding that warrants close attention is the role of the social sector, which influences changes in ecotourism entrepreneurship by as much as 60%. This highlights the critical importance of social dynamics in shaping ecotourism entrepreneurship and, consequently, in driving transformations toward a green economy.

When changes in ecotourism entrepreneurship are combined with social-sector transformation, the resulting impact on the green economy is maximized. This research approach and its findings have not been previously identified in the literature. The results further indicate that, in aligning with government policy objectives, the sector with the highest adaptive capacity is the social sector. Accordingly, government policy should urgently prioritize social-sector development, with particular emphasis on community participation and cultural transformation, and implement these measures in a concrete and systematic manner. Such coordinated change, aligned with the evolution of ecotourism entrepreneurship, is essential for achieving sustainable long-term development goals.

The development of ecotourism in Thailand can be strengthened through the following key approaches:

1. Promote public–private collaboration: Strong cooperation between government and the private sector is essential for effective ecotourism development. The public sector should support planning and infrastructure development, such as nature trails, sustainable resource management systems, and regulations encouraging the use of eco-friendly materials. The private sector can contribute by developing tourism services that prioritize sustainability, enhance visitor experiences, and promote conservation awareness.

2. Strengthen sustainable resource management: Sustainable resource management is central to the long-term success of ecotourism. Destinations should implement measures to prevent environmental degradation, including visitor limits, waste and pollution control, and the conservation of forests and key natural attractions. Clear management plans, supported by appropriate technologies, can improve efficiency and ensure sustainable destination development.

3. Enhance local community participation: Sustainable ecotourism should actively involve local communities as owners and stewards of tourism resources. Community-based activities can generate income while strengthening local economies and social cohesion. Government support is needed to build community capacity through guide training, resource management education, and assistance in developing distinctive local products for tourists.

4. Building integrated networks for systematic ecotourism development: Establishing networks among ecotourism destinations across different regions can promote coordinated and systematic tourism development. Such networks should involve public agencies, private sector actors, local communities, and other stakeholders, including researchers and conservation organizations. These networks facilitate knowledge sharing and the exchange of best practices for sustainable destination management, enhance the visibility of ecotourism sites, and support the creation of interconnected tourism routes that link multiple destinations.

As for the limitations of this study, it is subject to limitations arising from Thailand's relatively weak and outdated environmental legal framework. Environmental governance continues to rely primarily on the National Environmental Quality Promotion and Conservation Act B.E. 2535 (1992), with only limited amendments, alongside related legislation. As a result, legal mechanisms are often insufficient to effectively prevent or mitigate environmental impacts. Tourism development has significantly contributed to environmental degradation, particularly through the rapid growth of greenhouse gas emissions. Although tourism has been promoted as a national agenda, environmental protection has not progressed at a comparable pace. Consequently, this study could not fully incorporate legal and regulatory dimensions into the analysis or use them as a basis for defining comprehensive policy strategies.

CONCLUSIONS

This study investigates how transformations in ecotourism entrepreneurship shape Thailand's green economy policy, employing a holistic, systematic, and mixed-methods approach. Quantitative analysis was complemented by expert qualitative insights from sustainable development and ecotourism sectors.

The results identify the PAr-ARIMAX(1,1,1) model as the optimal analytical tool, demonstrating robust validity, no spurious associations, and excellent goodness-of-fit. This model thus provides a sound basis for policy formulation, strategic planning, and the sustainable management of Thailand's tourism sector. The result reveals that Ecotourism entrepreneurship exerts the strongest direct impact on the environmental sector, explaining 65% of the variance at a 1% significance level. A 1% increase in ecotourism entrepreneurship corresponds to a 65% rise in the environmental sector, underscoring its outsized influence relative to other modelled sectors. Accordingly, policies that promote ecotourism entrepreneurship can substantially advance environmental outcomes and accelerate the green economy transition.

At the same time, the social sector—especially community participation and cultural transformation—significantly affects ecotourism entrepreneurship, with an effect size of up to 60%. This suggests that green economy transformation requires more than shifts in entrepreneurship alone; government policy must address the interplay between ecotourism and social dynamics. Emphasizing community engagement, cultural adaptation, and active local stakeholder participation is therefore essential for effective ecotourism development.

In summary, integrating ecotourism entrepreneurship with progressive social sector change is the most effective strategy for advancing Thailand's green economy. Targeted government action to support entrepreneurs, build community capacity, and foster stakeholder collaboration is vital to ensure tourism aligns with both environmental and social sustainability, strengthening national development.

Multistakeholder co-management for developing sustainable coastal tourism: An insight from Nganteb beach, Malang, Indonesia. *Geojournal of Tourism and Geosites*, 67(3), 2260–2272. https://doi.org/10.30892/gtg.67338-1850

Abstract: This study aims to formulate a sustainable coastal tourism development strategy for Nganteb Beach, Malang Regency, Indonesia, by integrating geomorphological characteristics, ecological conditions, disaster risks, and stakeholder collaboration within a co-management framework. The study employed a mixed-method approach combining qualitative observations, literature review, and documentation with quantitative analysis using SWOT, Internal Factor Analysis Summary (IFAS), and External Factor Analysis Summary (EFAS) matrices. Weighted scoring was applied to internal and external factors to identify the strategic position and determine development priorities. The results indicate that Nganteb Beach possesses strong internal advantages, including unique coastal geomorphological characteristics, relatively stable shoreline conditions, high biodiversity, and considerable potential for nature-based tourism development. However, the destination continues to face several challenges, including limited accessibility, inadequate tourism infrastructure, disaster vulnerability, and declining interest in ecotourism activities. The SWOT quadrant analysis places Nganteb Beach in Quadrant II, indicating that a diversification strategy is required to utilize existing strengths while mitigating external threats. The findings demonstrate that Nganteb Beach has significant potential to be developed as a sustainable ecotourism destination through diversification strategies supported by collaborative governance among local communities, government institutions, and academic institutions. The integration of environmental conservation, disaster risk mitigation, sustainable tourism planning, and community-based management is essential to strengthen destination resilience and ensure the long-term sustainability of coastal tourism development.

Keywords: ecotourism, coastal geomorphology, SWOT analysis, sustainable tourism, co-management, Nganteb Beach

INTRODUCTION

Collaboration between communities and governments is crucial for improving the sustainability of ecotourism in South Malang. The beaches of South Malang, Indonesia, are renowned for their stunning coastal landscapes, characterized by sandy beaches, cliffs, and rocky shorelines. These features enhance the area's aesthetic appeal and serve as important habitats for various marine and terrestrial ecosystems, making them ecologically significant (Hadmoko et al., 2021; Irawan et al., 2024). However, the development of beaches in South Malang, including Nganteb Beach, presents several challenges. Issues such as environmental degradation and inadequate infrastructure pose significant threats to their sustainability (Gunawan et al., 2020; Irawan et al., 2023). Furthermore, the lack of integrated planning and coordination among community groups exacerbates these challenges. Each community group operates independently, lacking a unified vision for disaster risk reduction and sustainable tourism initiatives. This fragmented approach is further compounded by the limited involvement of local governments, resulting in the absence of a well-documented, organized planning framework (Irawan et al., 2021; Sumarmi et al., 2024). Recent studies highlight that stakeholder co-creation plays a crucial role in promoting climate-resilient and sustainable coastal tourism by integrating environmental conservation and tourism management (Boqué-Ciurana, 2025). However, such collaborative governance mechanisms are still rarely implemented in many emerging coastal tourism destinations, including several areas in Indonesia.

A comprehensive approach is needed to unlock the full potential of Nganteb Beach. Conducting a systematic analysis of Nganteb Beach's tourism potential is essential to identify its strengths, weaknesses, opportunities, and threats. These four elements serve as the basis for developing a roadmap for sustainable tourism development. This

analysis highlights the beach's unique geomorphological and ecological characteristics while addressing key challenges, including erosion control, disaster preparedness, and the implementation of conservation measures. Strategies such as integrated coastal zone management (ICZM) and community-based tourism models can be adopted to balance environmental conservation with economic development (Irawan et al., 2024).

Furthermore, involving local communities in the planning and management processes is crucial to ensuring sustainable outcomes. Empowering residents through training and promoting environmentally friendly practices can foster greater ownership and long-term commitment to sustainable tourism development (Sumarmi et al., 2024). Previous studies have explored various aspects of tourism development in coastal destinations. Research by Astina et al. (2021) indicates that SWOT analysis has been used to formulate policy strategies for ecotourism management at Goa China Beach, South Malang, Indonesia. However, most of these studies primarily emphasize tourism attractiveness, scenic beauty, available facilities, and visitor numbers. Similar findings have been reported in several recent studies, which indicate that tourism development assessments often focus on tourism attractiveness and visitor statistics while paying less attention to environmental dynamics and governance structures that influence long-term sustainability (Ali & Li, 2024; Smith et al., 2023). These approaches provide useful insights for understanding tourism potential, but they tend to offer limited guidance for integrated coastal tourism planning.

In addition, previous studies often overlook several important aspects related to the sustainability of coastal tourism. For instance, there has been limited analysis of coastline changes that may significantly influence the long-term sustainability of tourism destinations (Xu & Li, 2025). Environmental dynamics, particularly those related to coastal geomorphology and shoreline changes, play an important role in determining the resilience and sustainability of coastal tourism areas (Theocharidis et al., 2025). However, these aspects have rarely been incorporated into tourism development studies. Moreover, the external aspects of tourism development, particularly visitor interest in ecotourism and the role of stakeholders in tourism governance, are often not analyzed comprehensively. As a result, existing studies tend to provide only a partial understanding of the factors influencing sustainable tourism development. Furthermore, SWOT analysis in tourism studies is often limited to identifying factors that strengthen or weaken tourism development without clearly explaining the strategic actions that should be taken to support sustainable tourism management.

Therefore, a more comprehensive analytical framework that integrates environmental characteristics with multi-stakeholder collaboration is needed to support sustainable tourism development in coastal areas (Setiawan et al., 2025). In this context, this study aims to analyze the potential of Nganteb Beach for sustainable coastal tourism development by integrating several key variables, including geomorphological characteristics, tourism facilities, accessibility, coastline changes, and visitor interest in ecotourism. In addition, this study seeks to develop strategic recommendations through a SWOT-based approach to support collaborative tourism management between local communities and government institutions. The results are expected to provide policy recommendations that can be collaboratively implemented by the government and local communities and serve as a reference for other coastal areas facing similar challenges, thereby contributing to broader regional and national efforts toward sustainable coastal development (Irawan et al., 2023; Smith et al., 2023), which are based on collaboration between the government and local communities.

MATERIALS AND METHODS

Materials

The materials used in this study comprise both primary and secondary data to support the analysis of sustainable coastal tourism development at Nganteb Beach, Malang Regency, Indonesia. Primary data were obtained through direct field observations conducted at the study site. These observations focused on coastal geomorphological characteristics, including shoreline configuration, beach typology, cliff morphology, sediment composition, and coastal dynamics. In addition, observations covered ecological aspects such as mangrove distribution, coastal vegetation density, biodiversity conditions, and environmental quality, as well as existing tourism facilities, accessibility, safety infrastructure, and patterns of tourist activities.

Secondary data were collected to complement and strengthen the primary observations. These data include scientific articles and academic publications related to coastal geomorphology, ecotourism, and sustainable tourism management. Government documents and official reports were also used, particularly statistical data on tourism trends from the Indonesian Central Statistics Agency (BPS), coastal hazard maps from the National Disaster Mitigation Agency (BNPB) via the Inarisk platform, and regional planning documents on coastal and tourism development. In addition, satellite imagery and digital spatial data were used to analyze changes in the coastline, landform patterns, and spatial characteristics of the study area. Supporting information from online databases and institutional websites was incorporated to provide contextual data on wave characteristics, tidal conditions, and ecotourism trends relevant to Nganteb Beach.

Methods

The research object is Nganteb Beach, located in Sukorejo Hamlet, Tumpakrejo Village, Gedangan District, Malang Regency, Indonesia. The exact coordinates are 8° 40' 8.786 "South Latitude and 112° 34' 47.87" East Longitude.

This beach is located approximately 72 km south of the city center.

The research method combines qualitative and quantitative approaches. The quantitative approach is carried out using weights and scoring against predetermined parameters. A qualitative approach is employed to describe the condition of Nganteb Beach, drawing on observations and literature. The data collection techniques used are direct observation, literature review, and documentation studies. The research flow is illustrated in Figure 1.

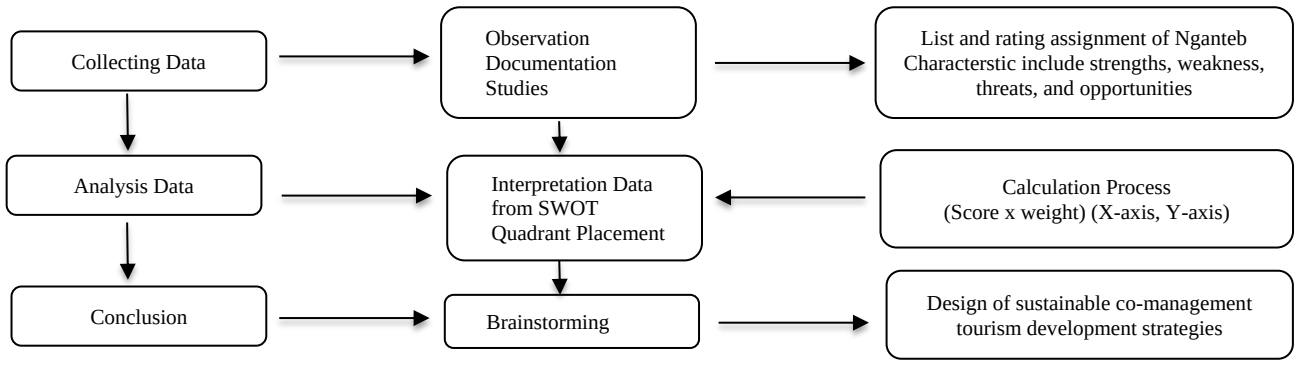

Figure 1. Research Flowchart

A qualitative descriptive approach was adopted to systematically describe the collected data, aligning with the factual conditions and theoretical framework. Data presentation involved interpreting the suitability of landforms for tourism activities and categorizing the findings into a structured narrative. Scores were assigned to factors based on their importance and impact, providing a quantitative basis for the SWOT analysis. The Internal Factor Analysis Summary (IFAS) evaluates the internal aspects of an organization or subject, focusing on Strengths and Weaknesses. Meanwhile, the External Factor Analysis Summary (EFAS) evaluates external factors that may impact Nganteb Beach, namely its opportunities and challenges. The calculation process for IFAS and EFAS is as follows:

1. Identify strengths, weaknesses, opportunities, and threats from a SWOT analysis.
2. Assign a weight between 0 and 1 to each factor, representing its level of importance. The total weight for all aspects in each analysis (IFAS and EFAS) must equal 1.
3. Calculation of the final score by multiplying the weight and score.
4. Add up all scores for IFAS and EFAS separately to get an overall score for internal and external factors.

The assessment instruments can be seen in Table 1 as follows:

Table 1. Criteria for Determining Scores and Weights

Criteria	**Score**			**Weight**
	1	**2**	**3**	
Internal Factor Analysis Summary				
Unique Coastal Geomorphology	There are 1-2 geomorphological forms	There are 3-4 geomorphological forms	There are more than 5 geomorphological forms	0.35
Stable Beach Profile	Coastline change >300 ha	Coastline changes of 100-300ha	Shoreline change <100	0.15
Biodiversity and cultural landscape	There are 1-5 biodiversities	There are 5-10 biodiversities	There are more than 10 biodiversities	0.21
Big beach waves with strong winds	Small beach waves with slight wind	Small beach waves with big wind	Big beach waves, big wind	0.11
The beach sand is soft and white	Black sand and coarse grains	Black sand with fine grains	The sand is white with fine sand	0.18
Basic facilities	Complete and good facilities	Complete but simple facilities	Incomplete facilities	0.15
Limited access to transportation	There are many transportation access options	There are 1-2 transportation accesses	There is only 1 transportation access	0.26
Long distance from the city center	Distance from city center <10km	Distance from city center 10-30 km	Distance from city center >30km	0.3
Lack of safety equipment	Standard safety equipment and warning signs are in place.	There are warning signs without any safety equipment.	There are no warning signs or safety equipment.	0.1
Lack of tourism promotion media	Have social media with lots of followers	Have social media with a few followers	Do not have promotional media	0.19
External Factor Analysis Summary				
Government and community support for tourism development	The government and society provide no support.	The government provides financial support for facility construction.	The government and community work together on financial support, promotion, and conservation.	0.6
Environmental Conservation Program	There is no environmental conservation	Environmental conservation is carried out, but not intensively	Ecological conservation is carried out intensively	0.4
Natural disasters	Does not have the potential for natural disasters	Has one potential natural disaster hazard with moderate risk	Having more than one natural disaster hazard with a high category	0.1
Fluctuations in Ecotourism Interest	Interest in ecotourism is high and continues to grow	Interest in ecotourism is high but declining	Low interest in ecotourism	0.25
Environmental Damage Due to Tourism	No environmental damage	Minor to moderate environmental damage	Major environmental damage	0.3
Competition with Other Destinations	Has no competition with other destinations	Have 1-5 competing destinations	Have more than five competing destinations	0.35

SWOT analysis includes the methodology used for weight allocation, weighted score calculation, and placement in the SWOT quadrants.

Weight Calculation

The weight of each factor is calculated by dividing the score of the factor by the total score within the same category (Strengths, Weaknesses, Opportunities, or Threats). The normalization ensures that the total weights for Strengths and Weaknesses equal 1, and the total weights for Opportunities and Threats also equal 1 (Chang & Huang, 2006). The formula for calculating the weights is:

$$\text{Weight for Factor} = \frac{(\text{Score of Factor})}{(\text{Total Scores of the Category})} \quad (1)$$

Where:

- Weight for Factor = relative importance of each SWOT factor (unitless);
- Score of Factor = rating assigned to a specific factor based on expert judgment (scale: 1–5);
- Total Scores of the Category = total score of all factors within the same SWOT category (unitless).

Weighted Score Calculation

The weighted score for each factor is obtained by multiplying the factor score by the calculated weight. This step reflects the proportional contribution of each factor to the overall SWOT evaluation (Helms & Nixon, 2010). The formula for calculating the weighted score is:

$$Weighted\ Score = \frac{(Score\ of\ Factor)}{(Total\ Scores\ of\ the\ Category)} \quad (2)$$

Where:

- Weighted Score = the contribution value of each factor in the SWOT analysis (unitless index);
- Weight of Factor = normalized importance value (unitless);
- Score of Factor = rating value assigned to each factor (scale: 1–5).

SWOT Quadrant Placement

The SWOT quadrant is used to assess the study area's strategic position. The X-axis represents the difference between the total weighted scores of strengths and weaknesses. In contrast, the Y-axis represents the difference between the total weighted scores of opportunities and threats (Helms & Nixon, 2010). The X-axis and Y-axis formulas for the SWOT Quadrant can be shown as follows:

$$\text{X} - \text{axis} = (\text{Total Weighted Score of Strenghts}) - (\text{Total Weighted Scores of Weakness})$$
$$\text{Y} - \text{axis} = (\text{Total Weighted Score of Opportunities}) - (\text{Total Weighted Scores of Threats})$$

Where:

- X-axis value = internal strategic position (unitless index);
- Y-axis value = external strategic position (unitless index);
- Total Weighted Score of Strengths (S) = sum of weighted scores for all strength factors;
- Total Weighted Score of Weaknesses (W) = sum of weighted scores for all weakness factors;
- Total Weighted Score of Opportunities (O) = sum of weighted scores for all opportunity factors;
- Total Weighted Score of Threats (T) = sum of weighted scores for all threat factors.

Next, a qualitative SWOT analysis is conducted using the Balanced Scorecard model to interpret the results and determine the study area's strategic position. A SWOT analysis diagram is presented in Figure 2.

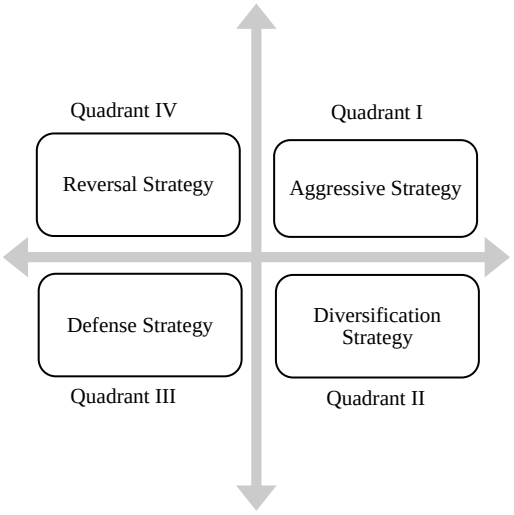

Figure 2. SWOT Analysis Diagram

RESULTS AND DISCUSSION

IFAS (Internal Factor Analysis Summary)

Nganteb Beach exhibits high geomorphological diversity, consisting of more than five coastal landform types, including cliffs, bays, headlands, sandy beaches, and estuarine zones. Based on the IFAS criteria, this condition places the study area in the highest geomorphological diversity class, contributing a weighted score of 1.05 to the internal factor assessment. The sandy beach terrain, gentle slopes, and cliffs provide a stunning backdrop, while the surrounding biodiversity enhances its ecological value (Hadmoko et al., 2021). Java's southern coast boasts towering headlands and limestone cliffs, set against coastal platforms and fringing reefs. These limestone cliffs feature notches and ridges at their base, as they developed on island banks and stacks, primarily through solutional processes. Satellite imagery shows the coastline formed at Nganteb Beach as a bay with pocket beaches. Cliff walls are present on the east and west sides of Nganteb Beach. These cliffs have changed over time due to waves from the south or the Indian Ocean. The presence of these cliffs also causes marine material to accumulate or settle in the center, creating a pocket beach.

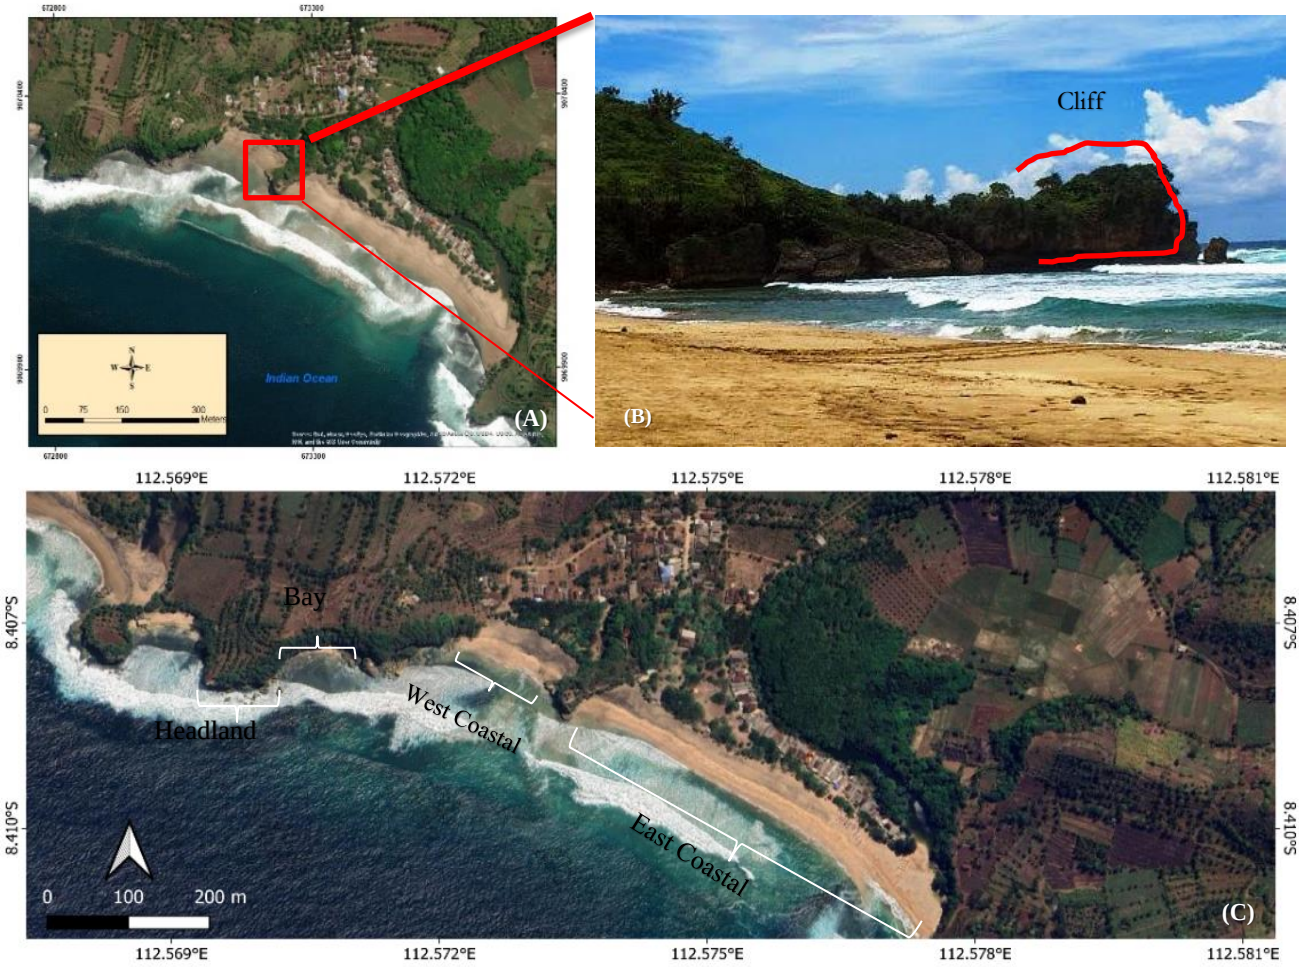

Figure 3. Landscape of Nganteb Beach: (a) satellite imagery showing the coastal location of Nganteb Beach, (b) coastal cliff morphology observed at the study site, and (c) geomorphological features of the coastline, including bay, headland west coastal, and east coastal zones. (Source: The authors)

Figure 3 illustrates the coastal landscape morphology of Nganteb Beach, which is characterized by several distinct geomorphological features, including coastal cliffs, sandy bays, and headlands. These landforms form a heterogeneous coastal landscape shaped by marine processes and geological structures. The cliff landscape represents erosional coastal landforms formed by the direct action of ocean waves on resistant rock formations. These cliffs are primarily composed of carbonate rocks belonging to the Wonosari Formation and form steep coastal slopes that directly face the Indian Ocean. Meanwhile, the bay landscape represents a depositional coastal environment where sediments accumulate under lower-wave-energy conditions between headlands. The sandy beach in the bay area is formed by the accumulation of sediments transported by rivers and marine processes. In contrast, the headland landscape consists of more resistant rock formations that protrude into the sea, controlling the overall shape of the coastline and influencing wave refraction patterns along the beach.

The morphology and type of the beach are determined primarily by the intensity, frequency, and strength of wave energy impacting the coastline. Based on its regional typology, Nganteb Beach can be classified as part of the Sub-Aerial Deposition Coast, which refers to coastal areas formed through the direct accumulation of sediments transported from terrestrial sources such as rivers, wind processes, or mass movement (Marfai et al., 2013).

This condition can be observed in the Nganteb coastal area, where sediment accumulation from river systems and the erosion of surrounding rocks contribute to the formation of sandy beach deposits. These sediments are transported from upstream areas and deposited along the coastline through fluvial and marine processes.

At a more local scale, Nganteb Beach can also be classified as a wave degradation coast, where marine erosion processes significantly influence coastal morphology. Continuous wave action gradually modifies the coastline by eroding exposed rock formations and redistributing sediments along the beach (Wibowo et al., 2022). As a result, the current coastal morphology reflects a combination of erosional and depositional processes that shape the spatial distribution of cliffs, bays, and sandy beach areas. In addition to marine sediment sources from the Indian Ocean, Nganteb Beach also receives sediment input from river systems that discharge into the eastern part of the study area.

These fluvial sediments are considered allogenic materials, originating from the weathering and erosion of volcanic and karstic rocks in the upstream region. The geological structure of Nganteb Beach is associated with the Wonosari Formation, which forms a karstic landscape composed of coral limestone, clay limestone, tuffaceous limestone, sandy limestone, marl, black peaty mudstone, and calcilutite (Sjarifudin & Hamidi, 1992). A cloudy white color characterizes coral limestone in this formation, which contains abundant fossil fragments and algae, with rough and sharp surfaces and layer thicknesses ranging from approximately 3 to 50 meters. Clay limestone is typically grayish-black and contains fossil fragments with interbedded layers several tens of centimeters thick. These lithological characteristics indicate that the formation represents carbonate platform deposits from the Middle Miocene to the Late Miocene.

Wave height is an important parameter influencing coastal vulnerability and shoreline dynamics, as it controls sediment transport processes and coastal erosion patterns. The average wave height at Nganteb Beach is approximately 0.7 m, with a significant wave height of about 1.4 m and average wind speeds of 11–13 km/h (Pasanglaut.com, 2025). These moderate wave conditions contribute to the redistribution of sediments along the coastline. In addition, an average wave height of 0.7 m, with significant waves of 1.4 m, is considered suitable for beginner-level surfing activities (Lapointcamps.com, 2025). The tidal range in the study area is categorized as relatively high according to the Coastal Ecosystem Vulnerability Index. Tidal fluctuations represent an important component of coastal processes because periodic sea-level changes influence coastal currents, sediment transport, and shoreline morphology (Wright, 1989). These tidal dynamics contribute to periodic changes in seabed conditions and the coastal profile.

Shoreline change analysis indicates that the total abrasion area between 2015 and 2024 was approximately 0.969 ha, corresponding to an average erosion rate of approximately 0.097 ha per year. This relatively low erosion rate suggests that the coastal profile of Nganteb Beach remains relatively stable. In the IFAS assessment, this condition is categorized as moderate-to-high coastal stability. Figure 4 illustrates shoreline changes observed between 2015 and 2024. The results indicate that there have been no significant changes in the overall beach area during the past decade. The limited abrasion observed along the coastline is offset by sediment deposition from the Sumberpelus River estuary, which contributes additional sediment to the coastal system. The estuary area also supports mangrove vegetation, which functions as a natural coastal protection system by reducing wave energy and stabilizing sediments.

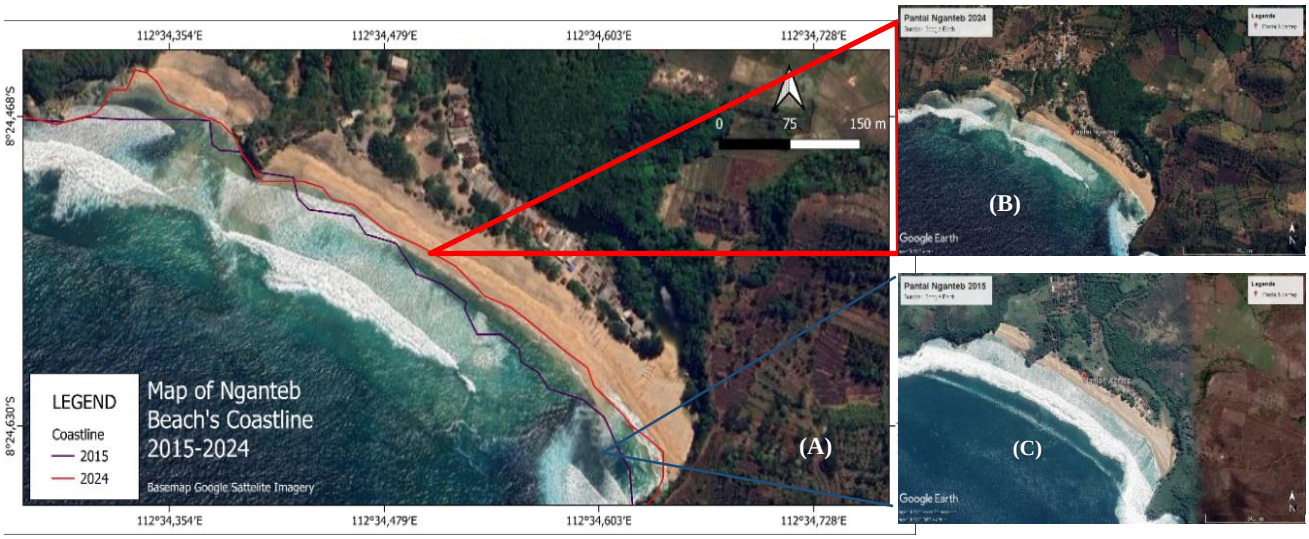

Figure 4. Map of Changes in the Nganteb Coastline 2015-2024:
(a) main shoreline change map, (b) satellite image 2015, (c) satellite image 2024. (Source: The authors)

Coastal vegetation plays a crucial role in preventing abrasion. Loss or damage to this vegetation can impact the surrounding ecosystem. Coastal plants typically have long, strong roots that help protect the substrate from wave action. (Feagin et al., 2019; Pantusa et al., 2022). Vegetation density from the coast to the land, coastal topography, substrate characteristics, and the condition of coral reef and seagrass ecosystems significantly influence the effectiveness of coastal vegetation in attenuating waves. The rich geomorphological landscape supports diverse ecosystems, such as mangrove forests. Furthermore, the coast offers a rich biodiversity and diverse natural resources. In addition to the

pretty good vegetation around the beach, Nganteb Beach also has Mount Batok, Mangrove Tourism, and Taman Ayu. Mount Batok stands at approximately 50 meters and offers religious tourism, featuring the oldest tomb tourists can visit. (Muluk et al., 2020). Mangrove Tourism is located at the Estuary of Nganteb Beach, which features several types of mangroves. Based on the results of a 2015 survey, the coastal ecosystem of Nganteb Beach is dominated by pioneer species (Sonneratia sp. and Nypa fruticans). The Mangrove Forest at Nganteb Beach does not directly border the beach but is approximately 100 meters from the shoreline. There are five main types of mangroves and two types of associated mangrove stands. Among them are Sonneratia alba Sm., Rhizophora mucronata Lamk., Excoecaria agallocha L., Xylocarpus granatum Koenig, and Nypa fruticans Wurmb (Lestyaningrum, 2016). Meanwhile, two types of associated mangroves are called Ringin Laut by the community because their shapes resemble a banyan tree with hanging roots.

The biodiversity of Nganteb Beach is also evident in Taman Ayu, which features numerous varieties of paper flowers, although they are unfortunately poorly maintained. Furthermore, a mangrove forest serves as an ecosystem for marine life, adding to its tourism value. The mangrove forest at Nganteb Beach was initiated by the Malang Regency Marine and Fisheries Department in 2015, with the planting of 14,100 mangrove (Rhizophora Mucronata) seedlings along the coastal area of Tumpak Rejo Village (Harahab & Setiawan, 2017). The local community then continues maintenance through the POKMASWAS (Community Development Group), fishermen's groups, and the LMDH (Forest Village Community Institution) Wana Karya (Wana Karya) of Tumpakrejo Village. In addition to its biodiversity, Nganteb Beach also boasts a rich religious culture, including the oceanic larung (larung samudra) held every 15 Suro. (Julianto, 2022), and the oldest tomb of Gunung Batok, which makes it a notable destination for religious tourism

EFAS (External Factor Analysis Summary)

Tourism statistics from BPS indicate a decline in tourist visits during 2023–2024 following a peak in 2022. This trend aligns with declining search interest in ecotourism, as measured by Google Trends, which was classified as a major external threat in the EFAS assessment. The number of tourist visits does not explicitly represent visits to Nganteb Beach, as no specific data is required. Therefore, the data collected is a general report of tourism visits to Malang Regency, which is considered the most representative of the number of tourist visits to Nganteb Beach and ecotourism in Malang Regency as a whole. A snapshot of tourist visits to Malang Regency, as reported by Statistics Indonesia (BPS), from 2019 to 2024, is shown in Figure 5 below.

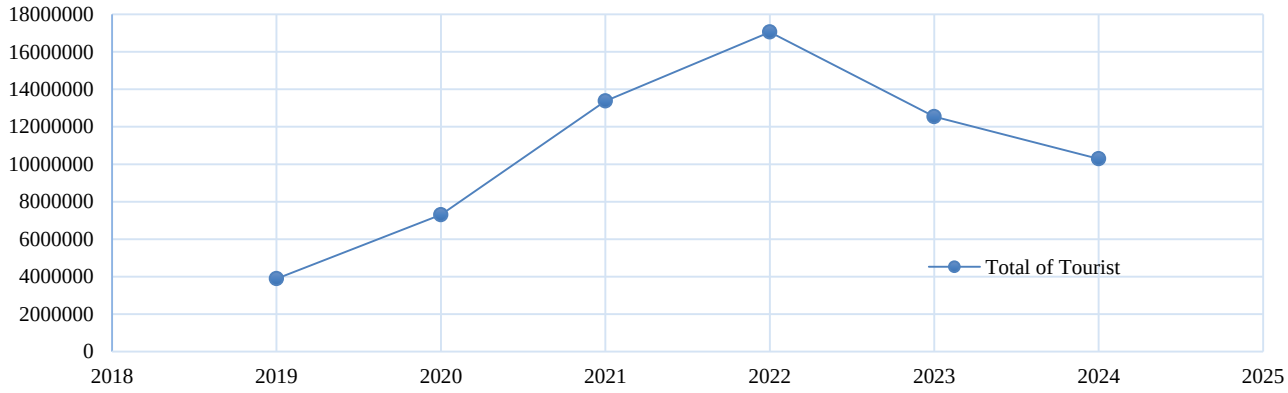

Figure 5. Graph of the number of tourist visits to Malang Regency
(Source: Statistics Indonesia - BPS Malang Regency, Tourism Statistics 2019–2024. https://malangkab.bps.go.id)

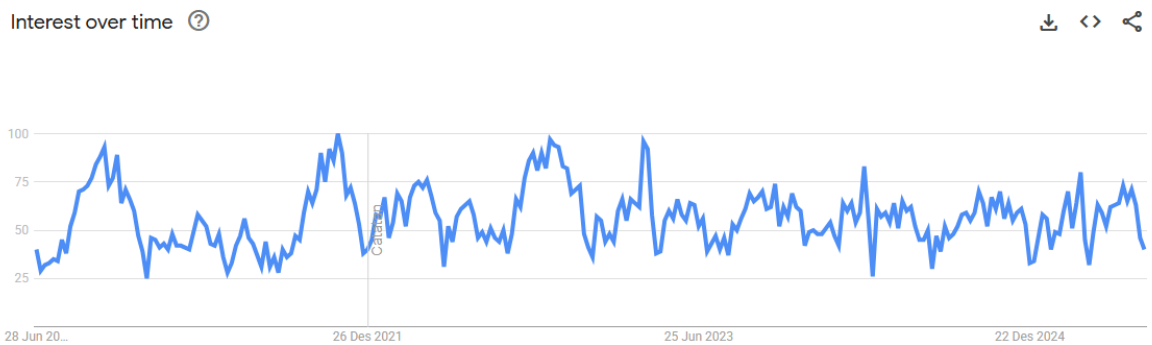

Figure 6. Google Trends results graph from ecotourism searches (Source: Authors' analysis based on Google Trends data (https://trends.google.com). Search keyword: Ecotourism) Time range: 2019–2024

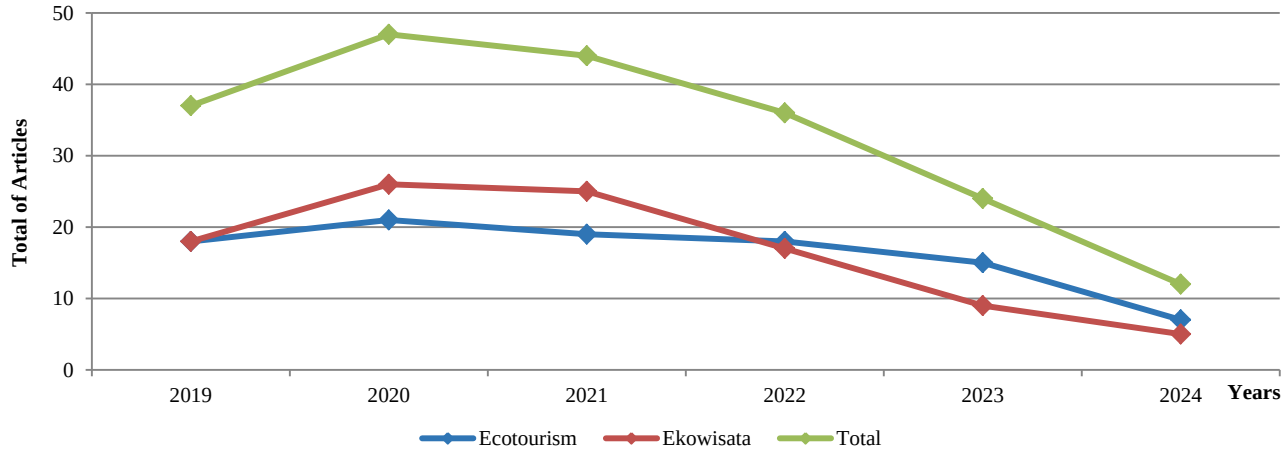
In 2019 and 2020, tourism declined due to the COVID-19 pandemic and the implementation of large-scale social distancing measures across the region. A significant increase began in 2021 as COVID-19 cases subsided and large-scale social restrictions started to be relaxed. Tourism peaked in 2022, only to decline again in 2023 and 2024. This could be due

to several factors, including: 1. A lack of compelling innovation in ecotourism, resulting in a lack of repeat visits; 2. The deterioration of natural tourism due to the large number of visitors in the previous year and inadequate tourism management. The community's general economic situation has deteriorated, leading to a decline in tertiary needs, such as entertainment. This graph aligns with Google Trends searches for ecotourism, which indicate a decline in search volume since 2023 (Figure 6). Searching results from academic databases show trends in ecotourism research. The graph in Figure 8 presents the number of journal articles related to the keyword “ecotourism” indexed in Google Scholar and Scopus.

A total of approximately 200 articles were identified using the keyword “ecotourism” within the selected time period. The results indicate fluctuations in the number of publications related to ecotourism. Previous studies show that coastal communities in Indonesia have become an important focus in ecotourism research, with dominant themes including ecology, ecotourism development, planning, community participation, and ecosystem management (Sisriany & Furuya, 2020). Publications on ecotourism showed an upward trend around 2020, following a period of relatively low numbers after 2012. The number of studies increased steadily between 2014 and 2019 and then declined again between 2022 and 2024 (Hamidi et al., 2023), as illustrated in Figure 7. The Malang Regency Tourism and Culture Office (Disparbud) offers opportunities for the public and tourism managers to promote tourism in Malang Regency through its official website (https://matic.malangkab.go.id/) and Instagram social media, as shown in Figure 8.



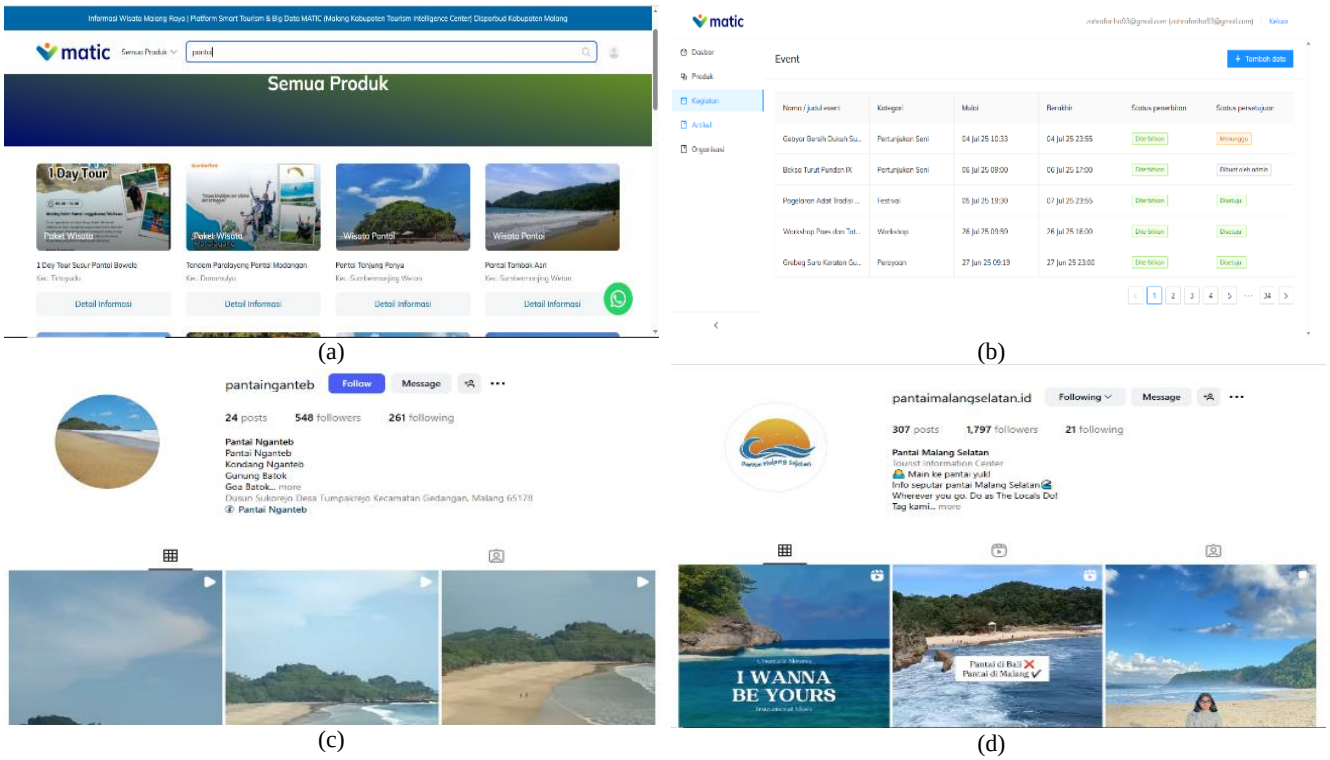


Figure 7. Graph of journal articles on the topic of ecotourism (Source: Authors’ analysis based on publication data retrieved from Google Scholar and Scopus databases using the keyword “ecotourism” (retrieved in January 2026)

(a) (b) (c) (d)

Figure 8. (a) User website interface page, (b) Admin website interface page, (c) and (d) Instagram account (Source: Authors’ documentation and compilation based on the official tourism website of Malang Regency (https://matic.malangkab.go.id) and the official Instagram account (@malangregencytourism)

The website provides opportunities for the general public and tourism managers to promote tourist attractions through news articles and engaging activities. Since 2005, both the business and tourism sectors have striven to increase the use of information technology and the internet, as evidenced by competition in the tourism market among developing countries (Untari & Satria, 2019). In addition, the ECDR noted that the major fundamental shift brought by e-tourism has increased the value of tourism, as evidenced by increased revenue in the tourism sector.

Additionally, there is a shift in information search from offline to online. Nganteb Beach is located in the subduction zone between the Indo-Australian and Eurasian plates, making it prone to earthquakes and tsunamis.

According to data from the Inarisk BNPB (National Disaster Mitigation Agency), as shown in Figure 9, the earthquake hazard at Nganteb Beach is classified as low to moderate. In contrast, the tsunami hazard is classified as high. The earthquake hazard was detected during processing of the focal mechanism in the South Malang region, which is characterized by a predominance of reverse and normal faults.

However, although this region is prone to earthquakes, the resulting earthquakes have limited potential to cause tsunamis because the earthquake hypocenters are located at depths of 30-100 km (Amalia, 2021; Prasetyo et al., 2024).

(a) (b)

Figure 9. (a) Tsunami Hazard at Nganteb Beach (b) Earthquake Hazard at Nganteb Beach (Source: Authors' compilation and interpretation based on hazard data from the InaRisk BNPB platform (https://inarisk.bnpb.go.id)

By emphasizing its unique geomorphological features and carefully managing potential threats, Nganteb Beach can be developed into a sustainable tourism destination that highlights the beauty and value of its natural landscape. Local communities continue to manage Nganteb Beach's tourism potential, but the government has yet to participate in beach management. Table 2 presents a SWOT analysis and strategies for enhancing Nganteb Beach's tourism potential, as follows.

Table 2. SWOT Analysis and Tourism Potential Strategy

	SWOT	Indicator	Weight	Score	Mark	Max Score
IFAS	Strengths	Unique Coastal Geomorphology	0.35	3	1.05	1.05
		Stable Beach Profile	0.15	2	0.3	0.45
		Biodiversity and cultural landscape	0.21	3	0.63	0.63
		Big beach waves with strong winds	0.11	3	0.33	0.33
		The beach sand is soft and white	0.18	3	0.54	0.54
		Total	1	14	0.95	3
	Weakness	Basic facilities	0.15	2	0.3	0.45
		Limited access to transportation	0.26	3	0.78	0.78
		Long distance from the city center	0.3	3	0.9	0.9
		Lack of safety equipment	0.1	2	0.2	0.3
		Lack of tourism promotion media	0.19	2	0.38	0.57
		Total	1	12	0.85	3
EFAS	Opportunity	Government and community support for tourism development	0.6	2	1.2	1.8
		Environmental Conservation Program	0.4	2	0.8	1.2
		Total	1	4	0.67	3
	Threats	Natural disasters	0.1	2	0.2	0.3
		Interest in ecotourism has declined in the last 2 decades	0.25	2	0.5	0.75
		Environmental Damage Due to Tourism	0.3	2	0.6	0.9
		Competition with Other Destinations	0.35	3	1.05	1.05
		Total	1	9	0.78	3
X-axis (SW)						0.10
Y axis (OP)						-0.12

The SWOT analysis places Nganteb Beach in Quadrant II (X = 0.10; Y = -0.12), indicating a Strengths–Threats (ST) strategic position. This condition suggests that diversification strategies are required to optimize internal strengths while

mitigating dominant external threats. Development efforts should prioritize leveraging geomorphological and ecological advantages to mitigate risks posed by declining ecotourism interest and potential natural disasters. The positive X-axis value reflects stronger internal strengths compared to weaknesses, whereas the negative Y-axis value indicates that external threats outweigh available opportunities. The SWOT quadrant position of Nganteb Beach is illustrated in Figure 10.

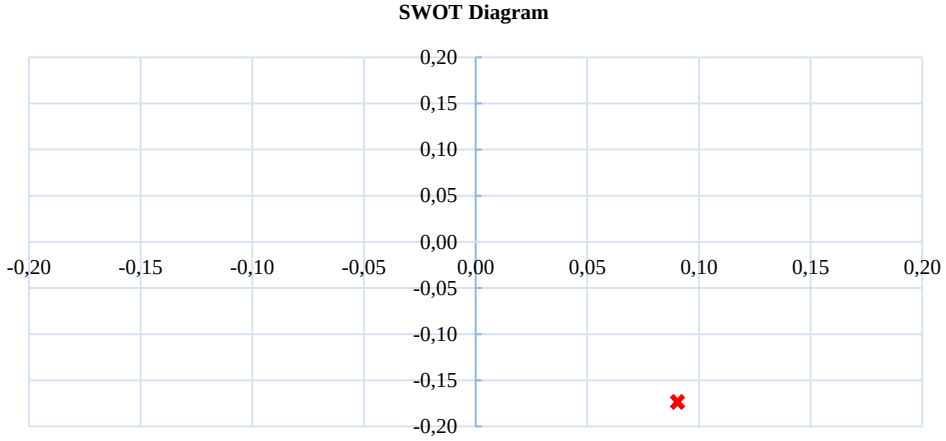

Figure 10. SWOT Quadrant Plot of Nganteb Beach

Based on the SWOT analysis in quadrant II, Nganteb Beach requires a diversification strategy for its development. In implementing this strategy, two primary principles are employed: leveraging internal strengths and mitigating external threats. Implementing these two principles is expected to lead to new opportunities through diversified commercial tourism activities, thereby mitigating pressure from external threats. Based on the results, internal strengths include unique coastal geomorphology, a stable coastal profile, biodiversity and culture, large waves with strong winds, and a soft, white beach. These factors must be maximized. Meanwhile, external threats include natural disasters, declining interest in ecotourism, environmental damage caused by tourism, and competition with other destinations. The details of the strategies, based on strengths and challenges, are presented in the following table.

Table 3. Details of diversification strategies for the development of Nganteb Beach tourism

Factor	Category	Diversification Strategy
Unique coastal geomorphology	The power to be optimized	Ensure that geomorphology is protected by implementing strict regulations and sanctions for visitors who damage geomorphological features.
Wave height 0.7-1.4 meters with strong winds		Optimized by holding a surfing training center for beginners
Beautiful view with a clean white sand beach		Optimized by providing a photobooth with an Nganteb beach background and affordable prices
Biodiversity and culture		Optimized with supporting fauna conservation, mangrove planting tourism, or a catalog of mangrove species in mangrove forests, so that it can be used as a conservation activity for education. Optimizing cultural preservation through tourism that applies the principle of "to do" tourism to add unique tourism value.
Tourism management by local communities		Forming tourism management that collaborates between local communities and the government.
Interest in ecotourism is declining.	Threats that must be faced	Increasing interest in ecotourism through optimizing social media as a promotional medium and improving transportation access to tourist locations that connect JLS with coastal tourism. Optimizing SEO on websites and YouTube ads for tourism promotion, as in the previous point, while increasing income from AdSense
Competition with other destinations		Emphasizing the conservation and cultural aspects to achieve diversified functions, namely as a tourist attraction and a center for research and education.
Potential natural disasters in the form of earthquakes and tsunamis		Reducing the risk of losses from natural disasters through structural and non-structural mitigation. For example, by expanding mangrove forest areas, providing evacuation signs and maps, and implementing an early warning system.
Environmental damage		Minimize environmental damage by implementing strict regulations, regular quality monitoring, and environmental conservation activities that serve as icons for tourism, such as Adiwiyata tourism.

Recommendations for developing the tourism potential of Nganteb Beach should be strategically aligned with the distinct roles and responsibilities of key stakeholders, namely government institutions, local communities, and academic actors. The SWOT analysis positions Nganteb Beach in the Strengths-Threats (ST) quadrant, indicating that development strategies must focus on leveraging strong internal capacities to mitigate dominant external threats. Although the area possesses significant internal strengths, particularly unique coastal geomorphology and high biodiversity, these advantages are not yet optimally supported by tourism infrastructure and are challenged by declining interest in ecotourism and environmental risks.

Infrastructure gaps and environmental sensitivity emerged as prominent weaknesses, while threats such as climate change pose significant challenges. Addressing these issues requires proactive measures, as outlined in Table 4. Key recommended actions include developing tailored ecotourism initiatives, strengthening local infrastructure to support sustainable tourism, and fostering collaboration with policymakers and stakeholders to ensure long-term resilience and adaptability.

Infrastructure limitations and environmental sensitivity are critical internal weaknesses, while external threats, including climate-related hazards and disaster risks, require immediate attention. Therefore, development efforts should prioritize strategic diversification by strengthening environmentally friendly infrastructure, improving accessibility, and integrating disaster risk mitigation measures. Investments in low-impact facilities, including pedestrian pathways, safety infrastructure, and zoning-based land-use regulations, are essential to protect sensitive geomorphological features while enhancing the visitor experience. By promoting responsible tourism that respects local customs and the environment, the area can attract tourists interested in both natural and cultural heritage (Marlina et al., 2022).

Key strategies involve fostering collaborative management by building partnerships between local communities, government agencies, and private stakeholders while ensuring participatory planning processes that strengthen community voice in decision-making. Infrastructure development is another key focus, aiming to improve accessibility and visitor experience through improved roads, transportation, and public facilities, all sustainably designed to reduce environmental impacts. Environmental protection is prioritized through the establishment of conservation zones, enforcement of regulations, and the promotion of eco-friendly tourism practices, including waste management and green accommodations. Furthermore, capacity development plays a crucial role in equipping residents with the skills necessary for hospitality and environmental management, empowering them to contribute actively to sustainable tourism initiatives. Financial support for conservation and community-based tourism initiatives is crucial for fostering long-term sustainability (Sumarmi et al., 2024).

Local communities play a crucial role in tourism, offering opportunities for income generation and preserving local traditions. Empowering residents through cooperatives for businesses, such as guided tours, eco-lodges, and handicrafts, can directly benefit communities. Cultural tourism should be promoted, showcasing local traditions and religious sites, such as Mount Batok, as unique attractions. Community-led conservation programs, such as tree planting and beach cleanups, can help maintain ecological balance while instilling environmental stewardship. Involving local communities in tourism planning and management has been highlighted as crucial. Training programs for residents in hospitality and environmental management can enhance service quality and promote conservation efforts (Arinta et al., 2022).

The role of academia is to provide research-based insights and innovative solutions that support sustainable tourism. Universities and research institutions can monitor geomorphological changes, biodiversity, and socioeconomic impacts, offering valuable data to guide development strategies. Educational programs for residents and tourists can help raise awareness about the preservation of Nganteb Beach's natural and cultural assets. Technology-based innovations such as virtual tours and mobile apps can further enrich the tourist experience. Collaboration with schools and universities on student-led projects can foster ecotourism initiatives and community engagement, while also ensuring a sustainable exchange of knowledge and skills. Detailed collaborations are shown in Table 4 below.

Table 4. Integrated Collaboration for Sustainable Tourism Development

Stakeholder Relations	Collaborative Action	Benefit	Challenge
Government ↔ Society	The government provides funding and infrastructure for community-managed tourism services.	Community-based tourism initiatives receive financial and logistical support, thereby improving residents' livelihoods.	Mismatch between government policies and community priorities. Lack of community participation.
Government ↔ Academics	Academic research to inform government policy on geomorphological conservation and tourism planning. Co-development of disaster management.	Evidence-based policies that reduce negative impacts. Improve disaster preparedness and mitigation.	Bureaucratic delays in implementing research findings—limited funding for academic collaboration.
Community ↔ Academics	Communities engage in educational programs and implement academic recommendations—local data support research.	Enhanced skills and knowledge in sustainable tourism. Community-driven conservation practices.	Lack of local awareness of academic contributions—financial barriers to collaboration.
Government ↔ Society ↔ Academics	Establish a multi-stakeholder forum for collaborative planning and decision-making. Create a joint action plan for conservation, tourism, and education.	A comprehensive tourism strategy. Alignment of goals among stakeholders. Sustainable regional growth.	Coordination challenges due to differing schedules and priorities. Resource allocation issues.

By aligning the efforts of these stakeholders with the government, community, and academics. Nganteb Beach can realize its full tourism potential. These collaborative approaches will maintain a balance between development and sustainability. Furthermore, a community-based approach must be integrated with environmental management to develop ecotourism that benefits both local communities and the environment (Arinta et al., 2023).

Furthermore, Marfai et al. (2022) explain that developing a comprehensive coastal management plan that considers both natural processes and human activities is crucial to ensuring the long-term stability and sustainability of the coastline. Establishing a regular monitoring program to track shoreline changes and sediment dynamics will facilitate timely decision-making and informed adaptive management strategies.

CONCLUSION

Nganteb Beach, characterized by its curved bay morphology and distinctive pocket beach formation, has significant potential for sustainable coastal tourism development. The geomorphological characteristics of the area, including cliffs, bays, and sandy beach deposits, contribute to the destination's unique landscape value.

These natural features not only enhance the beach's aesthetic appeal but also create favorable environmental conditions for recreational activities such as surfing and nature-based tourism. The relatively stable shoreline conditions and sediment inputs from nearby river systems further support the long-term sustainability of the coastal environment.

The results of the SWOT analysis indicate that Nganteb Beach possesses strong internal strengths, particularly its unique coastal geomorphology, natural landscape quality, and ecotourism potential.

However, several challenges remain, including limited infrastructure, accessibility constraints, and the need for improved tourism management. In addition, external threats, such as coastal hazards and environmental degradation, underscore the importance of implementing appropriate coastal management strategies. Therefore, sustainable tourism development at Nganteb Beach requires an integrated management approach that involves collaboration between government institutions, local communities, and academic stakeholders. Strengthening multi-stakeholder governance, improving tourism infrastructure, and promoting environmentally responsible tourism practices are essential steps to enhance the destination's competitiveness while preserving its ecological integrity. By integrating environmental conservation with strategic tourism planning, Nganteb Beach has the potential to become a model for sustainable coastal tourism development in South Malang and other coastal regions with similar characteristics.

Abstract: Sustainable tourism evaluates those destinations that balance economic growth with social well-being and environmental protection, rather than focusing solely on short-term economic gain. As a result, the management of natural resources and the preservation of social cohesion are becoming increasingly important in destination development. This study, using a combination of exploratory factor analysis (EFA) and hybrid multi-criteria decision-making methods, aims to identify and assess the factors influencing foreign tourists' selection of Albania as a tourist destination. Two hundred and seventy foreign tourists were surveyed to assess thirteen items that influence decision-making. EFA identified four main factors: destination sustainability practices, cultural attractions and facilities, perceived cost and value, and destination safety. Twelve tourism experts pair-wise compared criteria and sub-criteria obtained from the EFA on a scale of 1 to 9. The relative importance of the criteria and sub-criteria was determined using the Best–Worst Method (BWM). The Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) method was used to rank the four destination alternatives considered based on these weights. The results showed that 'cultural attractions and facilities' was the most influential criterion, followed by criteria related to cost and safety considerations, while sustainable practices had the lowest relative importance. The TOPSIS ranking showed that the Heritage and Culture Destination is the most preferred, as a result of its high performance in tourism services and cultural values, despite its moderate results in sustainability. The Riviera and Coastal Destination ranked second most preferred, reinforcing Albania's dual attractiveness as both a cultural and a coastal destination. The findings provide important insights for managing and prioritizing tourism development in a rapidly growing and highly competitive market, while protecting long-term sustainability and natural resources.

Keywords: sustainable tourism, tourist destination, factor analysis, expert judgment, multi-criteria decision making

INTRODUCTION

Tourism continues to play a significant role in supporting economic expansion, job creation, and regional development. The recovery of this sector after the COVID-19 pandemic showed how important tourism is for the economy and society in the long term. The growth of tourism affects business development and community development and is closely linked to cultural interaction between destinations (Qi & You, 2024). International tourism reached approximately 88% of pre-pandemic levels by 2023, highlighting the sustainability and long-term importance of the sector (UN Tourism, 2024). At the same time, increasing global competition between destinations has increased the need for strategic approaches that enhance destination attractiveness, service quality and overall competitiveness. Choosing a tourist destination is a complex decision-making process influenced by a number of factors that determine the attractiveness of a place. Tourists evaluate potential destinations based on their cultural and natural attractions, infrastructure quality, support service performance, and perceived cost and value for money (Kasapi & Nurja, 2019; Lamçe & Braimllari, 2025a). Perceived political stability and visitor safety are important factors that positively shape tourists' destination choices (Ding & Wu, 2022).

Technological development and digitalisation increasingly affect the competitiveness between destinations. The development of e-marketing strategies is a key determinant of competitiveness for tourism enterprises, especially in developing destinations such as Albania (Ramaj-Desku & Ukaj, 2021). Information and communication technology has changed the way tourism businesses communicate with markets, promote their services, and deliver offers, directly influencing service quality and tourists' perceptions (Gjika & Pano, 2020; Noti & Hasrama, 2025).

Understanding why tourists choose certain destinations is essential for tourism planners and destination managers, as it enables strategic improvements to match visitor preferences and improve competitiveness (Garcia et al., 2026).

Destinations that leverage their strengths by offering attractions, high-quality service, safe and sustainable experiences, and good value are in a better position to attract and satisfy visitors in a highly competitive market, driving sustainable growth and long-term success (Cimbaljević et al., 2025). From a broader perspective, destination competitiveness is closely linked to sustainable tourism development and entrepreneurial dynamics in the local economy (Garcia et al., 2026). As an emerging Mediterranean destination, Albania provides a suitable empirical context for examining these dynamics. It shares borders with Montenegro, Kosovo, North Macedonia, and Greece, while its western edge opens to the Adriatic Sea and its southern coast to the Ionian Sea. In recent years, the number of international tourists has increased significantly, as has the country's visibility as a tourist destination in global tourism markets.

In addition, Albania is increasingly perceived by international visitors as an affordable Mediterranean destination, where relatively low travel and accommodation costs represent an important element of its growing attractiveness. National statistics show that the number of foreign citizens entering Albania reached approximately 11.7 million in 2024 (INSTAT, 2024), highlighting the growing importance of tourism for economic growth and employment (Merko et al., 2025). Enríquez et al. (2025) assess Albania as a developing 'Sun, Sea and Sand' destination. According to them, the destination is characterised by coastal tourism, rich cultural heritage and increasing development pressures, and these characteristics make it suitable for investigating how tourists value experience, cost, safety and sustainability when selecting it as a destination. To operationalise destination competitiveness in a structured manner, this study conceptualises Albania's tourism offer through four broad destination typologies that serve as analytical alternatives in the decision-making model. These typologies reflect dominant patterns of tourism development and visitor experience rather than individual locations.

- Tirana (Urban) Destination: The capital of Albania, famous for its nightlife, cultural events, and long history.
- Heritage and Culture Destination: Berat, Gjirokastra and Butrint, three UNESCO destinations, as well as Kruja with the Skanderbeg Castle, represent cultural and historical heritage as well as traditional identity.
- Riviera and Coastal Destination: This category includes major coastal destinations, such as Vlora, Himara, Dhermi and Durres.
- Mountain and Lake Destination: This group comprises natural mountain locations, national parks, lakes, winter sports, adventure, as well as rural tourism and local customs.

These alternatives enable a comparative assessment of how attractions, infrastructure, cost, safety and sustainability affect tourists' preferences in different destination profiles. Against this background, the purpose of this study is to identify the key factors influencing foreign tourists' decisions to choose Albania as a destination by integrating exploratory factor analysis (EFA) with the hybrid Best-Worst Method (BWM) and TOPSIS approach.

The objectives of this study are:

- Identification of the main factors that influence this decision-making through EFA.
- Evaluation of the weights of criteria and sub-criteria through the BWM method.
- Ranking of the alternatives included in the study through the TOPSIS method.

The study seeks to help the tourist structures in the country to be as competitive as possible in the international market. By combining tourists' perceptual evaluations with expert-based prioritisation within a single analytical framework, this study contributes methodologically to destination competitiveness research and offers a robust decision-support tool for emerging tourism destinations. This study provides both practical and academic value to stakeholders in tourist development. The results show destination managers and policymakers the most important factors to make a destination more competitive and to use resources better.

From an academic standpoint, the study enhances the field by combining tourists' impressions and expert evaluations into a unified analytical framework applicable to analogous tourism settings.

The article continues with a literature review on hybrid methods used for destination competitiveness assessment, the methodology with a clear overview of the methods used, the results, discussions and conclusions of this study.

LITERATURE REVIEW

Studies in recent years have focused on analysing the factors influencing tourist destination choice using statistical and multi-criteria decision-making (MCDM) methods (Boonmee & Arimura, 2026; Lamçe & Braimllari, 2025a; Šostar et al., 2026). These studies consistently show that destination choice is a multidimensional process influenced by both individual tourist motivations and destination attributes, such as historical and cultural attractions, infrastructure, service quality, service costs, destination safety, and sustainability considerations (Cuong et al., 2026; Dahiya & Batra, 2016). In addition, perceived safety has increasingly been recognised as an important dimension of tourist experience, since tourists' perceptions of security and urban environment can shape their evaluation of destinations (Ilieș et al., 2025).

Some studies have used factor analysis to identify the latent factors underlying the basic dimensions of destination attractiveness. Alam et al. (2015) combined confirmatory factor analysis and structural equation modelling to identify economic, environmental, cultural, and community-related factors as significant determinants of tourists' decisions to visit Melaka, Malaysia. Using exploratory factor analysis, Seyidov & Adomaitienė (2016) showed that destination amenities, tourism infrastructure, natural environment, human resources, and price levels were the main factors influencing domestic tourists' decisions to visit Azerbaijan. These results highlight the importance of factors related to cost, accessibility, local hospitality, and destination attractions across different tourism contexts. Similar conclusions have been reported in more recent studies. For instance, Chae (2026) showed that the perceived quality of tourism services and the overall visitor experience significantly influence tourists' behavioural intentions and the attractiveness of cultural destinations.

In addition to factor analysis, many studies have applied MCDM methods to identify the importance of destination attributes or rank tourism alternatives (Göksu & Kaya, 2014; Ramos et al., 2024; Lamçe & Braimllari, 2025b; Sanjaya et al., 2026). The Analytical Hierarchy Process (AHP) is one of the most widely used methods for evaluating criteria that influence destination choice in tourism (Ramos et al., 2024; Lamçe & Braimllari, 2025b). For example, Blešić et al. (2021) showed that coastal quality, safety, and service-related factors were more influential than traditional infrastructure in the choice of Croatian coastal destinations by Serbian tourists. Their findings show that, environmental and experiential factors can have a greater impact on a destination's attractiveness than its physical infrastructure alone.

In the last decade, new multi-criteria decision-making methods have been widely used in studies focusing on tourism development, especially the Best-Worst Method (BWM) introduced by Rezaei (2015). This method is distinguished by its reduced number of pairwise comparisons and improved robustness, making it the preferred method for determining criterion weights among researchers. Nejat & Lajimi (2022) used the BWM method to assess the importance of factors influencing the return of foreign tourists to Iran. Their study showed that social environment and perceived value were more influential than factors related to infrastructure or marketing. It was observed that criteria related to sustainability and innovation had lower weights, suggesting a gap between conceptual awareness and decision-making.

Hybrid MCDM methods have also been widely used in this context. In their study, Mohamad & Jamil (2012) combined factor analysis with the hybrid AHP–fuzzy TOPSIS method and found that destination safety and cultural attractions had the greatest impact on tourists' destination choice. Lopes & Rodríguez-López (2022) combined the PROMETHEE II visual analysis with GAIA to rank wellness tourism destinations in Portugal. The authors showed that the most important factors were tourist attractiveness, cultural heritage, and service costs. Yang et al. (2022) applied a Bayesian BWM model combined with a PROMETHEE-based grey model to evaluate medical tourism operators. According to them, service quality, digital readiness and communication skills were the main determinants of performance evaluation. These studies illustrate the increasing methodological sophistication in tourism research and the suitability of hybrid MCDM models for evaluating complex destination systems. In his study, Çiçekdağı (2022) used the BWM-TOPSIS methods to evaluate the geo-tourism potential in Turkey. The author showed that natural attractiveness dominated other criteria such as adventure or socio-cultural features. Lamçe (2024) applied the hybrid AHP-TOPSIS-2N method to examine decision-making by domestic tourists when choosing a weekend destination. The author showed that factors such as tourist attractions and infrastructure had a greater influence on decision-making, whereas sustainability criteria had a lower impact. These results are also reported in other studies, suggesting that sustainability is often not given priority in short-term travel decisions (Nejat & Lajimi, 2022; Çiçekdağı, 2022). Similar observations have been reported in studies analysing tourists' perceptions of sustainable destinations. For example, Suhud et al. (2025) found that although sustainability initiatives can positively influence tourists' attitudes toward destinations, they do not always represent the primary determinant of visit intention.

In recent years, other hybrid multi-criteria decision-making methods have been applied to evaluate tourism destinations and support strategic planning. For instance, Šostar et al. (2026) combined Principal Component Analysis with the AHP method to analyse how promotional channels influence destination choice in Croatia, highlighting the increasing use of statistical and decision-making methods in tourism research. Similarly, Boonmee & Arimura (2026) proposed a hybrid evaluation framework combining AHP-weighted multi-criteria decision-making methods with data-driven techniques to assess the performance of cultural tourism destinations in Northern Thailand, highlighting the importance of structured evaluation models for improving destination competitiveness and sustainability.

In addition, Aria et al. (2025) used a stochastic multi-criteria acceptability analysis to evaluate tourism sustainability across Italian regions, showing that advanced multi-criteria models can support stronger, more policy-relevant tourism planning. These recent contributions confirm the increasing importance of integrating statistical techniques with MCDM methods for analysing complex tourism decision-making problems.

Overall, the literature shows strong agreement on the main factors influencing destination choice, especially cultural and natural attractions, service quality, safety, and value for money. Recent studies also indicate that tourist preferences are increasingly influenced by sustainability awareness, particularly among younger travellers. Šenková et al. (2026) found that generations Y and Z are more interested in sustainable tourism products and services. However, sustainability often has a smaller influence on real tourist decisions, especially in developing or emerging destinations. Although hybrid multi-criteria decision-making methods are widely used, relatively few studies combine empirically derived tourism factors with expert-based weighting and ranking within a single hybrid framework, particularly in the context of developing tourism destinations such as Albania. Recent studies focusing on the Albanian tourism sector also emphasise the importance of understanding destination performance and seasonality dynamics from a stakeholder perspective (Dhimitri et al., 2025). Therefore, this study employs an integrated EFA–BWM–TOPSIS framework to analyse factors influencing destination selection and evaluate tourism destination competitiveness.

RESEARCH METHODOLOGY

To conduct this study, initially based on the literature (Alam et al., 2015; Seyidov & Adomaitienė, 2016; Blešić et al., 2021), and in consultation with a tourism expert, thirteen items were selected that could influence foreign tourists' decisions to select Albania as a tourist destination. Three hundred questionnaires constructed in English, based on a five-point Likert scale ranging from 1 (not important) to 5 (very important), were distributed to foreign tourists accommodated in hotels in three main coastal destinations in Albania: Saranda, Durres and Vlora, in the summer of 2024, using a non-probability convenience sampling approach. After eliminating incomplete questionnaires and those

with contradictory answers, 270 valid questionnaires were retained for further analysis. According to the recommendation of Hair et al. (2009), a minimum sample size of at least five observations per variable is sufficient for factor analysis, the final sample size ensured an appropriate level of reliability and statistical robustness. An exploratory factor analysis was conducted on this data, the results of which served in the second phase of the study, where the BWM-TOPSIS method was used based on the judgments of 12 Albanian tourism experts to evaluate the criteria and sub-criteria that most influence the choice of a tourist destination, as well as to rank the alternatives. The criteria and sub-criteria used in the BWM analysis were taken directly from the factors and items identified through exploratory factor analysis, ensuring consistency between tourists' perceptions and the expert-based weighting process.

Exploratory Factor Analysis

EFA was performed on the data of 270 surveys included in this study. First, the suitability of the data for this analysis was assessed through the Kaiser-Meyer-Olkin (KMO) and Bartlett's test of sphericity. In the following, EFA enabled the discovery of factors that tourists consider when choosing a destination, among a set of thirteen observed items by grouping those that are highly correlated (Howard & Henderson, 2023). As an extraction method, principal axis factorisation was used, since the goal was to discover hidden factors rather than reduce the number of items considered. Oblique rotation Promax was employed, as the factors influencing the selection of a tourist location may exhibit correlations (Hair et al., 2009; Howard & Henderson, 2023). The quantity of factors was ascertained based on eigenvalues above 1. No items were excluded, as all had factor loadings above 0.50 and no significant cross-loadings greater than 0.30. The internal consistency of each factor was assessed using Cronbach's alpha values. Thus, the exploratory analysis identified the main criteria that influence tourists' destination choices in the Albanian context.

BWM for Criteria Weighting

After identifying the main decision-making factors, the study assessed their relative importance and incorporated them into a decision-making model. To determine the weight of each criterion and sub-criterion, the BWM was used, a relatively new multi-criteria decision-making technique proposed by Rezaei (2015), which has found widespread use in contemporary literature (Deng et al., 2020; Varchandi et al., 2024). One of the main advantages of this method is the reduced number of pairwise comparisons, only $2n - 3$ comparisons per n criteria, which makes BWM more efficient, less tedious for decision-makers, and contributes to improving the robustness of the results (Rezaei, 2015; Rezaei et al., 2016). A new questionnaire with 28 pairwise comparisons was distributed to 12 tourism experts with more than 8 years of professional or academic experience, including university professors, hotel managers and travel agency executives. Based on the factor structure identified through factor analysis, the questionnaire included 5 pairwise comparisons for the criteria and 23 for the sub-criteria**.** This sample size is considered appropriate for BWM applications in tourism research, as previous studies indicate that a panel of 10–15 experienced experts is sufficient for reliable BWM and MCDM analyses (Rezaei, 2015; Mardani et al., 2016). The individual judgments from the experts were aggregated using the geometric mean to obtain a single group-comparison matrix for the BWM analysis, a common approach in group decision-making applications. The implementation of BWM includes the following steps (Rezaei, 2015):

- The set of criteria that serves for decision-making is identified.
- Experts select the best criterion and the worst criterion.
- The preference of the best criterion over the other criteria is determined, and the preference of each criterion over the worst criterion is also determined, based on a 9-point scale from 1 (equally important) to 9 (extremely important).
- The calculation and normalisation of optimal weights are performed by solving a linear optimisation model that minimises the maximum absolute differences between the extracted weight ratios and the pairwise judgments of the experts.
- The consistency ratio (CR) was subsequently calculated, and values below the recommended threshold of 0.1 indicate acceptable consistency of the experts' judgments.

The resulting linear programming model was performed in RStudio, using the 'lpSolve' package.

TOPSIS for Ranking Alternatives

The TOPSIS method was used to rank the four alternatives in this study, based on the identified sub-criteria and their weights. This method is well-suited to such problems because it evaluates each alternative against an ideal reference point. In TOPSIS, the best alternative is the one with the shortest distance from the hypothetical ideal solution and the greatest distance from the negative-ideal solution (Hwang & Yoon, 1981). The performance of the tourist destinations with respect to each criterion was evaluated by the same panel of tourism experts involved in the BWM analysis. All criteria were treated as benefit-type and assessed using a nine-point Likert scale. When multiple expert evaluations were available, the geometric mean was used to aggregate individual scores for each alternative and criterion.

The implementation of TOPSIS includes the following steps (Hwang & Yoon, 1981):

- For our analysis, a decision matrix of four alternatives was initially constructed with respect to the 13 sub-criteria included in the analysis.
- A normalised matrix of the initial decision matrix was constructed.
- By multiplying the normalised weights of each sub-criterion, calculated with the BWM method, by the values of the corresponding column of the normalised matrix, the normalised weighted decision matrix was constructed.
- According to the TOPSIS procedure, the ideal solution (highest score for each factor) and the negative-ideal solution (lowest score) were identified, and the Euclidean distance of each alternative from these values was calculated.

- The relative closeness to the ideal solution was calculated for each alternative, and the highest value indicated the most preferred alternative, allowing for a ranking from best to worst.

The analysis was run in RStudio using the 'topsis' package. The study framework is presented in Figure 1.

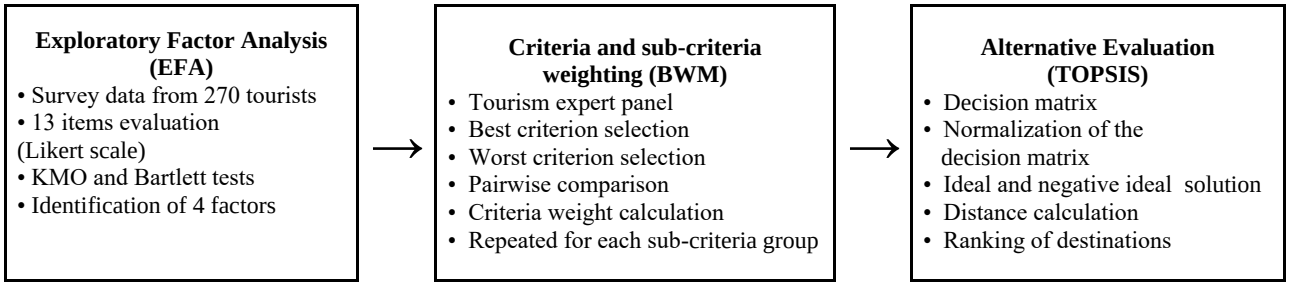

Figure 1. Research framework methodology (Source: Authors' elaboration)

By integrating BWM weighting and TOPSIS steps, we implemented a hybrid decision-making model: BWM provided the weights of the criteria, and TOPSIS provided the ranking of destinations using those weights. This hybrid EFA and BWM–TOPSIS approach represents an integrated decision-making framework applied in the context of tourism research in Albania. It enabled us not only to identify the main factors influencing destination choice but also to quantitatively prioritise decision-making alternatives (such as destinations to be developed or promoted) based on these factors. The combination of methods ensures that the conclusions are data-based and robust: the factor analysis phase bases the study on the empirical perceptions of tourists, while the multi-criteria decision-making analysis phase provides a rational tool for decision-makers to evaluate options in light of those empirically derived priorities.

RESULTS

Descriptive analysis of tourist profiles and item evaluations

The analysis of this study's results reveals the preferences and perceptions of foreign tourists who visited Albania over the last two years. In terms of their age, 27.75% were between 18 and 30 years old, 38.89% were between 31 and 50 years old, and 33.33% were over 50 years old. In terms of gender, males accounted for the largest share of the survey, about 53%. EU countries contributed 70.38% of all tourists, mainly from Italy and Germany. Among non-EU countries tourists, most came from Kosovo and Ukraine. Figure 2 shows the percentages by country of origin.

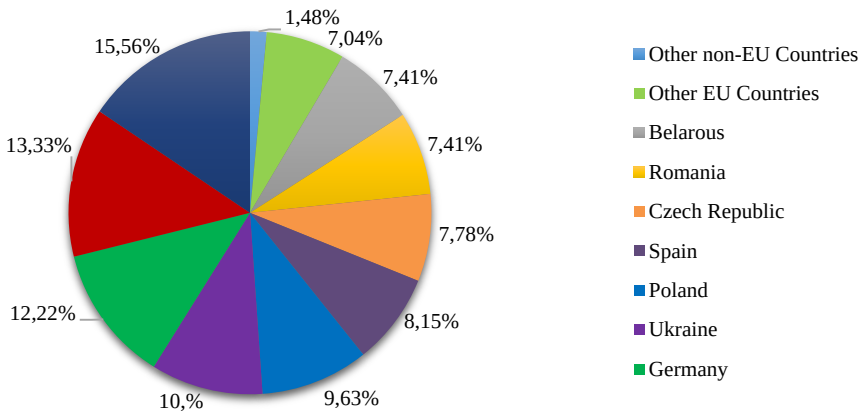

Figure 2. Distribution of tourists by country of origin (Source: Authors' elaboration based on survey data from 270 respondents)

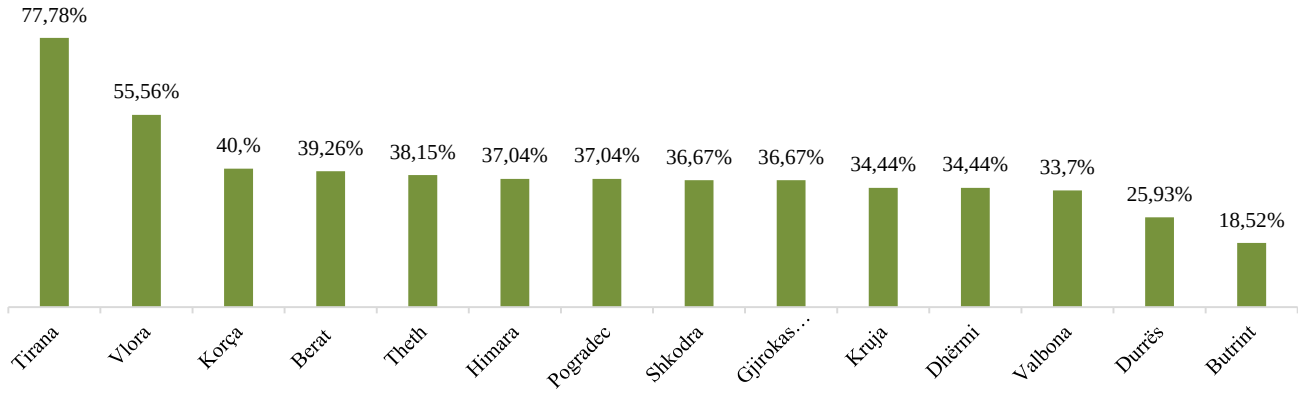

Figure 3. Destinations visited by tourists (Source: Authors' elaboration based on survey data from 270 respondents)

Albania, as a tourist destination, was visited by 43.7% of respondents through promotions by tourist agencies, 29.63% through acquaintances' recommendations, and 26.67% through social networks. Only 49.63% stated that it was their first time visiting Albania. The question of which of the listed destinations they had visited was answered as in Figure 3.

Tirana is the most visited destination (77.78%), reflecting its role as the capital and the location of Albania's primary international airport. The analysis shows that only 11.1% of tourists have visited exactly two destinations, while 41.9% and 46.3% have visited three and four destinations, under study respectively.

These results demonstrate that the tourism experience in Albania is largely multi-dimensional, thereby justifying the selection of four destination types as an analytical alternative. A 5-point Likert scale was used in the survey to rate 13 items that influence tourists' destination choices. The results of the descriptive analysis presented in Table 1 showed that, based on the mean values, the most highly rated items were 'Food and gastronomy experience', 'Quality of tourism services', and 'Road infrastructure quality'. The Cronbach's alpha reliability coefficient for each item ranged from 0.871 to 0.890. This coefficient for the total data was 0.885, suggesting a high internal consistency.

Table 1. Descriptive statistics for items in selecting a tourist destination (Source: Authors' calculations based on survey data from 270 respondents)

Items	Mean	St. Dev	Cronbach's Alpha
Accommodation price accessibility	**3.93**	1.05	0.872
Travel-related costs	3.62	1.17	0.871
Expenses for tourist activities	3.79	1.09	0.877
Perceived crime risk	3.55	1.15	0.881
Availability of emergency services	**3.95**	1.07	0.877
Sustainable accommodation practices	3.60	0.96	0.871
Environmental resource protection	3.57	1.09	0.875
Cultural heritage preservation	3.73	1.25	0.872
Tourism intensity and crowding	3.32	1.13	0.877
Food and gastronomy experience	**4.33**	0.84	0.879
Historical importance	3.82	1.02	0.890
Road infrastructure quality	**4.14**	0.98	0.874
Quality of tourism services	**4.15**	1.03	0.879

EFA results and factor structure

Exploratory Factor Analysis was used in the first part of the study to figure out how the hidden factors that affect the choice of a destination are structured. Two standard tests were applied to assess whether the data for the 13 items included in the survey were suitable for this analysis. The Kaiser–Meyer–Olkin measure of sampling adequacy was 0.81, which is higher than the ideal value of 0.6, as suggested by Kaiser (1974). Bartlett's test of sphericity ($\chi^2(253) = 3858.37$, $p < .001$) confirmed that the correlation matrix is not an identity matrix (Bartlett, 1951). Table 2 shows the results of the factor analysis, which found four factors accounting for 63.11% of the variance. The factor 'Destination sustainability practices' has four items with factor loadings between 0.6 and 0.803, and accounts for 19.30% of the variance.

Table 2. The results of factor analysis (Source: Authors' calculation based on survey data from 270 respondents)

Factors and Items	Factor loading	Eigenvalue	Variance (%)
Destination sustainability practices		5.607	19.30
Sustainable accommodation practices	0.726		
Environmental resource protection	0.803		
Cultural heritage preservation	0.600		
Tourism intensity and crowding	0.667		
Cultural attractions and facilities		1.627	16.04
Food and gastronomy experience	0.738		
Historical importance	0.608		
Road infrastructure quality	0.594		
Quality of tourism services	0.785		
Cost and perceived value		1.202	15.22
Accommodation price accessibility	0.878		
Travel-related costs	0.598		
Expenses for tourist activities	0.701		
Destination safety		1.011	10.59
Perceived crime risk	0.760		
Availability of emergency services	0.715		

The factor 'Cultural attractions and facilities' has four items with factor loadings between 0.594 and 0.785. It accounts for 16.04% of the variance. Three items with factor loadings between 0.595 and 0.878 define the factor 'Cost and perceived value', which explains 15.22% of the variance. Two items define the factor 'Destination safety', which explains 10.59% of the variance. For each factor, the Cronbach's alpha reliability coefficient was higher than 0.79 (Shrestha, 2021).

Weighting and ranking of criteria through the BWM–TOPSIS method

In the second phase of the study, a questionnaire was constructed with a structure of criteria and sub-criteria based on the factors and items identified through the EFA analysis, making it suitable for the application of the BWM-TOPSIS method. The assessments of the twelve tourism experts served as the basis for the analysis of the hybrid multi-criteria decision-making method. The BWM method was used to calculate the weights of the four factors and the local and global weights of their respective items, enabling their ranking. The calculated consistency ratio values at both the criteria and sub-criteria levels were below the recommended threshold of 0.1. The mean consistency ratio was below 0.052, and the maximum value did not exceed 0.073. The results are presented in Table 3.

Table 3. BWM weights and sub-criteria ranking (Source: Authors' calculations based on survey data from 270 respondents)

Criteria	Criteria weight	Sub-criteria	Sub-criteria local weight	Sub-criteria global weight	Ranking
Destination sustainability practices	0.113	Sustainable accommodation practices	0.166	0.019	12
		Environmental resource protection	0.254	0.028	11
		Cultural heritage preservation	0.441	0.049	8
		Tourism intensity and crowding	0.139	0.016	13
Cultural attractions and facilities	0.468	Food and gastronomy experience	0.209	0.095	5
		Historical importance	0.126	0.058	7
		Road infrastructure quality	0.253	0.116	3
		Quality of tourism services	0.412	0.188	1
Cost and perceived value	0.222	Accommodation price accessibility	0.706	0.177	2
		Travel-related costs	0.174	0.044	9
		Expenses for tourist activities	0.120	0.030	10
Destination safety	0.196	Perceived crime risk	0.599	0.108	4
		Availability of emergency services	0.401	0.072	6

'Cultural attractions and facilities' resulted the criterion with the highest weight (0.468), followed by 'Cost and perceived value' (0.222). The least valued criterion was 'Destination sustainability practices' with a weight of 0.113. The weights of the criteria and sub-criteria were used to calculate the global weights of the latter. According to the global sub-criteria weights, 'Quality of tourism services', 'Accommodation price accessibility', 'Road infrastructure quality', and 'Perceived crime risk' had the greatest influence on tourists' selection of Albania as a tourist destination.

The following sub-criteria, 'Tourism intensity and crowding' and 'Sustainable accommodation practices', had the lowest influence on the decision-making process. The TOPSIS method was used to evaluate four alternative tourist destinations in Albania: Tirana (urban) destination, Heritage and Culture destination, Riviera and Coastal destination, and Mountains and Lakes destination. The evaluation was based on the weighted criteria obtained from the BWM analysis and expert assessments of destination performance. These results are shown in Table 4 and are based on the distances to the positive ideal solution (D^+) and the negative ideal solution (D^-), as well as the closeness coefficient (C_i).

The Heritage and Culture Destination has the highest C_i value and is therefore ranked as the most preferred option.

Table 4. The results of the TOPSIS method (Source: Authors' calculations based on survey data from 270 respondents)

Alternatives	D^+	D^-	C_i	Ranking
Tirana (Urban) Destination	0.036	0.026	0.415	3
Heritage and Culture Destination	0.012	0.042	0.776	1
Riviera and Coastal Destination	0.030	0.026	0.462	2
Mountains and Lakes Destination	0.040	0.016	0.294	4

The ranking obtained using the TOPSIS method confirms the multidimensional nature of the destination's attractiveness. Destinations representing 'Heritage and Culture', such as Berat, Gjirokastra, and Butrint, are the most preferred as a result of their high performance in tourism services and cultural values, despite moderate results in sustainability. The Riviera and Coast areas were ranked as the second most preferred destination, reinforcing the dual attractiveness of Albania as a cultural and coastal destination.

DISCUSSION

To present a comprehensive picture of destination choice in the context of a developing destination like Albania, this study presents the advantages based on expert judgments through the BWM–TOPSIS method and tourists' ratings derived from exploratory factor analysis. The analysis through factor analysis in collaboration with hybrid multi-criteria decision-making methods is in line with current studies in the field of tourism (Khan et al., 2023). The dominance of cultural attractions and service-related attributes is consistent with previous findings that highlight social interaction, cultural experiences, and service quality as key drivers of tourism behaviour (Nejat & Lajimi, 2022).

Similar to the results reported by Çiçekdağı (2022), tourists in Albania showed a stronger preference for experience-related attributes than for sustainability-oriented concerns, such as eco-friendly accommodation or overtourism.

These findings are further supported by Blešić et al. (2021), who identified gastronomy, infrastructure, and destination image as essential elements of destination attractiveness. In the Albanian context, these results are consistent with studies that highlight destination infrastructure and image as important determinants of tourism preference (Godolja & Spaho, 2014; Braimllari, 2017; Kasapi & Nurja, 2019).

The high ranking of food and gastronomy experience further confirms that local cuisine plays an increasingly important role in destination competitiveness (Dulja et al., 2025; Phrammanachot et al., 2026). In tourists' ratings, items related to sustainability accounted for the largest share of the variance, whereas expert ratings ranked destination sustainability practices as the least influential criteria in destination choice. This result indicates a gap between sustainability awareness and decision-making behaviour, consistent with previous studies suggesting that sustainability is conceptually recognised but not prioritised in short-term travel decisions, especially in developing destinations (Dwyer, 2024; Guga & Qiqi, 2025; Suhud et al., 2025). Cost and perceived value, and destination safety were the other two factors identified by factor analysis, reinforcing previous findings that highlight price sensitivity, perceived value for money, and safety as fundamental criteria for international tourism demand (Mohamad & Jamil, 2012; Alam et al., 2015; Dębski & Nasierowski, 2017; Son et al., 2023; Ilies et al., 2025). This result also reflects Albania's emerging reputation as a low-cost destination in the Mediterranean region, where affordability and value for money play a significant role in tourists' destination choices.

Overall, tourist and expert assessments indicated that cultural attractions and facilities represent key competitive advantages for Albania. The quality of tourism services proved to be the most influential item, indirectly reflecting the growing role of organisational efficiency and digital readiness in enhancing tourist satisfaction and destination competitiveness (Gjika & Pano, 2020; Noti & Hasrama, 2025; Chae, 2026).

Furthermore, this study contributes to the literature by empirically confirming the divergence between sustainability awareness and actual decision-making, while assessing the applicability of the integrated EFA-BWM-TOPSIS framework for assessing destination competitiveness in new tourism contexts.

CONCLUSION

From a methodological perspective, this study contributes to the tourism literature by demonstrating the effectiveness of integrating EFA with the hybrid BWM-TOPSIS model to capture, within a single decision-making framework, the perceptions of 270 foreign tourists who visited Albania and the preferences of 12 Albanian tourism experts. In this way, the results provide a multidimensional understanding of the factors influencing the selection of Albania as a tourist destination and allow comparisons between tourists' perceptions and experts' preferences. Destination sustainability practices, cultural attractions and facilities, cost and perceived value, and destination safety were the four factors identified by the EFA analysis. Although 'cultural attractions and facilities' was not the dominant factor in terms of explained variance, it emerged as the most influential criterion in the experts' assessments and was reflected in the TOPSIS ranking, where heritage and cultural destinations were identified as the most preferred alternatives. Perceived cost and value, along with safety-related considerations, emerged as the main determinants of destination choice, indicating that affordability and perceived safety remain essential conditions for Albania's competitiveness as an international tourist destination.

The results of this study provide several suggestions for tourism policy in Albania. For example, cultural infrastructure and tourism services should continue to improve, with investments in road conditions and heritage preservation. Safety should remain an important element, particularly when promoting Albania to international tourists. Although sustainability ranks lower in short-term decision-making, it should not be neglected. As tourist expectations evolve, sustainability credentials may become more important, especially among young, environmentally conscious travellers (Šenková et al., 2026). Culture, cost, and safety had the greatest impact on decision-making, while sustainability, although conceptually assessed, remains a secondary driver in selecting a tourist destination. These findings are in line with recent literature on tourism planners in Albania seeking to increase competitiveness while maintaining authenticity and environmental responsibility. The proposed EFA–BWM–TOPSIS framework offers a robust and transferable tool for evaluating destination competitiveness across different tourism contexts.

Study limitations: Regarding this study's limitations, we can mention the sample size, which limits the generalizability of the findings, and the non-random but appropriate sample. The study focused only on Albania, limiting comparisons with other countries in the region and beyond to identify similarities or characteristics among similar destinations. Also, the survey data collection method did not avoid subjective responses influenced by tourists' recent experiences. Directions for future research: For further studies, it is recommended to expand the study to the Balkan region and to increase the number of respondents, tourists, and tourism experts. It is also of interest to apply more multi-criteria decision-making methods in order to enable comparison of their results. To better understand tourist preferences, the survey could be expanded to include new items.

Abstract: Tourism in Sub-Saharan African nations holds significant potential to drive economic growth. However, unstable economic growth, inadequate infrastructure, environmental degradation, and exchange rate volatility hinder the trajectory of tourism growth. Moreover, the digital economy's role in transforming tourism dynamics is an emerging destination in the SSA. Therefore, to gain a focused understanding of how these macroeconomic factors, i.e., economic growth (EG), infrastructure (INF), environment (ENV), digital economy (DGE), and exchange rate (ER) affect tourism in the top 5 tourist SSA nations is vital for crafting sustainable and inclusive growth tourism strategies. We employed the novel Method of Moments Quantile Regression (MMQR) to estimate heterogeneous effects at short-, medium-, and long-run quantiles for the period from 1995 to 2023. Additionally, we utilized the Dumitrescu and Hurlin panel causality test to assess causality. The MMQR estimates evidenced that economic growth and the digital economy have a favorable impact on tourism at all quantiles. The favorable effect across short-, medium-, and long-term quantiles can be attributed to higher disposable incomes and better access to digital platforms that facilitate travel planning, information dissemination, and service delivery. However, the rise in environmental degradation and higher exchange rates has a detrimental effect on the tourism industry. Environmental degradation reduces the aesthetic and ecological value of tourist destinations. Higher exchange rates make travel more expensive, reduce purchasing power, and discourage international travel. The practical implications include prioritizing economic development, allocating resources to digital transformation, and adopting thoughtful tactics for environmental sustainability. Policymakers should consider the complexities of exchange rate swings, which may create inflationary pressures from currency depreciation.

Keywords: tourism, digital economy, environmental degradation, exchange rates, Sub-Saharan African Nations, MMQR estimator

INTRODUCTION

The tourism industry offers an essential opportunity for African economies to achieve economic growth and structural transformation by promoting economic diversification, thereby increasing economic stability (Ekeocha et al., 2021). According to the tourism-led economic development hypothesis (TLGH), tourism contributes to economic growth through various channels. Indeed, tourism generates foreign-exchange earnings (Suhud et al., 2024), infrastructure investment, and employment (Antonakakis et al., 2015). It is widely acknowledged that Africa's natural resources play a significant role in driving its economy (Sharpley, 2002), and the COVID-19 pandemic has imposed substantial limitations on global trade, adversely affecting African economies (Ekeocha et al., 2021).

Although tourism declined in 2019-2020, it has shown a resurgence in 2021, offering a promising opportunity for recovery. In fact, the UNWTO[1] has observed an increase in international arrivals in Africa from 2021 (19.65 million) to 2022 (46.61 million). The upward trend in the tourism sector not only demonstrates resilience but also offers a potential solution to counteract the negative economic consequences of the lasting crisis. Thus, the tourism industry provides African economies which rely on the export of raw minerals and primary goods, with a way to protect themselves from unforeseen fluctuations in demand. Several African countries have popular tourist destinations due to their diversified, rich cultural heritage and distinctive landscapes. Among these African countries, Egypt, South Africa, Morocco, Kenya, and Tunisia rank among the top 5 tourist destinations (Okoroafor, 2023).

These countries not only offer a wide range of cultural and natural attractions but also serve as prime examples of the dynamics and trends that shape the overall tourism scene in Africa. Previous studies on tourism development in Africa did not include certain countries that exert substantial influence in the continent's tourism sector. This exclusion highlights a significant deficiency in the existing body of empirical literature, as these nations, which are actively involved in tourism,

can provide valuable instances for analysis. Hence, it is imperative to include these countries in the empirical analysis, as their experiences and strategies could offer invaluable empirical insights for the holistic advancement of tourism in Africa. Notably, there is limited empirical research on the relationship between tourism and economic growth in Africa, specifically focusing on the continent's involvement in the tourism sector and the factors that could improve the tourism industry. Indeed, some macroeconomic factors influence tourism development. First, the correlation between economic growth, as measured by GDP, and the tourism industry is intricate. An increase in GDP frequently results in higher disposable income, which in turn can boost demand for tourism. The digital age has ushered in a period of digitalization and connectivity that has had a profound influence on the tourism industry (Kuo et al., 20[1]9), a crucial element to be examined. Similarly, it cannot be neglected that trends in infrastructure can have a significant impact on tourism.

Rapid urbanization can lead to increased infrastructure development, potentially enhancing a region's overall attractiveness to tourists (Ma & Tang, 2023). Then, tourism can have negative environmental consequences, most notably increased carbon emissions from transportation and infrastructure development (Gössling, 2021). It is imperative to explore at how environmentally responsible policies affect tourist arrivals. Moreover, acknowledging the dynamics of exchange rates and their effects on tourism is critical for understanding these African countries' competitiveness in the global tourism market (Bahmani-Oskooee & Hegerty, 2008). Figure 1, plot (a) to (f) illustrates the graphical represention of variables.

Figure 1. (a) to (f) plot the graphical trends of economic growth, digital economy, infrastructure, carbon emissions, exchange rate, and tourism in the top 5 tourist SSA nations (a) Economic growth trends; (b) Digital economy trends; (c) Infrastructure trends; (d) Carbon emissions trends; (e) Exchange rates trends; (f) Tourism trends (Source: World Bank Development Indicators (WDI, 2025)

The objective of this study is to address the research gap in the existing empirical literature acknowledged earlier. The findings of this study will not only improve our understanding of tourism in the selected regions, but will also provide policymakers, businesses, and stakeholders with the data-driven insights they need to make informed decisions and implement strategies for long-term tourism development, economic growth, and increased global competitiveness in Africa.

The main aim of this study is to examine how macroeconomic factors influence the growth of the tourism sector in the top five Sub-Saharan African economies using panel data from 1995 to 2023. The primary goals are as follows: (i) to analyze the influence of economic growth, digital economy, infrastructure, carbon emissions, and exchange rate on tourism; (ii) to establish the causal relationship between these macroeconomic factors and tourism. To accomplish these goals, the study employed the method of moments quantile regression (MMQR) and panel Granger causality, respectively.

The subsequent sections of the paper are arranged as follows. Section 2 provides an overview of the empirical literature, while Section 3 demonstrates the specific data and methods used in the study. Section 4 provides the empirical findings, whereas Section 5 concludes the paper by offering policy suggestions.

EMPIRICAL LITERATURE REVIEW

Economic Growth and Tourism

Tourism is a significant contributor to the economy of many countries (Suhud et al., 2025). However, whether tourism drives economic growth is an important macroeconomic question for both policymakers and investors. Hence, exploring the link between tourism and economic growth has increased the interest of potential researchers. For instance, Albaladejo et al. (2023) examined data from 144 countries and found that increases in tourist arrivals are associated with higher GDP per capita. This positive relationship was observed across countries with varying levels of economic development. Wijesekara et al. (2022) suggested a reciprocal causal relationship, indicating that tourism can both contribute to economic growth and be influenced by it. Narayan et al. (2010) investigated the link in six (6) South Pacific island nations and found that the size of the tourism sector, as a percentage of GDP, has a significant and positive impact on economic growth in these small, tourism-dependent economies. Moreover, Hoti et al. (2005) investigated the impact of tourism diversification on Caribbean economic growth. Their research demonstrated that diversification strategies can improve the sustainability of economic growth, particularly in tourism-dependent regions. Also, Nyasha et al. (2021) investigated the impact of tourism diversification on economic growth in sub-Saharan Africa, emphasizing that diverse tourism products can reduce vulnerability to external economic shocks while also boosting GDP growth. Therefore, expanding tourism through the development of novel offerings and markets can enhance economic adaptability. Moreover, seasonal fluctuations in tourism can have a variety of effects on economic growth. Martín et al. (2014) examined data from Spain and found that tourism seasonality adversely affects economic growthin the regions that are heavily dependent on toursim. However, Wang et al. (2023) analyzed Chinese data and found that seasonality has an insignificant effect on the correlation between tourism and economic growth under certain conditions. Velikova & Tzvetkova (2018) investigated the impact of seasonality on Bulgarian tourism and GDP. The study emphasized the importance of managing seasonality to minimize fluctuations in GDP and ensure year-round economic stability. Tourism's contribution to GDP goes beyond direct contributions. In empirical research, the "multiplier effect" is well documented. Based on the literature we postulate that:

$\mathbf{H_1}$ Economic growth has a positive and significant effect on tourism in the top 5 SSA tourist economies.

Digital Economy and Tourism

The digital economy and tourism are two important sectors that are closely related and mutually beneficial. The digital economy acts as a catalyst for tourism. For instance, Siuta-Tokarska (2010) emphasized the critical role of technology in shaping modern tourism, driving innovation, and facilitating tourists' experiences. According to Sustacha et al. (2023), technology is reshaping the entire tourism value chain, from information search and trip planning to booking, in-destination experiences, and post-trip sharing. This comprehensive viewpoint emphasizes technology's transformative impact on tourism.

Moreover, Liu et al. (2020) found that tourists can use mobile technology to access real-time information, interact with reviews, and share their experiences, all of which influence their travel decisions. Similarly, Minazzi & Minazzi (2015) emphasized that mobile technology's multifaceted impact on the tourism industry, from information dissemination to real-time engagement. Additionally, Lim et al. (2024) found that augmented and virtual reality technologies can significantly enhance the quality of tourist experiences and increase satisfaction and intent to return. Beck et al. (2019) affirmed the outcomes of the Lim et al. (2024). Moreover, the empirical literature recognizes both the opportunities and challenges that technology presents in tourism. According to Gössling (2021), it is critical to address issues such as information overload, privacy concerns, and the digital divide. They do, however, emphasize the potential of technology to enable personalized travel experiences and improve destination management. Saprov (2023) also discussed the changing landscape of tourism technology and the need to address issues like cybersecurity, privacy concerns, and the digital divide. At the same time, they highlight the potential for technology to enable personalization, improve destination management, and provide new business models. Hence, based on this, we have postulated the hypotheses as under:

$\mathbf{H_2}$ The digital economy is a significant contributor to tourism in the top 5 SSA tourist economies, but a challenge in others.

Infrastructure and tourism

The infrastructure is a key facilitator of tourism, according to empirical research. Colacchio & Vergori (2023) studied the link between infrastructure and regional tourism development in Italy. Their findings emphasized the importance of well-developed transportation networks and other tourism-related infrastructure in attracting visitors and

driving regional economic growth. Similar outcomes have been reported by Adeola & Evans (2020). They emphasized that adequate infrastructure makes destinations more accessible and appealing to tourists. Similarly, Cheung & Law (2001) stated that the availability and quality of hotel infrastructure increases the length of stay and overall spending by tourists. Moreover, Sánchez-Sánchez et al. (2021) found that a well-developed cultural infrastructure attracts tourists. Then, the relationship between tourism and infrastructure is fraught with difficulties. Shafiee et al. (2023) investigated the concept of "smart tourism" and the integration of technology into destination infrastructure. Their research focuses on the importance of balancing infrastructure expansion with sustainability, with an emphasis on the role of smart infrastructure solutions. Also, sustainable tourism practices have emerged as an important consideration in infrastructure development. Based on this, we have postulated that:

H_3 Developed infrastructure is a significant contributor to tourism in the case of top 5 SSA tourist economies.

Exchange Rate and Tourism

The exchange rates have a consistent impact on international tourism demand. Empirical research by Tung (2019) indicates that local currency depreciation can make a destination more appealing to international tourists, whereas an appreciation can have the opposite effect in Vietnam. Moreover, currency fluctuations affect not only tourist arrivals but also their spending habits. Irandoust (2019) conducted research across 10 European countries on the relationship between tourism spending and exchange rates. According to the study, fluctuations in exchange rates can significantly alter tourist spending behavior, thereby affecting the overall economic impact of tourism. Alleyne et al. (2020) also investigated the impact of fluctuating exchange rates on international tourism demand in the United States. According to the study, exchange rate fluctuations can deter tourists, particularly those from countries with devalued currencies. Thirdly, the competitiveness of tourism destinations is influenced by exchange rates. Loganatan et al. (2019) investigated the relationship between Malaysia's tourism competitiveness and exchange rates. According to their findings, exchange rate movements have a significant impact on destination competitiveness, affecting a country's ability to attract tourists and compete with other destinations. In the same paper, they also examined the ramifications of Malaysia's exchange rate policies on the tourism industry. The study emphasized the importance of exchange rate stability and the role of government policies in fostering a favorable environment for tourism development. Hence, we postulate that:

H_4 Exchange rate fluctuation has a significant effect on tourism in the top 5 SSA tourist economies.

Environmental Degradation and Tourism

The issue of carbon emissions and their impact on tourism has garnered significant attention in recent years, as the tourism industry is both a contributor to and a recipient of the effects of climate change. Ali et al. (2024) found that tourism contributes substantially to global carbon emissions. However, Churchill et al. (2021) found that the aviation industry's impact on CO_2 emissions has been steadily increasing, posing environmental challenges for the tourism sector. Hence, the importance of considering the environmental impacts of tourism. Moreover, seasonal variations in tourist arrivals can affect CO_2 emissions. Le & Nguyen (2021) found that increased passenger volumes during peak tourist seasons can result in higher carbon emissions, underscoring the importance of sustainable management practices to minimize environmental impacts. Empirical research has also examined the effectiveness of CO_2-reduction policies and strategies in the tourism industry. Wang & Xi (2023) investigated the European Union's emissions trading scheme (EU ETS) and its consequences for the aviation industry. The study looked at the potential of emissions trading as a policy tool for reducing carbon emissions in the tourism industry.

H_5 Environment Degradation have a significant effect on tourism in the top 5 SSA tourist economies.

Conceptual framework

Based on the theoretical and empirical literature review, we developed the conceptual framework for our study as shown in Figure 2.

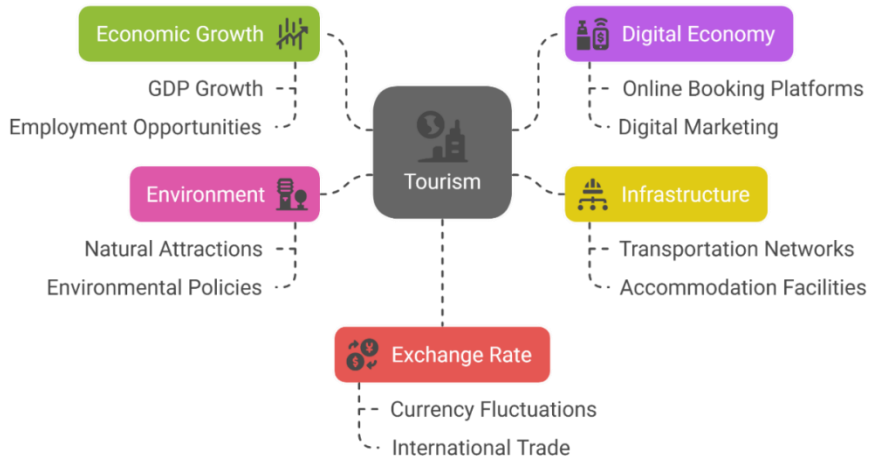

Figure 2. Conceptual Framework

MATERIALS AND METHODS

Data and Variables

Economic growth is a sustained increase in a country's real output over time, reflecting improvements in productivity, investment, technology, and labor efficiency (Ali et al., 2025a). The tourism sector contributes to economic growth by stimulating physical and human capital and driving technological innovation (Wu et al., 2026). However, economic growth plays a key role in stimulating tourism development by increasing income levels, boosting investment in infrastructure such as airports, roads, hotels, and transport systems, and enhancing service quality, thereby making destinations more attractive to international visitors (Alfehaid, 2026). The development of infrastructure significantly improves accessibility and connectivity, which are critical drivers of tourist arrivals (Smith, 2026). The development of the digital economy has become an important driver of tourism growth by increasing information accessibility, online booking systems, digital marketing, and smart tourism services (Liu & Zhao, 2026), which enhances tourist's travel experience and destination visibility (Liu & Huang, 2026). Besides, exchange rate fluctuations, for instance, currency depreciation, can make a destination cheaper for inbound visitors, thereby stimulating tourism inflows (Wickramaarachchi & Jayathilaka, 2026). Additionally, environmental quality has become an increasingly important factor affecting tourism sustainability, as pollution can reduce destination attractiveness and influence tourists' preferences toward environmentally sustainable destinations (Wang et al., 2026). Therefore, following the recent studies of Wu et al. (2026), Alfehaid (2026), Smith (2026), Liu & Zhao (2026), Wickramaarachchi & Jayathilaka (2026), and Wang et al. (2026), this study has developed the following econometric model:

$$\text{TOUR} = \text{f (EG, DGE, INF, ENV, ER)} \quad (1)$$

In Equation (1), TOUR, EG DGE, INF, ENV, and ER represent the economic growth, digital economy, infrastructure, environment, and exchange rate, respectively. Moreover, authors transformed equation (1) to:

$$TOUR_{it} = \forall_0 + \forall_1 EG_{it} + \forall_2 DGE_{it} + \forall_3 > INFS_{it} + \forall_3 ENV_{it} + \forall_4 ER_{it} + \mu_{it} \quad (2)$$

Where *i* denotes cross-section (i.e., top five sub-Saharan African tourist economies), *t* denotes time period of the study (1995 – 2023), $TOUR_{it}$ denotes tourism measured by international tourism (number of arrivals), eg_{it} represents the increase in economic output measured by GDP per capita (constant 2015 US dollars), DGE_{it} denotes the digital economy measured by total Patent applications, $INFS_{it}$ denotes infrastructure measured by population in the largest city (% of urban population), $CO2_{it}$ denotes environment measured by CO_2 emissions (metric tons per capita), and ER_{it} denotes exchange rate measured by official exchange rate (LCU per US$, period average). ∀0 denotes intercept, ∀1, 2, 3, 4 denote coefficients, and μit denotes the error term. The detailed description for all variables is listed in Table 1.

Table 1. Data synopsis (Source: "WDI = World development Indicators (2025), data is retrieved from https://databank.worldbank.org/reports.aspx?source=World-Development-Indicators")

Abbreviations	Variable	Measurement	Source
TOUR	Tourism	International tourism, number of arrivals	WDI (2025)
EG	Economic Growth	GDP per capita (constant 2015 US$)	
DGE	Digital Economy	Total Patent applications, non-residents and residents	
INF	Infrastructure	Population in the largest city (% of urban population)	
ENV	Environment	CO_2 emissions (metric tons per capita)	
ER	Exchange Rate	Official exchange rate (LCU per US$, period average)	

Econometric Model Selection Process: The selection of the suggested econometric model is categorized into three categories: Stage 1: Preliminary tests, Stage 2: Model Choice, and Stage 3: Robustness Check.

Stage 1. Preliminary Test: In stage 1, we first employed the Cross-sectional dependency (CSD) test to assess cross-sectional dependence. Neglecting this test may lead to a lack of consistency, reliability, accuracy, impartiality, and practicality. Second, due to the presence of CSD, we employed second-generation tests, such as CADF, CIPS, and RALS-ADF, to investigate the non-stationarity in the data. Third, we employed the Slop Heterogeneity test to assess coefficient slopes. Finally, to assess the long-term association among the variables, this research employed RALS-EG cointegration test.

Stage 2. Model Choice: Based on the characteristics of the data determined in stage 1, we selected the Method of Moments Quantile Regression approach. The classical quantile regression is characterized by its semiparametric nature, which allows it to operate without dependence on distributional assumptions and to exhibit resilience to irregularities in the data. Binder & Coad (2011) argue that the validity of Q.R. remains unaffected even when there is no conditional mean association between the variables being studied. This study employed a novel MMQR method to capture the conditional heterogeneity of the explained facet (Machado & Silva, 2019). The approach utilized in this study offers several benefits in effectively addressing the influence of individual effects and endogeneity within the parameters (Ali et al., 2025b; Khalid et al., 2026). Samour et al. (2024) suggested that the MMQR is the most suitable method for analyzing heterogeneity across quantiles. The formulation of the conditional quantile model incorporates estimations of the altered location and scale parameters (Machado & Silva, 2019).

$$Y_{it} = \delta_i + X_{it}' a + \left(\mathrm{B}_i + \mathrm{Q}_{it}' \sigma\right) \omega_{it} 0.75 em \quad (3)$$

The probability that the random variable $\left(B_i + Q'_{it}\sigma\right) > 0$ and equal to one. However, the parameters to be estimated are denoted as δ_i, α, B_i and σ. The variables δ_i and B_i represent the fixed effects of the model, while Q_{it} refers to the

differentiable transformation of the m-dimensional vector X. Following (Machado & Silva, 2019), the mathematical definition of a concept can be expressed as follows:

$$S_c = S_c(X), c = 1,2,3 \ldots., m \quad (4)$$

The subsequent approach is utilized to make estimations within the quantile context (Machado & Silva, 2019).

$$Q_y\left(\mathcal{T}/_{X_{it}}\right) = (\delta_i + B_i(q(\mathcal{T})) + X'_{it}a + Q'_{it}\sigma_q(\mathcal{T}) \quad (5)$$

In Equation 5, $Q_y\left(\mathcal{T}/_{X_{it}}\right)$ represents the conditional quantile $\mathcal{T}$ of the dependent variable given the vector of explanatory variables X'_{it}. The term δ_i denotes the individual-specific fixed effects capturing unobservable heterogeneity across units. X'_{it} is a vector of explanatory variables for country i at time t, while a represents the associated slope parameters. $B_i(q(\mathcal{T})$ term captures the heterogeneous distributional effect across quantiles and $Q'_{it}\sigma_q(\mathcal{T})$ term represents the conditional scale function that allows the variation of the error term to vey across the quantiles. This formulation enables the model to estimate the heterogeneous impact of independent variables across different points of the conditional distribution of the dependent variable. The tth quantiles of the data set are obtained by minimizing the given solution proposed by (Machado & Silva, 2019).

$$min_q \sum_i \sum_t \upsilon_{\mathcal{T}}(Z_{it} - (\mathrm{B}_i + \mathrm{Q}'_{it}\sigma_q)q) \quad (6)$$

In Equation (6), Z_{it} denotes the dependent variable for cross-section i and time t. The term B_i represents the individual-specific fixed effect capturing unobservable heterogeneity across the cross-sectional units. Q'_{it} refers to the vector of explanatory variables for cross-section i and time t, whereas $\sigma_q$denotes the conditional quantile level, typically ranging from 0 to 1. The function $\upsilon_{\mathcal{T}}$ represents the quantile loss function used in the estimation procedure.

Robustness Check: We have used the Dumitrescu-Hurlin Panel Causality Tests to assess the direction of causality between the study's components and to assess the robustness of the MMQR outcomes. Figure 3 depicts the framework of the methodologies employed in the present study. Figure 3 illustrates the methodological framework adopted in this study.

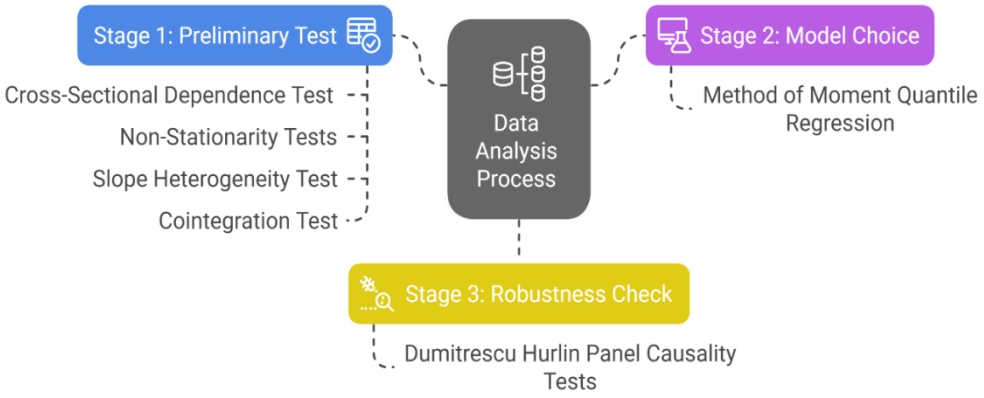

Figure 3. Methodological framework

RESULTS AND DISCUSSION

Descriptive Statistics

The descriptive statistics are presented in Table 2. The central tendencies for tourism, economic growth, the digital economy, infrastructure, carbon emissions, and the exchange rate are 6470768, 3202.996, 2071.024, 27.65913, 2.69438, and 22.15771, respectively. However, degree of dispersion of values from the central tendency for tourism, economic growth, digital economy, infrastructure, environment, and exchange rate are 3891729, 1475.851, 2617.274, 11.39786, 2.464544, and 31.55506, respectively. Moreover, Jarque-Bera outcomes indicate that the data are not normally distributed.

Table 2. Descriptive statistics estimations (Source: Author's compilation: Outcomes retrieved from EViews 13)

	TOUR	EG	DGE	INF	ENV	ER

CSD and Stationary Outcomes

Findings obtained from the CD test are displayed in Table 3, indicating that the null hypothesis of cross-sectional independence is rejected. Therefore, the results confirm that CSD exists. Given that we employed "second-generation panel unit root" methods. CIPS and CADF results indicate a mixed order of integration. Moreover, the RALS-ADF cointegration outcomes in Table 4 indicated mixed results with CIPS and CADF.

Table 3. CSD, CIPS, and CADF outcomes (Source: Authors compilation data retrieved from Stata 17; Note: *** denotes significance levels at 1% significance level. TOUR = tourism; EG = economic growth; DGE = digital economy; INF = infrastructure; CO2 = carbon emission; ER = Exchange rate)

SH and Cointegration Outcomes

The outcomes of the slope-heterogeneity test are shown in Table 5. The findings reveal that both Delta and adjusted Delta stitistics are statistically significant at the 1% level. The RALS-EG cointegration test is more effective at identifying cointegration relationships among variables. Furthermore, Table 6 presents the cointegration test's estimations. At the 10% level of significance, the test statistic for the EG cointegration test is -4.01, which is below the critical value (-3.98). Based on the evidence, the null hypothesis of no cointegration is invalid. The test statistic for RALS-EG is -4.23, which is less than the critical value of -4.19 at the 5% significance level. Thus, the null hypothesis is refuted. In conclusion, the findings provide empirical support for the existence of a cointegrating relationship among tourism, economic growth, the digital economy, infrastructure, carbon emissions, and the exchange rate.

MMQR Estimations

The outcomes of MMQR estimators are presented in Table 7. Outcomes of MMQR stated that economic growth has positively significant effect on the tourism throughout the quantiles such as lower quantiles (q1(1.318), q2(1.304), q3(1.293)) medium quantiles (q4(1.283), q5(1.274) q6(1.263)), and upper quantiles (q7(1.253), q8(1.245), q9(1.234)).

This implies that economic growth is associated with an increase in tourism activity. This finding is supported by prior scholarly works, such as the studies conducted by (Dogan & Zhang, 2023; Dritsakis, 2004; Kyara et al., 2021).

The outcomes affirmed the H_1. The notion of economic growth can be seen as a catalyst for tourism development in the top five sub-Saharan African tourist economies. As a nation undergoes economic expansion, it often results in higher incomes, improved infrastructure, and higher living standards. Africa's multifaceted tourism offerings, encompassing wildlife, cultural heritage, and natural landscapes, establish the continent as an appealing destination.

Moreover, outcomes suggest that African countries that experience economic development become more capable of highlighting and marketing their distinctive attractions, thereby fostering the expansion of the tourism industry. When a country's economy is thriving, the government can actively advance various sectors, including tourism. This involvement entails allocating the necessary funds to enhance activities within the sector, such as constructing more attractive infrastructures and investing in comprehensive marketing strategies to promote the country. For example, during the COVID-19 pandemic in 2020, the Moroccan government implemented measures to support tour operators, hotels, and domestic airlines. Additionally, during periods of economic prosperity, the local population has the financial resources to establish businesses and develop distinctive cultural activities, thereby attracting visitors to the country.

Additionally, the digital economy has a positive and significant relationship with tourism from lower quantiles (q2(0.112), q3(0.143), middle quantiles (q4(0.172), q5(0.198), q6(0.232)), and upper quantiles (q7(0.260), q8(0.285), q9(0.315)). However, the q1 outcome (0.071) is not significant. It is evident from the outcomes that the magnitude of the effect increases gradually from q2 to q9, suggesting that the digital economy plays a greater role in accelerating and attracting tourism in Sub-Saharan African nations. This outcome is confirmed by last studies like (Sustacha et al., 2023; Tang, 2023). Outcome affirmed H_2. The proliferation of connectivity and digital platforms has the potential to augment marketing endeavors, thereby facilitating the process of tourists' exploration and reservation of destinations within Africa.

The increasing prevalence of technology adoption has the potential to influence individuals' travel choices, particularly those in technologically proficient demographics, who may be more inclined to visit destinations aligned with current digital trends. Technological advancements, including virtual reality, mobile applications, and other innovations, are crucial factors in attracting and satisfying contemporary tourists. Undoubtedly, we find ourselves in a

contemporary era characterized by pervasive globalization, in which technology plays a pivotal role in facilitating it. The relevance of technology in tourism lies in its ability to shape individuals' desire to visit a particular country and to engage in firsthand experiences informed by prior observations.

This influence is primarily facilitated through the utilization of technology. For example, Kenya has formulated customized marketing strategies and allocated resources to enhance the tourism sector from 2021 to 2025.

Furthermore, technological advancements have greatly enhanced the travel experience for tourists. This is evident in the ease with which they can make reservations before visiting the host country, such as African countries, as well as their ability to plan their activities in advance, resulting in significant time savings. Additionally, the integration of technology has streamlined the payment process, ensuring it is both adequate and efficient.

Furthermore, there is a strong and negative correlation between environment degradation and tourism across all quantiles such as in lower quantiles q1(-0.123), q2(-0.136), q3(-0.147), medium quantiles q4(-0.156), q5(-0.164), q6(-0.175) and upper quantiles q7(-0.184), q8(-0.192), q9(-0.202). The consistent inverse and substantial correlation across all quantiles indicate that increased environmental degradation is associated with a decline in tourism. This result was observed in previous studies, including (Gössling, 2021). The outcomes affirmed H_4. In the realm of tourism in Africa, environmental considerations are highly relevant. The continent is renowned for its varied ecosystems, fauna, and scenic splendor, rendering it a prominent hub for ecotourism. A significant segment of Africa's tourism industry is dedicated to ecotourism, which involves tourists actively seeking immersive experiences in natural environments.

But environmental degradation, pollution, and concerns about climate change discourage tourists, particularly those who prioritize eco-friendly, sustainable tourism. The findings underscore the significance of carbon emissions management for African countries striving to establish themselves as sustainable tourism destinations. African countries can align their tourism strategies with changing global preferences by comprehending the adverse effects of carbon emissions. Tunisia, for example, as the fourth Arab nation to have released its Intended Nationally Determined Contributions (INDC) outlining plans to reduce greenhouse gas emissions, has demonstrated a strong commitment to addressing climate change, making it a prominent priority within its political and economic framework. Furthermore, this nation stands as a pioneer in the region by incorporating explicit acknowledgement of climate change into its recently revised Constitution: a sound and balanced environment, while contributing to the safety of the climate by all available means.

Besides, MMQR estimates that the exchange rate exhibits a significant negative association with tourism across all quantiles such as lower quantiles q1(-0.006), q2(-0.006), q3(-0.006), middle quantiles q3(-0.006), q4(-0.006), q6(-0.007), and upper quantiles q7(-0.007), q8(-0.007), q9(-0.007). The consistent inverse and substantial correlation across all quantiles suggest that a decrease in the exchange rate (leading to depreciation of the domestic currency) is associated with an increase in tourism. We observed this outcome in previous studies (De Vita, 2014; Irandoust, 2019; Song et al., 2018). The outcome affirmed H_5. A depreciated domestic currency can enhance the affordability of travel for international tourists, potentially increasing tourist arrivals. In Africa, where a substantial proportion of tourism relies on international visitors, these findings suggest that a devalued domestic currency can attract tourists. Cost-effectiveness becomes a pivotal factor, particularly for tourists from nations with stronger currencies. A more advantageous exchange rate can encourage people to travel to African destinations. Moreover, the MMQR outcomes showed that infrastructure does not affect tourism in the top five Sub-Saharan African tourist nations across the quantiles.

Outcomes that reject H_3 have been observed in previous studies (Arumugam & Abd Majid, 2023; Labadi et al., 2021). It affirms that tourists are attracted to the natural beauty of countries rather than to artificially developed infrastructure. Additionally, the causality outcomes are depicted in Table 8. According to the results, tourism has unidirectional causality with economic growth, the digital economy, and carbon emissions. Infrastructure has unidirectional causality with tourism, and the exchange rate and tourism have bidirectional causality.

Table 8. Dumitrescu and Hurlin panel causality test estimations Note: ** P-Value< 5%; EG= economic growth; TOUR= tourism; DGE= digital economy; INF= infrastructure; ENV= Environment; ER= exchange rate

CONCLUSION

This research paper investigates the impact of multiple variables, such as economic growth, digital economy, infrastructure, environment, and exchange rate, on tourism in the top five sub-Saharan African tourist economies between 1995 and 2023 with the help of econometrics methods. We used CSD for the cross-sectional dependency test, and CADF, CIPS, and RALS for the unit root tests. The present study uses the RALS-EG cointegration test to examine the enduring relationship between the variables under examination. The present study examines the short, medium, and long-term coefficients using the MMQR method. Moreover, empirical results from MMQR regression indicated that economic growth enhances tourism in the studied economies in the long run.

This result confirms that the effect of economic growth on tourism is accurate and significant. In addition, the outcome reveals that the digital economy boosts tourism in the long run. The results confirm that environmental

degradation has a substantial and adverse correlation with tourism. The consistent inverse and substantial correlation observed across all quantiles indicates that increased environmental degradation is linked to a decline in tourism.

Finally, as expected, the exchange rate has a negative and significant relationship with tourism. A high exchange rate decreases the tourism. Moreover, the Pairwise Dumitrescu-Hurlin Panel Causality Tests results reveal that Tourism has a unidirectional causal relationship with economic growth, the digital economy, and environmental degradation. Infrastructure has unidirectional causality with tourism, and the exchange rate and tourism have bidirectional causality.

Based on the findings presented, this study proposes the following policy recommendations:

First, Sub-Saharan African governments and policymakers must prioritize economic growth initiatives to invigorate the tourism sector. The implementation of proactive economic policies can create a favorable environment that supports tourism development. Also, implementing sustainable practices in the extraction of natural resources is crucial to securing enduring environmental and economic benefits. By effectively managing natural resources, the risk of depletion is mitigated, thereby fostering long-term economic stability.

Second, governments and stakeholders may deliberate on the allocation of resources towards the development of digital infrastructure, to bolster and augment the virtual representation of tourism-related services and attractions. The tourism industry must adopt and allocate resources towards digital transformation strategies. This encompasses various strategies such as online marketing, mobile applications, and e-tourism initiatives, all aimed at augmenting the overall tourist experience. Promoting the integration of digital technologies in the tourism industry, including initiatives related to e-tourism and digital payment systems, has the potential to enhance the positive outcomes.

Third, it is imperative to adopt a mindful approach towards preserving and advancing environmental sustainability. Preserving Africa's natural allure serves the dual purpose of safeguarding its ecological heritage and attracting tourists seeking genuine, untainted experiences. African nations have the potential to cultivate sustainable tourism, celebrate their cultural diversity, and generate long-term positive effects on their economies and the global perception of the continent by effectively managing the interplay between infrastructure development and the preservation of natural landscapes. Fourth, the African governments should promote eco-friendly initiatives, invest in green technologies, promote sustainable practices, and incorporate environmental considerations into tourism planning.

Finally, strategic exchange rate management should be pursued to enhance the growth of the tourism industry by attracting foreign currency and positively influencing the broader economy. While a more favorable exchange rate can stimulate tourism, policymakers must consider the complexities of currency devaluation, including the potential for inflationary pressures. It is imperative to strike a balance between the benefits of increased tourism and its broader economic ramifications. The study has some constraints, such as being limited to the top five tourist Sub-Saharan African Nations. We used the MMQR model to estimate outcomes using limited data from 1995 to 2023.

Moreover, the economic model specified in this research is based on the five macroeconomic factors. Hence, future studies can be carried out across all African nations and the top 10 European tourist nations using the CS-ARDL estimator. Additionally, potential researchers can expand our econometric model by adding more macroeconomic factors, such as inflation, political stability, and socio-economic factors.

Tri Hita Karana: The key to sustainable tourism and conservation at Gunung Kawi temple in Gianyar regency, Bali, Indonesia. *Geojournal of Tourism and Geosites*, 67(3), 2295–2304. https://doi.org/10.30892/gtg.67341-1853

Abstract: This study aims to develop and evaluate a strategic model for sustainable tourism grounded in the Balinese philosophy of Tri Hita Karana. Hita Karana is a strategy to maintain a balance between tourism and conservation. This study uses qualitative research methods. This study is located in Tampaksiring Village, Gianyar Regency, Bali. Informants include community leaders, managers of the Gunung Kawi Cliff Temple site, village officials, and visiting tourists. Data collection was conducted through interviews, observations, and documentation. Data analysis in this study used the interactive model of Miles and Huberman, which comprises three main steps: data reduction, data presentation, and conclusion drawing/verification. The CHGF model synchronises the government's role as an institutional anchor for spatial planning (Palemahan), the community's role as guardians of intrinsic cultural values (Pawongan), and the private sector's role as a catalyst for ethical innovation. This model does not eliminate the sanctity (Parahyangan) or structural integrity of the site. Therefore, this model is oriented toward high-value conservation to maintain a dynamic balance between 21st-century prosperity and 11th-century preservation. This study concludes that the sustainability of tourism at Pura Tebing Gunung Kawi fundamentally depends on the successful implementation of the Collaborative Heritage Governance Framework (CHGF), grounded in the Tri Hita Karana philosophy. The CHGF model explains that, in the modern era, preserving Pura Tebing Gunung Kawi requires integrating policies, market innovations, and social capital in line with Bali's characteristics.

Keywords: sustainable tourism, ecotourism, Tri Hita Karana, environmental conservation, sustainable development

INTRODUCTION

Bali, the world's premier tourism destination, offers cultural and natural diversity. Therefore, there needs to be an interesting development with unique characteristics to enhance the value of Indonesia's tourist destinations (Sumarmi et al., 2023). Tourism offers significant potential for developing the ecosystem and the national economy (Rivza et al., 2022). The transition of Tebing Gunung Kawi Temple from a place of worship to a tourism sector can boost the economy, empower the community, preserve the ecology, and preserve local culture (Ciacci et al., 2023). Perubahan penggunaan lahan untuk pariwisata jika dikelola dengan baik akan memberikan dampak positif baik pada budaya, struktur sosial, ekonomi dan lingkungan. Keberhasilan pengembangan pariwisata sangat tergantung pada partisipasi masyarakat local, karena masih dipegang teguhnya nilai-nilai tradisional (Putra et al., 2021). It is known that destinations in Bali receive positive feedback from tourists (80.36%) due to their natural beauty (Ramadhani et al., 2024).

The development of tourist destinations in Gianyar, including Pure Tebing Gunung Kawi, is still in the planning stage due to constraints caused by the pandemic and the lack of a legal framework for spiritual tourism (Wirawan et al., 2023). Tebing Gunung Kawi Temple is a geological and spiritual heritage site, making it one of the most popular tourist destinations in Bali, where local residents earn a living through spiritual and nature-based tourism. According to Wang et al. (2014), geological diversity has a non-renewable heritage. Tourism in Bali, rooted in local traditions and temples, is nature-based spiritual tourism linked to local wisdom, including the community's religious lifestyle, religious rituals, and temple architecture (Wirawan et al., 2023). The development of geotrails that integrate cultural, geological, and biological diversity has proven to boost tourism through environmental conservation education and artistic preservation. Therefore, conservation is necessary to preserve culture and the environment, as they are interrelated (Lestari et al., 2025).

Gunung Kawi Cliff Temple tourism is located on the banks of the Pakerisan River. It requires a deep understanding of sustainable management, given the environmental impact of tourism development (Amerson & Parsons, 2018).

The Balinese community has an environmental conservation strategy that integrates cultural values, ethics, and religious perspectives. Results of Mgbeadichie's research (2025), which found that the Uli tribe in Nigeria and the Chin community in Myanmar have a cultural heritage that is implemented in daily life, based on traditional knowledge and rituals, and that contributes to sustainable resource management and biodiversity conservation as a conservation policy. Cultural heritage conservation requires a balance of interdisciplinary methods, public participation, and a balance between tangible and intangible aspects, with the aim of sustainable development (Li & Tang, 2023; Mekonnen et al., 2022). Advances in sustainable conservation, marked by innovative monitoring technologies and materials, have made a significant contribution to cultural heritage preservation efforts (Di Turo & Medeghini, 2021; Pérez-Gandarillas et al., 2024).

Tri Hita Karana is a Balinese Hindu philosophy that explains harmony among three interrelated areas: God, humans, and the natural environment. This philosophical principle encourages responsible environmental management, social cohesion, and sustainable development by emphasising spiritual, social, and ecological relationships (Hisyam et al., 2024; Mildawani et al., 2024a). Various aspects of life in Bali uphold this philosophy, including religious activities, cooperation, urban planning, environmental management, tourism development, and cultural heritage preservation (Ardani et al., 2025; Mildawani et al., 2024a; Suryono, 2021). This philosophy encourages the government, the private sector, and the community to achieve sustainable tourism. Its implementation takes the form of land management in Bali, preservation of cultural heritage, use of natural resources, and legal practices (Kiriana et al., 2025; Wiryawan, 2024). Through synergy between government policy, local wisdom practices such as irrigation and vegetation management, and visitor education programmes, Pura Tebing Gunung Kawi aims to balance 21st-century economic prosperity with the protection of local wisdom for future generations (Jawabreh et al., 2024).

Research on conservation and sustainable tourism at Gunung Kawi Cliff Temple remains limited, highlighting several challenges and gaps. This is because the relationship between land use and cultural and natural values has not been thoroughly researched. Research on the relationship between spirituality, local customs, and nature remains very limited, for example, Tri Hita Karana, which influences conservation and natural resource management in Bali (Rosalina et al., 2023). In addition, literature reviews on sustainable tourism remain incomplete due to insufficient exploration of resilience, multi-stakeholder cooperation, and localization challenges (Zhang et al., 2022). The lack of exploration into the impact of environmentally friendly behaviour by tourists, mediated by cultural ties, at Gunung Kawi Cliff Temple, results in a lack of understanding of sustainable visitor practices (Cheng & Chen, 2022). Furthermore, other studies have also overlooked governance and socio-political complexities, including unequal participation by government and communities, which affect environmental conservation and cultural heritage (Lawasi et al., 2025). Research on the impact of conservation and biodiversity outcomes on tourism in Mount Kawi remains limited, underscoring the need for further empirical and interdisciplinary studies to sustain cultural preservation and sustainable tourism development (Kiriana et al., 2025).

Tourism facilities are often constructed without regard for environmental impact, disrupting ecosystems (Sutrisno et al., 2024). In addition, it causes gradual degradation of natural capital and the environment, including environmental pollution, changes in land use, and increased waste, thereby threatening the balance of biodiversity and ecosystems (Baloch et al., 2023). The gap between government policy and stakeholder cooperation in balancing tourism development with environmental conservation results in socio-environmental vulnerability (Javan et al., 2023). The limited empirical research on the environmental impact of infrastructure development thereby hinders evidence-based decision-making aimed at reducing negative consequences (Murphy & HUallacháin, 2025). The absence of comprehensive ecological assessments and facility monitoring will hinder sustainable management (Gavrilaș et al., 2025). Overall, the problem lies in policy enforcement, inadequate planning, and an interdisciplinary approach that emphasises the need to develop facilities to support economic growth without damaging the ecosystem. If sustainable tourism is not implemented, it will lead to a decline in tourist satisfaction. Therefore, sustainable tourism management can address environmental impacts through conservation, ensuring tourists are always satisfied with the natural and cultural conditions (Bentz et al., 2016). There is a gap in understanding and implementing the Tri Hita Karana concept, leading to an imbalance among ancestors, humans, and nature, which, in turn, impacts the environment and society. In addition, the lack of strong collaboration between the government, community, and private sector hinders effective, sustainable tourism.

The urgency of this research lies in the lack of consideration of ecological aspects in sustainable tourism management practices, which has resulted in an imbalance between cultural heritage and the environment. This study offers a new approach: integrating Tri Hita Karana into environmental conservation and sustainable tourism management, supported by multi-stakeholder collaboration, such as the pentahelix framework. The objective of this study is to utilise Tri Hita Karana as a strategy to maintain a balance between tourism development and environmental preservation, and to promote sustainable and responsible tourism. The application of this philosophy encourages ecological innovation and green human resource management in Bali's tourism sector, thereby contributing to long-term environmental and cultural sustainability. Broadly speaking, this study addresses the gap in systematically applying traditional Balinese wisdom to modern tourism challenges, aiming to harmonise economic growth with culture and ecological conservation.

Although various studies have examined the relationship between local wisdom, collaborative governance, and sustainable tourism development, there remain conceptual and empirical gaps in the existing literature. Previous studies have shown that the Tri Hita Karana philosophy plays a significant role in fostering harmony between humans and God (parahyangan), fellow humans (pawongan), and the environment (palemahan), and can serve as a source of legitimacy in the practice of international relations at the subnational level. However, such research remains largely descriptive and normative, and has yet to provide a comprehensive empirical analysis of the concrete implementation of these values in the management of tourist destinations (Intentilia & Utomo, 2025). Other research on forest-based ecotourism in Indonesia

indicates that sustainable tourism can contribute to environmental conservation and improved well-being among local communities. However, its implementation still faces various challenges, particularly regarding collaborative governance, conflicts of interest, and infrastructure disparities (Apriyanto et al., 2025). Furthermore, studies on the values of Balinese local wisdom, such as Tat Twam Asi and Menyama-Braya, indicate that the involvement of local communities is a key factor in the development of culture-based tourism; however, as these studies are limited to a single religious tourist destination, the generalisability of the findings to the broader context of tourism in Bali remains limited (Mulyana, 2025). Meanwhile, research on the governance of cultural heritage tourism through a collaborative governance approach in the Majapahit House Heritage Area indicates that collaboration among stakeholders can enhance tourism resilience; however, most of this research has not yet integrated the values of local wisdom as a key conceptual framework within models of sustainable tourism governance, nor has it comprehensively examined the relationship between environmental conservation, spiritual values, and tourism development within a single integrated strategic framework (Basyar et al., 2025). Therefore, this study aims to address this gap by developing a model for sustainable tourism and conservation strategies based on the Tri Hita Karana philosophy, applied to the Pura Tebing Gunung Kawi area in Tampaksiring, through a robust collaborative governance approach that integrates the roles of the government, local communities, and the private sector in maintaining a balance between cultural preservation, environmental protection, and the development of sustainable tourism.

This study aims to develop and evaluate a model for sustainable tourism and cultural heritage conservation in the Pura Tebing Gunung Kawi area, located in Tampaksiring, Bali, by integrating the local philosophy of Tri Hita Karana as the primary conceptual framework. Specifically, this study aims to analyse the interrelationships among spiritual values, community participation, and environmental management in tourism practices within this cultural heritage site, and to evaluate the roles of multi-stakeholder actors, including the government, local communities, and the private sector, in establishing sustainable collaborative governance. Furthermore, this study also aims to formulate the Collaborative Heritage Governance Framework (CHGF) as a strategic model capable of balancing the needs of environmental conservation and the preservation of cultural values with the demands of modern tourism development. As such, this study is expected to make a theoretical contribution to the literature on sustainable heritage tourism and to offer a practical framework for the management of cultural heritage sites grounded in local wisdom and multi-stakeholder collaboration.

MATERIALS AND METHODS

This study uses qualitative methods to explore complex social phenomena through in-depth, human-centred insights. (Denny & Weckesser, 2022). The research location is in Tampaksiring Village, Gianyar Regency, Bali. Gianyar Regency is located in Bali Province, between 08°18'48" – 08°38'58" South Latitude and 115°13'29" – 115°22'23" East Longitude (Figure 1).

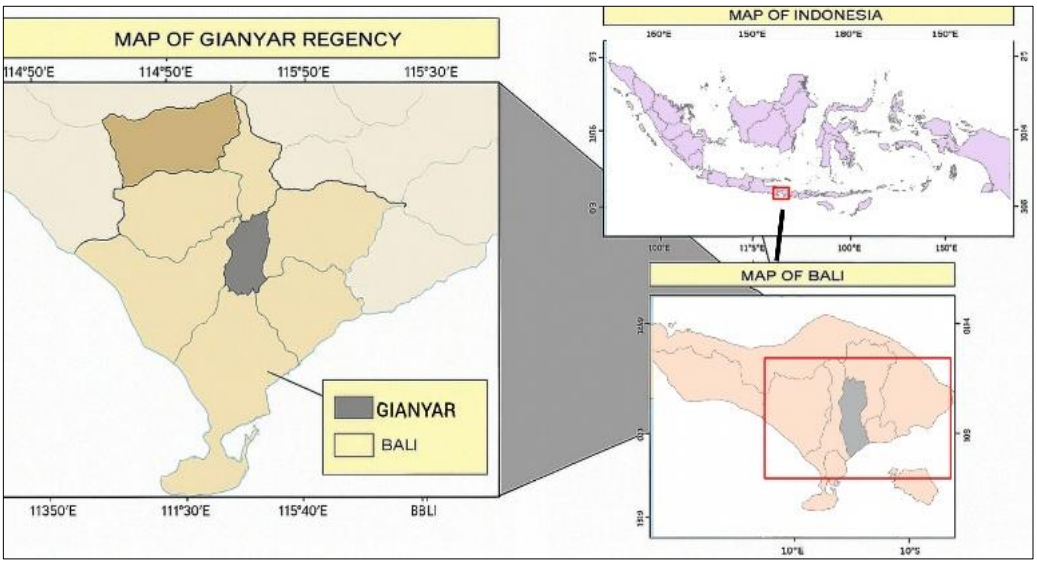

Figure 1. Research Location, Gianyar, Bali

The data sources in this study were primary and secondary data. Primary data were collected through in-depth interviews with key informants who had direct relationships with the research subjects, including community leaders, managers of the Gunung Kawi Cliff Temple site, village officials, and visiting tourists. Sampling was purposive, aimed at selecting informants with relevant experience (Mustadi et al., 2024). The characteristics and demographic information of the key informants are presented in Table 1.

Table 1. Informant Data

informant	informant's name
Tourism Manager	I Ketut Nuarke (75 years old)
Community Member	Mr. Rana (68 years old), Dadong (65 years old), Ajik Teguh (59 years old)
Tourist	Carlos (34 years old), Kyein (31 years old), Carla (28 years old)

These informants provided contextual insights into cultural values, community participation, and the opportunities and challenges of sustainable tourism development in the Gunung Kawi Temple area. Secondary data in this study include various relevant documents and archives, such as historical records of temples, cultural preservation policy documents, regional tourism reports, previous research results, scientific articles, and books and publications related to cultural heritage and sustainable tourism management, to strengthen written information. Observations through direct observation (da Costa et al., 2024) on the physical condition of the temple in geological terms and on tourism activities in both social and economic terms. To maintain the validity and legitimacy of the data, this study uses data triangulation techniques. The triangulation used involves combining diverse data sources to improve the validity and authenticity of the data through cross-verification, thereby obtaining unbiased data (Schlunegger et al., 2024). Data derived from interviews, observations, and documentation were combined to provide a more comprehensive understanding of the phenomenon under study (Papavasileiou & Dimou, 2025). Through this triangulation approach, the reliability of the data obtained is expected to increase, enabling a more comprehensive description of reality. The data, derived from interviews, observations, and documents, were analysed using Miles and Huberman's interactive model, which consists of three main steps: data reduction, data presentation, and conclusion drawing/verification. The stages of data analysis based on the Miles and Huberman interactive model are presented in Table 2. Data reduction is achieved through selection, simplification, focusing, and transformation, aiming to make data easier to manage and more meaningful.

Data presentation is achieved by organising and displaying data in an easily understandable manner, using tables, graphs, and narratives. The final step is to draw conclusions and verify them through data interpretation to identify patterns, while continuously checking for consistency and validity (Mustadi et al., 2024; Papavasileiou & Dimou, 2025).

Table 2. Data analysis from the Miles and Huberman model

Analysis Stage	Description
Data Reduction	Sort, simplify, and select data relevant to the research focus.
Data Presentation	Organise data in the form of descriptive narratives, interview excerpts, and thematic tables.
Conclusion Drawing	Interpret data, find patterns, and draw verifiable conclusions.

RESULTS AND DISCUSSION

Tebing Gunung Kawi Temple is a historical site believed to have been built in the 11th century, during the reign of King Udayana of the Warmadewa Dynasty. Located on the banks of the Pakerisan River, this temple consists of 10 buildings carved directly into the rock cliffs. The spatial distribution of the Gunung Kawi Temple complex and the location of the temple monuments carved into the northern and southern cliff faces are illustrated in Figure 2.

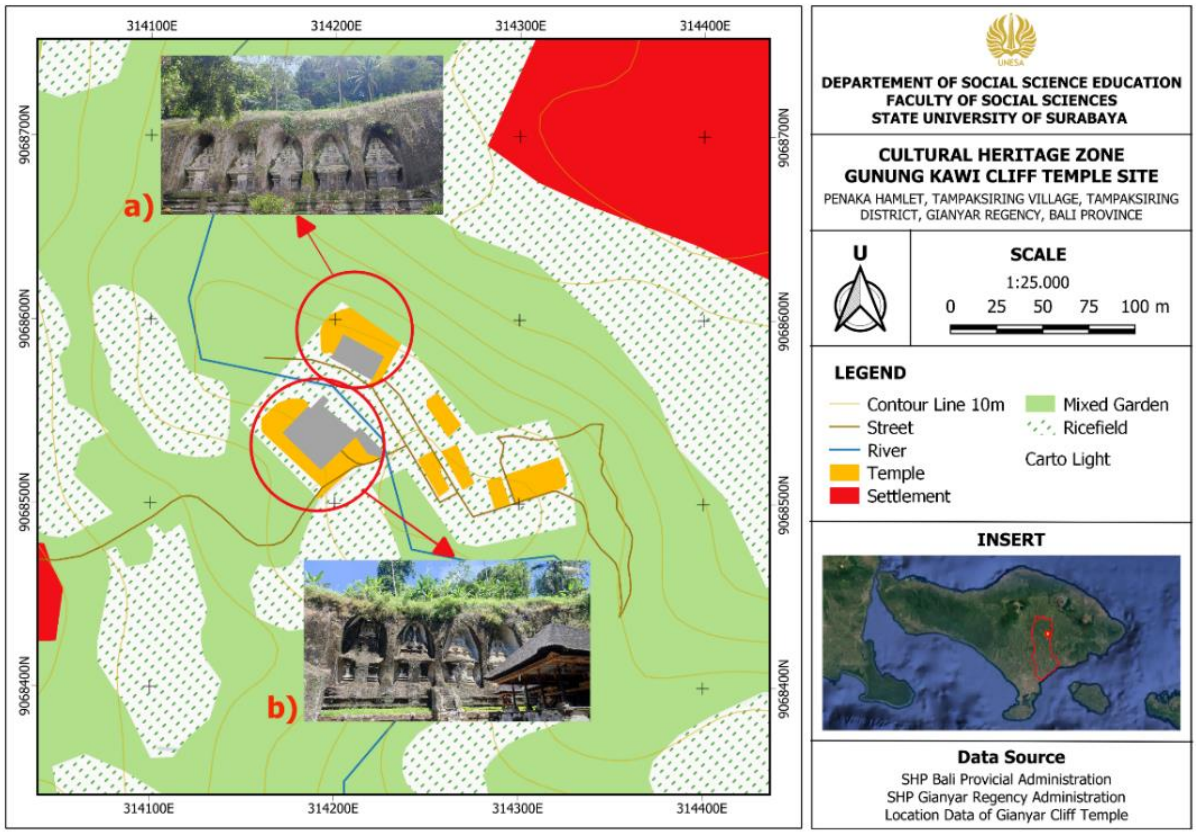

Figure 2. Spatial distribution of the cultural heritage site of Pura Tebing Gunung Kawi, Tampaksiring a) Temple monuments carved into the northern cliff face of the temple complex; b) Temple structures carved into the cliff face located in the southern part of the temple courtyard (Source: GIS data from the Provincial Government of Bali and the Regency Government of Gianyar; field photographs taken by the authors)

The photographs were taken during a field survey on 29 April 2025 in Tampaksiring Village, Tampaksiring Sub-district, Gianyar Regency, Bali Province, Indonesia. The Gunung Kawi Cliff Temple site offers a unique integration of human engineering and significant geological features. Based on field documentation, the temple structure was built on volcanic rock formations formed by ancient magmatic activity on Mount Batur. Stratigraphically, the rocks are arranged in layers following the principle of Lateral Continuity, which provides natural structural stability for the ten monuments carved directly into the cliff walls. Although these volcanic materials have high density and strong physical resistance, their intrinsic rock characteristics indicate they are particularly vulnerable to biochemical and physical weathering processes. The volcanic rock structure of Mount Batur is characterised by complex subsurface features, including shallow and deep magma chambers, as revealed in magnetic and gravity modelling studies on the island of Bali. These models also indicate the presence of intrusive rocks between Mount Agung and Mount Batur, as well as volcanic deposits covering the graben structure to a depth of 6 km, reflecting the eastward migration of volcanic activity (Suryanata et al., 2024).

The degradation of volcanic rock at sites such as Gunung Kawi Cliff Temple is influenced by environmental factors, including humidity, which can accelerate weathering and surface damage, posing challenges for conservation efforts. Although specific studies on rock degradation at Gunung Kawi Cliff Temple are limited, volcanic rock weathering is generally known to be influenced by humidity, temperature fluctuations, and biological activity, which can weaken rock structure over time. Understanding volcanic processes and the properties of volcanic rocks, as seen in eruptions such as Mount Batur, is essential for assessing the long-term stability and conservation needs of cultural heritage sites built on or near volcanic material. Integrating geological insights with environmental monitoring can help develop strategies to reduce the risk of degradation at significant historical sites (Malawani et al., 2021).

The main challenge in conserving this site is the degradation of materials caused by microclimatic factors, particularly high humidity and intense rainfall in the Pakerisan River area. Analysis shows that water infiltration into rock pores and cliff cracks accelerates the weathering process of the temple structure. This condition is exacerbated by biological threats, such as taproot tree growth, which can penetrate rock crevices, thereby increasing the risk of more extensive structural fractures.

As an environmental mitigation measure, the local community has implemented preventive local wisdom practices. This strategy includes modifying land use, such as converting Rice fields into dry plantations at the top of the cliff to minimise groundwater seepage towards the temple. In addition, community regulations prohibit the planting of vegetation with deep root systems in the cliff area to protect the integrity of the rock. These findings confirm that the sustainability of the Gunung Kawi Cliff Temple is highly dependent on the synergy between natural geological resilience and community-based conservation interventions. Although naturally solid, these rocks are susceptible to weathering due to high rainfall and humidity. Local communities apply ecological wisdom (the Palemahan aspect) by converting Rice fields into dry plantations to reduce water absorption, which accelerates rock weathering.

In addition, a strict ban on planting trees with taproots is enforced to prevent damage to the cliff structure through rock fractures. The involvement of local communities in participatory management is a key pillar of sustainability. The community plays an active role as guides, artisans, and guardians of tradition, preserving cultural values and improving local economic welfare. Spiritually, this site is maintained as a sacred place through the performance of regular rituals and unwritten rules that prohibit the destruction of reliefs, reflecting a commitment to Parahyangan values. The conservation rules and practices implemented at Gunung Kawi Temple to support the preservation of its cultural heritage and sustainable tourism are summarized in Table 3. The location of Gunung Kawi Cliff Temple, situated atop volcanic rock formed by ancient eruptions of Mount Batur, provides a naturally solid foundation due to the rock layers' lateral continuity. However, its position in the valley along the Pakerisan River makes the site vulnerable to high humidity and erosion, common challenges for volcanic structures in similar environments. Studies of volcanic landforms show that erosion processes develop over time, with the development of river basins and fluvial activity playing a key role in shaping volcanic rock surfaces and contributing to degradation. High humidity in river valleys can accelerate the weathering and erosion of volcanic rocks, potentially threatening the structural integrity of cliff temples carved directly into the rock.

Table 3. Conservation Rules and Practices

Conservation Rules and Practices Stage	Description
Natural Mitigation	Prohibiting the planting of trees to prevent roots from damaging the cliff structure.
Water Management	Converting Rice fields into dry plantations to reduce water absorption, which accelerates rock weathering.
Modern Technology	Regular evaluation and modern conservation by the Bali Cultural Heritage Conservation Centre are required to maintain the temple structure.
Visitor Control	Implementing a reservation system and limiting visitor numbers to reduce the impact of physical damage.

Understanding the geomorphological and hydrological dynamics of volcanic landscapes is essential for developing conservation strategies that reduce erosion and preserve such cultural heritage sites. Although specific erosion assessments for Mount Kawi are limited, insights from volcanic-erosion studies highlight the importance of monitoring drainage patterns and environmental conditions to protect these significant cultural structures.

The environmental conditions at the Gunung Kawi temple site are vulnerable to degradation from uncontrolled human activities, erosion, and infrastructure development that often disregard ecological balance. Modern conservation efforts emphasise the importance of regular environmental assessments and strict spatial planning to prevent damage to the site's authenticity and ecological harmony (Németh et al., 2021). Research on heritage sites in mountains and cliffs shows that environmental factors, such as humidity, erosion, and land-use changes, significantly affect the preservation

of cultural sites, requiring careful management to maintain sustainability (Saha et al., 2021; Yan et al., 2025). The study also shows that tourism pressure can exacerbate sites' vulnerability through increased foot traffic and inadequate visitor management, highlighting the importance of community involvement and awareness in conservation strategies (Flyen et al., 2023). In addition, salt weathering in humid conditions can accelerate the deterioration of stone heritage, suggesting that microclimate factors should be considered in conservation plans (Despotovic & Hauser, 2025). Overall, integrating environmental monitoring, sustainable tourism practices, and spatial controls is critical to maintaining the ecological and cultural integrity of the Kawi Temple site. The implementation of the Tri Hita Karana philosophy in supporting sustainable tourism and cultural heritage conservation at Gunung Kawi Temple is summarized in Table 4.

Table 4. Tri Hita Karana in Tourism & Conservation

Tri Hita Karana in Tourism & Conservation	Description
Parahyangan	Preserving the temple's function as a place of worship and sacred site through rituals that honour its spiritual values.
Pawongan	Involving the community as guides, artisans, and guardians of tradition to raise awareness of historical preservation.
Palemahan	Emphasising the harmony between natural forces (volcanic rock) and the environment surrounding the Pakerisan River.

Discussions on Tri Hita Karana in tourism and conservation emphasise its role in fostering harmony between spiritual, social, and environmental dimensions. The spiritual aspect (Parahyangan) involves preserving temples as sacred sites through ceremonies that honour their spiritual significance, ensuring cultural and religious continuity. The social aspect (Pawongan) highlights community involvement as guides, artisans, and guardians of tradition, thereby raising awareness and supporting historical preservation. The environmental aspect (Palemahan) focuses on maintaining harmony between natural elements, such as volcanic rock and the Pakerisan River ecosystem, and promoting sustainable interaction with the environment. Studies show that applying Tri Hita Karana in tourism management enhances sustainable development by integrating government roles, community empowerment, green marketing, and corporate social responsibility, leading to more responsible and inclusive tourism practices (Widhiasthini et al., 2025). Based on the findings of this study, an integrated strategy for sustainable tourism and cultural heritage conservation at Gunung Kawi Cliff Temple, Bali, is presented in Figure 3. This philosophy also underpins environmentally friendly innovations in Bali's tourism sector by balancing cultural values with environmental conservation. The concept of Palemahan in the Tri Hita Karana philosophy emphasises harmony between humans and the natural environment, promoting ecological balance as a key aspect of overall well-being. This principle encourages sustainable environmental practices rooted in local wisdom, such as converting terraced Rice fields on cliffs into dry plantations to reduce water seepage that can accelerate rock weathering, and prohibiting the planting of deep-rooted trees near cliffs to prevent root damage to rock structures (Astuti et al., 2021; Mildawani et al., 2024b). To achieve this strategy, multi-stakeholder synergy is required in cultural heritage governance: integration of government, community, and private sector.

Figure 3. Sustainable Tourism and Conservation Strategy at Gunung Kawi Cliff Temple, Bali

The sustainability of the Gunung Kawi Cliff Temple site depends heavily on a robust collaborative governance model that integrates the roles of the government, local communities, and the private sector. This synergy ensures that the historical integrity of the site is maintained while socio-economic growth can continue to be stimulated. The integration of the roles of the government, local communities, and the private sector in supporting sustainable tourism management and cultural heritage conservation at Gunung Kawi Cliff Temple is presented in Table 5.

Table 5. Integration of Government, People (Community), and Private Sector

Tri Hita Karana in Tourism & Conservation	Description
Government	Strengthening cultural heritage zoning policies, spatial planning regulations, and infrastructure development control in cultural heritage areas
Community	Serving as a key pillar in community-based tourism that supports local welfare without compromising historical values
Private Sector	Engaging in the development of sustainable tourism and creative industries that support Bali's cultural identity

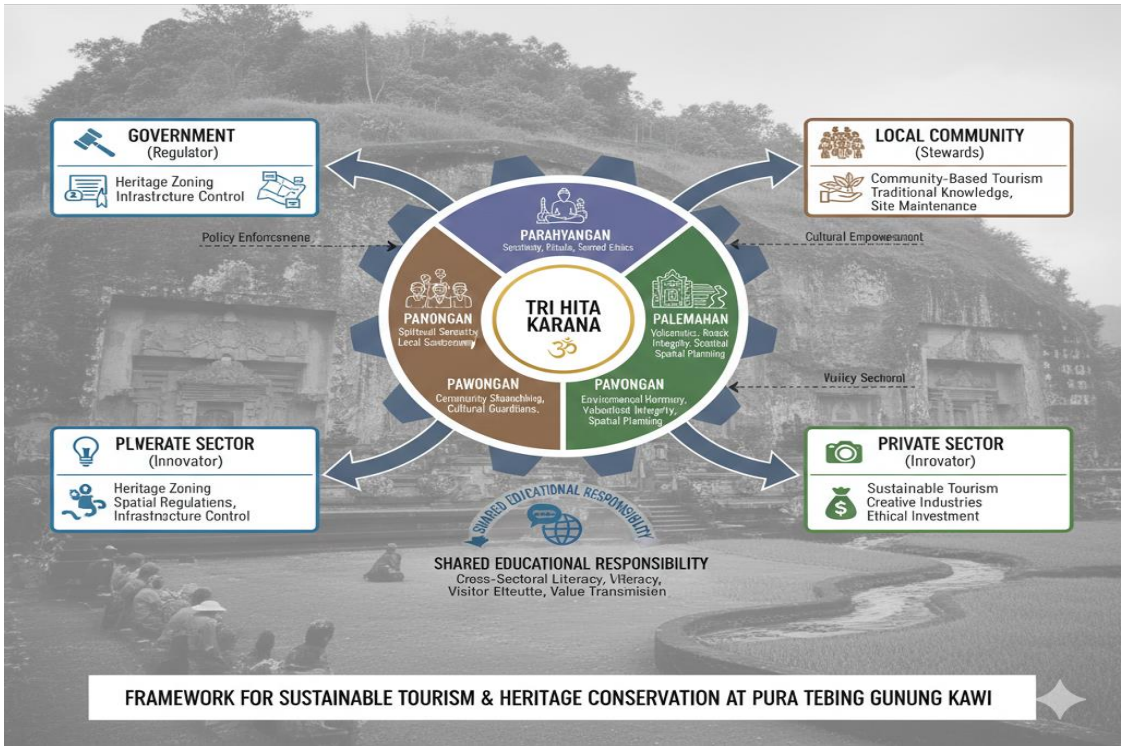

Figure 4. Cooperative Heritage Governance (CHG) Framework: Pura Tebing Gunung Kawi, Bali) (Source: The authors' conceptualisation based on field observations, interviews with stakeholders, and a review of the literature)

Based on the findings of this study, the proposed Cooperative Heritage Governance (CHG) Framework for Pura Tebing Gunung Kawi, Bali, is presented in Figure 4. The author is responsible for the conceptualisation, development of methodology, field research, data analysis, visualisation, and manuscript writing, including the conceptualisation and initial design of the Governance Framework. Cooperative Heritage Governance (CHG), as outlined in this study, explains the integration of cultural values, environmental conservation, and collaborative tourism governance at Pura Tebing Gunung Kawi, Bali, based on the philosophical principles of Tri Hita Karana. This research contributes to the study of sustainable cultural heritage tourism by proposing a Collaborative Cultural Heritage Governance Framework that integrates local philosophical values with stakeholder-based governance mechanisms. This framework demonstrates how the principles of Tri Hita Karana can be implemented as a practical governance model to balance cultural heritage conservation, environmental sustainability, and tourism development. The role of the government is to establish a regulatory and spatial control framework. The government acts as the primary regulator, focusing on strengthening cultural heritage zoning policies. This includes implementing strict spatial regulations and strategic control over infrastructure development within and around protected cultural heritage sites. By establishing clear legal boundaries, the government mitigates the risks of excessive commercialisation and unauthorised land-use changes that could threaten the site's authenticity.

This top-down institutional support is essential for maintaining physical and environmental stability in the Pakerisan Watershed Area (Wang et al., 2023). The Community as the Main Pillar of Community-Based Tourism (CBT): At the grassroots level, local communities are the central pillar of sustainable tourism. Through the Community-Based Tourism (CBT) model, residents are not merely passive spectators but active participants who serve as cultural guides, artisans, and guardians of tradition. This participatory approach ensures that income from the tourism sector contributes directly to local welfare without compromising the site's historical and spiritual values (Lajçi et al., 2022).

The community's proximity to this site creates a layer of organic protection, as their livelihoods are closely intertwined with the preservation of this cultural heritage, the Private Sector as Sustainable Development, and the Creative Industry. The private sector contributes to this ecosystem by developing sustainable tourism products and promoting creative industries that align with Bali's cultural identity. Instead of pursuing a mass tourism model, private entities are encouraged to invest in high-value, low-impact tourism experiences that respect the site's carrying capacity. This collaboration stimulates local entrepreneurship and increases Mount Kawi's global visibility by marketing ethical cultural experiences (Raihan, 2024) educational Synergy as Cross-Sector Literacy. A critical component of this integration is the creation of educational synergy across all sectors. Collaborative initiatives are designed to improve visitors' understanding of local ethics, religious values, and the temple's historical significance. By educating tourists about etiquette at sacred sites, stakeholders collectively reduce the risk of cultural desecration and physical degradation. This integrated management strategy demonstrates that preserving 11th-century monuments in the 21st century requires a careful balance between strict regulation, communal ownership, and ethical private investment (Mihardja et al., 2023).

Preserving Tebing Gunung Kawi Temple in the 21st century requires shifting from conventional site management to a Collaborative Heritage Governance framework. This model integrates the unique strengths of the government, local communities, and the private sector into a cohesive ecosystem that balances economic aspirations with conservation

imperatives. The government serves as a vital institutional anchor, enforcing strict cultural heritage zoning policies and spatial regulations designed to mitigate the risks of anthropogenic degradation and uncontrolled infrastructure encroachment within the Pakerisan Watershed Area. This regulatory framework is essential to preserving the structural integrity of the 11th-century volcanic stone temple from environmental and modern land-use pressures. By establishing a clear legal mandate, the state ensures that the historical authenticity of the site remains protected from the detrimental effects of unregulated commercial expansion (Fairbrass et al., 2024).

Complementing this top-down governance, local communities serve as the primary guardians of the site's intrinsic value, spearheading community-based tourism initiatives that align socio-economic well-being with the preservation of tangible and intangible cultural heritage. By positioning residents as active managers rather than passive participants, this model fosters a deep sense of ownership, ensuring that traditional rituals and spiritual functions continue to animate these physical monuments (Chiarini et al., 2022). Simultaneously, the private sector acts as a catalyst for sustainable innovation, shifting the tourism paradigm from mass consumption to a high-value, low-impact creative industry that respects Bali's cultural identity. This tripartite integration is ultimately realised through a nexus of shared educational responsibility, in which cross-sector collaboration transforms visitor behaviour. By synchronising government historical archives, communal traditional knowledge, and private sector communication platforms, a comprehensive framework is formed to make tourists aware of the ecological fragility and sanctity of the site, ensuring that 21st-century economic prosperity and the conservation of ancient architectural treasures coexist in a state of dynamic equilibrium (Ruban et al., 2023; Demkova et al., 2022).

CONCLUSION

This study concludes that the sustainability of tourism at Pura Tebing Gunung Kawi fundamentally depends on the successful implementation of the Collaborative Heritage Governance Framework (CHGF), grounded in the Tri Hita Karana philosophy. The CHGF model explains that, in the modern era, preserving Pura Tebing Gunung Kawi requires integrating policies, market innovations, and social capital in line with Bali's characteristics.

The government, as the palemahan aspect, has strict zoning policies to protect the structural integrity of volcanic rocks from the threat of anthropogenic degradation and infrastructure encroachment in the Pakerisan River Basin. The community, as the pawongan aspect, has the strength of the site's intrinsic values. The community also actively participates in governance, ensuring that economic growth does not neglect the principles of preventive conservation.

Private sector involvement as a catalyst for the creative industry within the CHGF framework also strengthens destinations' competitiveness without exceeding environmental carrying capacity, thereby creating an ethical, non-exploitative tourism ecosystem. Ultimately, CHGF serves as an instrument for preserving the Parahyangan dimension, ensuring that spiritual sanctity remains at the core of all activities at this site. This tripartite synergy offers a solution to the dichotomy between current economic needs and the need to conserve the past. By integrating local values into modern governance policies, this model ensures the achievement of a sustainable dynamic balance. These findings make a significant theoretical contribution to global cultural heritage management, affirming that multi-stakeholder collaboration grounded in local wisdom is key to addressing future challenges in preserving world heritage sites.

Spatial distribution of tourism resources in Udon Thani, Thailand: A GIS-based approach for sustainable and community-oriented tourism planning. *Geojournal of Tourism and Geosites*, 67(3), 2305–2313. https://doi.org/10.30892/gtg.67342-1854

Abstract: Contemporary tourism is increasingly shifting from a volume-based model toward a quality-oriented approach that emphasizes sustainability, local identity, and the redistribution of tourism activities to secondary cities and rural areas. This study aims to quantitatively assess the spatial distribution patterns and clustering dynamics of tourism resources in Udon Thani Province using geospatial analytical techniques, including the Nearest Neighbor Index (NNI), hot spot analysis (Getis-Ord Gi*), and Kernel Density Estimation (KDE). The analysis is based on a georeferenced dataset of tourism resource points derived from field surveys and secondary spatial databases. The NNI results indicated that tourism resources in Udon Thani exhibited a statistically significant dispersed pattern (NNI = 1.5689, $p < 0.001$), suggesting that the observed distribution was not random but reflected underlying spatial contexts and community settlement patterns. However, hot spot analysis identified areas of significant clustering of tourism activities, particularly in Mueang Udon Thani District, as well as in parts of Ban Dung and Nam Som Districts, which hosted specialized attractions with strong drawing power. Meanwhile, the KDE analysis confirmed the role of Mueang Udon Thani District as the provincial tourism core and highlighted the potential of secondary areas to support linked cultural and community-based tourism activities. The findings provide spatial evidence to inform the delineation of tourism development zones, the design of integrated tourism routes, and the formulation of balanced and sustainable tourism policies at the provincial level. This study contributes to the growing body of cultural and community-based tourism research by providing a data-driven framework for identifying spatial heterogeneity and supporting evidence-based tourism planning in emerging secondary destinations.

Keywords: tourism resources, GIS, spatial analysis, sustainable tourism, spatial clustering

INTRODUCTION

Over the past decade, global tourism has shifted from a volume-based model toward a quality-oriented approach that places greater emphasis on sustainability, diverse experiences, and place-based tourism. Travelers increasingly seek destinations with distinctive local characteristics and are dispersing from primary cities to secondary cities and rural areas to reduce congestion and environmental impacts (Lane el al., 2022). At the same time, advances in digital technologies and the availability of spatial data have transformed the analysis of travel behavior, route planning, and destination management (Zeng et al., 2025). Consequently, geospatial tools and spatial analysis have become integral to tourism planning and policy formulation in many countries (Šoltésová et al., 2025). In Thailand, recent tourism development strategies have similarly prioritized income redistribution to regional areas, the promotion of secondary cities, and the expansion of cultural (Manosuthi, 2024), community-based, and nature-based tourism (Yodsurang et al., 2021). These strategies operate within broader frameworks of sustainable development and the creative economy and aim to reduce disparities between major tourism destinations and emerging areas with development potential. Prior to the COVID-19 pandemic, tourism played a crucial role in Thailand's economy, generating approximately USD 60.5 billion in revenue from international tourists and accounting for around 18% of GDP (Sangkaew et al., 2025). The pandemic, however, caused a significant decline in tourism revenue in 2022 before recovery began in 2023 and 2024 (Sangnak, 2025). During this period, Thailand recorded approximately 35.5 million international tourists and a total tourism revenue of about 1.67 to 1.8 trillion Thai baht.

These developments underscore the importance of effective spatial planning and tourism management, particularly at the provincial level (Bozdağ, 2023). Udon Thani Province, for example, possesses a wide range of tourism resources but

still lacks systematic quantitative analyses of their spatial distribution. In particular, limited empirical evidence explains whether tourism resources are clustered, dispersed, or randomly distributed across space.

Understanding these spatial patterns is essential for guiding infrastructure development, managing tourism pressure, and formulating area-based tourism policies (Luo & Peng, 2024). Recent advances in Geographic Information Systems (GIS) enable more efficient and systematic spatial analysis, making GIS a critical tool for tourism planning and policy development (Gao et al., 2025; Akay, 2026). The Nearest Neighbor Index (NNI) is widely used in point pattern analysis to classify spatial distributions as clustered, random, or dispersed (Ding et al., 2024). In parallel, Kernel Density Estimation (KDE) supports the visualization of spatial intensity by producing density surfaces that highlight areas of concentration and areas with development potential (Xu et al., 2024). Together, these techniques provide a robust analytical framework for examining the spatial structure of tourism resources. Accordingly, this study analyzes the spatial distribution patterns of tourism resources in Udon Thani Province, Thailand, by applying the NNI and KDE within a GIS-based analytical framework (Wang et al., 2026). The findings aim to enhance spatial understanding of tourism distribution structures and to provide empirical evidence to support tourism development planning, resource allocation, and the formulation of sustainable, area-based tourism policies at both provincial and regional levels (Chalkidou & Mavridis, 2026).

MATERIALS AND METHODS

Study Area

Udon Thani Province is a major regional hub in northeastern Thailand, located between latitudes 17°13′ and 18°10′ north and longitudes 102°00′ and 103°30′ east. The province plays an important role in the regional economy, transportation, and tourism, and hosts a wide range of tourism resources distributed across both urban and rural areas.

Cultural and historical tourism constitutes a key component of the province's tourism profile, with prominent attractions such as the Ban Chiang Archaeological Site in Nong Han District, a UNESCO World Heritage Site that reflects the development of prehistoric human civilization (Noichan et al., 2024). In addition, Udon Thani contains numerous religious sites and local cultural landmarks located in both urban centers and rural communities.

The province also offers diverse natural and ecotourism resources, including forested areas, mountainous landscapes, and water bodies. Notable examples include Phu Phra Bat Historical Park, which features distinctive natural rock formations integrated with archaeological remains, and Huai Luang Reservoir, a popular recreational destination for residents and visitors. Moreover, several community-level natural attractions show strong potential for further development as conservation-oriented tourism sites. Community-based and lifestyle tourism represents another important dimension of tourism in Udon Thani Province, reflecting the distinctive identity of Thail Isan culture.

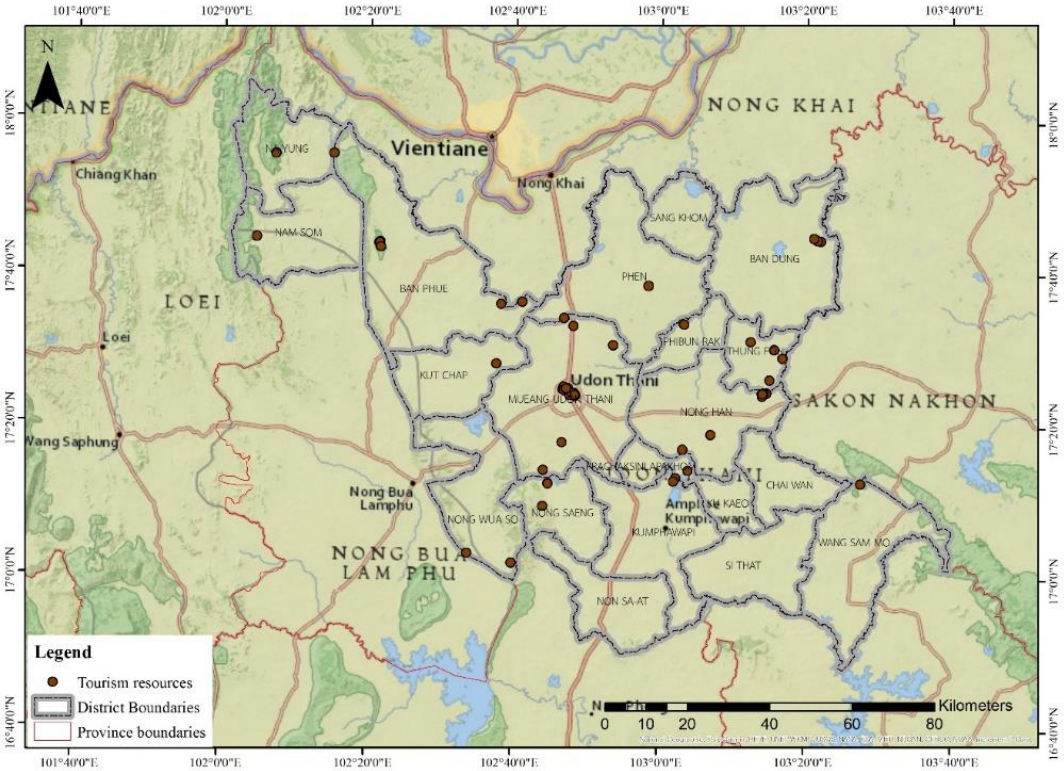

Figure 1. The Study Area Map

Local communities surrounding the Ban Chiang area in Nong Han District, as well as agricultural communities across various districts, offer opportunities to integrate tourism activities with learning experiences related to local livelihoods, traditional knowledge, and the grassroots economy (Suriyankietkaew et al., 2025). At the same time, urban tourism and

cross-border trade are concentrated primarily in Mueang Udon Thani District, which functions as a transportation, service, and commercial center and serves as a key link to neighbouring countries in the Greater Mekong Subregion (Kokkhangplu et al., 2025). Given this diversity of tourism resources, understanding spatial distribution patterns and density is essential for effective tourism development planning and appropriate spatial management. As shown in Figure 1.

Data Collection

This study employed spatial data on tourism resources represented as point features, with each point indicating the geographic location of a tourism site. The data were obtained from field surveys and reliable spatial databases. All location data were verified for positional accuracy and standardized to a common coordinate reference system to ensure consistency and accuracy in subsequent spatial analyses.

The dataset subsequently underwent spatial data preparation following standard analytical procedures. First, duplicate point locations were identified and removed to prevent potential bias in spatial index calculations. Next, all spatial data were transformed into a single projected coordinate system appropriate for distance measurement and quantitative spatial analysis. Finally, an initial assessment of spatial distribution patterns was conducted through exploratory mapping to evaluate overall distribution characteristics and to prepare the dataset for subsequent analyses using the NNI and KDE.

METHODS

This study adopted a quantitative research design, integrating spatial analysis with spatial statistics to examine the spatial distribution patterns and density of tourism resources in Udon Thani Province, Thailand. The analysis focused on point-based spatial data and applied Exploratory Spatial Data Analysis (ESDA) to systematically identify clustering patterns of tourism resources and assess their spatial density within the study area.

Spatial distribution patterns were examined using the NNI, which was used to determine whether the distribution of tourism resources exhibited clustered, random, or dispersed patterns (Yu et al., 2025). The NNI was calculated as the ratio between the observed mean nearest-neighbor distance and the expected mean distance under a random spatial distribution (Xu & Wang, 2021), as shown in Equation 1:

$$NNI = \frac{d_{observed}}{d_{expected}} \quad (1)$$

where:

$d_{observed}$ = the average distance between each point and its nearest neighbor

$d_{expected}$ = the expected mean distance assuming a random spatial distribution

NNI values were interpreted as follows: NNI < 1 = clustered pattern, NNI ≈ 1 = random pattern, and NNI > 1 = dispersed pattern. Statistical significance was further assessed using Z-scores to determine whether the observed spatial pattern differed significantly from a random distribution.

In this study, spatial statistical analysis using the Getis-Ord Gi* method was applied to examine the distribution of point-based spatial data in order to identify areas with statistically significant concentrations that are higher or lower than the surrounding average. This method is particularly suitable for cultural tourism analysis, especially when identifying cultural cores such as clusters of temples or historical heritage sites. The Getis-Ord Gi* analysis produces Z-scores and p-values (Zikirya et al., 2024) which are used to identify Hot Spots, defined as areas with high concentrations of tourism activities or resources, and Cold Spots, defined as areas that remain underutilized (Zhao et al., 2023).

The results of the Getis-Ord Gi* analysis were used to support the design of tourism routes, planning for the development of new tourism attractions, prioritization of areas for conservation, and evidence-based policy decision-making. This approach is particularly relevant in areas characterized by strong and complex cultural dimensions, such as temple communities in historic urban areas or riverside zones that reflect traditional community livelihoods. The Getis-Ord Gi* statistic is expressed as Equation 2. The arithmetic mean Xand the standard deviation S\ are defined in Equations 3 and 4 (Ord & Getis, 1995; Anselin et al., 2010; Yuan et al., 2025), respectively.

$$G*_i = \frac{\sum_{j=1}^{n} w_{i,j} - \overline{X}\sum_{j=1}^{n} w_{i,j}}{S\sqrt{\frac{\left[n\sum_{j=1}^{n} w_{i,j}^2 - \left(\sum_{j=1}^{n} w_{i.j}\right)^2\right]}{n-1}}} \quad (2)$$

$$\bar{X} = \frac{\sum_{j=1}^{n} x_j}{n} \quad (3)$$

$$S = \sqrt{\frac{\sum_{j=1}^{n} x_j^2}{n} - \overline{(X)^2}} \quad (4)$$

where:

x_j = the attribute value of location j, such as the number of temples or density values;

$w_{i,j}$ = the spatial weight between locations i and j, such as proximity; $\bar{X}$ = the mean of all attribute values;

S = the standard deviation of the attribute values; n = the total number of spatial points. Furthermore, spatial density analysis using KDE was applied to assess the spatial density of tourism resources by transforming point-based data into a continuous density surface per unit area. This approach enables the identification of areas with varying levels of concentration of tourism resources (Pang et al., 2025). The general KDE function is expressed in Equation 5:

$$KDE\ (X)\ =\ \sum_{i=1}^{n} K\left(\frac{d_i}{h}\right) \qquad (5)$$

where:

d_i = the distance from the location of interest to point i,

h = the bandwidth parameter, which defines the spatial influence of each point; K = the kernel function

The selection of the bandwidth parameter was determined based on the spatial distribution characteristics of the data and the scale of the study area in order to reflect density patterns that are appropriate for spatial and policy interpretation.

The results derived from the NNI and the KDE technique were synthesized to explain the spatial distribution patterns of tourism resources and to systematically classify density levels across the study area. These results provide an empirical basis to support spatial tourism development policies, the allocation of resources and infrastructure, and the redistribution of tourism activities toward emerging potential areas to reduce spatial concentration and promote sustainable tourism development at the provincial level. The analytical framework of this study is illustrated in Figure 2.

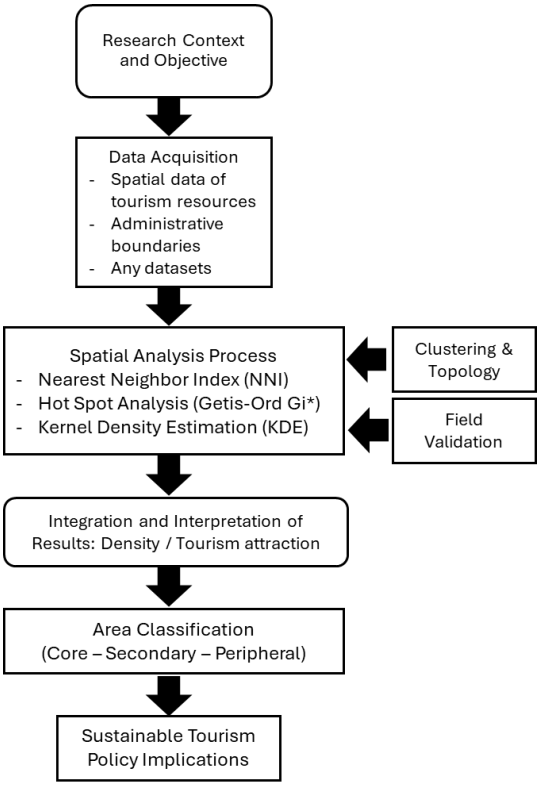

Figure 2. The Conceptual Framework

RESULTS AND DISCUSSION

Spatial Distribution Analysis of Tourism Resources Using the Nearest Neighbor Index (NNI)

The survey of tourism resources in Udon Thani Province identified a large number of tourism sites. From this dataset, 60 tourism sites with high potential and strong attractiveness to visitors were selected and classified into eight categories. The distribution is summarized below:

- Historical tourism sites: 4 sites
- Cultural tourism sites: 2 sites
- Community-based tourism sites: 5 sites
- Market-based tourism sites: 6 sites
- Memorial sites: 1 site
- Museum-based tourism sites: 3 sites
- Natural tourism sites: 10 sites
- Religious tourism sites: 29 sites

A spatial analysis of these tourism resources was then conducted using GIS and the NNI to assess whether their spatial distribution exhibited clustered, random, or dispersed patterns. The analysis produced a Nearest Neighbor Ratio (NNR) of 1.568879, indicating a dispersed spatial pattern. The corresponding z-score was 8.499937, demonstrating a statistically significant deviation from a random distribution. In addition, the p-value was 0.000000, indicating a very high level of statistical significance and an extremely low probability that the observed pattern occurred by chance. These results indicate that tourism resources in Udon Thani Province are more widely spaced than would be expected under a random spatial distribution and that the observed dispersion is not the result of random variation. The spatial distribution pattern of tourism resources is illustrated in Figure 3, which presents the results of the Average Nearest Neighbor analysis.

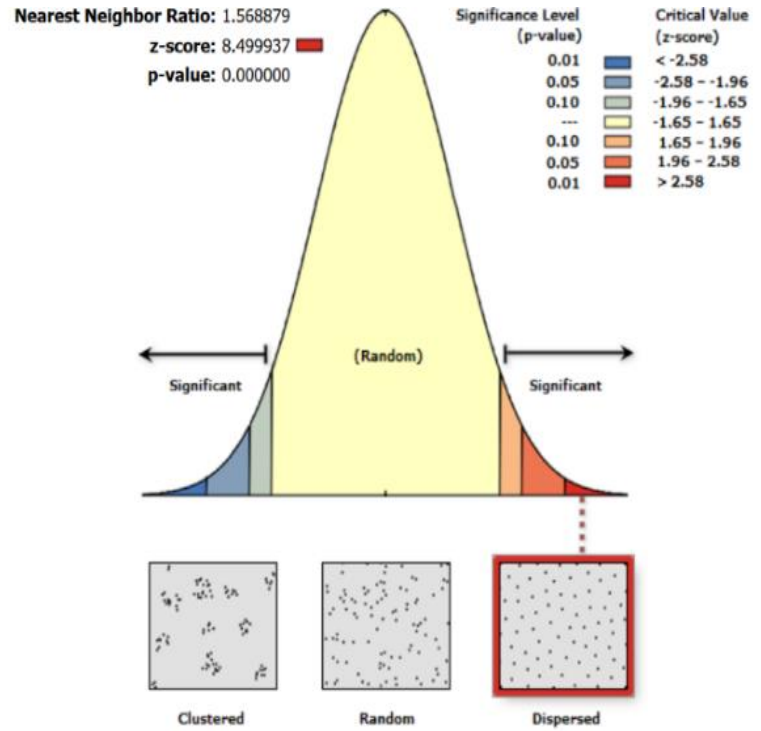

Figure 3. Results of the Average Nearest Neighbor Analysis

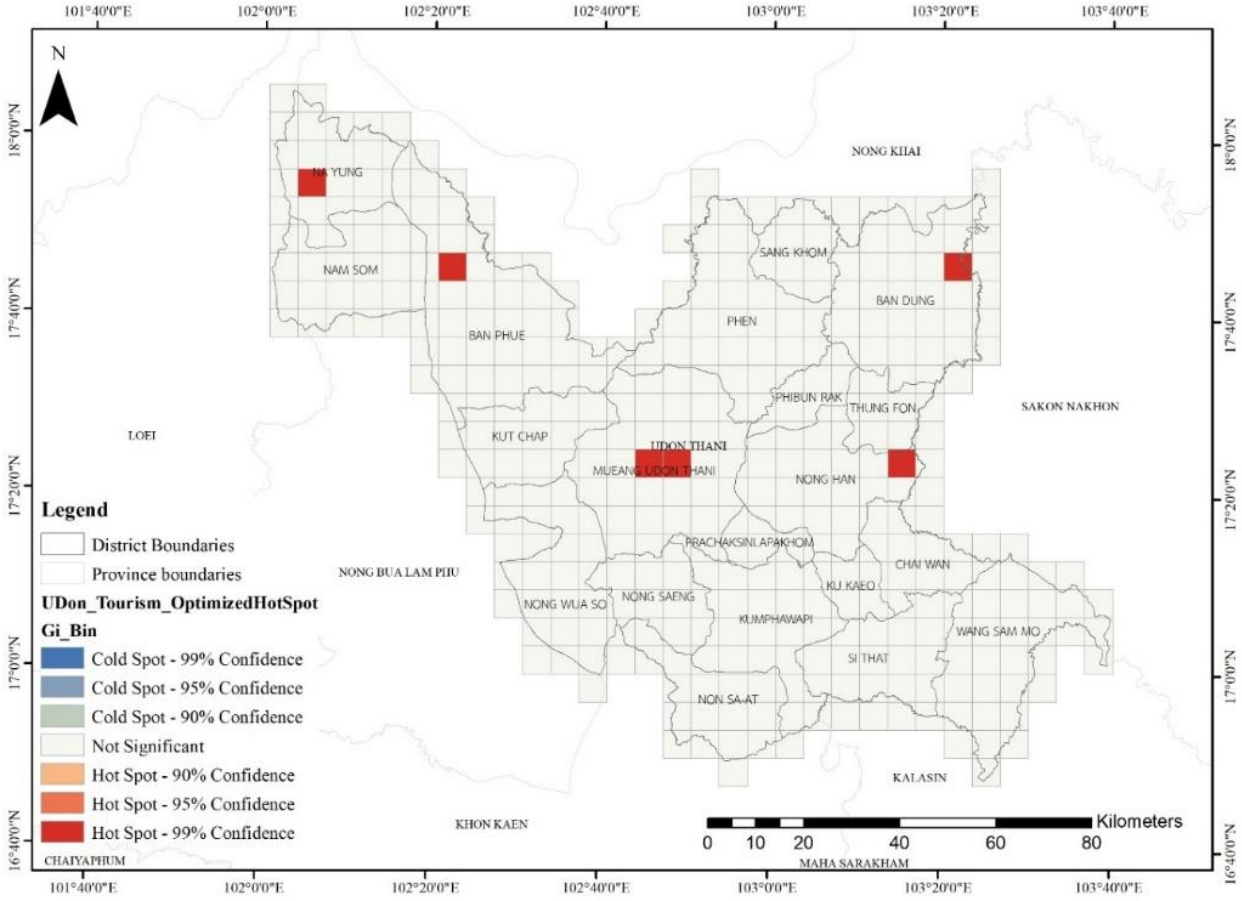

Figure 4. Hot Spot Map of Tourism Resources in Udon Thani

Subsequently, tourism resources in Udon Thani Province were analyzed using the Optimized Hot Spot Analysis tool. The entire study area was divided into uniform square grids to facilitate statistical analysis using the Getis-Ord Gi* statistic

(Gi_Bin). This approach enabled the identification of spatial patterns of tourism resource concentration by classifying areas into different levels of statistical significance, including Cold Spots (low concentration), Not Significant Areas, and Hot Spots (high concentration). These categories were identified at confidence levels of 90%, 95%, and 99%, respectively.

The results derived from the spatial analysis map indicate that the area identified as a hot spot at the highest confidence level (99%) is Mueang Udon Thani District, which functioned as the provincial center for economic activities, services, and transportation. This area exhibited a high density of tourism-related activities. Additional hot spots were identified in the northern part of the province near Nam Som District, which was characterized primarily by nature-based tourism, and in the northeastern area, likely within Ban Dung District. A key attraction in this area was Kham Chanod, a site associated with belief-based and spiritual tourism linked to local reverence for the Naga, In Thai cultural belief, the Naga is a revered mythological serpent associated with sacred sites and water landscapes, contributing to the development of belief-based and spiritual tourism, which attracted a continuous flow of visitors.

Hot spot areas were also observed along the boundary between Thung Fon and Nong Han Districts, where distinctive forms of cultural tourism were present, including Ban Chiang and the handicraft community of Ban Non Sa-at.

These areas demonstrated strong potential for the development of community-based and ecotourism-oriented tourism activities that continued to attract visitors. The spatial distribution of these hot spot areas is illustrated in Figure 4.

The identification of these areas as statistically significant clusters of tourism resources provides a basis for delineating priority tourism development zones at the provincial level.

This information can also be used as an empirical reference for the design of area-based tourism promotion policies, particularly for the development of new tourism routes that link surrounding areas with high-potential hot spots.

Spatial Density Analysis of Tourism Resources Using Kernel Density Estimation (KDE)

Spatial density analysis of tourism resources in Udon Thani Province was conducted using KDE. The results illustrate the spatial distribution of tourism resources across the province, with density values classified into five levels and visualized using a color gradient ranging from dark blue, indicating low density, to dark red, indicating high density.

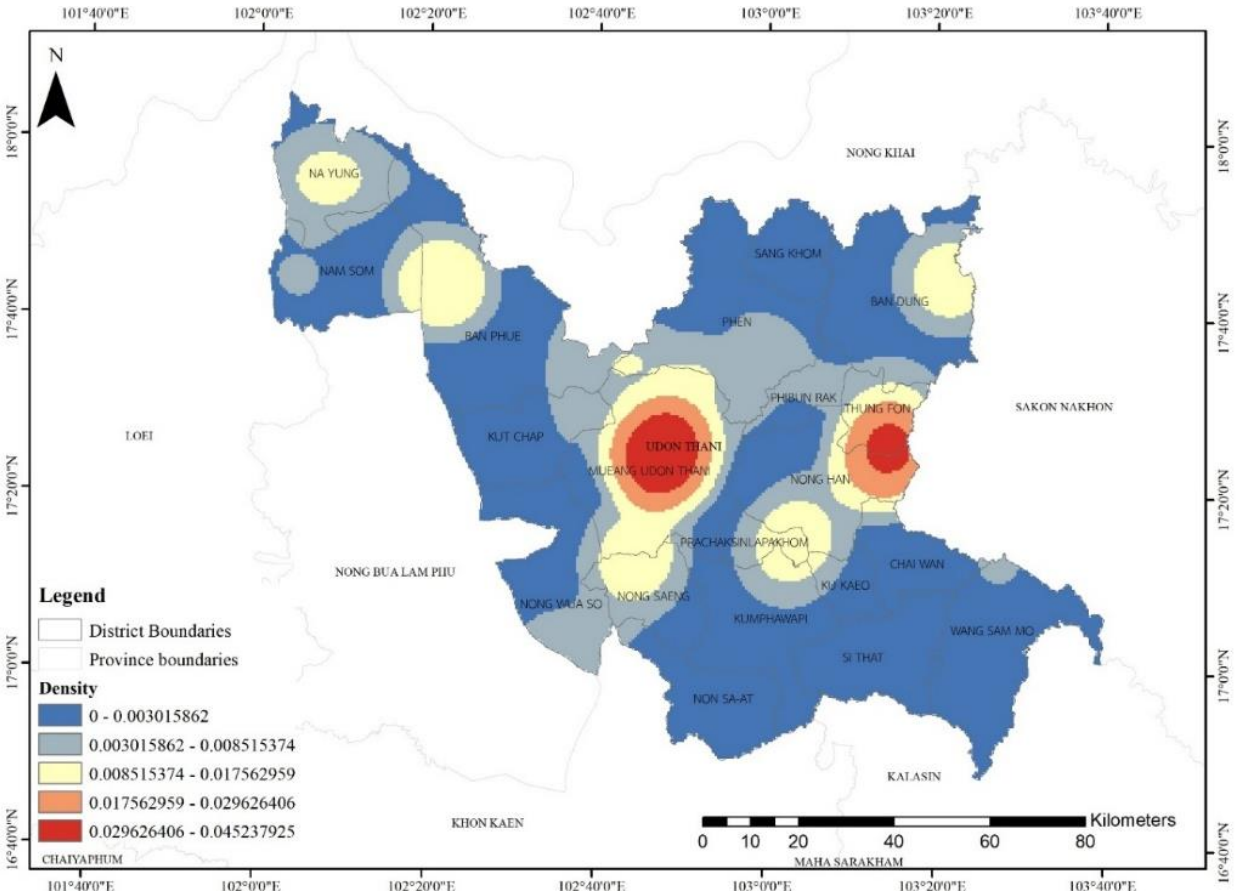

Figure 5. Spatial Density Analysis of Tourism Resources in Udon Thani

The analysis revealed that the area with the highest concentration of tourism resources was Mueang Udon Thani District, which serves as the provincial core. This was followed by Thung Fon District, where the Ban Non Sa-at sedge weaving community is located, indicating strong potential for further development as a cultural tourism and creative economy destination. Nong Han District, situated southwest of Thung Fon, exhibited a comparable level of tourism density and represents an area with opportunities for linkage with Thung Fon in terms of transportation routes, cultural

connections, and community-based activities. Nong Han District is also recognized for its potential in agricultural and historical tourism. In addition, surrounding districts such as Kumphawapi, Prachaksinlapakhom, and Phen demonstrated moderate to high density levels, suggesting opportunities to extend and connect cultural tourism activities associated with local handicraft groups to adjacent areas. In contrast, peripheral districts, including Si That, Wang Sam Mo, and Kut Chap, exhibited relatively low tourism density. These areas may require additional support in terms of infrastructure development or creative tourism initiatives to enhance their long-term tourism potential. The spatial density patterns of tourism resources identified through KDE analysis are illustrated in Figure 5.

DISCUSSION

The spatial distribution analysis of tourism resources in Udon Thani Province using the NNI indicates that the 60 identified tourism sites, classified into eight categories, exhibited a statistically significant dispersed pattern. The NNR of 1.568879, together with a high z-score of 8.499937 and a p-value of 0.000000, confirms that the observed spatial arrangement of tourism resources significantly deviates from complete spatial randomness, following the standard interpretation of the Average Nearest Neighbor method (Zhang et al., 2022). Instead, this pattern reflects underlying structural factors, including physical geography, transportation networks, settlement patterns, and socio-cultural development across the province (Wang et al., 2022; Du et al., 2024).

The dispersed spatial pattern observed in this study appears to be closely associated with the distinctive characteristics of Udon Thani Province, particularly the high proportion of religious and natural tourism sites. Religious tourism sites alone accounted for 29 of the 60 identified locations and were typically embedded within local communities distributed throughout the province rather than concentrated in a single urban core (Sae-Ngow et al., 2025). This finding contrasts with the spatial structure of highly commercialized urban tourism and is consistent with rural tourism frameworks, in which tourism resources are spatially dispersed and strongly anchored in place-based identities (Wang et al., 2023).

However, when considered alongside the results of the Optimized Hot Spot Analysis using the Getis-Ord Gi* statistic, a more nuanced spatial pattern emerged (Kato, 2025). While the overall distribution of tourism resources was dispersed, statistically significant clusters of tourism activity were evident in specific locations. The most prominent hot spot, identified at the 99% confidence level, was located in Mueang Udon Thani District. This result underscores the district's role as the provincial center for economic activity, transportation, and services, which facilitates the concentration of diverse tourism activities, including cultural attractions, museums, and commercial tourism (Xu et al., 2025).

The spatial density analysis using KDE further complements the hot spot analysis by providing a continuous representation of tourism density rather than discrete cluster classifications (Li et al., 2024). The KDE results confirm that Mueang Udon Thani District had the highest concentration of tourism resources, while Thung Fon and Nong Han Districts exhibited secondary density levels. This pattern suggests a gradual outward expansion of tourism activities from the urban core to surrounding areas through cultural, community-based, and occupational tourism initiatives (Kun et al., 2025).

Meanwhile, peripheral districts such as Si That, Wang Sam Mo, and Kut Chap displayed relatively low tourism density, revealing spatial imbalances in tourism development across the province. These disparities may be attributed to limitations in infrastructure, accessibility, or the absence of clearly differentiated tourism activities. From a policy perspective, the findings highlight opportunities to utilize areas with moderate tourism density as "linkage" or "buffer zones" between high-density hot spots and lower-potential areas (Vanhuele & Vanneste, 2025). Such an approach could help distribute tourism benefits more evenly and reduce spatial concentration (Adamczyk & Wałdykowski, 2022).

These results will have a significant impact on the area's tourism policy and growth. Provincial tourism plans should not exacerbate the already crowded urban core. Instead, they should focus on functional differentiation and spatial linkage. For instance, the Mueang Udon Thani District should be the main place for services, transportation, and coordination. Secondary districts like Thung Fon and Nong Han should be turned into cultural and community-based tourism corridors (UNWTO, 2018). Putting money into infrastructure that links different parts of the area, interpretive networks, and popular tourist attractions will help these secondary locations deal with more visitors and fix problems with space. The limitation of this study employs point-based tourist resource data and static spatial analyses, which do not incorporate temporal dynamics, visitor flows, or behavioral interconnections among venues.

Future research may integrate mobility data, time-series analysis, or spatial econometric models to examine the temporal evolution of tourism activities and the influence of policy interventions on geographical diffusion processes (Worachairungreung et al., 2026). These kinds of changes would make spatial analysis much better at helping provincial governments make decisions about tourism based on real information.

CONCLUSION

This study identified a total of 60 tourism sites with development potential in Udon Thani Province, classified into eight categories, with religious tourism sites constituting the largest proportion. This pattern reflects the province's strong cultural and belief-based tourism identity. Spatial distribution analysis using the Nearest Neighbor Index (NNI = 1.5689, $p < 0.001$) revealed a statistically significant dispersed pattern of tourism resources, indicating that their spatial arrangement is not random but shaped by local spatial contexts and community settlement patterns.

However, the Hot Spot Analysis using the Getis-Ord Gi* statistic demonstrated the presence of statistically significant clusters of tourism activities, particularly in Mueang Udon Thani District, as well as in selected areas of Ban Dung and Nam Som Districts. These locations represent specialized tourism destinations with strong attraction potential.

Furthermore, the Kernel Density Estimation (KDE) results confirmed that Mueang Udon Thani District functioned as the primary tourism activity center of the province, while Thung Fon and Nong Han Districts exhibited potential as secondary areas for linking cultural and community-based tourism activities.

A key implication of this study is that the findings provide a spatial evidence base to support the delineation of tourism development zones, the design of integrated tourism routes, and provincial-level tourism policy planning in Udon Thani Province. Policy efforts should prioritize the redistribution of tourism development toward secondary potential areas in order to promote spatial balance and long-term sustainability.

Despite its contributions, this study has several limitations that should be considered when interpreting the results. The analysis relies on tourism resource data representing a specific time period and may not capture seasonal variations or newly emerging tourism sites. In addition, the results are sensitive to the definition of the study area and parameter selection, particularly the bandwidth used in the KDE. The exploratory nature of the analysis also limits causal interpretation, as factors such as accessibility, infrastructure, and tourist behavior were not explicitly examined. Moreover, policy interpretations should be approached with caution, as areas with high tourism density may face carrying capacity constraints if not supported by appropriate management strategies.

Career anxiety among tourism guidance students: Exploring fears of AI-driven technological displacement. *Geojournal of Tourism and Geosites*, 67(3), 2314–2325. https://doi.org/10.30892/gtg.67343-1855

Abstract: There is an increasing body of academic research on how artificial intelligence (AI) will disrupt tourism, but there is a gap in studying tourism guidance students' career anxiety—who are perhaps most likely to experience job displacement from AI—and in testing educational conditions that act as moderators of their anxiety. This study fills that gap by examining AI-related career anxiety, perceptions of threat, and coping profiles among 312 students enrolled in undergraduate and graduate-level tourism guidance courses at three Egyptian universities. Based on the Career Transition Theory, we found five dimensions of anxiety: fear of being displaced by information supersession; economic insecurity; professional identity humiliation; emotional role redundancy; and self-doubt related to adaptability. All five anxiety dimensions were identified as being of great concern. However, Students whose curriculum included a component related to the direct application of AI were found to have a 0.63 standard deviation reduction in anxiety. The study produced three distinct coping profiles - Active Adapters, Uncertain Pragmatists, and Anxious Resisters - all of which demonstrated starkly different trajectories regarding commitment to their careers. The results have implications for how universities reform their curricula, for how career counselling is provided, and for how national tourism workforces are assembled.

Keywords: tourism guidance, career anxiety, AI Displacement, Technology Threat Appraisal, Professional Identity, Egypt

INTRODUCTION

The rise of AI has led to a drastic shift in the tourism guidance field. For thousands of years, tourism guides have developed their profession through cultural empathy, local knowledge, emotional connection with visitors, and relationship-building. The AI disruption (as noted by Buhalis et al. (2019) and Ivanov (2019a)) is changing this area dramatically compared to changes experienced by other service industries due to the overall level of development now seen in these technologies compared to earlier years, which have always been primarily reliant upon a human guide's cognitive and communication abilities (Huang & Rust, 2018; Tussyadiah, 2020). According to the 2025 World Economic Forum Future of Jobs Report, 92 million jobs in various sectors of the economy, including tourism (where information delivery and guest interaction are highly dependent on), are at risk of being automated until 2030 (Kang et al., 2024; Yuan & Liu, 2025).

In the vein of tourism is a critical part of Egypt's economy. The sector accounts for about 12% of Egypt's gross domestic product (GDP) and employs millions of people directly and indirectly through supply chains under pressure (Abdellah et al., 2025). Career guidance students in tourism have been particularly affected by this transformation of the tourism industry because they are simultaneously investing in educational capital, their career aspirations, and their identity. Their career path is becoming less clear (El Hajal, 2025; El Hajal & Rowson, 2020). However, for career guidance students in tourism, AI-enhanced technology is perceived as a potential threat to their professional callings because it may affect the core human attributes they associate with their profession. The skills that they have been developing, such as local area knowledge, personalized story production/creation, the study of group dynamics through management practices,

and cross-cultural/area-based emotional intelligence, will be the same types of skills that advanced AI systems are currently focused on in order to produce simulated versions of these skills (Akhilesh & Kumar, 2025; ÇOlak, 2023). Therefore, career guidance students pursuing a person-centered approach to their profession are likely to have increased anxiety about the future viability of their profession. Anticipating that their career will be disrupted has been shown to have a psychological impact similar to that of being unable to find a job (Bakir et al., 2025; Koo et al., 2021).

The current research project's theoretical framework is based on Career Transition Theory, supplemented by Technology Threat Appraisal and Professional Identity Development theories. Career Transition Theory helps researchers better understand how individuals experience employment-related uncertainty and how they respond to disruption (Li et al., 2019; Zhang & Jin, 2023). Technology Threat Appraisal theory provides an alternative lens through which to conceptualise AI's potential threat and includes two components: first is primary appraisal — which is the initial assessment of AI's potential for meaningful obstruction to an individual — and second is secondary appraisal, which refers to the evaluation of resources available to cope with possible threats (Chung & Tan, 2025). Professional Identity Development frameworks help explain how associations with career paths influence both the degree of anxiety individuals may feel surrounding AI and what type of adaptive behaviour(s) they might display (Mingotto et al., 2020; Rydzik & Kissoon, 2023). Therefore, the purpose of this study is to explore how demographic factors, education, technology experience, and institutional context relate to AI-based career anxiety. The following questions will guide this research:

- (RQ1): Which aspects of AI advances cause the most anxiety in students studying tourism guidance?
- (RQ2): How do individual and educational experiences influence perceptions of AI as a threat?
- (RQ3): How do students cope with this perceived threat, and are these coping methods effective at maintaining their career commitment?

LITERATURE REVIEW

AI Integration in Tourism and Hospitality Services

Over the last 10 years, the rapid growth of AI in tourism/hospitality operations has transformed the travel experience. From researching a destination to reviewing it after your trip, AI has transformed every stage of the travel experience (Bulchand-Gidumal, 2022; Dogru et al., 2023) and has helped differentiate between human interactions and those facilitated by AI (Kim et al., 2024; Limna, 2023). Smart destination management platforms improve the travel experience by consolidating information about weather, transportation systems, social media activity, and users' preferences to provide real-time travel recommendations. According to Katsanakis et al. (2025) and Buhalis et al. (2019), AI-based systems provide a level of accuracy and relevance in their recommendations that no human travel guide, using only their own cognitive abilities, could match. This creates an auto-improving intelligence that continually delivers better performance and lower operating costs (Huang & Rust, 2018). Multilingual conversational AI solutions can assist hundreds of travellers at once, in dozens of languages, without ever tiring or showing any signs of cultural insensitivity; a characteristic that directly diminishes one of the largest sources of professional value for human guides (Ivanov & Webster, 2019b; Lukanova & Ilieva, 2019).

Advanced AI technologies have evolved far beyond merely delivering information about tourism experiences (Hamarat et al., 2024; Mingotto et al., 2020). Using complex language models, virtual tour guides will provide unique narratives that include historical research, cultural representation through humour tailored to specific age groups, and emotional responses to tourists' emotions (Akhilesh & Kumar, 2025; Huang & Rust, 2018). Advanced computer vision systems can identify features associated with architecture and culture (including cultural artefacts) with high accuracy and provide real-time, copious contextual descriptions (documentation) of those features (Tussyadiah, 2020). While a traditional human tour guide may only be able to lead up to a few dozen tourists at once, AI technology is able to support an unlimited number of users 24 hours a day and will do so with a lower cost per user per hour (Ivanov & Webster, 2019a, 2019b). These merging capabilities pose a significant technical challenge to the provision of tourism guides in terms of scale (Zvaigzne et al., 2025). Thus, we hypothesize that:

H1a: The greater the perceived capability of AI in information delivery, the higher the level of informational displacement fear among tourism guidance students.

H1b: Students who perceive AI as capable of replicating multilingual and emotional interaction will report significantly higher overall career anxiety than those who do not.

H1c: The perceived economic advantage of AI over human guides (cost and scalability) will be positively associated with economic insecurity dimensions of career anxiety.

Human Capital Displacement Through AI Innovation

The current AI-based technology wave brings something different from the previous waves of industrial change (Rydzik & Kissoon, 2023; Tuomi et al., 2020). Historically, automation threatened mostly routine jobs that relied on rote physical work, as many of the abilities that were once thought to be safe from automation are being replicated through the use of AI technology, such as empathy, creativity, and social adaptability (Huang & Rust, 2018; Mingotto et al., 2020). Recent investigations into the requirements of large language models also indicate that the possibility of AI eliminating existing tour guide jobs in tourism-related information dissemination within the next 10 years could exceed 75% (Kang et al., 2024; Yuan & Liu, 2025). Without these estimates, one could dismiss the anxiety within the industry regarding AI and its potential impact on the job market as based solely on speculation (Hamarat et al., 2024; Ivanov & Webster, 2017).

While the economic losses associated with technological unemployment are widely recognized, there also exists a psychological, social, and identity-related aspect to the effects of such unemployment which is particularly acute in

occupations with strong vocational attachment on the part of workers (Koo et al., 2021; Zhang & Jin, 2023). According to Li et al. (2019) and Bakir et al., (2025), workers and students who believe that there's a high risk of automation in their chosen profession have greater occupational anxiety, lower work engagement levels and increased plans to leave the profession prior to experiencing actual displacement from work. For tourism guidance students, this threat is especially profound due to the fact that guidance work is not only a job but a vocational identity based on human-centred values and the belief in the irreplaceable value of authentic human interaction within cultural exchange (Anggari, 2024; El Hajal, 2025). The threat posed by AI systems to the way that guidance work exists as a source of fundamentally human-centered economic value and human-centered identities will produce greater intensity of psychological response and provide less rational reassurance than would be found in occupations in which the professional identity is less closely tied to human-specific skills (Ersoy & EhtİYar, 2023; Raina, 2023). Thus, we hypothesizes that:

H2a: Tourism guidance students who perceive a high probability of AI-driven job displacement will report significantly higher levels of career anxiety than those who perceive a low probability.

H2b: Perceived threat of AI-driven occupational displacement will be negatively associated with career commitment among tourism guidance students.

H2c: Students with stronger vocational attachment to the tourism guidance profession will experience greater professional identity erosion anxiety in response to AI displacement threats.

Student Career Development and Professional Identity Formation in the AI Era

The student population at universities is an important population to study in relation to AI-related career anxiety, which may be significantly altered before they enter the workforce (El Hajal & Rowson, 2020; Grobbelaar & Verma, 2024). Research findings regarding professional identity development indicate that the educational context is a key contributor to how students form beliefs about their profession's future and their own ability to adapt to these changes in that profession (El Hajal, 2025; Yadav & Bora, 2025). As argued by Zhang & Jin (2023) and El Hajal (2025), a curriculum that directly and critically addresses AI transformation will enable students to recognize potential AI-related threats and build greater confidence in their ability to adapt to them. Additionally, there are substantial differences in how tourism guidance programs address AI transformation. Some have developed dedicated courses that focus on the human-AI relationship and the importance of AI literacy for those employed in the tourism industry, whereas others provide traditional guidance training without reflecting on the impact of technology on the tourism guidance profession (Anggari, 2024; Kömürcü et al., 2021). These differences in curriculum create natural conditions for studying the moderating effect of AI on students' anxiety levels toward future careers – this study will focus on these differences.

Perceptual differences, including individual characteristics, influence how someone perceives the threats posed by AI technology. Higher levels of technology self-efficacy lead to greater perceived opportunity because AI offers vast potential to enhance one's job performance, but also lower pre-displacement anxiety, resulting in proactive coping (Chung & Tan, 2025; Yang et al., 2019). Those from peer networks who are optimistic about AI will have a lower degree of perceived threat because students will make moderate-sized social comparisons with their AI-optimistic peers (Koo et al., 2021). Another individual difference that has been studied is that of gender; findings suggest that female students have higher AI-related career anxiety than male students — especially in tourism, where there is a significant gender imbalance in the labour pool (Martínez-Roget et al., 2025; Rydzik & Kissoon, 2023). Thus, we hypothesize that:

H3a: Students enrolled in curricula with formal AI integration will report significantly lower career anxiety than students in traditional curricula without AI content.

H3b: Technology self-efficacy will moderate the relationship between AI threat perception and career anxiety, such that higher self-efficacy will attenuate the positive effect of threat perception on anxiety.

H3c: Female tourism guidance students will report higher levels of professional identity erosion and emotional role redundancy anxiety than male students.

H3d: Students who engage in active coping strategies in response to AI disruption will demonstrate higher levels of career commitment than those who employ avoidant coping strategies.

MATERIALS AND METHODS

Research Design and Philosophical Orientation

This research uses a quantitative cross-sectional survey approach that acknowledges the complexity of the psychological and social world while still adhering to systematic measurement and statistical inference (Tuomi et al., 2020; Tussyadiah, 2020) to test the study's conceptual model (Figure 1).

The measurement instruments used in this study were modified versions of validated scales: Career Anxiety Inventory (CAI-17) measuring five different dimensions of AI-related occupational anxiety, with a total of 17 questions rated on a five-point Likert scale; Artificial Intelligence (AI) Threat Perception (ATP-9, alpha = 0.89); Technology Self-Efficacy (TSE-8, alpha = 0.86); Professional Identity Strength (PIS-6, alpha = 0.79); Coping Strategy Orientation (CSO-12, alpha = 0.84). A pilot study with 30 students confirmed that the items were understood clearly, and the mean time to complete was about 22 minutes. Statistical significance was evaluated using the standard alpha level of .05.

Effect sizes were reported for each analysis, enabling meaningful interpretation of the data. All results were reported in accordance with APA and JARS-Quant reporting rules. The full set of survey items across all five scales is presented in Appendix 1 below. Items were generated to reflect the theoretical constructs described in the conceptual framework, grounded in the literature reviewed in Section 2, and refined through the pilot study.

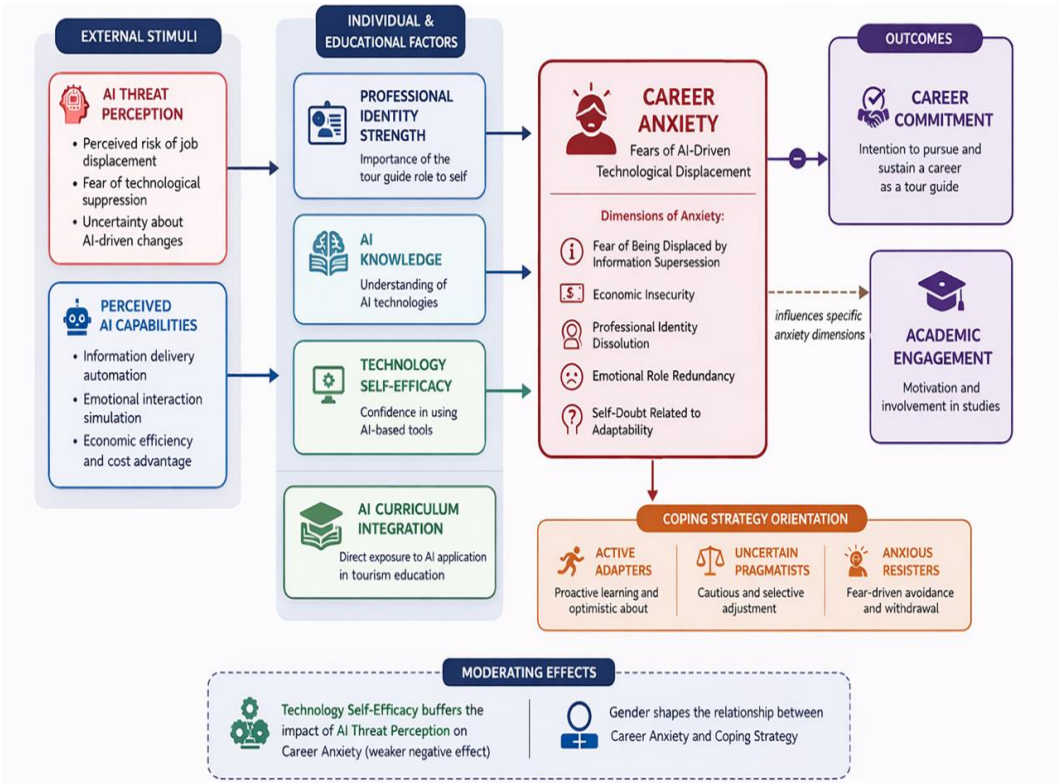

Figure 1. Conceptual Framework

Sample and Data Collection Procedures

Three distinct Egyptian universities recruited 312 undergraduate (n=201) and postgraduate (n=118) tourism students from three notably different educational backgrounds. Students were selected from the Faculty of Tourism and Hotel Management at Alexandria University, Helwan University (n=104), and Suez Canal University (n=90).

Two professional translators translated the survey instrument into Arabic, and it was then back-translated for equivalence in meaning. The three universities selected as study sites represent three very different profiles of institutions: an urban, research-oriented university that incorporates artificial intelligence (AI) into its curriculum (Alexandria University); a large metropolitan university with a more traditional curriculum for guidance (Capital University); and a regional/college that serves a large international vacation destination (Suez Canal University).

Each institution has a very different level of access to the technology used to teach and learn tourism guidance, and therefore a very different level of comfort and willingness to explore new technologies.

A structured random sampling of students was conducted, and the final total of 312 completed surveys included 168 (53.8%) female respondents and 144 (46.2%) male respondents. The year of study for the students was first year (n=58, 18.3%), second year (n=78, 24.4%), third year (n=100, 32.1%), and fourth year/postgraduate (n=79, 25.2%).

Students were asked to provide information regarding their prior formal education regarding AI in tourism; a total of 31.4% of the students reported having received any formal curriculum related to AI in tourism, but the percentage of students varied by university: Alexandria University (51.7%), Helwan University (23.1%), and Suez Canal University (12.2%). Despite the fact that the variance in AI education levels across the three institutions mirrors the differences noted throughout the region, the level of anxiety regarding AI used in tourism was not influenced by prior formal education. Data was collected between January and February of 2026. Harman's single-factor test and the unmeasured latent factor method were used to assess common method bias; both tests found no significant bias (Koo et al., 2021).

Analytical Approach

We design four phases to understand how anxiety relates to the experiences of college student anxiety and coping through a series of analyses. The first phase included confirmatory factor analysis to establish psychometric properties of all measurement instruments and model fits using CFI, TLI, RMSEA, and SRMR indices. The second phase computed descriptive statistics and bivariate correlations. The third phase used hierarchical multiple regression, with Block 1 containing demographic variables, Block 2 containing institutional/curricular variables, and Block 3 containing psychological variables. The fourth phase evaluated a structural equation model that examined the integrated theoretical framework regarding the outcome variables of academic engagement and career commitment.

Finally, cluster analysis (using Ward's hierarchical method along with K-means refinement) identified meaningful sub-groups of students exhibiting varying degrees of anxiety levels and coping strategies.

Reliability and Validity of Measurement Instruments

All CR values exceeded the recommended threshold of 0.70. Convergent validity was assessed by examining the average

variance extracted (AVE) for each scale, with acceptable convergent validity established when AVE ≥ 0.50 (Nunnally, 1978; Fornell & Larcker, 1981). All scales met this criterion. Factor loadings for all items were statistically significant ($p < 0.001$) and exceeded the recommended minimum of 0.50. Discriminant validity was established by confirming that the square root of each construct's AVE exceeded the inter-construct correlations involving that construct (Fornell & Larcker, 1981). Criterion-related validity was supported by the pattern of significant associations between scale scores and theoretically expected outcomes: for example, higher ATP-9 scores were associated with higher CAI-17 scores ($\beta = 0.54$, $p < 0.001$), and higher TSE-8 scores were associated with lower CAI-17 scores ($\beta = -0.33$, $p < 0.001$), consistent with theoretical expectations. Cross-cultural validity was supported through the systematic translation and back-translation protocol described in Section 3.1, and pilot testing with 30 students confirmed item clarity. Table 1 summarizes the reliability and validity indices for all five scales.

Table 1. Reliability and Validity Summary for All Measurement Scales

Scale	Items (n)	Cronbach's α	CR	AVE	Factor Loadings (range)	Evidence Type
Career Anxiety Inventory (CAI-17)	17	0.92	0.91	≥ 0.50 (all dims)	0.64–0.84	Convergent; discriminant; criterion validity via CFA
AI Threat Perception (ATP-9)	9	0.89	0.88	≥ 0.50	0.61–0.79	Convergent; known-groups validity (high vs. low AI exposure)
Technology Self-Efficacy (TSE-8)	8	0.86	0.85	≥ 0.50	0.59–0.78	Convergent; incremental validity in regression (ΔR^2=0.183)
Professional Identity Strength (PIS-6)	6	0.79	0.80	≥ 0.50	0.55–0.74	Convergent; discriminant from TSE; gender-invariance tested
Coping Strategy Orientation (CSO-12)	12	0.84	0.83	≥ 0.50	0.57–0.81	Convergent; cluster differentiation validity (3 profiles, F=78.42)

Note. CR = Composite Reliability; AVE = Average Variance Extracted. All factor loadings significant at $p < 0.001$. AVE ≥ 0.50 and CR ≥ 0.70 thresholds following Fornell &Larcker (1981). Cronbach's α thresholds following Nunnally (1978).

RESULTS AND DISCUSSION

Descriptive Profile of the Sample

The gender ratio of the sample was 53.8% female (n=168), consistent with the overall female/male ratio in Egyptian tourism guiding programs. The average age of participants was 21.3 years (SD=2.1; Range: 18-31), with the largest number enrolled in the 3rd year of their undergraduate program (32.1%). The average GPA of participants was 3.14 (SD=0.47) based on a 4.0 GPA scale, while participants' average use of technology was 3.42 on a 5-point scale, indicating a moderate-to-high degree of familiarity with technology prior to participating in the Program (Table 2).

Table 2. Participant Demographic and Educational Profile (N=312)

Variable	n (%)	Variable	n (%)
Age	312	Female	168 (53.8%)
Year 1	57 (18.3%)	Male	144 (46.2%)
Year 2	76 (24.4%)	GPA (4.0 scale)	312
Year 3	100 (32.1%)	Technology Engagement Score	312
Year 4 / Postgraduate	79 (25.2%)	AI Curriculum Exposure	98 (31.4%)

Overall Career Anxiety Levels

The mean overall career anxiety score was significantly above the normative score (3.67, SD = 0.71) across all five dimensions of the CAI-17 (i.e., from 1 = not at all to 5 = extremely). Therefore, the level of AI-related career anxiety measured in this study is a very great concern according to CAI-17 (as identified in the CAI-17 manual). This average score is higher than that of hotel employees (Koo et al., 2021), hospitality graduates currently experiencing AI-related disruptions (El Hajal, 2025), and tourism workers in general (Hamarat et al., 2024). With respect to the five anxiety dimensions, the greatest mean score was observed for Information Displacement Concern (3.94, SD = 0.68), which suggests that there is concern that the encyclopaedic knowledge and instantaneous recall of information possessed by the AI systems have rendered humans unable to provide information and guidance (Huang & Rust, 2018). The second-highest mean score was for Economics Insecurity (3.81, SD = 0.74), followed by Professional Identity Erosion (3.72), Emotional Role Redundancy (3.61), and Adaptational Self-Doubt (3.31). The pattern of mean anxiety scores, therefore, reveals a theoretical basis for understanding how to respond to those AI competencies that are most distressing to students, as they pertain to (information aggregation), economic efficiency, and cognitive scalability. The ranking of mean anxiety, therefore, may reflect an accurate assessment of AI risk rather than a form of technophobia. As such, there are implications for how educators address students' concerns (Bulchand-Gidumal et al., 2026; Katsanakis et al., 2025) (Table 3 and Figure 2).

Table 3. Career Anxiety Inventory (CAI-17): Descriptive Statistics by Dimension (N=312)

Anxiety Dimension	Mean	SD	Anxiety Dimension	Mean	SD
Informational Displacement Fear	3.94	0.68	Emotional Role Redundancy	3.61	0.82
Economic Insecurity	3.81	0.74	Adaptational Self-Doubt	3.31	0.88
Professional Identity Erosion	3.72	0.79	**OVERALL CAI-17 COMPOSITE**	**3.67**	**0.71**

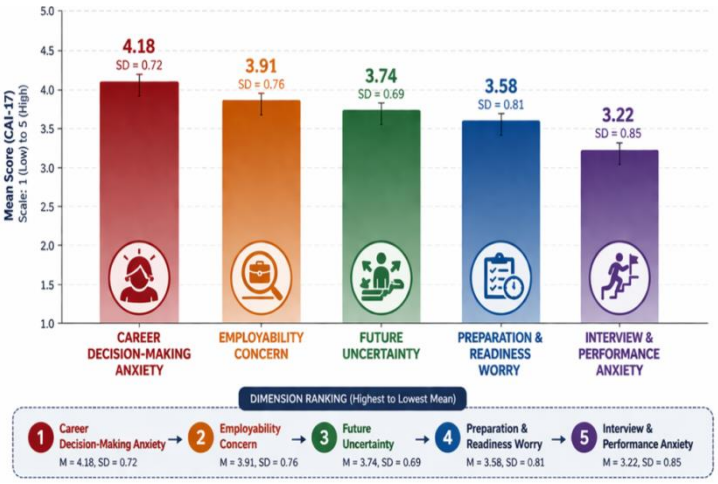

Figure 2. Career Anxiety Dimension Bar Chart

AI Threat Perception Patterns

The AI Threat Perception scale (ATP-9) found that 87.5% of all surveyed individuals regarded AI systems as a "moderate to very high" threat to their job prospects. The overall mean ATP score was 3.89 (SD=0.63), and the compressed distribution indicates a general consensus that AI represents a considerable challenge to careers. The specific ATP items with the highest mean scores related to AI's information capabilities (M=4.21, "AI systems will know more about where to go than any human tour guide"), the economic incentives for adopting AI systems (M=4.14), and the emotional simulation of advanced AI (M=3.97). These findings illustrate that students' threat perception is grounded in their understanding of AI capabilities, not simply in being overly anxious—a significant distinction, as dismissing students' worries as exaggerated or unfounded will have both empirical and pedagogical implications (Lakhapate, 2023; Zvaigzne et al., 2025). The relatively low score of "Certification through AI will replace Accreditation through Humans" (M=3.22) reflects students believe that professional licensing is providing some protection from AI, which should be of interest to national tourism policymaking because clear regulatory guidelines concerning human tour guide certification should greatly decrease the amount of fear caused by economic uncertainty (Bakir et al., 2025; Kang et al., 2024) (Table 4).

Table 4. AI Threat Perception Scale (ATP-9): Item-Level Means (N=312)

ATP Item	Mean	SD
AI will surpass human informational knowledge about destinations	4.21	0.61
Economic incentives strongly favour AI over human guides	4.14	0.67
AI will replicate emotional connection with tourists	3.97	0.74
AI language capabilities will eliminate the multilingual advantage of human guides	3.88	0.79
AI personalisation will exceed human adaptation capacity	3.77	0.81
AI availability (24/7) creates unfair competitive conditions	3.71	0.86
Tourists will prefer AI for efficiency and cost reasons	3.65	0.88
AI quality will be more consistent than human guide performance	3.58	0.91
AI certification will replace human accreditation requirements	3.22	0.97

Influence of Curriculum AI Integration on Career Anxiety

The average career anxiety score for students exposed to the formal AI curriculum in tourism (n=98, 31.4%) was 3.24 (SD=0.68), compared with 3.87 (SD=0.69) among those who did not receive the formal curriculum (n=214). The difference in means (0.63 SD) was significant ($t(310)=6.84$, $p<0.001$, Cohen's $d=0.73$), indicating that integrating AI into the curriculum is one of the most influential, modifiable moderators of career anxiety across all occupational types. Furthermore, the effect sizes seen in this study for AI-integration in curriculum outperformed those reported for previous reskilling interventions in tourism in India and Europe (El Hajal, 2025; Yadav & Bora, 2025). AI-Curriculum students' Technology Self-Efficacy scores were significantly higher (M=3.78 vs. 3.12, $p<0.001$), and AI-knowledge scores were also significantly higher (M=3.91 vs. 2.84, $p<0.001$). Approximately 62% of the variance in anxiety attributable to the curriculum effect is mediated by self-efficacy and AI-knowledge, consistent with the competence-building process outlined in the STAARA awareness model proposed by Zhang & Jin (2023). Experiencing AI through various human-AI complementary frameworks (i.e., those that acknowledge enduring human advantages compared to AI, such as cultural empathy, ethical decision-making, and depth of relationships) has been linked to the greatest reductions in both Emotional Role Redundancy and Professional Identity Erosion anxiety outcomes (Anggari, 2024; Mingotto et al., 2020). This research supports that a meaningful shift in anxiety profiles requires real competence-building and reframing rather than simply providing information (Table 5 and Figure 3).

Table 5. Career Anxiety by Curriculum AI Integration Status (N=312)

Variable	AI Curriculum (n=98)	No AI Curriculum (n=214)	t-value	p-value	Cohen's d
Overall CAI-17	3.24 (0.68)	3.87 (0.69)	6.84	<0.001	0.73
Informational Displacement Fear	3.51 (0.71)	4.15 (0.65)	7.12	<0.001	0.81

Economic Insecurity	3.47 (0.74)	3.98 (0.73)	5.21	<0.001	0.61
Professional Identity Erosion	3.22 (0.81)	3.97 (0.78)	7.05	<0.001	0.86
Technology Self-Efficacy	3.78 (0.65)	3.12 (0.71)	-7.25	<0.001	0.79
AI Knowledge Score	3.91 (0.58)	2.84 (0.74)	-11.93	<0.001	1.32

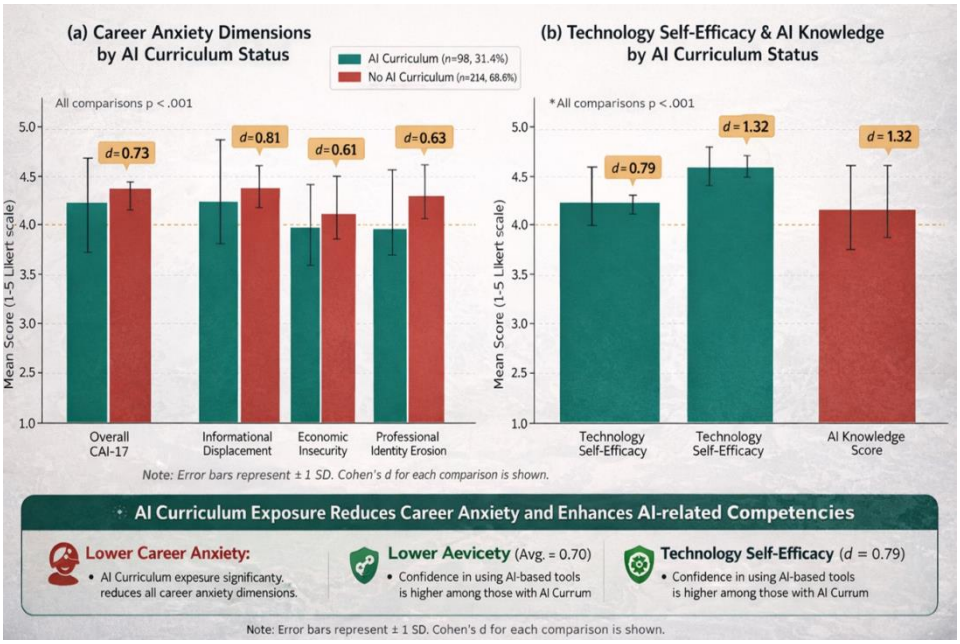

Figure 3. AI Curriculum Effect

Gender Differences in AI Career Anxiety

A gender analysis of the profiles of career anxiety revealed gender differences for students (with female students having a higher mean overall career anxiety score (M=3.79, SD=0.68) than male students (M=3.53, SD=0.73). Although the statistical significance of the results is moderate (t(310)=2.79, p=0.006, Cohen's d=0.31), the practical significance is moderate as well. Gender differences were greatest for Professional Identity Erosion (female M=3.91, male M=3.50, d=0.52) and Emotional Role Redundancy (female M=3.78, male M=3.42, d=0.44), whereas differences in Informational Displacement, Fear, and Economic Insecurity were lower and less consistent. In general, the results may suggest that female students have a heightened level of sensitivity concerning AI threats, especially related to the relational/emotional period of guidance, which, as noted by El Hajal (2025) and Drexler & Beckman Lapre (2019), female students are generally more invested in their professional identities. The use of multi-group structural equation modelling (SEM) confirms that the core theoretical paths were structurally invariant across gender, meaning that the same underlying causal mechanisms function for both male and female students despite being offset by gender-based differences in mean-level anxieties (Koo et al., 2021; Martínez-Roget et al., 2025) (Table 6).

Table 6. Career Anxiety Dimensions by Gender (N=312)

Anxiety Dimension	Female (n=168)	Male (n=144)	t	p	d
Overall CAI-17	3.79 (0.68)	3.53 (0.73)	2.79	0.006	0.31
Professional Identity Erosion	3.91 (0.74)	3.50 (0.84)	3.88	<0.001	0.52
Emotional Role Redundancy	3.78 (0.79)	3.42 (0.85)	3.28	0.001	0.44
Economic Insecurity	3.87 (0.72)	3.74 (0.77)	1.31	0.191	0.17
Informational Displacement Fear	3.99 (0.65)	3.88 (0.72)	1.21	0.228	0.16
Adaptational Self-Doubt	3.41 (0.85)	3.20 (0.91)	1.80	0.073	0.24

Technology Self-Efficacy as an Anxiety Moderator

Self-Efficacy with Technology (TSE) is the individual characteristic with the strongest predictive value for lower career-related anxiety, as shown by stepwise hierarchical regression analysis, which statistically controls for demographic and curricular variables, accounting for 18.3% of the variance in anxiety (ΔR^2=0.183, ΔF=69.74, p<0.001). The TSE Beta Coefficient was −0.42 (95% CI [−0.52, −0.32]), meaning that one (1) unit increase in self-efficacy with technology represents a 0.42-point decrease in overall career-related anxiety. This finding is consistent with the results of Zhang & Jin (2023), which demonstrated that workplace self-efficacy beliefs mediated the relationship between job insecurity and the expectation of future employment opportunities with STAARA awareness, and with Chung & Tan (2025), which demonstrated that self-efficacy in the workplace mitigated the effects of robotic work-related threat evaluations. Moderation analysis results indicated that TSE was a moderating factor in the relationship between perceived AI threats and career-related anxiety (interaction beta = -0.31, p < 0.001). Students who possessed high self-efficacy with technology demonstrated significantly lower levels of anxiety at high perceived threat than students with low TSE. The buffers created

by TSE in the relationship between perceived threats and anxiety can support initiatives to promote confidence amongst students in their ability to work with AI-integrated tourism industry products to eliminate the psychological distress experienced by many in this sample (e.g., (El Hajal, 2025; Yadav & Bora, 2025) (Table 7).

Table 7. Hierarchical Regression: Predictors of Overall Career Anxiety (N=312)

Predictor Block	Variables	ΔR^2	Beta	p

Total Model R^2	All blocks combined	**0.536**	—	**<0.001**

Coping Strategy Profiles

Through cluster analysis, three unique coping strategy profiles emerged: Active Adapters (n=89, 28.5%), Uncertain Pragmatists (n=89, 28.5%), and Anxious Resisters (n=134, 42.9%). Active Adapters show very strong scores in proactive skill development, AI literacy acquisition, and hybrid role preparation using what Anggari (2024) refers to as "complementarity orientation" (the development of new skills that compliment other existing skills) as well as El Hajal (2025) refers to as "resilience orientation" (a person's ability to bounce back from adversity and maintain motivation and focus in the face of new challenges). Active Adapters also reported significantly lower amounts of career-related anxiety (M=2.97, SD=0.71) and much higher amounts of commitment to their chosen careers (M=4.21, SD=0.58) relative to the Uncertain Pragmatist group (career anxiety, M=3.68; career commitment, M=3.74) or the Anxious Resister group (career anxiety, M=4.12; career commitment, M=3.47). Regarding the representation of the Active Adapters at each institution, Alexandria University had the highest proportion at 49.4%, with Helwan and Suez Canal Universities following at 19.2% and 14.4%, respectively. This difference supports the conclusion that differences in the integration of AI technologies into course curricula exist across these institutions and lend credence to the institutional basis of student coping orientation.

The Anxious Resister cluster represents a potential crisis; this cluster of students has the highest levels of anxiety, uses avoidant coping strategies, reports the lowest levels of AI course exposure (13.4%), and feels the least amount of commitment towards their future career. This student population represents the greatest risk to the labour market as a result of job insecurity, according to what Kang et al. (2024) identified as the "labour leakage risk" associated with AI-induced job instability (Kömürcü et al. 2021; Mabungela, 2023) (Table 8 and Figure 4).

Table 8. Coping Strategy Cluster Profiles

Profile	n (%)	Anxiety M (SD)	Career Commitment M (SD)	AI Curriculum (%)
Active Adapters	89 (28.5%)	2.97 (0.71)	4.21 (0.58)	58.4%
Uncertain Pragmatists	89 (28.5%)	3.68 (0.64)	3.74 (0.67)	28.1%
Anxious Resisters	134 (42.9%)	4.12 (0.62)	3.47 (0.74)	13.4%
ANOVA F-statistic	—	F=78.42, p<.001	F=34.17, p<.001	χ^2=41.3, p<.001

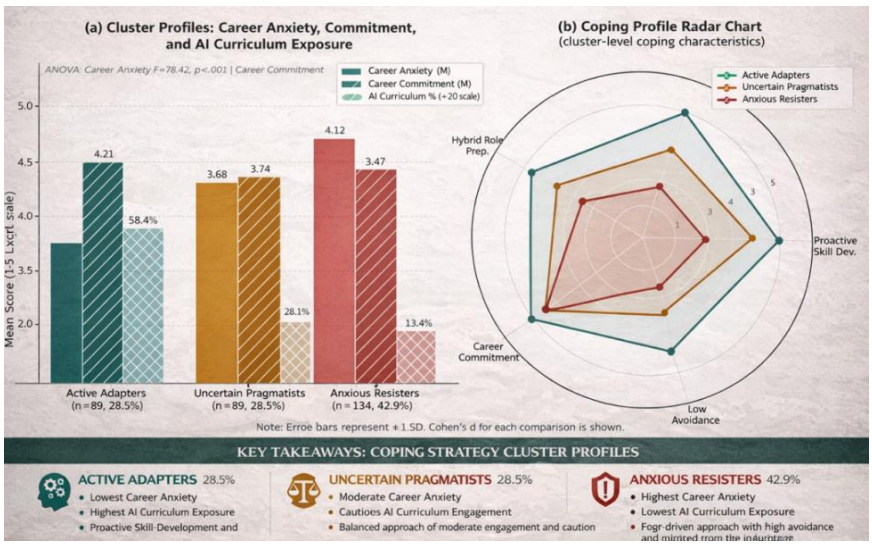

Figure 4. Coping Profiles

Structural Equation Model Results

Our structural equation models supported the hypothesized relationships among variables. The model fit indices indicated an adequately fit model (CFI = 0.94, TLI = 0.92, RMSEA = 0.055 [90% CI: 0.041 - 0.069], SRMR = 0.061).

The standardized regression coefficient for AI threat perception and overall career anxiety was 0.54 ($p < 0.001$), confirming that the cognitive appraisal of the severity of AI threat is the primary source of student anxiety; this finding aligns with Koo et al.'s (2021) and Bakir et al.'s (2025) documentation of an appraisal mechanism related to threats. The moderator effects of technology self-efficacy on the fear of AI in the workplace were also significant (moderated effect: $\beta = -0.31$; $p < 0.001$); technology self-efficacy also had a direct, negative relationship with career anxiety ($\beta = -0.33$; $p < 0.001$), supported by Zhang & Jin's (2023) and Li et al.'s (2019) findings. In addition, professional identity strength had a statistically significant direct positive relationship with career anxiety ($\beta = 0.22$; $p < 0.001$), thereby confirming the identity paradox. Career curriculum that provides opportunities to integrate AI has a direct ($\beta = -0.19$; $p = 0.004$) and indirect ($\beta = -0.14$; $p = 0.007$) effect on reducing career anxiety through increased technology self-efficacy. These results support dual-pathway effects of a career curriculum that integrates AI. Career anxiety also has a significant negative effect on career commitment ($\beta = -0.46$; $p < 0.001$), while active coping has a direct positive effect on career commitment ($\beta = 0.31$; $p < 0.001$). The model accounted for 53.6% of the variance in career anxiety and 41.2% of the variance in career commitment (Table 9 and Figure 5).

Table 9. Structural Equation Model Path Coefficients

Structural Path	Beta	SE	z	p	95% CI
AI Threat Perception → Career Anxiety	0.54	0.046	11.74	<0.001	[0.45, 0.63]
Tech Self-Efficacy → Career Anxiety	−0.33	0.051	−6.47	<0.001	[−0.43, −0.23]
Professional Identity → Career Anxiety	0.22	0.055	4.00	<0.001	[0.11, 0.33]
AI Curriculum → Career Anxiety (direct)	−0.19	0.066	−2.88	0.004	[−0.32, −0.06]
AI Curriculum → TSE (indirect pathway)	0.33	0.061	5.41	<0.001	[0.21, 0.45]
Career Anxiety → Career Commitment	−0.46	0.049	−9.39	<0.001	[−0.56, −0.36]
Active Coping → Career Commitment	0.31	0.054	5.74	<0.001	[0.20, 0.42]

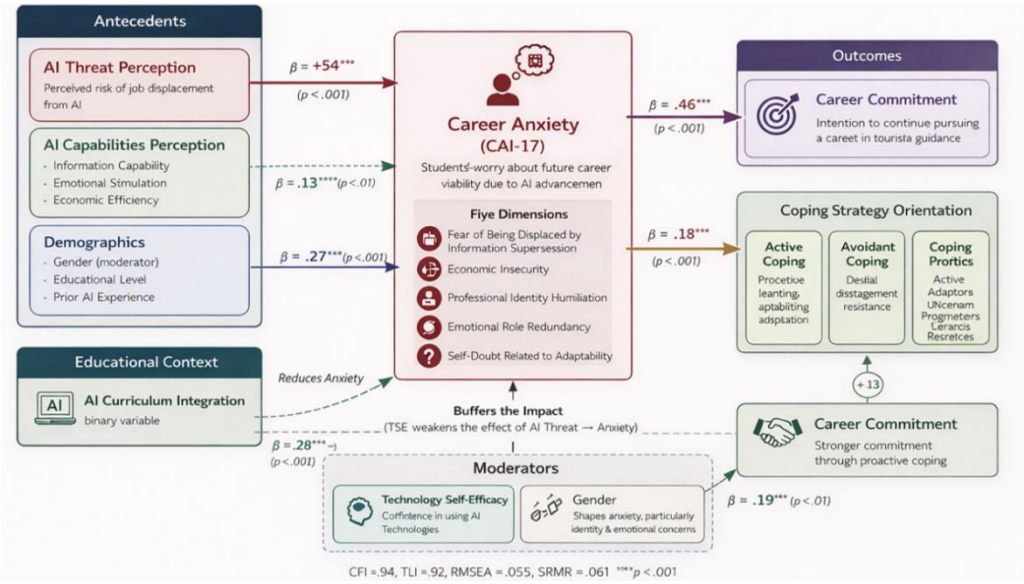

Figure 5. Tested SEM Model

Predictors of Career Commitment Maintenance

Career commitment maintenance despite heightened anxiety levels had four major positive predictor factors identified through binary logistic regression analyses. The most significant predictor of career commitment maintenance despite high anxiety was Active Coping Orientation (OR=4.23; 95% CI [2.61,6.85]; p<0.001). Students who exhibited a profile of active, adaptive coping strategies were over four times more likely to remain committed to their careers during periods of high anxiety, which underscores the importance of the resilience orientation described by El Hajal (2025). The second most influential predictive factor associated with career commitment maintenance despite high anxiety levels was exposure to AI-integrated curriculum (OR = 2.87; 95% CI [1.74,4.73]; p < 0.001). The third- and fourth-strongest predictive factors associated with career commitment retention despite anxiety were Technology Self-Efficacy (OR= 2.14; 95% CI [1.38,3.32]; p<0.001) and internship experience in AI-integrated tourism contexts (OR= 1.98; 95% CI [1.19,3.29]; p=0.009), respectively. Conversely, high levels of AI Threat Perception significantly reduced the probability of career commitment retention (OR=0.42, p<0.001), and membership in the Anxious Resister cluster (OR=0.31, p<0.001) was also negatively correlated with career commitment retention. These findings provide educators with clear points of leverage for developing targeted interventions to improve student career commitment outcomes (Anggari, 2024; Grobbelaar & Verma, 2024) (Table 10).

Table 10. Binary Logistic Regression: Predictors of Career Commitment Maintenance (N=312)

Predictor	OR	95% CI	p	Direction
Active Coping Orientation	4.23	[2.61, 6.85]	<0.001	Positive
AI Curriculum Exposure	2.87	[1.74, 4.73]	<0.001	Positive

Technology Self-Efficacy	2.14	[1.38, 3.32]	<0.001	Positive
Internship in AI-Integrated Context	1.98	[1.19, 3.29]	0.009	Positive
AI Threat Perception (high)	0.42	[0.27, 0.65]	<0.001	Negative
Anxious Resister Cluster Membership	0.31	[0.19, 0.51]	<0.001	Negative

DISCUSSION

Theoretical Contributions

This research offers several contributions to the theoretical framework of career anxiety in AI-disrupted work settings. To begin, it expands upon Career Transition Theory in tourism with regard to the anticipatory phase of career disruption. Moreover, it has been confirmed that Technology Self-Efficacy moderates the relationship between threat perception and anxiety, thereby extending Career Transition Theory's self-efficacy constructs to a specific realm of occupational threats related to Artificial Intelligence (AI) (Li et al., 2019; Zhang & Jin, 2023). This theory adjunct corresponds with Huang & Rust's (2018) theoretical proposition that individuals will need to develop an awareness of their mechanical and analytical intelligence capabilities to thrive in an environment characterized by coexistence with AI, and it corresponds to Tussyadiah's (2020) request for theoretical models that encompass the dual employment impacts of automation within the tourism sector. The results of this research suggest that elements of the appraisal process should continue to be studied to better understand how to foster positive adaptations among students in response to perceptions of AI technology as a threat. The second finding indicates that interventions designed to enhance the perceived strength or reliability of professional identity will lead to greater performance than interventions designed to enhance the perceived flexibility or adaptability of professional identity (Chung & Tan, 2025; Koo et al., 2021). Moreover, the third finding indicates that the concept of Professional Identity Resilience (PIR) can be used to measure the extent to which students have a flexible professional identity that enables successful adaptation to AI technology. Three main coping profiles for students based on empirical efforts provide additional types of contributions to the literature on planning for student careers when used as a basis for tourism education researchers to create a person-based framework for developing differentiated approaches for student support based on the student's coping profile rather than by treating all students going towards careers in the tourism field equally (Bakir et al., 2025; El Hajal, 2025).

Managerial and Educational Implications

The implications of this research are significant for administrators, curriculum designers, and career advisors within the tourism industry. The ability to incorporate an AI-based curriculum was found to be the strongest modifiable predictor of decreasing career-related anxiety, suggesting a need for an extensive reform of the tourism-related curriculum.

The research findings support the development of specifically designed modules on AI literacy for tourism professionals, allowing students to have opportunities to use AI tools in their work in a guidance capacity, as well as helping students evaluate AI's potential and limitations and how to create a professional identity that incorporates the unique human attributes necessary to successful cultural/heritage tourism. Career guidance providers should provide career counselling services that include AI Transition Coaching as a component of all career-steering services, in particular helping students develop their technology self-efficacy through successive use of AI-assisted career counselling activities and mentored reflection on the unique contributions of humans to hybrid human/AI service environments.

According to the findings, developing defined frameworks for people and AI to work together is important for organisations in the tourism industry, as these frameworks will outline the roles people play and the value each contributing factor offers in delivering services using AI. The Anxious Resister type is comprised of 42.9% of the sampled population for this study and indicates a large percentage of the up-and-coming tourism guide profession that is potentially at risk for dropping out of the industry due to a lack of understanding about their respective roles, along with the value they offer the overall organisation by utilising AI technology. Developing mentorship and internship programmes that provide students with real-world exposure to successful professionals operating as guides using the technology would foster employee retention.

The odds ratio of 1.98 for interning in AI-driven tourism guides demonstrates how limited exposure can shift students' views of AI from exclusive to inclusive. Many of the future goals for Egypt's national tourism policy will benefit from paying closer attention to how psychological factors affect workers' attitudes toward using AI to assist them in their jobs. The establishment of comprehensive professional standards within existing licensure frameworks can provide clear definitions of what constitutes successful human/AI collaboration in licensed guidance services. These standards will also give students clarity about their professional capacity to work as a licensed human guide, which may help reduce their anxiety about the economic impact of AI-based technology on their careers and future job prospects. In addition to including traditional measures of academic success, university quality assurance processes must also evaluate how well students are preparing psychologically to work in professional settings where AI will transform how professionals interact with their industry and profession.

Research Limitations and Future Directions

The study has several limitations. Causation cannot be determined because the data is collected as a snapshot in time, so we are unsure whether integrating AI into programs reduces anxiety or whether students with lower anxiety are opting into programs that have integrated AI. Longitudinal research that follows students from enrollment until they enter the workforce would enable us to determine causation more reliably. The sample comes from three universities in Egypt, which limits our ability to generalize to other geographic or cultural settings. Comparative studies that include tourism programs from the Middle East, Europe, and Asia would enable us to determine whether the patterns of anxiety identified with AI disruption in the study were universal or culturally specific. The use of self-reporting to gather the data also introduces the possibility of bias in the results. Future studies that could build upon the findings of this study might use both behavioral

measures of how students cope with anxiety in conjunction with self-reported measures related to coping with anxiety to provide evidence of convergent validity. The only perspective presented was that of the students who participated in this study; therefore, the AI's perceptions of other stakeholders, such as practicing tour guides, industry employers, and tourism faculty, would provide additional support for the students' views presented in this study. Finally, additional research could explore developing and validating the Professional Identity Resilience construct proposed in the theoretical contributions section, and determining how different AI tool typologies affect anxiety profiles related to one's career.

CONCLUSION

This research's results provide a clearer view of career-related anxiety in Egyptian tourism-guiding students regarding possible job loss due to AI-driven career displacement; in addition, they identify specific educational and psychological components that can help shield against the most severe damaging effects of this anxiety (Ersoy & EhtİYar, 2023; Hamarat et al., 2024). The mean career anxiety for students in this research was 3.67 (high relative to those measured by hotel workers (Koo et al., 2021; Yuan & Liu, 2025), suggesting students have significant concerns about how their jobs will be affected by AI. The predominance of Informational Displacement Fear (M = 3.94), as the most intense of the four types of career anxiety, is theoretically important; it indicates that students have become aware that the information part of their jobs as traditional guidance practitioners corresponds exactly to the areas in which the current wave of development in AI is the most advanced. This finding shows the students are not technophobic; rather, their concerns regarding AI are based on evidence from their evaluations of AI's capabilities; this distinction is important to note because educators who characterise student anxiety as unreasonable or overblown will never be able to address their real sources of concern.

Abstract: This study aims to examine the impact of artificial intelligence (AI), organizational intelligence (OI), and the agile Scrum methodology on operational management in the housekeeping departments of luxury hotels located in Lima, Panama City, Bogotá, and Mexico City, with a particular focus on operational efficiency, employee satisfaction, and guest service perception. A quantitative correlational–explanatory research design was adopted. Data were analyzed using structural equation modeling (SEM) to evaluate the direct and mediating effects of AI, Scrum, and organizational intelligence on key operational and human performance outcomes within luxury hotel housekeeping operations. The results reveal significant positive effects of the Scrum methodology on operational efficiency ($\beta = 0.65$) and job satisfaction ($\beta = 0.58$), as well as a strong positive effect of AI on operational efficiency ($\beta = 0.61$). Organizational intelligence emerged as a key mediating variable, exerting significant positive influences on operational efficiency ($\beta = 0.68$) and employee satisfaction ($\beta = 0.55$). The SEM model demonstrated acceptable overall goodness-of-fit indices ($\chi^2/df = 2.34$; CFI = 0.94; TLI = 0.92; RMSEA = 0.056; SRMR = 0.045), supporting the proposed theoretical framework. This study contributes original empirical evidence by integrating AI, agile management practices, and organizational intelligence within a unified model applied to housekeeping operations in luxury hotels across major Latin American cities. It advances the literature by highlighting the mediating role of organizational intelligence in digital transformation and operational professionalization within hospitality service environments.

Keywords: organizational intelligence, housekeeping, artificial intelligence, Scrum, luxury hospitality, SEM, agile management

* * * * * *

INTRODUCTION

The luxury hotel industry is undergoing a profound transformation driven by digitalization, intelligent automation, and agile management of operational processes. In this context, housekeeping departments—traditionally characterized by their hierarchical and manual structure—face the challenge of adapting to environments where operational efficiency, service quality, and guest experience are defined by the strategic use of information (Ivanov & Webster, 2020). This evolution requires new organizational capabilities focused on learning, flexibility, and continuous innovation. Recent literature underscores that hotels that successfully integrate artificial intelligence (AI) tools with agile management models, such as Scrum, not only optimize time and resources but also strengthen communication, autonomy, and collaboration among operational staff (Rigby et al., 2016, Denning, 2018). These technological and methodological transformations constitute fertile ground for the development of organizational intelligence (OI), understood as an organization's systemic capacity to process information, learn collectively, and make knowledge-based strategic decisions (Albrecht, 2003; Choo, 1998).

In the hospitality industry, AI-enabled technologies facilitate the collection, processing, and application of information across different service and operational contexts, supporting the progressive transformation of hotel management practices (Huang et al., 2022). Therefore, OI is not only conceived because of technology use, but also as a mediating mechanism between digitalization, agile management, and organizational efficiency. Despite advances in the literature on organizational intelligence and agile management, there is limited empirical research that analyzes, in an integrated manner, the role of OpI in the operational performance of housekeeping in luxury hotels in Latin America. This scientific gap motivates the present research, whose purpose is to model the structural relationships between AI, Scrum, OI, operational efficiency, job satisfaction, and service perception, through the application of structural equation modeling (SEM). The study is based on a quantitative, correlational and explanatory approach, and contributes to international literature by offering empirical evidence on how the combination of technological intelligence (AI), collective

intelligence (Scrum) and organizational intelligence (OI) enhances the professionalization of housekeeping and promotes the digital transformation of the luxury hotel sector in Latin America. Several studies have indicated that over 30% of negative reviews in high-end hotels are directly or indirectly related to failures in housekeeping cleanliness, maintenance, and coordination, even when other services exhibit high levels of performance (Parasuraman et al., 1988; Jones, 2018). This finding demonstrates that the perceived quality of hotel service is built upon internal processes that, while invisible to the guest, are crucial for the reputation, loyalty, and financial performance of hotel organizations.

In parallel, the integration of artificial intelligence (AI) in the hotel industry has advanced significantly in areas such as revenue management, digital marketing, and customer service. However, its application in labor-intensive operational processes, such as housekeeping, remains in its early stages and understudied from an organizational and strategic perspective, particularly in Latin American contexts (Ivanov & Webster, 2020; Huang et al., 2022).

AI applied to housekeeping allows for optimized cleaning scheduling, anticipation of operational demands, reduction of human error, and improved task traceability, but its real impact depends on the organization's ability to transform data into actionable knowledge. In this context, organizational intelligence (OI) emerges as a key construct. OI is defined as an organization's collective capacity to process information, learn from experience, and make effective decisions systematically (Choo, 1998; Albrecht, 2003). From this perspective, technology alone does not guarantee sustainable performance improvements; it is the interaction between technology, people, and organizational structures that allows for the generation of lasting competitive advantages. Additionally, the adoption of agile methodologies such as Scrum has demonstrated positive effects on team coordination, collaborative problem discussion, and continuous improvement in highly dynamic environments (Rigby et al., 2016, Denning, 2018). Although, Scrum was originally conceived for software development, its application in people-intensive service sectors has gained relevance, especially in organizations facing high operational variability, such as luxury hotels. Despite these advances, the literature reveals a significant gap in the integrated empirical analysis of the impact of AI, Scrum, and OI on housekeeping performance, particularly from robust quantitative approaches such as structural equation modeling (SEM).

Furthermore, there is a scarcity of multinational comparative studies in Latin America, a region characterized by the increasing professionalization of luxury hospitality, but also by structural challenges in talent management and technology adoption. These challenges are particularly relevant in the hospitality sector, where sustainable development is closely linked to employment conditions, human rights, and the quality of work within tourism organizations (Baum & Hai, 2019). From a destination management perspective, the competitiveness and sustainable development of tourism destinations require strategic planning, stakeholder coordination, and the systematic analysis of tourism resources and market conditions (Bigné et al., 2000). In response to this gap, the present study aims to model the structural relationships between artificial intelligence, the Scrum agile methodology, and organizational intelligence, and to analyze their impact on operational efficiency, job satisfaction, and service perception in the housekeeping departments of luxury hotels in Lima, Panama City, Bogotá, and Mexico City. Using a quantitative, correlational-explanatory approach and SEM, this research seeks to contribute robust empirical evidence to the international literature on hospitality.

LITERATURE REVIEW

Digital transformation in the luxury hotel industry has become a structural and cross-cutting process that redefines business models, organizational dynamics, and the overall guest experience. Beyond simply adopting emerging technologies, this phenomenon involves a profound reconfiguration of operational processes, decision-making systems, and the ways in which employees, guests, and suppliers interact. Gretzel et al. (2020) argue that smart hotels are characterized by the systemic integration of digital technologies, advanced data analytics, and organizational capabilities geared toward continuous learning, enabling them to create highly personalized and efficient experiences.

In this context, the digitization of internal processes—such as reservations management, revenue management, predictive maintenance, and housekeeping operations—significantly contributes to improving task traceability, service quality control, and responsiveness in demand. The use of property management systems (PMS), mobile platforms, and AI-based tools allows for optimized resource allocation and reduced operational errors, critical aspects in luxury establishments where customer expectations are particularly high.

However, Mariani & Baggio (2021) warn that a considerable number of digitization initiatives fail due to a lack of alignment between the implemented technology and the existing organizational culture.

This challenge is especially relevant in operational areas such as housekeeping, characterized by high workloads, high staff turnover, and, in some cases, limited digital skills. Resistance to change, coupled with the perception of technology as a control mechanism rather than a support tool, can significantly limit the impact of innovation. From a strategic perspective, digital transformation in luxury hotels should be understood as a socio-technical process, in which technology acts as an enabler of change, but whose effective performance depends on the ability of people to interpret information, coordinate actions, develop digital skills and learn collectively within the organization

Artificial Intelligence applied to Housekeeping

The application of AI in hotel operations has demonstrated positive effects on efficiency, service quality, and guest satisfaction (Al-Hyari et al., 2023). In the area of housekeeping, AI-based systems enable predictive cleaning scheduling, intelligent task assignment, and the generation of real-time reports on room status (Huang et al., 2022). Recent studies indicate that intelligent automation can reduce cleaning times by 15% to 30%, as well as decrease coordination errors between shifts (Khonjun et al., 2025). Furthermore, the incorporation of robotic devices and

intelligent sensors helps reduce the physical workload of personnel and improve working conditions (Belanche et al., 2021). However, the literature agrees that AI does not automatically generate value. Ivanov & Webster (2020) emphasize that the positive impact of automation depends on the organization's ability to integrate technology with learning and decision-making processes. In this sense, organizational intelligence emerges as a mediating mechanism that allows data to be transformed into actionable knowledge.

Scrum and Agile Management in the Hospitality Industry

The application of artificial intelligence (AI) in hotel operations has demonstrated significant effects on operational efficiency, service consistency, and resource optimization. In housekeeping, considered one of the most labor-intensive functions in luxury hotels, AI-based systems automate and improve critical processes through predictive cleaning scheduling, intelligent task allocation, and the generation of real-time reports on the status of rooms and common areas (Huang et al., 2022). These solutions rely on the analysis of large volumes of data from property management systems (PMS), occupancy sensors, and mobile platforms used by operational staff. Recent literature indicates that intelligent automation in housekeeping can reduce cleaning times by 15% to 30%, while also decreasing coordination errors between shifts and improving synchronization with other departments, such as reception and maintenance (Khonjun et al., 2025).

Furthermore, the incorporation of robotic devices, such as autonomous vacuum cleaners and smart carts, along with IoT sensors, helps to reduce the physical workload of staff, minimize ergonomic risks, and improve working conditions—factors that are particularly relevant in contexts of high operational demands (Belanche et al., 2021).

However, empirical evidence agrees that AI does not automatically generate value or guarantee sustainable performance improvements. Ivanov & Webster (2020) emphasize that the positive impact of automation depends on the organization's capacity to integrate the technology with learning, adaptation, and informed decision-making processes. In this sense, organizational intelligence emerges as a key mediating mechanism that allows the transformation of data generated by AI systems into actionable operational knowledge. The effectiveness of these solutions is therefore contingent upon staff training, digital leadership, and the existence of an organizational culture that fosters human-machine collaboration.

Organizational intelligence as a mediating variable

Organizational intelligence (OI) has been conceptualized as an organization's systemic capacity to create meaning from information, generate collective knowledge, and make effective decisions in complex and dynamic environments (Choo, 1998). This perspective views organizations as interpretive systems, in which data acquires value only when it is processed, shared, and used in a coordinated manner by organizational actors. Albrecht (2003) expands on this notion by highlighting the central role of leadership, organizational culture, and information systems in the development of OI, emphasizing that intelligence resides not only in technology but also in the interaction between people, processes, and structures. In the context of luxury hospitality, characterized by high service standards, human capital-intensive operations, and highly variable demand, organizational intelligence (OI) becomes a key strategic resource. This capability allows operational and management teams to transform real-time information—generated by AI systems, digital platforms, and agile management tools—into coordinated actions, shared learning, and sustained improvements in service quality. OpI also facilitates the anticipation of operational problems, rapid adaptation to changes in guest preferences, and the alignment of individual efforts with the hotel's strategic objectives. From an analytical perspective, organizational intelligence (OI) acts as a mediating variable between technology and organizational performance.

Specifically, it bridges the gap between artificial intelligence applied to operations and agile management practices, such as Scrum, by enhancing teams' ability to interpret information, prioritize tasks, and make collaborative decisions. Without adequate levels of OI, the implementation of AI or agile methodologies tends to produce fragmented or short-term results. Conversely, when OI is well-developed, these tools are integrated seamlessly, amplifying their positive impact on operational efficiency, employee job satisfaction, and the guest experience. Therefore, the aim of this study is to examine how Organizational Intelligence mediates the relationship between artificial intelligence applications and agile management practices such as Scrum, and their effect on organizational performance in the hospitality industry.

MATERIALS AND METHODS

Research and design approach

This study adopts a quantitative, correlational-explanatory approach with a non-experimental, cross-sectional design. This approach is particularly relevant when the research objective is to analyze structural relationships between latent constructs and evaluate complex theoretical models without resorting to the direct manipulation of independent variables (Hair et al., 2021; Kline, 2016). In organizational and hotel management studies, this type of design allows for the identification of association patterns and explanatory effects that contribute to the empirical validation of conceptual frameworks previously proposed in the literature. In the specific context of luxury hotels, operational and organizational processes are deeply integrated into real-world service delivery dynamics, where experimental intervention could generate operational biases, affect guest service quality, or raise ethical dilemmas related to staff management.

For this reason, the use of experimental designs is limited from both an ethical and operational perspective, reinforcing the appropriateness of an observational rather than an experimental approach. The cross-sectional design allowed us to capture the perceptions of housekeeping staff at a specific point in the digital transformation process, corresponding to the period 2024–2025. This methodological strategy provided a representative snapshot of the degree of adoption of artificial intelligence, agile management practices, and the levels of organizational intelligence present in the organization at the time

of the study. It also facilitated the analysis of the combined impact of these variables on operational and human performance indicators, such as perceived efficiency, work coordination, and job satisfaction. While this design does not allow us to establish definitive causal relationships, it offers robust empirical evidence to test the proposed theoretical model and generate relevant implications for strategic management in luxury hotels.

Context and study population

This research was conducted in officially categorized five-star luxury hotels located in four Latin American capital cities: Lima (Peru), Panama City (Panama), Bogotá (Colombia), and Mexico City (Mexico). These cities were intentionally selected due to their strategic importance as regional tourism hubs, their high concentration of high-end hotels, and their role as pioneering markets in the adoption of digital technologies applied to hotel management. Furthermore, these urban destinations have a diverse tourism demand—corporate, leisure, and event-related—that requires high levels of operational efficiency and service quality. Previous empirical research on urban tourism in Latin America has identified differentiated tourist segments in major cities such as Lima, Bogotá, and Mexico City, including visitors particularly attracted by lodging and restaurant services, highlighting the strategic relevance of hospitality infrastructure within urban destinations (Carvache-Franco et al., 2023).

The Latin American context is particularly relevant to the proposed analysis, given that it combines accelerated processes of digital transformation with structural challenges associated with human capital management, informal employment, and heterogeneity in levels of technological training. In this sense, the study provides empirical evidence from emerging economies, helping to balance the predominance of research focused on developed economies. Previous comparative evidence from Latin America and the Caribbean has also demonstrated heterogeneous patterns in tourism performance and its relationship with economic growth across countries in the region (Olivera et al., 2021).

From a broader tourism perspective, crisis events can expose structural vulnerabilities in destinations and organizations, highlighting the importance of adaptive capacity and strategic responses to changing environmental conditions (Hall, 2010). Within the hospitality sector, evidence from Peru further indicates that eco-innovation in accommodation establishments can contribute to sustainability, resource optimization, and competitive advantages, reinforcing the strategic relevance of innovation-oriented practices in hotel management (Cántaro Márquez et al., 2023).

The environmental transformation of the hotel industry has, however, long raised questions about whether green practices represent substantive organizational commitments rather than merely symbolic or promotional initiatives (Pizam, 2009) The target population consisted of operational staff, supervisors, and managers in the housekeeping department, a key area for value creation, perceived quality, and internal efficiency in luxury hotels. Using official records from national tourism entities, industry information, and estimates of average payrolls per establishment, a total population of approximately 1,240 employees in this department was determined.

The inclusion of different hierarchical levels allowed for the capture of diverse perspectives on the adoption of artificial intelligence, agile management practices, and organizational intelligence. This multinational approach strengthens the external validity of the study and responds to the calls in recent literature for comparative and transnational research in emerging tourism contexts (Mariani & Baggio, 2021).

The distribution of the estimated study population by country, city, and occupational category is presented in Table 1.

Table 1. Study population by country (housekeeping departments in five-star hotels) (Source: Authors' own elaboration based on official tourism accommodation records from the competent national tourism authorities of Peru, Panama, Colombia, and Mexico (2024–2025), including MINCETUR - Peru; ATP – Panama; the National Tourism Registry – RNT – Colombia; SECTUR–DataTur - Mexico)

Country / City	Hotels (5 stars)	Operation	Supervisors	Managers	Total (N)
Peru / Lima	10	280	40	10	330
Panama / Panama City	8	210	30	10	250
Colombia / Bogotá	9	270	35	10	315
Mexico / Mexico City	10	290	40	15	345
Estimated total (N)	—	1,050	145	45	1,240

Based on this population framework, an intentional sampling with predefined criteria was applied, obtaining 120 valid surveys, distributed equally among the four countries (n = 30 per country), as shown in Table 2.

Table 2. Distribution of the sample by country and position (n = 120)
(Source: Authors' own elaboration based on fieldwork, direct observation, and survey data collected during research visits, 2025)

Country / City	Operational (n)	Supervisor (n)	Manager (n)	Total (n)
Peru / Lima	22	6	2	30
Panama / Panama City	21	7	2	30
Colombia / Bogotá	23	5	2	30
Mexico / Mexico City	22	6	2	30
Total (n)	88	24	8	120

Inclusion criteria

- Formally belong to the housekeeping area during the study period (2024–2025).
- Have a minimum of one year of experience in operational or supervisory roles.

- Participate in innovation, digitization or agile management processes within the hotel.
- Having given informed and voluntary consent for participation.

Exclusion criteria

- Workers with less than six months of seniority.
- External personnel hired through outsourcing.
- Surveys with incomplete or inconsistent data.
- Hotels without official certification or with operations suspended during the study.

Sampling and selection criteria

A non-probabilistic, purposive sampling method was used, a technique widely employed in organizational studies when it is necessary to select participants with specific characteristics related to the phenomenon under study (Hair et al., 2019). The inclusion criteria considered: (i) formal membership in the housekeeping area, (ii) a minimum of one year of experience, (iii) participation in innovation or digitization processes, and (iv) informed consent.

The final sample size was 120 valid surveys (30 per country), a figure that meets the minimum requirements for the application of SEM, considering the complexity of the model and the number of estimated parameters (Kline, 2016).

Measuring instrument

The data collection instrument consisted of a structured Likert-type questionnaire with five points, composed of items distributed in five constructs: applied artificial intelligence, agile management with Scrum, organizational intelligence, operational efficiency and job satisfaction/service perception.

The items were adapted from scales validated in previous studies (Albrecht, 2003; Choo, 1998; Hair et al., 2021) and contextualized to the hotel housekeeping environment. A panel of experts in hotel management and research methodology evaluated the content validity of the instrument. The instrument consisted of a structured Likert-type questionnaire with five points (1 = strongly disagree, 5 = strongly agree), composed of items distributed across five constructs:

1. AI Prediction
2. Agile Management with Scrum
3. Organizational Intelligence
4. Operational Efficiency
5. Job Satisfaction and Service Perception

The items were adapted from previous research by Albrecht (2003), Choo (1998) and Hair et al. (2021). Confirmatory factorial validation (CFA) showed convergent validity (AVE > 0.50) and composite reliability (CR > 0.70) in all constructs.

Data Procedure and Analysis

Data collection was carried out using anonymous digital questionnaires, distributed with the support of human resources management. The data were analyzed using SPSS v.28 for descriptive statistics and AMOS v.26 for structural equation modeling. The Maximum Likelihood (ML) method was used and absolute, incremental and parsimonious fit indices (χ^2/df, CFI, TLI, RMSEA and SRMR) were evaluated, following the criteria established by Hair et al. (2019).

RESULTS AND DISCUSSION

Structural Equation Modeling (SEM) analysis allowed for the empirical validation of the proposed theoretical framework, revealing significant and coherent relationships between the variables artificial intelligence (AI), Scrum agile methodology, organizational intelligence (OI), operational efficiency, job satisfaction, and service perception.

The use of SEM proved particularly suitable for this study, as it enabled the simultaneous analysis of direct and indirect relationships between latent constructs, as well as the evaluation of OI's mediating role within a complex explanatory model. The results of the confirmatory factor analysis demonstrated adequate construct validity for all factors analyzed. Specifically, the composite reliability values exceeded the recommended threshold (CR > 0.70), while the mean variance extracted reached values greater than 0.50 (AVE > 0.50), supporting both the internal consistency of the instrument and the convergence of the items within their respective constructs (Fornell & Larcker, 1981; Hair et al., 2021). Furthermore, discriminant validity was verified, demonstrating that each construct captures a distinct theoretical phenomenon, an essential condition for the robustness of the structural model. In terms of overall fitness, the SEM model achieved satisfactory indices aligned with the ranges recommended by the specialized literature. The values obtained (χ^2/df = 2.34; CFI = 0.94; TLI = 0.92; RMSEA = 0.056; SRMR = 0.045) indicate an optimal fit between the theoretical model and the empirical data, confirming the adequacy of the structural specification. These results guarantee the overall validity of the model and allow progress toward a substantive interpretation of the proposed relationships.

Structural analysis of direct and indirect relationships

Structural analysis revealed that the Scrum agile methodology has positive and statistically significant effects on two key dimensions of organizational performance. First, a high impact on operational efficiency was observed ($\beta = 0.65$, $p < 0.001$), suggesting that the adoption of agile practices—such as iterative planning, follow-up meetings, and team self-organizations substantially contributes to optimizing workflows in the housekeeping area. Second, Scrum showed a

significant effect on job satisfaction ($\beta = 0.58$, $p < 0.001$), indicating that collaborative work environments, with greater clarity in roles and objectives, strengthen staff commitment and motivation. This result is consistent with self-determination theory, which suggests that work environments that support autonomy, competence, and relatedness foster higher levels of motivation and psychological well-being (Deci & Ryan, 2000). Additionally, artificial intelligence demonstrated a direct and significant impact on operational efficiency ($\beta = 0.61$, $p < 0.001$). This result confirms that the incorporation of predictive systems, intelligent task assignment algorithms, and real-time digital monitoring tools contributes to improved time management, shift coordination, and process control in housekeeping.

However, the direct effect of AI on human variables, such as job satisfaction, was less pronounced, reinforcing the idea that technology alone does not guarantee comprehensive improvements in organizational performance. In this context, the model's most relevant finding is the role of organizational intelligence as a mediating variable between agile management practices, AI adoption, and operational and human outcomes. The results reveal that OI has a positive and significant impact on both operational efficiency ($\beta = 0.68$, $p < 0.001$) and job satisfaction ($\beta = 0.55$, $p < 0.001$).

These coefficients confirm that teams with greater capabilities in collective learning, information interpretation, and shared decision-making achieve higher levels of productivity and employee well- being. The mediation of organizational intelligence suggests that the benefits of AI and Scrum are fully realized only when the organization has effective mechanisms for transforming data into actionable knowledge. Without a well-developed organizational intelligence framework, technology and agile methodologies tend to produce fragmented or short-term impacts. This finding is consistent with recent evidence showing that the impact of AI on organizational performance is strengthened by organizational capabilities such as digital innovation and organizational agility (Alhomaid & Al-Romeedy, 2026).

Impact on service perception

Regarding guest experience, the results show that both operational efficiency ($\beta = 0.70$, $p < 0.001$) and job satisfaction ($\beta = 0.52$, $p < 0.001$) significantly influence the perception of housekeeping service. This finding reinforces the idea that perceived quality depends not only on processes visible to the customer, but also on internal factors related to staff well-being and effective team coordination. Furthermore, the mediation of organizational intelligence reinforced the indirect link between artificial intelligence and service perception, confirming that information-based decisions, when interpreted and applied collectively, consistently contribute to improving the guest experience. In this way, organizational intelligence is positioned as a key mechanism for translating technological innovation into perceived value.

Complementary operational performance indicators

From a practical perspective, the analysis was complemented by quantitative operational performance indicators (see Table 3), which reflect tangible improvements following the joint implementation of AI, Scrum, and organizational intelligence. These indicators include reductions in average cleaning times, improvements in inter-shift coordination, and increased service consistency, empirically supporting the results obtained through the SEM model. Taken together, these findings confirm the relevance of an integrated approach that combines technology, agile management, and organizational intelligence to strengthen sustainable performance in the luxury hotel industry.

Table 3. Quantitative indicators derived from the SEM model (Source: Authors' own elaboration based on housekeeping operational records, field observations, and survey data collected during the study, 2024–2025)

Indicator	Initial situation	Post-implementation	Variation (%)
Average cleaning time per room	42 min	32 min	-23.7%
Task assignment errors	11%	3%	-72.7%
Internal staff satisfaction	58%	82%	+41.4%
NPS index associated with the cleaning service	63.9	85.0	+21.1 points

The results obtained from the structural equation modeling (SEM) confirm the strategic relevance of integrating the agile Scrum methodology, artificial intelligence (AI), and organizational intelligence (OI) into the management of housekeeping in luxury hotels. This combination should not be understood as a sum of isolated tools, but rather as a systemic synergy between advanced technology, organizational learning, and collaborative management practices. Together, these elements allow for the transformation of traditionally rigid, standardized processes highly dependent on hierarchical control into flexible, adaptive systems oriented toward knowledge-based decision-making—a crucial aspect in hotel environments characterized by high operational variability and demanding high service quality standards. The most significant finding of the study lies in the mediating role of organizational intelligence, which substantially strengthened the links between Scrum adoption, AI use, and operational and human outcomes.

This result aligns with the theoretical proposals of Choo (1998) and Albrecht (2003), who argue that organizational intelligence (OI) enables organizations not only to process information efficiently but also to construct collective meaning, learn from experience, and respond effectively to dynamic and uncertain environments. In this study, teams with higher levels of OI achieved superior performance in operational efficiency ($\beta = 0.68$) and job satisfaction ($\beta = 0.55$), demonstrating that knowledge management and collective learning capacity are key determinants of organizational performance in the context of luxury hospitality. Furthermore, the results confirm that adopting Scrum promotes an organizational culture based on responsible autonomy, interdisciplinary cooperation, and continuous feedback—elements that are particularly valuable in human capital-intensive operational areas such as housekeeping.

As Rigby et al. (2016) and Denning (2018) point out, agile methodologies facilitate team self-organization, increase process transparency, and strengthen a sense of shared purpose. In this study, implementing Scrum reduced average cleaning times by 23.7% and decreased task assignment errors by 72.7%, generating tangible improvements in productivity and coordination. These results align with the findings of Serrador & Pinto (2015), who demonstrated that teams adopting agile approaches in service environments exhibit higher levels of organizational performance and employee satisfaction compared to those operating under traditional frameworks.

For its part, artificial intelligence strengthened data-driven decision-making, contributing directly and significantly to operational efficiency ($\beta = 0.61$). This finding is consistent with the arguments of Ivanov & Webster (2020) and Huang et al. (2022), who contend that intelligent automation and predictive systems improve resource allocation, task traceability, and the ability to anticipate customer needs. In the case analyzed, AI did not replace human decision-making but rather acted as a catalyst for organizational intelligence, providing actionable information that facilitated coordination among Scrum teams and reduced operational uncertainty. This result reinforces the notion of human-machine complementarity, particularly relevant in high-touch services such as luxury hospitality. The structural model also revealed that both operational efficiency ($\beta = 0.70$) and job satisfaction ($\beta = 0.52$) significantly influence guest perception of service.

This finding empirically reinforces the service-benefit chain theory proposed by Heskett et al. (1994), which posits that external service quality is a direct consequence of internal service quality and employee well-being. Hotels with higher levels of operational efficiency and more consolidated agile management not only showed increases in productivity but also improved guest perception regarding the consistency, cleanliness, and reliability of the service received—critical aspects of the luxury experience. From a theoretical perspective, these results provide relevant empirical evidence to the literature on smart hotel management, demonstrating that organizational intelligence acts as a key mediating mechanism between emerging technologies and organizational outcomes. In this way, a technocentric view of innovation is overcome, showing that the true value of AI and agile methodologies is realized when the organization possesses internal capabilities to interpret, share, and apply the knowledge generated. In this sense, the housekeeping area ceases to be conceived as an operational unit subordinate to routine and control and is instead positioned as a strategic space for organizational innovation, the professionalization of human talent, and the generation of sustainable value.

In summary, the study supports the premise that the future of housekeeping in luxury hotels depends on its ability to learn, adapt, and make collective decisions through AI systems integrated with agile management frameworks and high levels of organizational intelligence. These findings not only confirm the hypotheses of the proposed theoretical model but also broaden the scope of organizational intelligence theory applied to the hospitality sector. Taken together, the results consolidate an emerging paradigm of hotel management based on knowledge, technology, and agility, capable of responding to the growing demands for efficiency, quality, and customer experience in contemporary luxury hotels.

Synthesis of the structural model

Figure illustrates the final validated model, showing the standardized coefficients and the significant relationships between the main variables. In summary, the study's results confirm that the strategic combination of agile methodologies such as Scrum, artificial intelligence, and organizational intelligence drives intelligent organizational transformation into luxury hotels. This integration not only optimizes operational processes and team coordination but also strengthens collective learning and data-driven decision-making. As a result, there is a comprehensive improvement in internal productivity, staff well-being, and service consistency, leading to higher levels of guest satisfaction and a sustainable competitive advantage for high-end hotel organizations.

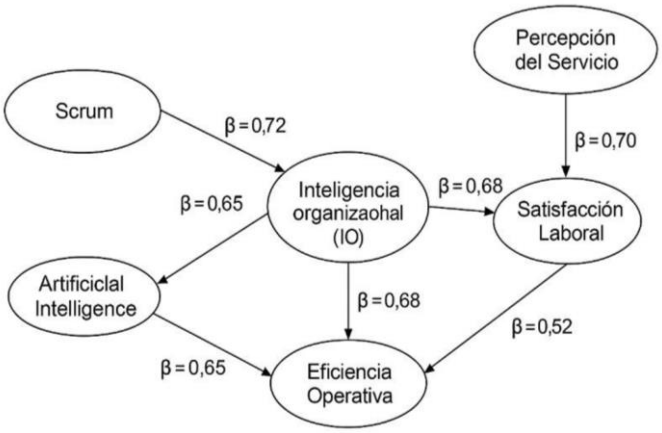

Figure 1. Structural equation model of the impact of Scrum, AI and OI on housekeeping efficiency
(Source: Authors' own elaboration using IBM SPSS AMOS, 2025)

CONCLUSION

This study demonstrated that integrating organizational intelligence (OI) with the Scrum agile methodology and artificial intelligence (AI) constitutes an innovative, coherent, and highly efficient management model for housekeeping in luxury hotels. Unlike traditional approaches focused solely on task automation, the results show that the true value of

digital transformation emerges when technology is combined with organizational capabilities geared toward collective learning, collaboration, and informed decision-making. Structural equation modeling (SEM) empirically confirmed that organizational intelligence acts as a key mediating variable between agile management practices and operational performance. In particular, OI enhances the effects of Scrum and AI on critical outcomes such as operational efficiency, employee job satisfaction, and guest service perception. These findings reinforce the notion that technological innovation alone does not guarantee sustainable improvements in organizational performance if it is not accompanied by cognitive and social processes that transform information into actionable knowledge. The most relevant results of the study can be summarized in five key aspects. First, it is evident that the Scrum agile methodology and AI strengthen organizational intelligence by promoting collaborative work dynamics, greater transparency in processes, and more effective use of data for decision-making. Second, OI directly improves operational efficiency ($\beta = 0.68$) and job satisfaction ($\beta = 0.55$), establishing itself as the cognitive axis that connects technology with human behavior within the organization. Third, operational efficiency ($\beta = 0.70$) and job satisfaction ($\beta = 0.52$) significantly impact service perception, empirically validating the service-benefit chain model proposed by Heskett et al. (1994).

Additionally, the results confirm that artificial intelligence contributes to task prediction and traceability, optimizing time management and reducing operational errors by 72.7%, which translates into greater service consistency and reliability. Finally, the SEM model achieved robust fit indices (CFI = 0.94; TLI = 0.92; RMSEA = 0.056), confirming its statistical soundness and theoretical coherence. Taken together, these results allow us to conclude that the development of organizational intelligence in housekeeping fosters staff professionalization, service sustainability, and the digital transformation of the Latin American hotel sector. In short, the convergence of technological intelligence, collective intelligence, and organizational intelligence constitutes a solid path toward operational excellence and smart hospitality, strengthening the competitive positioning of luxury hotels in Latin America.

Funding: This research received no external funding. The APC was funded by the authors.

Informed Consent Statement: The study was conducted in accordance with the ethical principles of the Declaration of Helsinki. Participation was voluntary, and we obtained informed consent from all participants before they completed the questionnaire. We ensured participants' anonymity and confidentiality throughout the study.

Data Availability Statement: The data presented in this study are available on request from the corresponding author. The data are not publicly available due to confidentiality and privacy considerations concerning the participants and the participating hotel establishments.

Acknowledgement: The authors would like to express their sincere gratitude to the housekeeping staff, supervisors, and managers of the luxury hotels in Lima, Panama City, Bogotá, and Mexico City who voluntarily participated in this study and shared their time, experiences, and insights. Their collaboration was essential for the successful collection of empirical data and the validation of the proposed structural model.

Conflicts of Interest: The authors declare no conflict of interest. This research received no external funding; therefore, no funding body had any role in the design of the study; in the collection, analysis, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

Use of Generative AI: Generative artificial intelligence tools were used solely to support the initial exploratory identification of potentially relevant literature during the literature review process. All identified sources were subsequently independently verified, screened, and evaluated by the authors using the established inclusion and relevance criteria. Generative AI was not used for primary data collection or statistical analysis. The authors take full responsibility for the accuracy, integrity, and originality of the manuscript.

Tourism development in the West Kazakhstan economic district: Current trends and forecasts. *Geojournal of Tourism and Geosites*, 67(3), 2335–2344. https://doi.org/10.30892/gtg.67345-1857

Abstract: As a major economic diversification strategy, tourism in Kazakhstan has gained significant attention as a means of economic development in the region, but the West Kazakhstan Economic District is still underresearched. The paper fills the latter gap by integrating both bibliometric analysis of the scientific output and econometricзирование of the tourism flows to the four administrative units of the Aktobe, Atyrau, West Kazakhstan and Mangystau. With an emphasis on the official statistical trends related to the years 2003-2024, we review the patterns of visitors, housing facilities, and occupancy rates, and place the results of the empirical study in the context of the general academic discourse on the theme of sustainable tourism, cultural heritage, and regional inequalities. Bibliometric analysis (PRISMA and VOSviewer) shows that there is an increasing tendency of the research to move away from descriptive methods and more advanced analytical techniques, but the Western regions are still left behind in the scope of scientific interest. According to our econometric forecasts, on the basis of HoltWanters exponential smoothing model (ETS), we can see the existence of heterogeneous trends among regions: Mangystau is the main region of growth with high stability and rising tourist expenditures, and Aktobe and West Kazakhstan are gradually, yet steadily improved. In turn, Atyrau is very volatile, indicating a structural mismatch between demand and supply. The combination of bibliometric knowledge with time-series forecasting offers contributions to theory and practice, including evidence of uneven development in tourism in Kazakhstan and the presence of the district as a microcosm of the larger national issues. The results highlight the necessity of policy cohortation, which balances infrastructural investments, institutional redesign and input of local communities, in a bid to guarantee the sustainability of tourism development in the western region of the nation.

Keywords: West Kazakhstan district, tourism development, bibliometric analysis, ETS model, forecasting, sustainable tourism

* * * * * *

INTRODUCTION

The development of tourism in Kazakhstan has attracted increasing attention in recent decades, as it represents an important instrument of diversification of the national economy and regional development. The need for a sustainable model of tourism and regionally differentiated policies is emphasized in the literature (Aimagambetov et al., 2017; Trišić et al., 2021). Research indicates that tourism can contribute to local communities through employment, income growth and infrastructural development (Aliyeva et al., 2019), while the concept of the "experience economy" confirms the growing

demand for authentic experiences and cultural values (Kenzhebekov et al., 2021). More modern works, based on advanced econometric analyses, enable a deeper understanding of tourism demand factors and more reliable development forecasts (Serikbayeva et al., 2025), while limited resources, insufficient promotion and infrastructural weaknesses are recognized as key challenges in the field of ecotourism (Tleuberdinova et al., 2025). Despite the growing literature, tourism in the West Economic District of Kazakhstan remains under-researched, although the region possesses significant natural and cultural resources and lags in diversification and strategic positioning (Smanov et al., 2025).

This gap justifies the goal of the research: providing a comprehensive insight into the current state of tourism in West Kazakhstan and identifying key opportunities and perspectives for future development, through linking a systematic review of the literature with bibliometric analysis and econometric forecasts.

RQ1. How did the trends in the number of visitors in the regions of West Kazakhstan change during the period 2003–2024, and are there significant differences between them?

RQ2. To what extent did the changes in the number of rooms and the occupancy rate follow the growth of tourist traffic and can we talk about overcapacity in certain regions?

RQ3. How do the relationships between the number of visitors and the income from accommodation differ by region and what does this say about the average spending of tourists?

RQ4. What are the main thematic areas and research trends in the tourism literature in Kazakhstan and to what extent have the western regions been represented in scholarly analyses?

RQ5. What forecasts of the development of tourism until 2030 does it provide?

The innovativeness of this study is reflected in its integrated approach that connects the analysis of empirical data on tourist flows with a bibliometric review of research production. In this way, the work simultaneously illuminates real economic trends and the way in which they are recognized in the scientific community. A special contribution lies in the use of the ETS model (Holt–Winters Exponential Smoothing Model) for forecasting future trends in tourism in West Kazakhstan, with precise validation of the forecast through relevant metrics. This methodological framework enables more reliable forecasting and offers practical guidelines for the improvement of regional tourism policies.

At the same time, the study opens new directions of research in the context of the Central Asian area, providing a basis for comparative analyzes and the transfer of knowledge to similar economic and social frameworks.

LITERATURE REVIEW

The development of tourism in Kazakhstan attracts the attention of researchers, but approaches in the literature develop in different directions. Early works, such as that of Batyrova et al. (2018), provide useful insights into structural problems of competitiveness and institutional weaknesses, but critically, their focus on identifying barriers does not deepen understanding of the mechanisms of sustainable development. Also, the works that follow (Ramazanova et al., 2019; Seken et al., 2019) often dwell on descriptive analyses, recognizing the potential of rural tourism, but without providing concrete solutions for overcoming infrastructural and promotional barriers. Although these works emphasize the importance of rural tourism, they are not sufficiently linked to concrete institutional strategies that would enable long-term sustainability.

Kozhokulov et al. (2019) provide a valuable analysis of the socioeconomic effects of tourism in the Issyk-Kul region of Kyrgyzstan, but their research, like most similar studies in Kazakhstan, is not fully applied to the western part of the country, and often ignores the specific challenges that Kazakhstan faces in terms of regional dislocation and political factors. In the following works, like Altynbassov et al. (2021) and Chlachula et al. (2021), there is a broader framework, which includes aspects of education, regulation and ecotourism, but these are still not linked to economic projections and sustainable development models. Many studies fail to conduct analyzes that would allow for the assessment of the long-term effects of these initiatives, while their recommendations are often based on general claims about potential without clear concrete guidelines for implementation. Since 2023, research has increasingly focused on the specifics of each region, but works such as those of Sergeyeva et al. (2023) and Saparov et al. (2024) still limit the analyzes to the micro level, not integrating quantitative models that would allow the creation of predictions for future development.

Salauatova et al. (2024) and Kadyrbekova et al. (2024) shift the focus to cultural heritage and its strategic application in tourism, but do not offer concrete instruments to overcome the recognition of cultural resources as market value. Although these works can be considered significant for the detailed investigation of micro aspects of tourism, their contribution to strategic planning and implementation remains weak due to the lack of quantitative tools and long-term forecasts. Recent studies, such as the works of Omirzakova & Wendt (2025) and Konysbek et al. (2025), focus on institutional and infrastructural constraints, but still do not consider the complexity of institutions that shape tourism development in the specific regional and cultural contexts of Kazakhstan. Panibratov et al. (2025) provide a broader perspective through the analysis of international integration, but their work does not deal deeply enough with the challenges that Kazakhstan has in terms of developing sustainable tourism, taking into account the environmental, social and political spheres.

Although the results of these researches are useful, their practical application and integration into actual policies and strategies of tourism development in Kazakhstan remains uncertain and undefined. Previous literature shows that researchers have successfully identified the key challenges and resources of tourism in Kazakhstan, but often without quantitative validation and forecasts to enable operational planning. Wendt (2020) provides a critical review of the weaknesses of previous research, emphasizing the need for quantitative models and geoinformation tools, which is directly related to our bibliometric approach. Similarly, Daye et al. (2020) emphasize that the development of tourism in Kazakhstan should not be viewed in isolation, but within the framework of international processes, especially in the context of China's

"Belt and Road" initiative. Their work is methodologically based on qualitative approaches through the analysis of the views of local stakeholders, which is important for understanding the political-economic conditioning of the tourism sector, but at the same time shows limitations when it comes to measuring long-term trends and predicting future flows.

Despite these contributions, the methodological base of tourism research in Kazakhstan remains modest. Dominant methods still include descriptive statistics, comparative case studies and qualitative surveys, while GIS analysis and bibliometric approaches are occasionally used to map potential and research trends (Chashina et al., 2020; Popović et al., 2025). However, econometric time series and ETS forecasting models are rarely included in analyses, even though they would enable more reliable forecasts and operational planning. For example, Akhmedenov (2020) assesses the possibilities of religious tourism in West Kazakhstan, but uses descriptive and evaluative methods, without including projections that would confirm the long-term potential of the identified resources.

Similarly, studies of natural recreational potential (Chashina et al., 2020) map resources and indicate their importance, but do not offer quantitative models to show development dynamics. In this sense, the justification of our methodology stems precisely from the lack of works that connect bibliometric analysis of research production (using PRISMA and VOSviewer protocols) with econometric forecasts of tourist traffic (ETS model).

Such an integrated approach enables a simultaneous observation of real economic trends and the way in which they are recognized in the scientific community, which overcomes the limitations of previous studies and provides a more reliable framework for strategic planning of tourism in the West Kazakhstan region.

METHODOLOGY

The research was conducted with the aim of reviewing the development of the tourism sector in West Kazakhstan, with a special focus on four administrative units: Aktobe, Atyrau, West Kazakhstan and Mangistau, as well as on the unified West Kazakhstan Economic District. In this paper, West Kazakhstan is viewed through the prism of the West Kazakhstan Economic District, an administrative-statistical unit that includes four areas: Aktobe, Atyrau, West Kazakhstan and Mangistau (Rosen et al., 2000). The term district in this context means a unified economic unit that exceeds the boundaries of individual areas (regions) and is used in official statistics and strategic documents of the Republic of Kazakhstan to monitor macroeconomic flows (Robinson et al., 2023). Unlike the administrative "region" (e.g. West Kazakhstan Region), which refers to one area, the economic district includes several areas and enables a more comprehensive overview of development processes (Smith, 2019). This is precisely why this paper uses the term West Kazakhstan Economic District, because it best reflects the broader scope of the research and enables a comparable analysis of tourist traffic and economic effects at the level of an integrated whole, rather than individual areas.

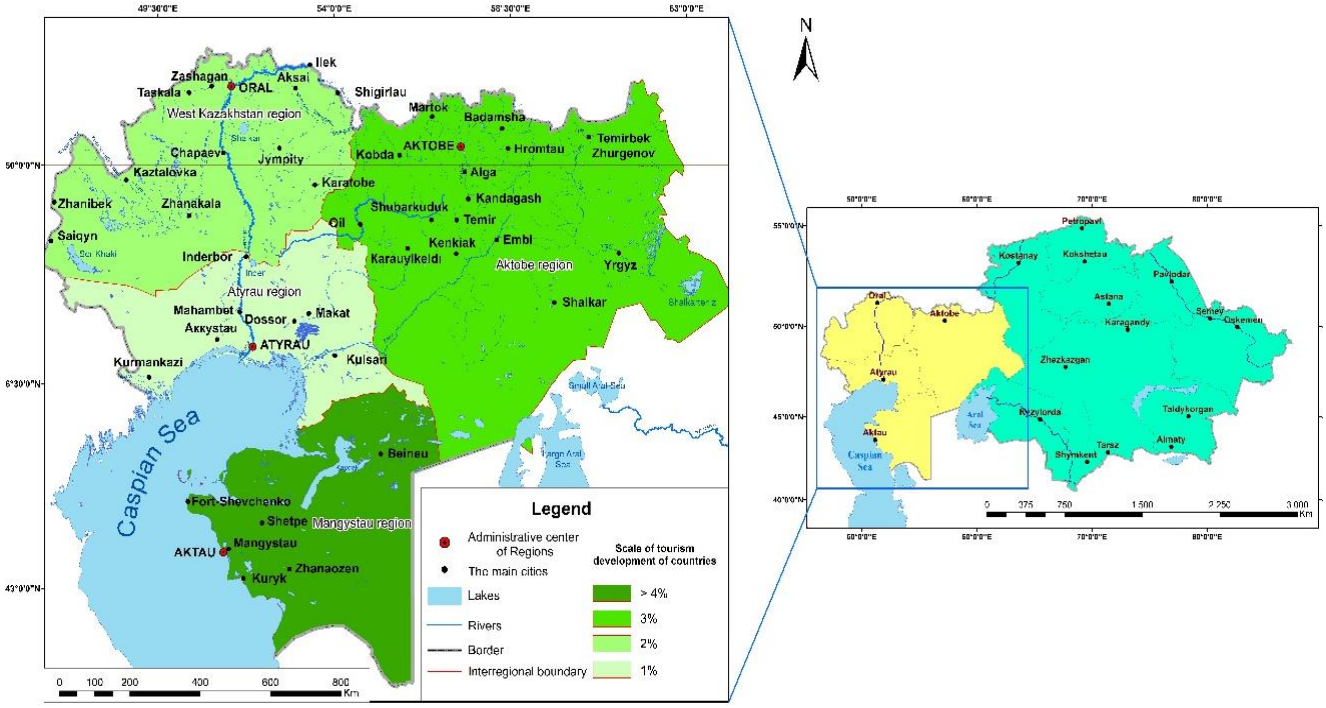

Figure 1. Research area

For the sake of a theoretical foundation and clear positioning of the work in the existing literature, a bibliometric analysis of research on tourism in Kazakhstan was conducted (Lazarides et al., 2025). The analysis included works indexed in the Web of Science and Scopus databases, supplemented by Google Scholar and EBSCOhost, for the period 2003–2024, which enabled an overview of long-term research trends and oscillations caused by economic and global crises. The empirical part is based on official statistical data on the number of tourists, accommodation capacities and

occupancy rates, which simultaneously monitors the quantitative growth and actual capacity utilization at the regional level. For the projection of tourist flows, the Holt–Winters ETS model with a dampened trend, adjusted to an annual series without seasonality, was applied (Nurhamidah et al., 2020). The parameters were estimated using the maximum likelihood method, and the validation was performed using an "out-of-sample" approach for the period 2020-2024, with the application of RMSE and MAPE accuracy indicators (Adeyinka & Muhajarine, 2020).

The final projections until 2030 should be interpreted as moderate recovery scenarios and not as direct assessments of the effects of individual policies. All analyzes were conducted in the Python environment (pandas, statsmodels, scikit-learn, matplotlib), in accordance with the modern practice of quantitative research (Zhu et al., 202 1).

RESULTS

Bibliometric analysis

The research was carried out using a bibliometric approach, based on the analysis and visualization of scientific production on the development of tourism in Kazakhstan, which enabled a quantitative insight into research trends, key terms and patterns of author collaboration, as well as their interpretation in a wider theoretical and practical context.

The search for relevant literature was performed in the Web of Science (WoS) and Scopus databases, supplemented by Google Scholar and EBSCOhost for greater coverage. The search strategy was based on a combination of the keywords "Kazakhstan", "tourism development", "sustainable tourism", "ecotourism", "tourism management" and "cultural heritage", where the Boolean operators AND and OR were used to expand and narrow the results, while the operator NOT was applied to exclude irrelevant works. Only peer-reviewed scientific articles in English with clear thematic relevance were included in the analysis, while conference papers, chapters in monographs, dissertations and publications in other languages were excluded. The time frame is not limited in advance, but the included works are available until 2023.

The selection process was conducted in accordance with the PRISMA 2020 guidelines. From the initial 176 identified papers, after removing duplicates and irrelevant records, 144 articles were included in the analysis. The bibliometric analysis was carried out using the VOSviewer software, which enables the mapping of co-occurrence of keywords and co-authorship networks. Out of a total of 823 identified terms, 36 keywords were singled out that appeared at least five times, thus covering the most relevant thematic areas.

Visualisations with a time dimension clearly indicate a shift from earlier research into tourism potential towards contemporary topics of sustainable tourism, cultural heritage and the application of GIS technologies. Literature management was performed in the Mendeley program, while the use of multiple databases, clear inclusion criteria and a transparent selection procedure ensured reliability, reduction of bias and reproducibility of the research. The PRISMA diagram (Figure 2) shows the flow of literature selection from the initial identification to the final sample.

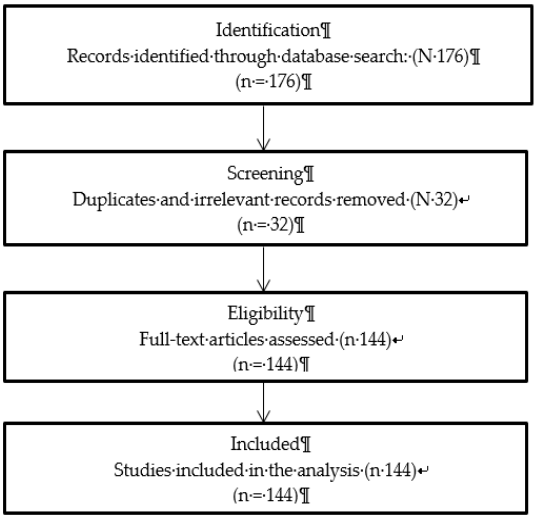

Figure 2. PRISMA diagram

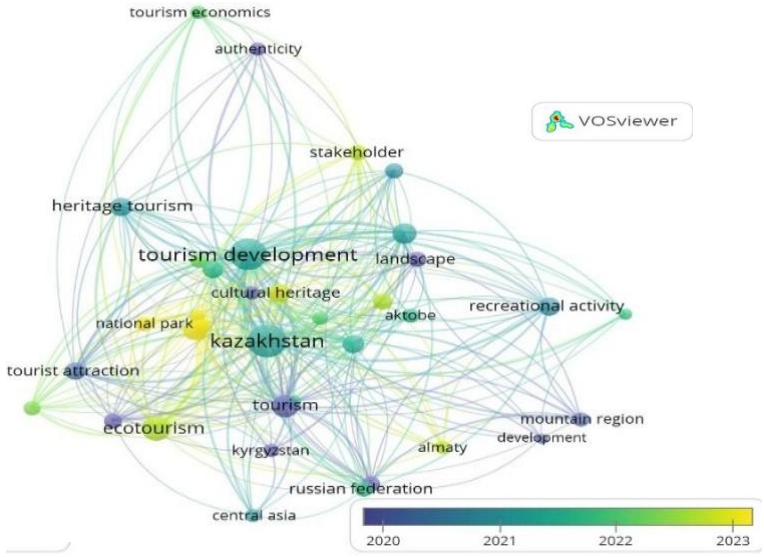

Figure 3. Overlay visualization of keywords

An overlay visualisation of keywords shows how the research focus has changed over time. Earlier works (marked in shades of blue) were mostly related to topics such as tourism, recreation and regional development, while more recent research (in shades of yellow) emphasises sustainable tourism, cultural heritage and the role of national parks. The most prominent terms remain 'tourism development' and 'Kazakhstan', which connect different thematic clusters (Figure 3).

Cluster visualization of keywords groups research topics into several interconnected clusters. The red cluster includes concepts related to sustainable development, ecotourism and tourist attractions, while the green cluster includes topics such as tourist destinations, stakeholders and tourism management. The blue cluster highlights regional aspects, including Central Asia, Kyrgyzstan and Almaty, while the purple one includes concepts related to development and tourism potential. The clusters formed in this way indicate the main research directions and their mutual connection (Figure 4).

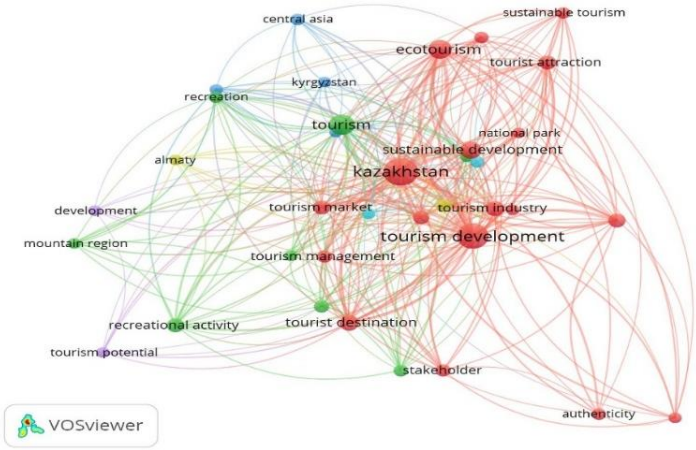

Figure 4. Cluster visualization of keywords

Trend analysis

In the period 2020–2024. the tourist region of Mangistau records an extremely strong growth in accommodation capacity and income. Income from accommodation increased from 4.1 to 17.5 billion tenge, while the number of tourists increased from 144.145 to 408.899. As incomes grew significantly faster than the number of visitors, an increase in the average consumption per tourist is evident, from about 28.5 to more than 42.8 thousand tenge, which indicates not only a quantitative growth, but also a qualitative shift in the tourist offer. The data from Table 1 confirm the long-term growth of tourist traffic in the regions of West Kazakhstan, with pronounced regional differences. Mangistau stands out as the most stable and dynamic destination, while Aktobe and the West Kazakhstan region record moderate but steady growth. In contrast, Atyrau shows pronounced oscillations, which indicate greater dependence on external factors. At the level of the West Kazakhstan Economic District, tourism is becoming an increasingly important part of the regional economy, which confirms the need for an integrated view of the development of tourism in the western part of Kazakhstan.

Table 1. The number of visitors served at the locations during the reporting (Bureau of National Statistics of the Agency for Strategic Planning and Reforms of the Republic of Kazakhstan, Statistics of Tourism – Dynamic Tables (2003–2024) year).

2015	83.589	211.756	94.461	176.068	565.874
2016	84.744	200.003	86.868	192.081	563.696
2017	100.450	184.353	112.321	205.904	603.028
2018	124.401	209.060	100.686	240.798	674.945
2019	133.417	249.766	108.454	222.539	714.176
2020*	85.050	84.534	41.466	160.504	371.554
2021*	145.023	46.303	76,180	291.931	559.437
2022*	186.637	160.149	101.276	310.217	758.279
2023*	185.326	171.775	166.560	390.332	913.993
2024*	248.295	156.473	172.315	462.723	1.039.806

Table 2 shows the growth of accommodation capacities in all regions of West Kazakhstan in the period 2003–2024, with differences in the intensity of growth. The largest absolute increase in the number of rooms was recorded in the Atyrau region, while Mangystau recorded stable and continuous growth throughout the period. Aktobe and the West Kazakhstan region show a gradual increase in capacity, but with lower values compared to Atyrau and Mangystau. At the level of the West Kazakhstan Economic District, the total number of rooms increased from 1.440 in 2003 to 13.037 in 2024, which indicates a strong expansion of accommodation infrastructure in the observed period.

Table 3 shows that the occupancy rate of accommodation facilities in the West Kazakhstan Economic District during the observed period moved at a relatively low level, with pronounced differences between regions. Mangistau records the highest values in certain years, with a maximum of 90.9% in 2011, but also later oscillations. Atyrau continuously has

lower occupancy rates, which remain below 15% after 2020. The Aktobe and West Kazakhstan regions show moderate and more stable values, mostly in the range of 20% to 35%. At the level of the whole economic district, the overall occupancy rate varies between 16.7% and 52.0%, with the lowest values recorded in the period after 2020.

Econometric forecasts of tourist traffic

In order to estimate the future flows of tourism in the West Kazakhstan Economic District, the ETS model based on time series was applied. Parameters were estimated using the maximum likelihood method. A value of $\alpha = 0.50$ shows a balanced appreciation of past and recent data, while a low $\beta = 0.05$ indicates gradual and stable growth. The damping coefficient $\varphi \approx 0.99$ provides moderate and realistic projections without excessive extrapolation (Table 4).

The validation results show that the ETS model provides relatively stable forecasts for most regions, with the lowest error rates observed in Mangystau and Aktobe, where MAPE remains below 30%. In contrast, the Atyrau region displays the highest forecast uncertainty (MAPE ≈ 98%), indicating significant volatility in tourist arrivals. The aggregated West Kazakhstan economic district shows moderate accuracy, with results consistent with regional heterogeneity (Table 5).

Table 4. Estimated parameters and validation metrics of the ETS model

Region	Alpha (α)	Beta (β)	Phi (φ)
Aktobe region	0.50	0.05	0.99
Atyrau region	0.50	0.05	0.99
West Kazakhstan region	0.50	0.05	0.99
Mangystau region	0.50	0.05	0.99
West Kazakhstan economic district	0.50	0.05	0.99

Table 5. Forecast accuracy of the ETS model for West Kazakhstan Regions (2020–2024)

Region	RMSE (2020-2024)	MAPE% (2020-2024)
Aktobe region	47260	28.67
Atyrau region	93165	97.76
West Kazakhstan region	49432	52.45
Mangystau region	81946	27.86
West Kazakhstan economic district	221883	33.32

2029	250172	194032	181007	500055	1125265
2030	257120	200445	186326	517118	1161010

It is projected that the tourist inflow into all parts of West Kazakhstan will keep increasing, albeit in different dynamics, until 2030. The most sustainable and robust increase will be in the Mangistau region, where the number of visitors will grow between 430.059 in 2025 and 517.118 in 2030. The regions of Aktobe and West Kazakhstan demonstrate moderate and stable growth, with 257.120 and 186.326 visitors, respectively. The Atyrau region is even more unstable, but is also expected to grow to 200.445 visitors by the same year, out of 167.725. On the scale of the cohesive West Kazakhstan Economic District, the gross arrivals will rise to more than 1.16 million by 2030, which proves the overall promising tourism potential of the region (Table 6). Figure 5 highlights both past fluctuations and future growth trajectories, showing clear regional differences in stability and intensity of tourism development.

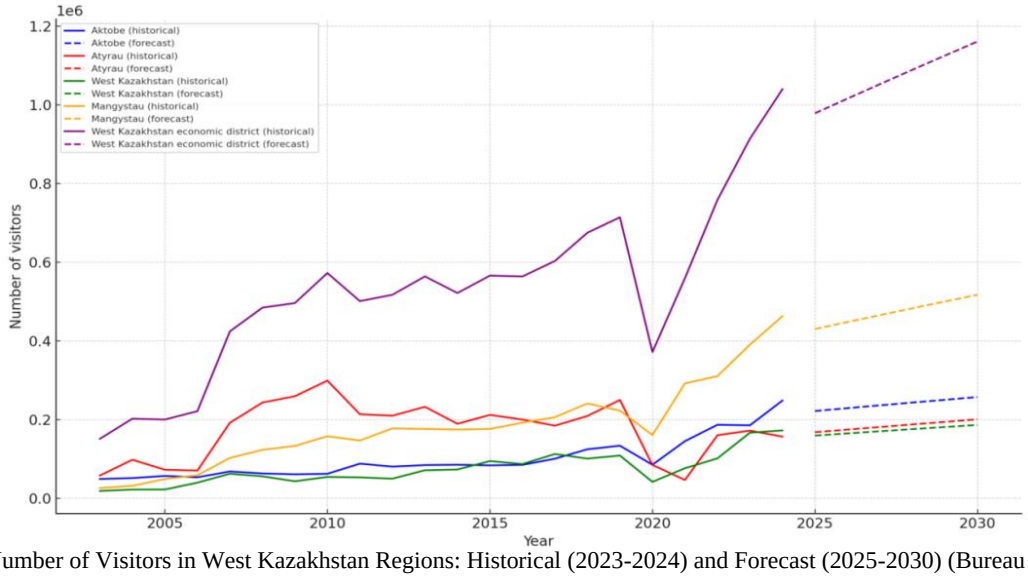

Figure 5. Number of Visitors in West Kazakhstan Regions: Historical (2023-2024) and Forecast (2025-2030) (Bureau of National Statistics of the Agency for Strategic Planning and Reforms of the Republic of Kazakhstan, 2004–2024).
*Note: The y-axis uses scientific notation (e.g., 1e6 = 1.000.000). All values are expressed as the number of visitors

DISCUSSION

This research is focused on the analysis and projection of tourism development in the West Kazakhstan Economic District, with the aim of looking at regional differences, identifying key potentials and limitations, and providing quantitative forecasts that can contribute to strategic planning and sustainable development of tourism. Our results confirm that tourism in the West Kazakhstan Economic District is going through a phase of accelerated growth, but with marked regional differences. The dynamics of visitors shows a stable growth in Aktobe and West Kazakhstan region, while Mangistau is recognized as the engine of development, with the most intense and stable trends (RQ1). This finding coincides with the literature that emphasizes the wealth of natural and cultural resources of this region (Chashina et al., 2020), but also confirms previously identified infrastructural limitations that slow down the wider development of tourism (Saparov et al., 2024; Sergeyeva et al., 2023). In contrast to them, Atyrau shows oscillations, which is in line with research that indicates the dependence of tourism in this region on external factors, including the energy sector and underdeveloped promotional infrastructure (Omirzakova & Wendt, 2025). The analysis of accommodation capacity shows that the highest growth was recorded in Atyrau, but with a low and unstable occupancy rate (RQ2). This imbalance between supply and

demand indicates overcapacity, which confirms the criticisms of the authors who emphasize institutional weaknesses and inconsistency of tourism policies (Wendt et al., 2021; Konysbek et al., 2025). In contrast, Mangistau shows capacity growth accompanied by high utilization, which confirms the synchronized development of supply and demand. Aktobe and West Kazakhstan recorded a moderate increase in capacity, with a more stable ratio of supply and demand, but also without major qualitative shifts, which confirms that smaller regions remain in the shadow of more dominant destinations.

The observed differences in income further confirm the heterogeneity of the region (RQ3). Our findings show that in Mangistau, average spending per tourist has increased significantly, which is in line with global trends of the "experience economy" (Kenzhebekov et al., 2021). At the same time, in Atyrau, despite the strong growth of capacity, the average consumption stagnates, which indicates that the increase in infrastructure is not accompanied by the development of tourism products with more added value. This difference coincides with the conclusions of Kadyrbekov et al. (2024), who emphasize that cultural heritage and authentic experiences are becoming key differentiators, but are still underutilized strategically.

At the bibliometric level, our results confirm that research production in Kazakhstan is growing, but that the western regions remain marginalized (RQ4). While the works of Ramazanov et al. (2019) and Seken et al. (2019) highlight the potential of rural tourism, they rarely include the western areas, which remain in the shadow of the central and eastern regions. This gap in the literature justifies the integration of bibliometric analyzes with our empirical findings, as it shows how research flows do not fully match real growth trends. Finally, the econometric forecast until 2030 shows that Mangistau will continue to be the leading destination, while Aktobe and West Kazakhstan are experiencing stable but moderate growth. Atyrau remains unstable, with a high level of forecasting error (MAPE ≈ 98%), confirming its volatility and dependence on external shocks (RQ5). These results differ from the findings of Panibratov et al. (2025), who emphasize the role of international integration and the "Belt and Road" initiative in the growth of tourism, because our models show that such impulses are not evenly distributed across regions, but rather privilege certain areas.

This raises the important issue of sustainability and regional balance, which previous research has not sufficiently addressed. Our findings confirm previous claims about the importance of tourism for the diversification of the Kazakh economy (Salauatova et al., 2024), but at the same time emphasize that this development is not homogeneous. While some regions are experiencing stable growth and increasing attractiveness, others are facing institutional weaknesses, infrastructural gaps and fluctuations that make long-term planning difficult. This is precisely why the integration of bibliometric analyzes and econometric models offers a more reliable framework for viewing real processes and provides guidelines for the creation of differentiated regional tourism policies in Kazakhstan.

CONCLUSION

The analysis of tourism development in the West Kazakhstan Economic District showed that this part of the country has strategic importance in the national and regional context. As an area that encompasses various natural resources, cultural values and socioeconomic structures, the district is a training ground where both the advantages and limitations of tourism development in Kazakhstan can be best observed. Its importance is multifaceted: economic, because tourism increasingly contributes to the diversification of local economies; social, because it can encourage the participation of communities and strengthening of social cohesion; cultural, because it has a rich heritage that is important for positioning the country on the international market; and infrastructural, because it raises issues of even development and availability of regions. In this way, this district becomes a paradigmatic example of how tourism can shape the processes of transformation of post-Soviet spaces, but also how institutional restrictions and uneven regional patterns can slow down its potential.

The review and analysis confirm that the study of tourism in Kazakhstan requires an interdisciplinary framework. Early works emphasized macroeconomic aspects and competitiveness (Batyrova et al., 2018), while recent research increasingly includes dimensions of sustainability, participation of local communities and valorization of cultural resources (Saparov et al., 2024; Kadyrbekova et al., 2024). Thus, tourism in Kazakhstan fits into global theoretical debates on sustainable development and the experience economy, where authentic experiences and cultural values become key to attracting tourists (Issakov et al., 2025). The bibliometric analysis of this work confirms that research streams are moving from general descriptive studies to more analytically sophisticated approaches, including econometric models and GIS analyses, which contributes to a better theoretical understanding of tourism as a complex socio-economic phenomenon. The obtained results have direct consequences for the shaping of policies. It is necessary to strengthen the coordinated institutional framework that would connect national, regional and local actors in joint development strategies. Infrastructure investments, especially in transport and tourism capacities of rural areas such as Aktobe and West Kazakhstan, are a prerequisite for a more even inclusion of these areas in tourist flows. At the same time, digital promotion of cultural heritage and destinations is necessary, since global competitiveness increasingly depends on visibility on digital platforms. Greater participation of the local population is also key - not only through employment, but also through active participation in the creation and innovation of the tourist offer. In this way, tourism can contribute to economic benefits, social cohesion and long-term sustainability.

The research results also have important political implications that go beyond the purely economic significance of tourism in the West Kazakhstan Economic District. It is shown that tourism can become an instrument of regional cohesion, because more even development of the sector reduces socioeconomic differences between more developed areas (eg Mangistau) and those that are lagging behind (Aktobe, West Kazakhstan). Thus, tourism contributes not only to the diversification of the economy, but also to political stability through the balancing of regional inequalities. Also, tourism can be used as a tool of foreign policy. The role of the Belt and Road Initiative and the growing connectivity of Kazakhstan with international markets (Daye et al., 2020; Panibratov et al., 2025) show that tourism development strengthens the country's position as a bridge

between Europe and Asia. Especially the western regions, due to their geographical position, can become a symbol of the "land-linked" economy, which opens up space for the strategic positioning of Kazakhstan within the framework of global integration. Institutional weaknesses and fragmented tourism policy, pointed out by numerous authors (Wendt et al., 2021; Konysbek et al., 2025), require the consolidation of the regulatory framework. This implies the adoption of a unique national tourism strategy that would include local authorities, the private sector and international actors, as well as control mechanisms to ensure sustainability, not just quantitative growth. Strengthening tourism has the potential to increase the political participation of local communities. The inclusion of the population in shaping tourism policies not only strengthens social cohesion, but also encourages trust in institutions, which is especially important in rural and peripheral areas.

This research has several important limitations. The analysis is primarily based on secondary sources and includes only works published in English, while publications in Russian and Kazakh could have provided additional insights. In addition, the work is focused on scientific articles indexed in international databases, while the so-called "grey literature" (reports of international organizations, national strategies, local plans) was not part of the analysis, although it often contains valuable practical data. Most of the analyzed studies remain descriptive, with a short-term time horizon and without longitudinal comparisons that would allow a deeper understanding of the dynamics of development.

These limitations reduce the possibility of full generalization of the findings, but at the same time point to directions for improvement of methodological approaches. Based on the identified findings, key directions for future research can be identified. It is necessary to develop longitudinal studies that would enable the monitoring of changes in a longer time frame and the testing of the effects of tourism policies. An integration of quantitative and qualitative methods, including bibliometric networks, GIS technologies and econometric forecasting models, is needed to provide a comprehensive analysis. Special attention should be paid to the western regions of Kazakhstan, as they remain underexplored compared to the central and eastern parts of the country, although they possess significant resources and potential. Future research should also focus more on the impact of tourism on local communities, social justice and participation, because sustainable development does not only mean economic growth, but also the strengthening of social capital and cultural cohesion.

From geodiversity to cultural narratives: An integrated ecocultural tourism framework for sustainable development in Belitong UNESCO Global Geopark, Indonesia. *Geojournal of Tourism and Geosites*, 67(3), 2345–2359. https://doi.org/10.30892/gtg.67346-1858

Abstract: Belitong UNESCO Global Geopark possesses outstanding geological, biological, and cultural resources; however, its tourism development has predominantly emphasized geodiversity, while cultural heritage remains insufficiently integrated into destination management. This study develops an integrated ecocultural tourism framework that positions cultural heritage as a core component of sustainable geopark development. A qualitative exploratory approach was employed through a systematic literature review, field observations, semi-structured interviews with key stakeholders, and focus group discussions. The collected data were analysed using SWOT analysis supported by Internal Factor Analysis Summary (IFAS) and External Factor Analysis Summary (EFAS) matrices to formulate strategic development priorities. The findings reveal that Belitong Global Geopark possesses substantial strengths, including rich geodiversity, biodiversity, tangible and intangible cultural heritage, strong community participation, and UNESCO Global Geopark status. The IFAS–EFAS assessment places the geopark in Quadrant I, indicating that an aggressive (SO) strategy is the most appropriate approach for sustainable destination development. The proposed framework prioritises the integration of cultural narratives into geotourism interpretation, community empowerment, conservation-based tourism products, responsible digital promotion, and collaborative governance among stakeholders. This study contributes theoretically by advancing an ecocultural perspective that challenges conventional geocentric geopark management and methodologically by combining qualitative inquiry with structured strategic analysis. The proposed framework offers a transferable model for integrating geoheritage conservation, cultural sustainability, and community-based tourism in UNESCO Global Geoparks and comparable heritage destinations worldwide.

Keywords: cultural heritage, sustainable tourism, geopark, ecoculture tourism, SWOT analysis

INTRODUCTION

The growing demand for authentic and distinctive travel experiences has driven the rise of ecoculture tourism, a form of tourism that blends ecological conservation with the protection of cultural heritage (Hurdawaty & Dhalillah, 2022). This approach is a tourism strategy that integrates the natural environment, cultural heritage, and local communities to provide economic benefits while preserving cultural identity and promoting environmental management (Moli, 2011). Ecoculture tourism is increasingly recognized as a valuable approach for boosting regional economies. It aims to balance the preservation of cultural heritage with tourism growth, despite potential conflicts between the two (Diarta, 2017). This supports the goal of sustainable and inclusive tourism, which aims to balance environmental and social safeguarding with economic benefits (Nenotek et al., 2025). The ecocultural tourism approach to the development of geoparks is a strategic approach that integrates nature conservation, cultural heritage, and local economic development.

An example of a developing geopark in Indonesia is the Belitong Global Geopark, designated a UNESCO Global Geopark in 2021. This recognition offers Belitung Island many opportunities to enhance its tourism appeal by leveraging its geological wealth, biodiversity, and cultural potential. The concept of geoparks, which integrates the protection and sustainable use of geological heritage, has become a popular natural tourist attraction in Indonesia (Sagala et al., 2018).

Geoparks are not just places to protect geological features; they are also places to promote local economic growth through tourism and education (Fauzi & Misni, 2022). For Belitung Island, incorporating cultural heritage into the geoparks framework is essential to draw tourists from Indonesia and abroad (Gordon, 2018b).

Integrating cultural elements into geotourism is crucial; it enriches visitors' experiences and fosters a greater understanding of the region's identity (Santangelo & Valente, 2020).

Belitong Global Geopark can boost its economic gains from tourism while protecting its unique cultural assets by incorporating cultural heritage into sustainable tourism plans. Geoparks emphasize environmental protection, improving tourism infrastructure, and fostering local economic development. For them to be successful, people in the area need to be involved to help people and the environment get along (Rosyidie et al., 2018). The integration of cultural heritage into the sustainable management of the Belitong Global Geopark requires a holistic, multidisciplinary approach that involves collaboration among government agencies, local communities, tourism operators, and academic institutions.

The integration of cultural heritage into sustainable tourism management requires a deep understanding of the interaction between tangible and intangible cultural heritage. Cultural heritage, such as sites and artifacts, provides a picture of man's relationship with his environment in the region's past. In contrast, intangible cultural heritage, including traditional music, dance, cuisine, and folklore, continues to be part of the daily lives of the people of Belitung.

This thorough approach ensures that tourism development respects and strengthens local communities' cultural identity, fostering pride and a sense of belonging. The sustainability of ecoculture tourism in Belitong Global Geopark relies on adopting sustainable tourism practices that reduce environmental impacts while increasing benefits for the local community. Implementing sustainable tourism practices can also stimulate economic activity and create employment opportunities in rural areas surrounding geoparks (Kikuchi et al., 2011; Ólafsdóttir & Dowling, 2014).

Belitong Global Geopark includes geosites spread across Belitung Regency and East Belitung Regency. The development of this geopark is the result of collaboration between two local governments aimed at encouraging local economic growth through sustainable tourism. Although the potential of biodiversity and geology has been recognized in the management of geoparks, cultural heritage, especially tangible cultural heritage, has not been fully integrated into their development strategies. In fact, this cultural heritage significantly enriches the narratives of tourist destinations and provides a more authentic experience for tourists.

The cultural heritage of the objects in the Belitong Global Geopark reflects the way of life of the people of Belitung, who have long interacted with and adapted to their environment. These values not only strengthen local identity but can also be an important element in the development of culture- and environment-based tourism, or ecoculture tourism. Therefore, it is important to evaluate the approach to developing tourist destinations in the region, especially in integrating the cultural dimension into geopark management. Belitong Global Geopark aims to promote environment-focused tourism on Belitung Island by engaging the local community, visitors, and tourism stakeholders (Farsani et al., 2011). Several studies have examined Belitong Global Geopark, emphasizing the need to develop it into a sustainable tourism destination. These studies mainly focus on strategies such as conservation, empowering local communities, encouraging collaboration among stakeholders, and promoting locally based approaches. They offer both conceptual and practical frameworks for developing geoparks that not only boost the economy but also enhance local identity and protect the environment.

Although several studies have comprehensively reviewed aspects of geotourism, community empowerment, environmental conservation, and collaborative destination management, most have not discussed in depth the role of cultural heritage, both tangible and intangible, in supporting the development of the Belitong Geopark.

Most geopark research focuses on geodiversity but ignores cultural narratives as an adhesive—studies such as those conducted by Aryanto et al. (2022), Khoirunnisa et al. (2021), and Wibowo et al. (2024) concentrate more on geology, ecotourism, and community empowerment aspects, without detailing how local culture, traditions, history, and customary practices can serve as interpretive and educational assets in geotourism development. Although some studies mention cultural heritage, such as folklore, myths, or traditional products (geoproducts), culture is generally treated as a supplementary or contextual element rather than as a core strategic component of geopark management. In fact, within the UNESCO Global Geopark, cultural heritage—particularly when combined with the geological landscape—serves as one of the key pillars of a holistic and sustainable geopark approach. This gap underscores the need for research to explore and promote local cultural heritage as a core component of geopark interpretation, enhance tourism experiences, and develop strategies to maintain regional identity. This paper proposes an integrated framework that makes cultural heritage the heart of destination development rather than just a complement. The cultural approach will enhance the geopark's storytelling and foster a stronger sense of community in the local area. Thus, the current studies provide a solid foundation in the physical and socio-economic aspects, but still leave ample room for exploring cultural meaning, local values, and traditional wisdom to support the sustainability and differentiation of geopark destinations globally.

This research aims to develop a framework for creating ecoculture tourism-based tourist destinations in Belitong Global Geopark by evaluating prior research and in-depth interviews with local communities and policymakers. The findings of this study are expected to serve as a reference for developing sustainable tourism that is not only oriented towards nature conservation but also towards cultural preservation and the improvement of local community welfare.

This research makes two main contributions. Firstly, it provides empirical evidence that underscores the importance of the often-overlooked cultural pillar as a key strategic component in geopark management, going beyond traditional geocentric approaches. Secondly, it introduces quantified IFAS-EFAS analysis, adding rigor and depth to the development of accurate, data-driven strategies (SO/WO/ST/WT).

Thus, the framework of thought and strategic approaches generated in this study offers a template that other geoparks can adapt to systematically integrate cultural heritage into their sustainable tourism development planning, while bridging the gap between geo-heritage conservation and socio-cultural vitality.

LITERATURE REVIEW

The foundation of geoparks, consisting of geodiversity, biodiversity, and cultural diversity, must be managed and developed sustainably. A UNESCO Designated Sites (UDS) model plays a significant role in achieving the 17 Sustainable Development Goals (SDGs) under the United Nations 2030 Agenda. UDSs are not only important as cultural or natural heritage locations; They also play a direct and indirect role in the achievement of various sustainable development goals, from basic human needs to social, economic, cultural, environmental, and global collaboration aspects (Luo et al., 2022).

An analysis of several studies on the development of the Belitong UNESCO Global Geopark reveals a consistent trend: cultural heritage, both tangible and intangible, is more often positioned as a complementary element than as a significant attraction—most studies, including those conducted by Kusumah et al. (2023) acknowledge local cultural values, such as myths and medicinal plant knowledge, but the primary focus remains on the site's geological characteristics—similarly, research by Wibowo et al. (2024) and Surya-& Efrianto (2022) that highlights the transformation and promotion of Open Pit Nam Sa Lu; the constructed narrative remains centered on the mine's geological heritage, with culture serving as a backdrop that enriches the story. The dominance of geological heritage as a significant attraction reflects an approach to management in which culture serves as a value binder to create a holistic tourism experience, not as an equal partner.

A study on geodiversity in Khorat Geopark, Thailand, was done by Jaroon Duangkrayom et al. (Duangkrayom et al., 2022). The Khorat Geopark region has a geological diversity from the late Jurassic period to the present. Sedimentary rock formations undergo uplift and erosion, forming the Khorat Plateau with unique landscapes, such as a cuesta. Traces of geological history include dinosaur fossils from the early Cretaceous period, mammal fossils, including ancient elephants, and other important geological features. The management of this Geopark is carried out through a bottom-up approach, namely the involvement of local communities, local governments, and education. One of the models used is the Home-Temple-School (HTS) approach to increase awareness of geoconservation and community empowerment.

In fact, if examined more deeply, the potential for cultural heritage to become the main attraction equivalent to geological heritage is enormous. The concept of ecocultural tourism offers a new paradigm by positioning ecological and cultural diversity as the main attractions, integrated and equal. In the context of Belitong Global Geopark, this means that the cultural heritage contained in a geosite is not just an addition to the story, but is the core of a tourism narrative that explains the relationship between the community and its landscape—the local knowledge of medicinal plants identified by Kusumah et al. (2023) can be transformed into distinctive health education tour packages—additionally, derivative products like teran honey and handicrafts, studied by Arrosyad et al. (2021) and Aryanto et al., (2022) are more than mere souvenirs; they serve as tangible symbols of sustainable local knowledge.

Adopting an ecocultural tourism approach shifts cultural heritage from a secondary consideration to a crucial element that enriches tourism stories and reinforces the local community's identity. This supports sustainable tourism principles focused on adaptability and inclusive participation, allowing the wider community to benefit from engagement. The tourism narrative evolves from simply explaining how granite rocks form to depicting how Belitung's people adapt, survive, and develop civilization within this distinctive geological setting. An interpretive process, as described by Henriques & dos Reis (2021), which blends cultural resources with their natural surroundings, will create a more meaningful and transformative experience for visitors and help protect the local area's identity. The combination of cultural heritage and unique landscapes can also be observed in the Sangkurilang Mangkalihat Karst area of East Kalimantan. In this area, rock art and archaeological remains represent civilization, depicting the livelihoods and culture of prehistoric humans. At the same time, the landscape displays a beauty rooted in the unique karst landscape (Haryono et al., 2022).

Furthermore, this approach directly supports the growth of sustainable, inclusive alternative economies. It involves developing geoproducts from local materials, as mapped by Yuliawati et al. (2019), fits within a broader ecocultural tourism framework. The micro, small, and medium enterprises ecosystem not only sells products, but also sells the stories, traditions, and knowledge inherent in those products. This creates a global value chain that not only strengthens the local economy post-pandemic, as Arrosyad et al. (2021) have found, but also serves as a vital instrument in preserving local people's cultural traditions in daily life from extinction. Therefore, a paradigm shift from viewing cultural heritage as a complement to seeing it as the main attraction, on par with geological heritage, is inevitable. The concept of ecocultural tourism provides a theoretical and practical framework to make this happen. With the multi-actor collaboration highlighted by Pujiyono (2022) furthermore, the ongoing community empowerment emphasized by Khoirunnisa et al. (2021) Belitong Global Geopark has the potential to become a destination showcasing geological marvels. It would serve as a living museum, revitalizing and preserving its cultural traditions and people. In the end, this balanced approach will foster a sustainable, inclusive, and conservation-focused tourism model, while also supporting the socio-economic empowerment of the local communities. Based on the previous descriptions, this research aims to develop an integrated ecocultural tourism framework for Belitong UNESCO Global Geopark by positioning cultural heritage as a core component of sustainable geopark management, rather than merely a complementary element to geological heritage.

MATERIALS AND METHODS

This research employs a qualitative, exploratory, and analytical approach to examine sustainable tourism development strategies grounded in cultural heritage in geopark areas. This approach was chosen to capture the complexity of interactions between cultural, environmental, and governance elements in the context of destination management.

The research was carried out in layers, starting with literature reviews and field surveys and progressing to strategic analysis to gain a comprehensive understanding of local dynamics.

The research begins with a systematic literature review of national and international scientific publications on sustainable tourism, geoparks, and cultural heritage. The scope review was conducted according to the protocol of Arksey & O'Malley (2005) by analyzing 13 peer-reviewed articles published between 2019 and 2024. This stage aims to identify conceptual frameworks, research gaps, and relevant strategic indicators for further analysis in the local context.

Field surveys were conducted to validate findings from literature studies and collect primary data. Data collection techniques include participatory observation and semi-structured interviews. Observations were conducted at nine geosites related to tangible and intangible cultural heritage. The focus of observation includes destination elements such as attractions, accessibility, amenities, activities, ancillary, and the role of local communities (Andrianto & Sugiama, 2016). Interviews were conducted with 10 groups of key informants, selected purposively for their participation and expertise in the research topics.

Interviews were conducted using an open-ended approach to allow in-depth and interpretative data exploration. The data obtained include perceptions, experiences, and evaluations of informants regarding the condition of the destination. These data serve as the basis for identifying strategic indicators.The selection of informants is based on the criteria proposed by Sugiyono (2017): direct relevance to the research issue, capacity to understand the context, active involvement, and availability of time. Based on these criteria, the informants selected were academics, administrators of the Tourism Awareness Group (Pokdarwis), village heads, traditional leaders, cultural experts, historians, and officials from the Tourism Office and the Geopark Management Agency. This method seeks to gather extensive, varied data and facilitate cross-verification of perspectives from different stakeholder sources. To strengthen the data's validity, a Focus Group Discussion (FGD) was conducted with representatives from the informant group. The FGD acts as a triangulation method to verify findings and complement data from observations and interviews. The entire data collection process follows ethical research protocols by obtaining informed consent, maintaining anonymity, and respecting participants' right to withdraw at any time. The qualitative data is then analyzed through a content-based approach that involves coding and categorizing themes. Additionally, the data is categorized into internal factors (strengths and weaknesses) and external factors (opportunities and threats), and analyzed using the SWOT framework. The IFAS and EFAS matrices are used to quantify the weight and score of each strategic indicator. The assessment was conducted by the research team using a qualitatively adjusted Likert scale based on consensus. Weights and ratings were assigned based on the importance and actual conditions of each indicator. The total weight of all factors was set at 1.00 to ensure proportionality.

To identify the strategic steps needed in the development of ecocultural tourism-based tourist destinations, SWOT quadrant analysis is used in the context analysis, taking into account the influence of internal and external factors derived from the scoping data. The use of the SWOT matrix aims to formulate a development strategy plan by comparing external factors, including opportunities and threats, with internal factors, including strengths and weaknesses (Iversen, 2011; McTavish & Pirro, 1990). The results of this analysis will provide a basic overview of the strategies needed to achieve the goals based on the logic of maximizing potential and opportunity while minimizing obstacles and threats, in the hope of producing outputs in the form of targets and actions to achieve those goals (Goranczewski & Puciato, 2011). Data and information from internal and external factors were analyzed using the Internal Strategic Factor Analysis Summary Matrix (IFAS) and the External Strategic Factor Analysis Summary Matrix (EFAS) to determine the best development strategy.

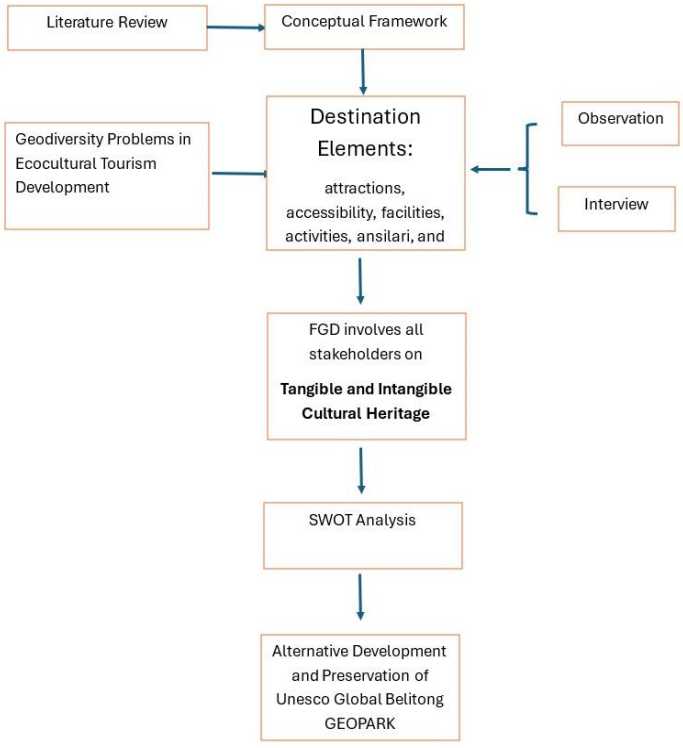

Figure 1. Flow chart of the methodology step

Furthermore, weights, ratings, and scores for each indicator of strengths, weaknesses, opportunities, and challenges were calculated by researchers. They were determined by comparing the importance of each indicator for each criterion, based on the results of surveys, interviews, and focus group discussions (FGDs). The total weight was 1.00, distributed on a scale from 1 (very significant) to 0.0 (unimportant). The rankings used a scale ranging from 4 (excellent) to 1 (very weak), with intermediate scores of 3 (good) and 2 (weak) (Benzaghta et al., 2021; Gurel, 2017). The results of this analysis then serve as a reference for the development of sustainable tourism in the Belitung Geopark area and the surrounding environment through an ecocultural tourism approach, in line with the guidelines for sustainable tourism destinations developed by the UNWTO-Global Sustainable Tourism Council (Day & Romanchek, 2020). The problem solving of integrated ecocultural tourism for sustainable development in Belitong UNESCO Global Geopark can be described as the following flow chart (Figure 1.).

RESULTS

The Belitong Global Geopark and the surrounding environment

Geographically, Belitong Global Geopark is located on Belitung Island. Administratively, this geopark is located in two regencies, namely Belitung and East Belitung, in the Bangka Belitung Islands Province, Indonesia. The region was officially recognized by UNESCO as part of the Global Geopark network in 2021 for its unique geological heritage, high biodiversity, and a rich local culture that is still preserved and integrated into a single intact landscape. From a geological perspective, this area holds extraordinary geological value, including old granite rocks, metasedimentary rocks of the Kelapa Kampit Formation, distinctive tor formations, ancient rock outcrops, and former tin mines, which are now a center for geotourism and education. In terms of biodiversity, Belitong Global Geopark includes a diverse ecosystem, ranging from lowland tropical forests, rangas forests, mangrove areas, to shallow sea areas rich in coral reefs and endemic biota. Unique species such as the Belitong tarsier (*Cephalopachus bancanus saltator*) and the *kantong semar* (*Nepenthes sp*.) add to the importance of this area as a conservation habitat. Meanwhile, from a cultural perspective, this geopark represents the rich local heritage, including the customs and traditions of coastal communities and fishermen, typical cuisine, mining historical sites, and folklore and myths that are still alive in the community's collective memory. The combination of these three elements—geology, biodiversity, and culture—makes Belitong Global Geopark not only a conservation area but also an educational, inspiring, and representative space for the principles of sustainable development grounded in earth heritage (Ismayanti et al., 2022).

This geopark has a regional character, encompassing land, coastal, and ocean areas, with geosites spread across various sub-districts. This area also includes a geosite that presents ancient granite landscapes, tropical forests, coastal ecosystems, and cultural heritage that continues to this day (Table 1). The physical environment around the geopark is very diverse, ranging from outcrops of metasedimentary rocks hundreds of millions of years old, mangrove forests, marine waters with coral reefs, to reclaimed areas of former mines that have been restored as ecotourism zones (Ismayanti et al., 2022). Geographically, several geosites are associated with past cultural heritage, such as past settlement sites and other archaeological remains that reflect the past Belitung people's adaptation strategy to the surrounding environment (Novita, 2019; Novita & Adi, 2020). In addition, geosites in the water are associated with maritime cultural heritage, such as sunken ships and colonial-era lighthouses, indicating that this waterway is a busy shipping route along the world's spice route (Novita et al., 2020).

Table 1. List of Belitong Global Geopark Geosites (source: Ismayanti 2022)

No.	Geosite	Administrative Location	Category Dominance
1	Tanjung Kelayang	Sijuk District, Belitung Regency	Geology + Culture
2	Pulau Lengkuas	Sijuk District, Belitung Regency	Geology
3	Batu Berlayar	Sijuk District, Belitung Regency	Geology
4	Bukit Peramun	Sijuk District, Belitung Regency	Geology + Biodiversity + Culture
5	Open Pit Nam Salu	Kelapa Kampit District, East Belitung Regency	Geology + Culture
6	Tebat Rasau	Simpang Renggiang District, East Belitung Regency	Biodiversity + Culture
7	Gunung Lumut	Simpang Pesak District, East Belitung Regency	Biodiversity + Geology
8	Juru Seberang	Tanjungpandan District, Belitung Regency	Geology + Ecology
9	Burung Mandi	Damar District, East Belitung Regency	Geology + Culture
10	Desa Buku Limau	Manggar District, East Belitung Regency	Culture + Biodiversity
11	Batu Itam	Sijuk District, Belitung Regency	Geology
12	Batu Kembar	Sijuk District, Belitung Regency	Geology
13	Batu Garuda	Sijuk District, Belitung Regency	Geology
14	Batu Baginde	Membalong District, Belitung Regency	Geology + Culture
15	Tanjung Tinggi (Pantai Laskar Pelangi)	Sijuk District, Belitung Regency	Geology + Pop Culture
16	Batu Mentas	Badau District, Belitung Regency	Biodiversity + Geology
17	Gunung Kubing	Membalong District, Belitung Regency	Geology
18	Tebing Kelambu	Sijuk District, Belitung Regency	Geology
19	Pantai Punai	Membalong District, Belitung Regency	Ecology + Culture
20	Batu Begalang	Manggar District, East Belitung Regency	Geology + Culture
21	Pulau Pasir	Sijuk District, Belitung Regency	Geology
22	Danau Biru	Badau District, Belitung Regency	Geology + Ecology
23	Kerangas Forest	Simpang Pesak District, East Belitung Regency	Biodiversity
24	Gurumedang Tektite	Kelapa Kampit District, East Belitung Regency	Geology

Tangible Cultural Heritage associated with Geosite in Belitong Global Geopark

Of the total geosites in the Belitong Global Geopark, there are nine geosites associated with archaeological remains. In general, these remains date to the period before tin was industrialized on this island. Archaeological research shows that Belitung Island was a developing area in the past because it lay along maritime trade routes. In addition, this area is a stopover for foreign traders and a place for exchanges with locals.

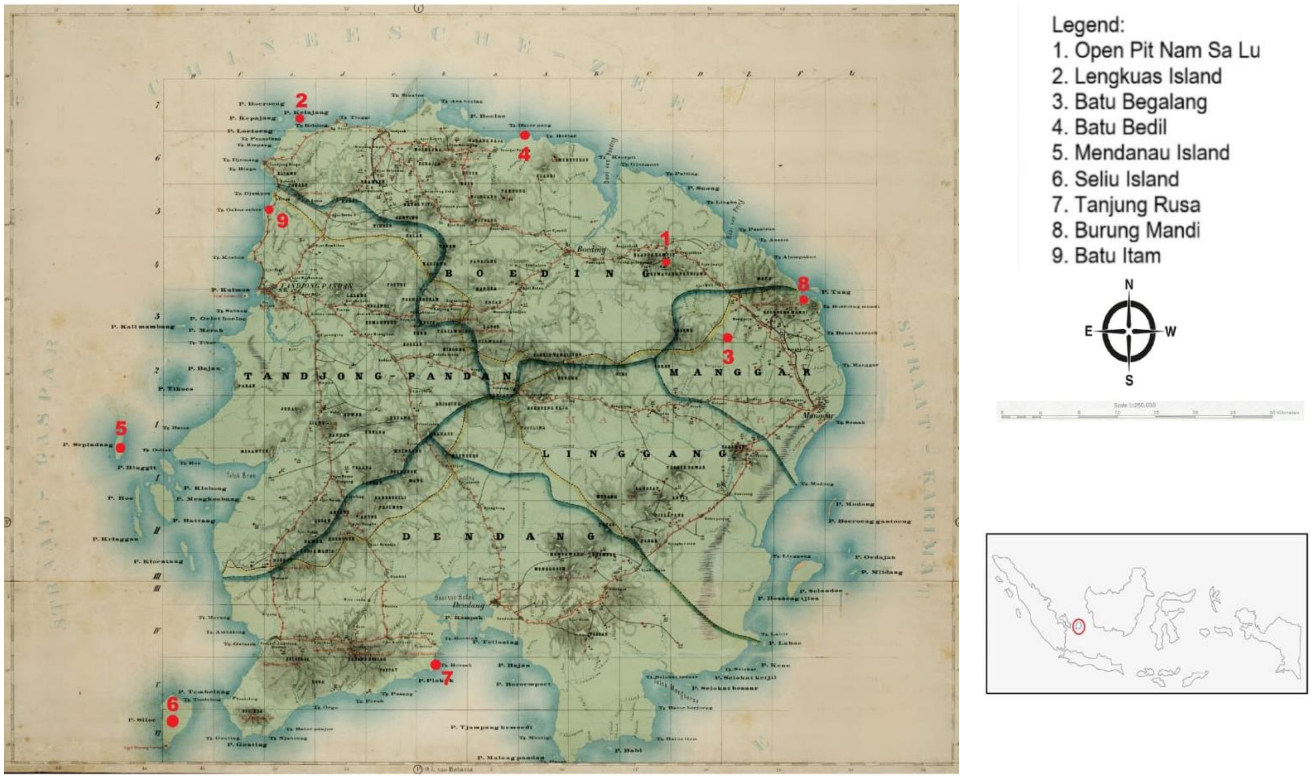

Figure 2. Geosites in Belitong Global Geopark Associated with Archaeological Sites (Source: Modified by Author from Orienteeringskaart. Ruiting van den topograph-dienst voor kaartbladen Billiton Maatschapij, 1892; Ismayanti, 2022)

Based on archaeological remains found on the mainland, housing on Belitung Island is estimated to have developed since the 13th-14th century. However, based on archaeological remains found in the waters off Belitung, it is possible that settlements in this area existed as early as the 9th-10th centuries. The existence of archaeological sites also suggests that settlements in the past were not coastal but inland, near fields, and mobile, following the growing season. The crops they grow in the fields are used to meet their daily needs. In addition to farming, the people of Belitung Island also process forest products for trade (Nijhoff, 1927; Novita et al., 2023). Settlements in this inland area developed until the end of the 19th century. When the Dutch East Indies government opened tin mines on Belitung Island, these settlements were moved. The settlements were arranged along a network of roads connecting Tanjungpandan, the administrative center, with Manggar, the central production city, and the tin-mining areas. Based on the road network, Belitung Island appears to be divided into two parts: the coastal part, which stretches north and south, and the central part, which divides the island's interior (Figure 2). Overall, geosites in Belitung associated with archaeological remains are listed in Table 2.

Table 2. Tangible Cultural Heritage at Belitong Global Geopark

No.	Geosite	Geographical Location	Tangible Cultural Heritage	Chronology
1	Open Pit Nam Sa Lu	• Terrestrial landform • Located in the mainland area of Belitung Island, not in the coastal area	Remnants of colonial tin mining (open pits, chimneys, house of parit head)	Early 20th century
2	Pulau Lengkuas	• Insular landform • Small islands in the waters off the coast of Belitung Island	Colonial Era Lighthouse	Late 19th century
3	Batu Begalang	• Terrestrial landform • Located in the mainland area of Belitung Island, not in the coastal area	• Remnants of pre-colonial settlements • Ancient Cemetery	17th century-Early 20th century
4	Batu Bedil	• Coastal landscape • Located in the coastal area of Belitung Island	• Remnants of pre-colonial settlements • Ancient Cemetery • Wrecksite	• 13th-14th century • 17th century-Early 20th century • Early 20th century
5	Kepulauan Mendanau	• Insular landform • Small islands in the waters off the coast of Belitung Island	Colonial Era Lighthouse	Late 19th century

6	Pulau Seliu	• Insular landform • Small islands in the waters off the coast of Belitung Island	Wrecksite	Early 20th century
7	Tanjung Rusa	• Coastal landscape – cape • Located at the tip of Belitung Island's mainland, which juts out into the sea	• Remnants of pre-colonial settlements • Ancient Cemetery • Wrecksite	• 13th-14th century • 17th century-Early 20th century • Early 20th century
8	Burung Mandi	• Coastal landscape • Located in the coastal area of Belitung Island	Ancient temples	Early 20th century
9	Batu Itam	• Marine landform • Located in marine waters, not on the mainland	Wrecksite	9th century

Within the UNESCO Global Geopark framework, geosites are assessed not only for their geological value but also for their capacity to illustrate the interaction between Earth processes and human history. The geosites associated with archaeological remains in Belitung Island and its surrounding waters exemplify this geo-cultural dimension, where geomorphological settings have directly influenced patterns of human occupation, resource utilization, and maritime activities across time. From a geomorphological perspective, the geosites are distributed across inland terrestrial, coastal, insular, and marine environments. This spatial diversity aligns with UNESCO's emphasis on landscape-scale interpretation, whereby geological features provide the physical framework for cultural development.

The inland geosite of Open Pit Nam Sa Lu, located within the interior of Belitung Island, represents a terrestrial geomorphological unit shaped by mineral resources. Its associated archaeological remains of colonial tin mining demonstrate how geological endowment structured historical land use and technological adaptation, reinforcing the site's geo-cultural significance (Novita & Adi, 2020) (Figure 3). In contrast to the Batu Begalang Geosite, although located in the mainland area of Belitung Island, this geosite represents a land geomorphological unit that shows sustainable use as a residential space, social activities since pre-colonial times (Novita et al., 2025) (Figure 4).

Figure 3. Geosites Nam Sa Lu located within the interior of Belitung Island. (a) Geosite open pit Nam Sa Lu, (b) Remain of a Chimney at a Colonial Tin Mining Site (Source: Research Documentation, 2022)

(a)   (b)

Figure 4. Geosites Batu Begalang Associated with Pre-Colonial Settlement Sites. (a) Batu Begalang Geosite, (b) Kubuk Kik Dukun Site (Source: Research Documentation, 2022)

The Burung Mandi geosite further demonstrates the geo-cultural complexity of coastal environments. Located adjacent to the shoreline, its geomorphological stability supported the construction of ancient temple structures, underscoring that coastal landforms were not solely utilized for economic or maritime purposes but also held religious and symbolic meanings within past societies (Novita & Adi, 2020) (Figure 5). Coastal and insular geosites such as Pulau

Lengkuas, Kepulauan Mendanau, and Pulau Seliu are situated within offshore island geomorphological settings. Their isolation from the mainland and direct exposure to marine processes rendered these locations strategically important within historical maritime networks. The presence of colonial lighthouses and shipwreck sites illustrates the role of insular landforms in navigation, trade, and sea-based mobility, reflecting the inseparable relationship between coastal geomorphology and maritime cultural heritage (Novita & Adi, 2020) (Figure 6).

(a)   (b)

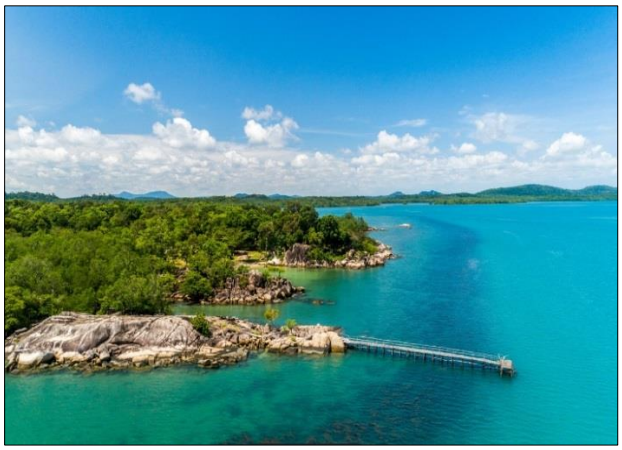
Figure 6. (a) Geosites Kelayang Island Associated with Kelayang Island Lighthouse as Colonial Sites (Source: Research Documentation, 2022)



(a)   (b)

Figure 7. Geosites Batu Bedil Associated with Pre-Colonial Settlement Sites and Colonial Era Wrecksite (a) Geosite Batu Bedil, (b) Padang Pendam Site (Source: Research Documentation, 2022)

Geosite Batu Bedil and Tanjung Rusa, occupy coastal geomorphological units characterized by rocky shorelines and promontories (Novita & Adi, 2020; Purnama et al., 2025). These transitional landforms function as interfaces between terrestrial and marine systems, a key concept in geo-cultural heritage interpretation.

Archaeological evidence of pre-colonial settlements, ancient cemeteries, and shipwrecks at these locations indicates sustained human engagement with coastal landscapes, highlighting their long-term cultural significance shaped by

geomorphological conditions (Figure 7). Finally, Batu Itam, situated within a fully marine geomorphological setting, represents underwater geo-cultural heritage. Its association with shipwreck remains emphasizes the importance of submerged landscapes in preserving archaeological evidence of historical seafaring, consistent with UNESCO's recognition of underwater cultural heritage as an integral component of geo-cultural systems.

Intangible Cultural Heritage associated with Geosite in Belitong Global Geopark

The existence of intangible cultural heritage around the geosite is inseparable from the people who have lived in this area over time. The natives of Belitung Island are Malays. Vorderman (1891) called it Billiton Maleisch or Belitung Malay. It is also mentioned that the Malay people of Belitung speak a Malay dialect, but it differs from other Malay dialects. Archaeological research shows that, to fulfill their lives, the people of this island use two ecosystems: land and water. People in the central part of the island live as farmers, while in the coastal part, in addition to being fishermen, some live as farmers. In some areas of Belitung's coastal region, people use both subsistence systems.

In the past, the agrarian tradition of the Belitung people involved moving fields, known as beume. The cultivated crop is rice, harvested once a year. The *beume* tradition is a farming practice among the Belitung Malay community that begins with clearing land by cutting down trees and burning them. This process is known as *nebas nunu*. After the land is cleared, the following process is to plant seeds called *nugal*. The following process is the harvest period, known as *ngetam*, during which the crop is taken. As the last procession of this farming tradition, a traditional ceremony called *maras taun* was held. *Maras Taun* is a rice-harvest thanksgiving ceremony held once a year.

Currently, the people of Belitung no longer plant rice; they cultivate pepper and palm oil. Pepper has been cultivated for generations, while the people of Belitung have cultivated palm oil for only the last 20 years. Even though rice is no longer grown by the people of Belitung, the tradition of moving fields is still practiced. This is evident in the pepper planting system. The people of Belitung know the pepper plant as *sahang*. Pepper gardening activities begin with cutting and burning to clear shrubs and secondary forests. The slashing was carried out using a machete and an axe. The land used as a garden is used for 7 to 10 years, corresponding to the productive period of pepper plants. After this time, they usually move to another place to start planting new seedlings. This activity lasted continuously until finally returning to the first land.

The maritime tradition of the people of Belitung is reflected in their subsistence system, which utilizes aquatic resources from rivers and the sea. The maritime tradition of the Belitung people is reflected in the term used to describe sea activities. Some terms in the seafaring tradition are based on the tools used to catch fish. The equipment used to catch fish includes nets, spears, and *bubu*. In addition to fish, the collected aquatic resources include crabs, shrimp, squid, shellfish, and sea cucumbers.

In addition, this maritime knowledge is also seen in the tradition of water transportation. The people of Belitung use two types of boats to explore their waters. Based on their size, the boats found in Belitung are medium- and small-sized, known locally as sampan. Geographically, the rivers in the northern and southern parts of Belitung Island differ. The rivers in the northern part are generally sloping and easy to navigate. Therefore, the people of Belitung trade commodities using medium-sized boats with a cruising range of 12-15 miles, which can travel down rivers to the interior. Ethnographic observations show that to reach dwellings in the interior, small boats are used to explore areas where former dwellings once stood. These boats can also explore the sea for up to 5 miles.

In general, medium-sized boats are built by combining Southeast Asian and Chinese shipping traditions. The Southeast Asian shipping tradition is characterized by the use of wooden pegs to connect the hull boards and between the hull boards and the tusks (Al Fiqri, 2020; Manguin, 1980). The boat's structure generally retains a tapered bow with a crowbar that fuses with the keel. While the Chinese shipbuilding tradition can be seen in the use of nails to connect boards and tusks, the rudder fins at the back of the boat, and the creation of spaces under the deck to place the ship's engines or cargo (Al Fiqri, 2020; Manguin, 1993).In addition to boats with combined technology, in Belitung, there are also medium-sized boats known as *kater*. This boat is a type built from a single log, with a hole drilled through its center. *Katers* in Belitung are used only for sea exploration because they feature outriggers that maintain stability,

preventing them from being easily overturned by waves or wind. Geographically, this boat is used primarily by people on the east coast of Belitung. In general, the shape of the *kater* is influenced by the Bawean people's boat, introduced by the Dutch East Indies government during tin mining in the 19th century.

Using cultural heritage in geopark areas offers valuable insights into how coastal communities adapt to their environment. The maritime tradition in the geopark showcases how Belitung's people have adapted to their coastal surroundings. As an ecotourism draw, these maritime practices can attract visitors by providing a genuine and distinctive experience of the region's cultural and natural heritage (Lacher et al., 2013). The maritime tradition within the geopark is a key aspect of its tourism appeal, promoting sustainable travel and enhancing the area's cultural richness. Visitors can experience the natural beauty and distinctiveness of the geopark's ecosystem while gaining insight into and valuing the culture of the Belitung Malay community. By leveraging maritime traditions, such as fishing practices and boatbuilding techniques, coastal communities can showcase their cultural heritage and generate income through ecotourism.

Using cultural heritage offers numerous opportunities for sustainable development, preserving cultures, stimulating economic growth, and encouraging cross-cultural exchange (Singtuen et al., 2022). By adopting responsible tourism practices, local communities can preserve their unique identities and increase their environmental awareness and socio-economic well-being (Rodrigues, 2006). The development of ecotourism, including geotourism, cultural preservation, and protection of community interests in the Belitong Global Geopark, must be carried out in a balanced manner so that the local community can benefit in the long term.

SWOT Analysis of Ecoculture Tourism in the Belitong Global Geopark Area

Recognizing the importance of the value and existence of diverse resources in the Belitong Global Geopark area and its surroundings, the people of Belitung Island, with the support of the local government, initiated the formation of a community institution called the Tourism Awareness Group (*Pokdarwis*). The goal is to manage the use of protection-based resources as an integrated sustainable geotourism attraction. Geotourism, which is often thought to focus only on geological tourism, actually refers to the relationship of a much broader geological heritage, which shapes the character of the fauna and flora of the region, as well as the adaptation efforts of the people from the past to the present that determine the heritage of traditions and cultures of daily life (Dowling, 2014; Gordon, 2018b). This relationship is rarely explored as an alternative to integrating the site's heritage diversity into a sustainable ecotourism-based tourist destination.

Results from secondary data analysis, derived from literature reviews across various sources, can identify dominant variables related to internal factors within the geopark area and its surroundings. These factors include, among others, the diversity of attractions, accessibility, facilities, activities, and quality of life of the local community. Meanwhile, external factors include a range of strategic elements that affect the geopark area and its surroundings, including policies, paradigm shifts, tourism trends, institutional and community programs, and competitors.

The data and information were then analyzed using the SWOT method to identify internal factors that reveal potential strengths and weaknesses, as well as external factors that highlight opportunities and challenges in developing ecotourism in the Belitong Geopark area as an integrated, sustainable tourism destination. The potential strengths and weaknesses in the Belitong Global Geopark area are shown in Table 3.

Table 3. SWOT Analysis of Ecoculture Tourism in the Belitong Global Geopark Area (Source: Data processed, 2024)

Key Internal Factors	
Strengths	**Weaknesses**
Attraction of Geodiversity and Biodiversity	Special interest tourism has not been optimally developed
Attraction of Cultural Heritage Diversity and Living Culture Diversity	Tourism activities provide less experience and knowledge to tourists
Village Tourism Awareness Community Group	Homestay facilities have not been developed
Diversity of traditional culinary production	Inadequate Infrastructure in Some Areas
Attraction of Plantations, Fisheries, and Livestock	
Diversity of Tour Packages	
Listed as a UNESCO Global Geopark	
Local Communities' openness to visitors	
Accessibility to and from tourist attractions in destinations is adequate	
Key Eksternal Factors	
Opportunities	**Threats**
Local Government's Sustainable Tourism Development Policy	Climate Change
Advances in information technology in support of responsible promotion	Impact of garbage and waste from tourism activities
UNESCO Global Geopark becomes a strong brand of Belitong Global Geopark	Changes in land use and ownership
	Competition from Other Destinations
	Cleanliness, Health, Safety, and Environmental Concerns

This potential will serve as the basis for the strategy's approach to leveraging strengths to overcome weaknesses by reviewing existing opportunities and threats. To develop the necessary strategies for cultural ecotourism in the Belitong Global Geopark area, an external-internal factor analysis strategy (EFAS-IFAS) was used to assign weights and assessments to each variable in the SWOT analysis. Data and information from internal and external factors were analyzed

using the Internal Strategic Factor Analysis Summary Matrix (IFAS) and the External Strategic Factor Analysis Summary Matrix (EFAS) to determine the best development strategy (Benzaghta et al., 2021; Gurel, 2017).

The examination of internal and external factors was displayed in matrix format, with weights allocated to variables indicating their impact on the ecoculture tourism in the Belitong Global Geopark. The researchers weighted and ranked the factors based on the results of surveys, interviews, and focus group discussions (FGDs). The total weight was 1.00, distributed on a scale from 1 (very significant) to 0.0 (unimportant). The rankings used a scale ranging from 4 (excellent) to 1 (very weak), with intermediate scores of 3 (good) and 2 (weak). The score was derived from the multiplication of weights and rankings to calculate the total score for both internal and external criteria. The scores and weights for each indicator on the strengths, weaknesses, opportunities, and challenges variables are calculated as described in Tables 4.

Table 4. The Weighting of Internal and External Factors of Ecoculture Tourism in the Belitong Global Geopark Area (Source: Data processed, 2024)

Key Internal Factors	Weight	Rating	Score
Opportunities			
Local governments' Sustainable Tourism Development Policy	0.3	4	1.2
Advances in information technology in support os responsible promotion	0.2	3	0.6
UNESCO Global Geopark becomes a strong brand of Belitong Global Geopark	0.5	4	2
Total Opportunities	**1.00**		**3.8**
Threats			
Climate Change	0.1	2	0.2
Impact of garbage and waste from tourism activities	0.2	3	0.6
Changes in land use and ownership	0.3	3	0.9
Competition from other destinations	0.1	3	0.3
Cleanliness, Health, Safety, and Environmental Concerns	0.3	4	1.2
Total Threats	**1.00**		**3.2**
Key Internal Factors	**Weight**	**Rating**	**Score**
Strengths			
Attraction of Geodiversity and Biodiversity	0.15	4	0.6
Attraction of Cultural Heritage Diversity and Living Culture Diversity	0.15	4	0.6
Batu Bedil Tourism Awareness Community Group	0.11	3	0.33
Diversity of traditional culinary production	0.09	2	0.18
Attraction of Plantation, Fisheries, and Livestock	0.1	3	0.3
Diversity of Tour Packages	0.1	2	0.2
Listed as a UNESCO Global Geopark	0.11	4	0.44
Local Community openness to visitors	0.09	2	0.18
Accessibility to and from tourist attractions in destinations is adequate	0.1	3	0.3
Total Strengths	**1.00**		**3.13**
Weaknesses			
Special interest tourism has not been optimally developed	0.15	2	0.30
Tourism activities provide less experience and knowledge to tourists	0.25	3	0.75
Homestay facilities have not been developed	0.35	3	1.05
Inadequate infrastructure in some areas	0.25	2	0.50
Total Weakness	**1.00**		**2.60**

DISCUSSION

Based on Table 5, it can be seen that for internal factors describing the feasibility of the Belitong Global Geopark area and its surroundings as a sustainable and integrated cultural ecotourism destination, a total score of 3.13 and a weakness score of 2.60 were obtained. Meanwhile, based on Table 6, it can be seen that for external factors affecting the development of the Belitong Global Geopark area and its surroundings as a sustainable and integrated tourist destination based on cultural ecotourism, the opportunity score is 3.80 and the threat score is 3.2. These values describe the basic framework of the strategy, using strengths as the primary capital to maximize the resources of attraction owned, while minimizing remaining weaknesses by taking advantage of opportunities and addressing threats effectively. The results of the calculations for these values are presented in Table 5, based on the priority coordinate position of the cultural ecotourism development strategy within the Belitong Global Geopark Area and its surroundings.

Table 5. IFAS and EFAS Coordinate (Source: Data Processed, 2024)

Location	∑ S - W	∑ O-T	Coordinates (X, Y)
Belitong Global Geopark Area	3.13 – 2.60 = 0.53	3.8 – 3.2 = 0.6	0.53; 0.60

Furthermore, by placing the IFAS value on the horizontal (x) axis and the EFAS value on the vertical (y) axis in the diagram, it can be determined that the best strategy is Quadrant I (Offensive Strategy), as both x and y values are positive. Furthermore, by placing the IFAS value on the horizontal axis (x-axis) and the EFAS value on the vertical axis (y-axis) on the diagram, it can be determined that the best strategy is in Quadrant I, i.e., the Offensive Strategy, because the x and y values are both positive, as shown in Figure 8.

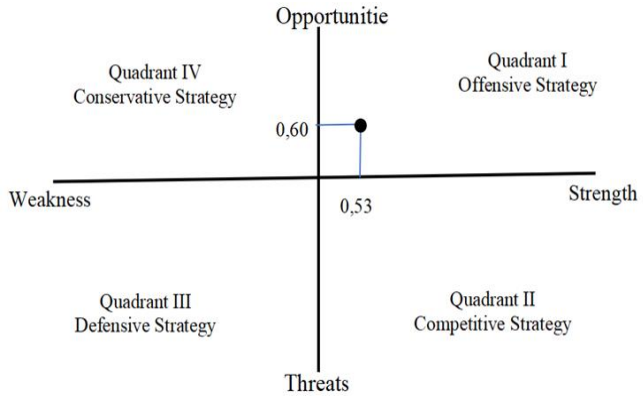

Figure 8. SWOT Diagram 4 Quadrant (Source: Data Processed, 2024)

The diagram above explains that to develop ecotourism in the conservation area of Belitong Global Geopark and its surroundings, it is necessary to implement an aggressive strategy by leveraging internal forces to capitalize on existing external opportunities (SO). Given that most of the region's natural and cultural resources are non-renewable, such as geological and cultural heritage sites (tangible and intangible) from the past, priority should be given to the three main pillars of geopark development: conservation, education, and the economic empowerment of local communities. Some alternative (aggressive) strategies that can be developed in the Belitong Global Geopark area and its surroundings as integrated sustainable tourism destinations include:

1. Preservation of the environment, natural resources, and cultural resources
2. Involvement of local communities in an active role through community-based tourism
3. Improving the quality and quantity of infrastructure, accessibility, and tourism facilities
4. Digitally responsible marketing
5. Development of eco-friendly special interest tourism products based on education
6. Implementation of sustainable tourism destination governance policies

By combining strengths, weaknesses, opportunities, and threats, several alternative strategies have been identified, as shown in Table 6.

Table 6. Internal and External Analysis Strategy of Ecoculture Tourism in the Belitong Global Geopark (Source: Data Processed, 2024)

	Strength	**Weakness**
Opportunities	**SO Strategy**	**WO Strategy**
	• Integration of the diversity of local natural and cultural attractions. • Improvement of geological sites as global geoparks through sustainable tourism approaches • Strengthening conservation efforts of geoparks as education-based tourism attractions • Increasing the involvement of the community in the management of the area through cooperation with stakeholders • Development of local community empowerment through patterns of cooperation on a regional, national, and international scale. • Development of special interest tourism products based on conservation and education.	• Empowerment of local communities through capacity building in the field of Ecoculture tourism. • Increased collaboration with stakeholders related to infrastructure and tourism facilities. • Strengthening digitally responsible promotion. • Developing various environmentally friendly events in a sustainable manner
	Strength	**Weakness**
Threats	**ST Strategy**	**WT Strategy**
	• Maintaining the carrying capacity and capacity of the area through visitor governance that can provide a quality experience and knowledge • Strengthening the sustainability of supervision and control of the use of the geopark and its surroundings through clear regulations • Development of special interest tourism products that are environmentally friendly, unique, and high-quality.	• It is necessary to improve the quality of human resources, including foreign language skills and the regeneration of tourist village managers. • Strengthening the quality and capacity of local communities related to tourism management. • Development of economic activities through local products • Strengthening the protection, development, and utilization of the diversity of natural and cultural attractions in a sustainable manner • Increasing the role and involvement of the community in the development of facilities, product development, and waste management.

The aggressive strategy (SO) derived from this analysis has a high potential for success because it directly leverages Belitong Global Geopark's greatest strength—its diverse natural and cultural heritage, both tangible and intangible—to

seize key opportunities such as UNESCO status and government policies. This strategy works by transforming the existing 'diversity' from merely a list of assets into an integrated narrative of the journey. Thus, each strength does not stand alone but is reinforced by other strengths and elevated by the UNESCO brand (Opportunity) to create a unique tourism experience that is highly educational and difficult for competing destinations to imitate.

Research findings on the weak integration of culture in geopark management align with Gordon's (2018a) study, which identified similar tendencies in several European geoparks, where cultural heritage is often still considered a supplementary element to geosites. However, the aggressive, community-based strategies proposed for Belitong Global Geopark actually offer a fundamentally different model, born from its unique socio-ecological context. Unlike many European geoparks, where communities may be highly structured and industrialized, the communities in Belitong still firmly hold onto traditional agricultural (*beume*) and maritime practices in their daily lives. This context is crucial. Strategies like boosting community involvement in management (SO-4) and enhancing responsible digital promotion (SO-2) will not be effective if they copy the European model. Instead, these initiatives should leverage existing social networks, such as Pokdarwis (Tourism Awareness Groups), to foster authentic tourism stories. Visitors will not only experience the scenery but also gain firsthand insights from local cultural practitioners into traditions such as pepper farming and boatbuilding.

Although this SO strategy is promising, implementing it faces complex challenges inherent to the local context. The main difficulty lies in converting social and cultural capital into a globally recognized tourism product without sacrificing authenticity. Capacity building efforts (WO-1) aim to empower the community, extending beyond just offering foreign language training. Instead, they focus on enabling locals to act as 'interpreters' of their cultural heritage. This enables them to share traditional knowledge with tourists engagingly and educationally. Additionally, a key challenge is preserving ecological sustainability amid growing digital promotion and increased visitor numbers (SO-2). As popularity rises, it can quickly threaten the fragile geosite's carrying capacity and turn cultural traditions into performances. To address this, the strategy must be balanced with strict destination management policies (SO-6), such as a quota-based ticket reservation system and tourism protocols that include conservation messages in promotional content, ensuring opportunities are exploited without compromising the site's core values.

CONCLUSION

This research found that to understand the value of Belitong Global Geopark and to design its sustainable development strategy, it is essential to integrate three main pillars: geological heritage, biodiversity, and cultural heritage. The results of the SWOT-IFAS-EFAS analysis indicate that the most recommended strategy is the Aggressive (SO) approach. It emphasizes internal strengths, such as diversity, biodiversity, and local culture, while also capitalizing on external opportunities, including UNESCO branding, government policies, and technological advancements. With this integration, the geopark can serve as a platform to enhance the economy, education, and the preservation of Belitung's cultural identity, in addition to serving as a conservation site.

Theoretically, this research makes a significant contribution by offering a nature tourism framework that places culture—both visible and invisible—central to the management of a geopark. It questions the traditional geocentric model. This method views culture as a strategic tool that can differentiate destinations rather than just as a complement. The methodological innovation comes from the use of a quantified IFAS-EFAS matrix and an enriched SWOT analysis. This provides more accurate and applicable strategic priorities for other geoparks.

In terms of implementation, the results of this study provide recommendations for geopark managers, the government, and local communities. This guide covers creating tourism products tailored to specific interests through cultural narratives, building capacity among local tourism groups, improving infrastructure, and promoting digital tourism, while adhering to conservation principles. To preserve the geopark ecosystem, it is crucial to enforce destination management regulations, especially concerning waste management, land-use controls, and the area’s carrying capacity.

However, research findings may be affected by the extent to which they are generalized. These limitations include a limited number of informants, uneven coverage of geosites, and subjectivity in assigning weights to SWOT-IFAS-EFAS. Therefore, future research is recommended to identify the most effective methods for integrating culture by quantitatively validating the impact of SO strategies, studying tourists' perceptions and experiences, and conducting comparative studies with geoparks in Southeast Asia. To assess the long-term impact of tourism development on cultural authenticity and environmental carrying capacity, ongoing monitoring is necessary. To enrich the interpretive narrative of the geopark and ensure the sustainability of local knowledge, in-depth ethnographic research related to intangible cultural heritage, such as beume traditions, maras taun, and boat technology, should be conducted.

Author Contributions: For research articles with several authors, a short paragraph specifying their individual contributions must be provided, as follows: Conceptualization, H. and AN.; methodology, NS; software, IBPPY; validation, EW, SS and IBPPY; formal analysis, NL; investigation, AN; resources, NL; data curation, H.; writing—original draft preparation, EW; writing—review and editing, SS; visualization, H; supervision, NS; project administration, AN; funding acquisition, AN. Abstract: Throughout human evolution, cultures and societies form and transform with time. In some cases, societies change their unique cultural representations and develop into something quite different. In other cases, entire social structures disappear and are replaced by new ones that subsequently often repopulate an area. Some societies or cultures ended abruptly, the reasons for their disappearance in many cases remain either unknown, obscured and/or debatable, like the Classic Maya period in Meso America. In Ecuador, such questions have been formulated regarding the end of the Valdivia culture in coastal Ecuador. Valdivia was one of the earliest and most complex ceramic cultures of the Americas, dating back to the Early Formative period of pre-Hispanic Ecuador, where it inhabited between 3800-1450 BC. The circumstances that contextualize the end of the Valdivia tradition have long been an issue of debate. New discoveries at the Papayita geosite near the city of Portoviejo, have yielded specifically a domestic activity area of the Valdivia Phase 8 culture (ca. 1700 BC). Such new data may contribute to adding some information about the socioenvironmental dynamics that probably contributed to the end of the Valdivia tradition in this region. Besides late Valdivia ceramics, we encountered burials inside the approximately 85 cm thick greyish-beige colored ash layer. This context suggests that the internment took place shortly after the pyroclastic material fell and thus bear a direct chronological relation to the phenomenon. The excavation results and the stratigraphic units studied clearly indicate that after the ashfall, the place remained uninhabited or abandoned and never resettled until modern times. The following geochemical, geochronological and provenance studies of the ashes identified a previously documented volcanic event in northern Manabi, but revealed its true extent as an enormous volcanic eruption of the Pichincha Volcanic complex, some 3,500 years ago. Additionally, we speculate that there is further evidence that the volcanic event might have been triggered by a very strong marine earthquake, which also generated a mega-tsunami on the nearby shoreline. Such revelations are new and may allow the most adequate reconstruction of the abrupt ending of the Valdivia culture in significant areas of coastal Ecuador, converting the Papayita area into an extraordinary geosite of high geological and historic importance.

INTRODUCTION

Throughout human evolution, cultures and societies form and transform with time (Boyd & Richerson, 1985). In some cases, societies change their unique cultural representations and develop into something with enough differences to distinguish themselves as a different culture from their ancestral origins, even though they still maintain cultural similarities (Mace & Holden, 2005). In other cases, entire social structures disappear and are replaced by radically different new ones that may subsequently expand into a region (Tainter, 1988). These complex transformations have been subsumed in literature under the general concept of cultural evolution (Stark et al., 2008).

In certain historical contexts, entire societies disappear and are replaced by new ones that subsequently often repopulate an area after a significant period of abandonment (Zeidler, 2016). Some groups change so fast that, in a few centuries, their material culture, economic systems, and social organization change entirely; as such, archaeologists have classified them as separate cultural entities (Hood, 1996). Furthermore, there are also cultures or societies that exhibit a

remarkably long trajectory, continuing their activities with very few changes over millennia. Thus, the duration, paucity, and success of a certain group of people, together with their territorial expansion and cultural transformation, are still major issues in the understanding of their survival as a resilience process of humankind.

However, a phenomenon cannot be understood simply through the knowledge of how it began; we also need to know how it ends to comprehend the full nature of the socio-historical process. This applies to both natural and sociohistorical processes alike. Understanding the origin of a society, as well as how it manifests itself in the archaeological record, is just as important as understanding its demise. The disappearance or replacement of a culture may be sudden and due to multiple reasons, such as natural disasters, warfare, or internal social crises. Often, the vanishing of a previously prosperous and productive society remains unsolved due to a lack of documented evidence. The reasons for abrupt endings in many cases remain either unknown, obscured, or debatable, as seen in the Classic Maya period in Mesoamerica, the Mesopotamian cultures in the Middle East, or the Viking settlements in Greenland (Braun et al., 2023; Evans et al., 2018; Borreggine et al., 2023). In the history of the Ecuadorian coast, such issues of collapse and replacement occurred almost regularly. A society that abruptly ended more than three thousand years ago was the Valdivia Culture. This group disappeared almost suddenly around 3.5 ka ago (Hill, 1972; Lunniss, 2019; Lunniss, 2023a; Lunniss, 2023b; Lunniss & Ubelaker, 2025; Zeidler et al., 1998; Jadán Veriñez, 2017). Despite the multiple causes that might have caused the Valdivian collapse, we propose that an ecological cataclysm following the volcanic eruption of Guagua Pichincha, dated approximately to 1500 BC, triggered the end of Valdivia.

The predominant aim of the current research has been to present new evidence contributing an explanation of the most likely cause of the demise of the Valdivia tradition. The data presented are focused to the archeological geosite of Papayita in the central part of the Manabí Province on the Ecuadorian coast. There, the recent archeological excavations combined with geochemical provenance analysis and the evaluation of a major volcanic impact, allowed reconstruction of a major catastrophic event that has been responsible for an environmental and human disaster leading to the end of Valdivia society in the form it existed for over two thousand years. The results may also indicate that such natural events with their associated consequences for humanity may repeat themselves and the lessons to be learned should be used and applied in modern society.

EVOLUTION AND DEVELOPMENT OF THE VALDIVIA CULTURE IN ECUADOR

The Valdivia Culture is one of the earliest and most complex ceramic cultures of the Americas (Ford, 1969; Hoopes, 1994; Raymond, 2008). It is a significant subject of research due to its early development and influence on subsequent regional cultures. This culture dates back to the Early Formative period of pre-Hispanic Ecuador, existing between 3800-1450 BC (Zeidler & Ubelaker, 2021; Marcos, 1998). When first identified in the late 1950s, researchers initially believed Valdivia represented a simple hunter-fisher society (Estrada, 1958; Meggers et al., 1965). The people of the Valdivia culture have been gatherers and fishermen, but from their beginnings, their main subsistence activity was based on a sophisticated, structured agriculture, which allowed them to maintain a greater degree of sedentism and higher quality of life than their preceramic predecessors, the Las Vegas people (Zevallos Menéndez, 1980; Marcos, 1978; 1982; 2010; Pearsall, 1979; Stahl & Stothert, 2020). As a matter of fact, it was famously claimed that its appearance in the Pacific coast of Ecuador was due to a transpacific connection with the Jomon culture from Japan (Estrada et al., 1962). This hypothesis has since been strongly discredited by evidence for an *in-situ* Valdivia evolution (Lathrap et al., 1975). Archaeological data confirms that Valdivians were a fully agricultural society that shifted to sedentary village life, building upon the domestication of plants initiated during the prior Las Vegas culture (Lathrap et al., 1977; Rowe & Duke, 2020; Staller, 2001; Delgado-Espinoza, 2008; Staller, 1994; Raymond et al., 2003; Zeidler, 1994; Kanomata et al., 2019; Zeidler & Isaacson, 2003).

Valdivia sites are distributed across the western lowlands, where populations established themselves near fertile riverbanks, developing technological solutions such as the construction of *albarradas* (water reservoirs) to collect rainwater. At the eponymous site and Real Alto, excavations revealed large villages organized around central plazas with ceremonial mounds reaching up to 13 meters in height. These structures served ritual and social purposes, as evidenced by the decorated pottery and the famous female figurines found in association with ceremonial offerings. Their survival was based on sophisticated, structured agriculture applied to maintain a certain quality of life (Zevallos Menéndez, 1980).

The ending of the Valdivia culture, however, is still controversial and of high interest to researchers of social as well as natural sciences, as its trigger or reason may contribute to understand the potential survival or demise of societies in the past (Tainter, 1988; Brunk, 2002; Middleton, 2012). In the case of Valdivia, it was stated that while its appearance is somehow better known, its vanishing is unclear (Hill, 1972). Furthermore, Zeidler and Pearsall's groundbreaking study in the Jama valley have provided sound evidence and generated some provocative hypotheses, among them the possibility of the Valdivia collapse due to major environmental transformations (Zeidler & Pearsall, 1994). Mainly of those, the various Andean volcanic eruptions that affected the coastal regions of Ecuador during the Late Formative (Zeidler, 1994; Isaacson, 1994). A further cause may imply overpopulation with a subsequent societal crisis due to less available food resources (Hendrixson & Hartmann, 2019). Also, it has been discussed that a climatic crisis, most likely based or associated with a prolonged drought has emerged the culture to leave these coastal lowlands, towards further south (Zeidler, 2012). Whichever the real cause was of the most likely southern migration of the greatest part of the Valdivia culture from the Ecuadorian shores, it occurred at once, meaning in a very short period some 1500 years B.C. (Schwarz & Scott Raymond, 1996).

Therefore, regarding the end of this tradition, the archaeological record reveals a complex and fragmented regional landscape. In the southern and central-southern coast, studies illustrate a gradual process of cultural transformation. There, Valdivia appears to evolve into the Machalilla phase (1500–800 BC), which acted as a direct heir to Valdivian

traditions (Staller, 1994). However, this continuity is not observed elsewhere. In the central coast of Manabí, specifically in areas like the Jama Valley, there is a stark hiatus representing nearly 400 years of total abandonment following the volcanic cataclysm (Zeidler, 1993). This region shows no immediate transition, remaining depopulated until the eventual arrival of the Chorrera Culture (1000–300 BC). Further to the North, a third pattern emerges. In these regions, Valdivian populations seem to have bypassed the Machalilla stage entirely, exhibiting a direct transition toward Chorrera or its local northern variant known as Tabuchila (1200–500 BC). In the Coaque Valley, for instance, Valdivian traditions persisted until approximately 1300 BC, showing subtle cultural shifts that align more closely with highland groups like Cotocollao than with the coastal Machalilla. This regional divergence, transformation in the south, abandonment in the center, and a separate transition in the north, highlights the devastating and localized impact of the Guagua Pichincha eruption (Isaacson, 1994), which specifically disrupted the central Manabí province as evidenced at Papayita. Subsequently, based on the importance of the archeological and volcanic findings at this area, Papayita qualifies to be a geosite, which should be protected and allowed to be visited by generations to come. Therefore, it is clear that a this specific geosite, the evidenced catastrophe marked the conclusion of a tradition that had endured for nearly 2400 years, forcing a radical reconfiguration of the prehistoric Ecuadorian landscape.

GEOLOGY AND CORRESPONDING HAZARDS OF THE STUDY AREA

Geodynamic setting

The western rim of the South American continent is an active geodynamic setting (Taboada et al., 2000; Hinz et al., 1999). Ecuador which is situated on the northwestern edge of South America, undergoes subductional processes due to a convergent plate boundary as a result of the collision between the oceanic Nazca Plate and the continental South American and Caribbean continental plates, which are both separated by the Guayaquil-Caracas Mega Shear (Figure 1; Gutscher et al., 1999; Egbue & Kellog, 2010). The subduction of the Nazca plate gives rise to four extensive, NNW-SSE aligned volcanic arcs (Ferrari & Tibaldi, 1992; Aizprua et al., 2020). Some 1000 km west of the Ecuadorian continental platform, active volcanism in the archipelago is characterized mainly by the Galapagos hot spot, besides other origins (O'Connor et al., 2007; Harpp & Weis, 2020; Rojas-Agramonte et al., 2022). Volcanism in the Galapagos is evidenced by more than 3,000, mostly monogenetic volcanoes, besides some voluminous shield volcanoes (White et al., 1993). Hereby, due to the eastern drifting of the underlying Nazca oceanic plate, a volcanic alignment from west to east is created, which is named the Carnegie Ridge (Harpp et al., 2003). This volcanic chain represents an aseismic volcanic ridge, which moves and finally collides towards the Ecuadorian continental margin with a velocity of as low as 5 cm per year at a latitude between 1°N and 2°S (Pilger, 1984).

Nonetheless, an aseismic ridge like the Carnegie Ridge becomes an obstacle in the oblique subduction process, which have resulted in past and present as a potential valve within the subduction zone of very strong marine quakes, earthquakes as well as tsunamis along the Ecuadorian coast (Pararas-Carayannis, 2012; Toulkeridis et al., 2022; Toulkeridis et al., 2019).

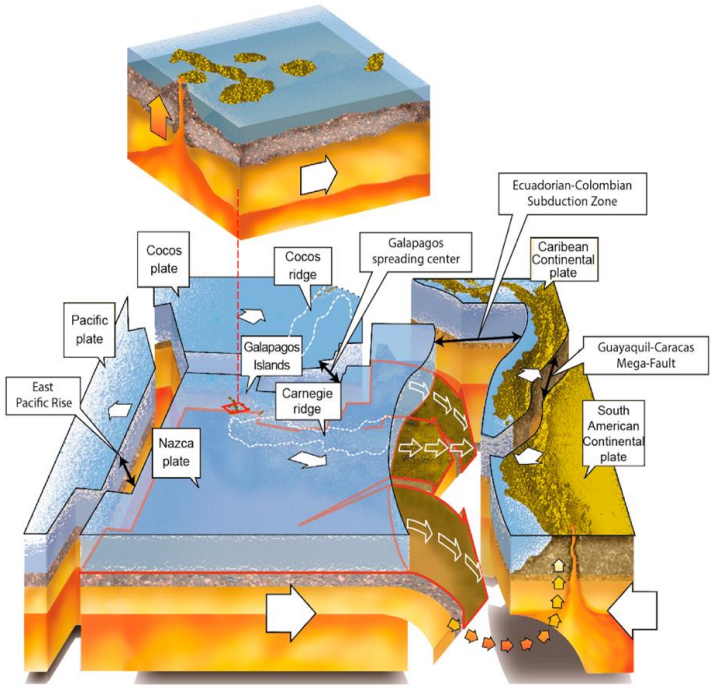

Figure 1. The geodynamic situation of Ecuador with its associated tectonic plates, corresponding separating plate boundaries and volcanic aseismic ridges (Toulkeridis et al., 2021)

Earthquakes and tsunamis in Ecuador

Due to the geodynamic constellation, the Ecuadorian continental platform which situated along the Pacific Rim, is a frequent target of earthquakes, marine quakes and tsunami impacts (Gusiakov, 2005; Matheus-Medina et al., 2018). There

appear primary-generated tsunamis of tectonic as well secondary-generated tsunamis due to submarine landslide origin (Shepperd & Moberly, 1981; Pontoise & Monfret, 2004; Ratzov et al., 2007; 2010; Ioualalen et al., 2011; Pararas-Carayannis, 2012; Toulkeridis et al., 2022). Severe seismic activity has reached registered magnitudes higher than 8 Mw, while, based on paleo-tsunami deposits, even stronger marine quakes may have appeared in the historic past (Figure 2; Quiñónez-Macías et al., 2023; Chunga & Toulkeridis, 2014; Satake et al., 2020). Further tsunamis along the Ecuadorian coast may be generated by seismotectonic extensional processes, like in the Gulf of Guayaquil, besides other zones (Chunga et al., 2019). Within the last two centuries, tsunamis with various intensities one being of up to 8.8 Mw in 1906 impacted the Ecuadorian coast (Rudolph & Szirtes, 1911; Kelleher, 1972; Beck & Ruff, 1984; Kanamori & McNally, 1982; Swenson & Beck, 1996). Other prominent events of tsunami impacts along the Ecuador–Colombia subduction zone occurred in 1942 (Mw=7.8), 1958 (Mw=7.7) and 1979 (Mw=8.2), which are within the 600-km long rupture area of the great 1906 event (Collot et al., 2004). Several strong earthquakes have also been registered within the Ecuadorian coastal area, of which the most recent one reached 7.8 in 2016 (Ye et al., 2016; Toulkeridis et al., 2017). Based on multiple studies of risk perception, preventive measures and degree of preparedness of the Ecuadorian public as well as authorities, any potential future impact of tsunamis as well as earthquakes along the coastal line, will have severe consequences in the strategic and highly developed infrastructure, socio-economic activities, human settlements as well as health and life situation of inhabitants and visitors (Suárez-Acosta et al., 2021; Toulkeridis et al., 2021; Celorio-Saltos et al., 2018; Del Pino de la Cruz et al., 2021).

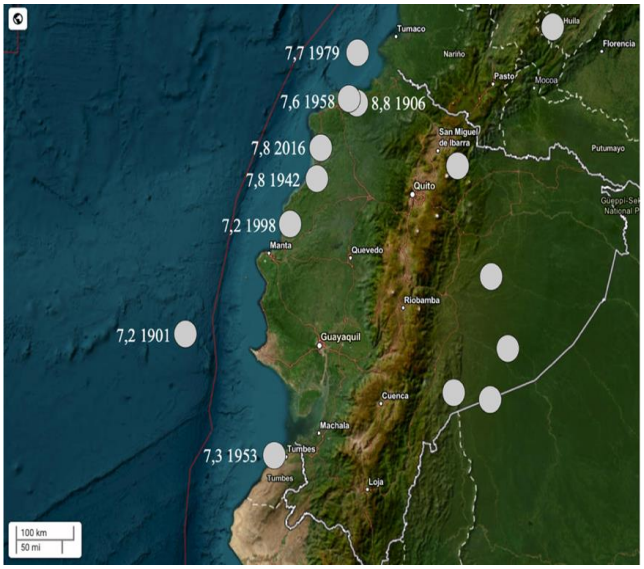

Figure 2. Different epicenters of earthquakes mostly along the coast of Ecuador with a magnitude higher than 7 Mw, of which some generated also tsunamis in the last 120 years (Navas et al., 2018; USGS/NEIC, 2026)

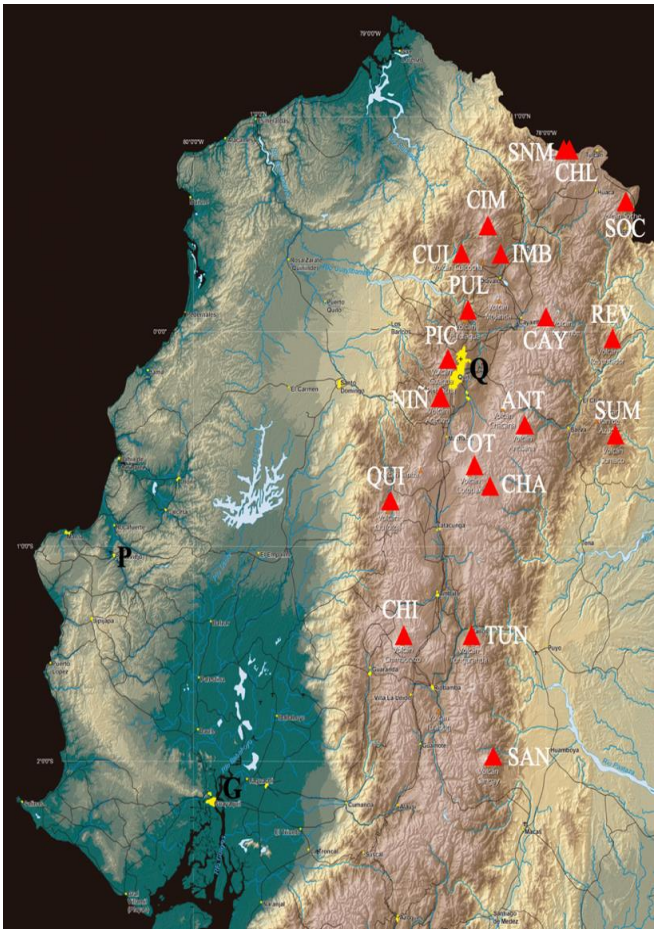

Figure 3. Distribution of the 19 active volcanoes of Ecuador. Volcanism in Ecuador

Ecuador exposes one of the highest densities of volcanoes on the planet due to the Galapagos hot spot and due to the subduction zone, where some 250 volcanoes appear in the highlands, exposing some 19 volcanoes, which are considered to be active (Figure 3; Toulkeridis, 2011; Toulkeridis, 2013). Of these volcanoes, the Volcanic Explosivity Index (VEI) may reach a degree of up to 7 (Toulkeridis & Zach, 2017; Global Volcanism Program, 2025). There are at least seven volcanoes of the most dangerous which have reached VEI´s of 5 or higher, which as strong as to be able to alter significantly the local and may even the regional landscape. These volcanoes are Cotopaxi, Guagua Pichincha, Sumaco, Soche, Cuicocha, Quilotoa, Pululahua and Chalupas distributed on all four volcanic arcs of Ecuador forming part of the Northern Andean Volcanic Zone (NAVZ; Stern, 2004; Melián et al., 2021; Padrón et al., 2008). While Chalupas has been active some 200 ky and potentially 18 ky ago, all other volcanoes have been active in more recent times (Córdova et al., 2020; Hammersley et al., 2022). Volcanic deposits of different hazards, such as debris avalanches, far-reaching lava flows and pyroclastic density currents are usually encountered within the vicinity of the volcanic edifices or complexes, while ash deposits may reach thousands of kilometers covering extensive areas (Jenkins et al., 2015; Favereau et al., 2018; Pardini et al., 2025).

METHODOLOGY

Fieldwork

The discovery of the Papayita geosite happened during the construction of an *albarrada* or water reservoir for irrigation purposes and farming activities. The area is located on a hilltop characterized by gentle slopes and a relatively narrow East-West extension that measures approximately 400 meters east to west. The site lies between the city of Portoviejo to the east and the town of Picoaza to the west. It is part of the foothills that face the famous Cerro Hojas-Jaboncillo that contains the immense 35 km^2 Manteño site (Figure 4). The excavation was initiated as a response to an emergency situation when the construction exposed some aboriginal burials as well as ceramic artifacts. At that point since the site is located within the boundaries of the heritage area of the Hojas-Jaboncillo Archaeological Park, the National Institute of Cultural Heritage (INPC) joined forces with the Archaeological Laboratory of the Universidad Técnica de Manabí and organized a small rescue archaeology mission in order to recuperate as much of the scientific data possible from the exposed and impacted zone of the geosite.

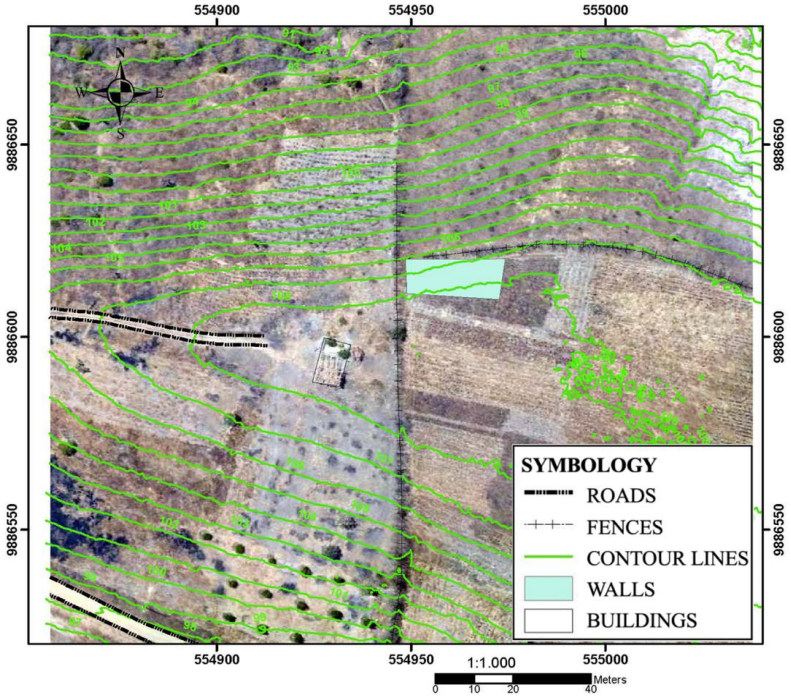

Figure 4. The field area of the Papayita geosite is situated right next to the city of Portoviejo (Parish of Picoazá), within the archeological park Cerros Hojas-Jaboncillo, some 15 km from the current shoreline (Topography and Photo image courtesy of INPC)

Microscope and geochemistry

Since in a previous study some charcoal material has been separated of the Papayita geosite and subsequently dated by the C14 method, it was known that the timeframe of the explosive event that produced the studied coastal ash layer to have an age of some approximate 3,500 years. Therefore, we sampled several ash layer horizons of a variety of volcanoes, which have had a past activity around the time of the deposition of the studied geosite and correspondingly seemed to be the most likely provenances. These included volcanoes and their corresponding deposits of the Cotopaxi and Niñahuilca stratovolcanoes, the Chalupas super-volcano, Cuicocha, Pululahua and Quilotoa calderas and the Pichincha volcanic complex (Toulkeridis, 2013; Hidalgo et al., 2008; Robin et al., 2008; Papale & Rosi, 1993). The further procedure has been previously described in a variety of studies (Toulkeridis et al., 2015; Vaca et al., 2016; Toulkeridis et al., 2025). The ash samples were characterized through a multi-scale analytical workflow combining optical microscopy, field emission scanning electron microscopy (FEG SEM) with energy dispersive spectroscopy (EDS), and X-ray diffraction (XRD). The investigation began with direct visual inspection to establish an initial textural and mineralogical context. High magnification digital microscopy (up to 1000X) enabled the rapid recognition of particle morphologies and mineral fragments, while complementary observations with a Celestron portable optical microscope (model 44302 A; 10X–150X) provided micrometric resolution down to 0.01 mm, refining early assessments of grain size and surface features.

Building on these preliminary observations, high-resolution imaging was conducted using a TESCAN MIRA3 FEG SEM, capable of resolving features as small as 1.2 nm. Fine-grained material was mounted on SEM stubs using a dual adhesive system to avoid compositional interference during elemental analysis and subsequently sputter coated with 99.99% pure gold to ensure optimal conductivity (Toulkeridis et al., 1998; Paéz-Barrera et al., 2024; Toulkeridis et al., 2025). Micrographs acquired under high vacuum conditions at magnifications of 150X and 8000X (4096 × 4096 pixels) revealed the detailed surface textures, vesicular structures, and morphological diversity characteristic of the ash particles. Elemental compositions were determined using a BRUKER EDS system integrated within the SEM chamber, equipped with an XFlash 6 30 detector offering a spectral resolution of 123 eV at Mn Kα. This configuration enabled precise quantification of major and minor elements associated with individual particles. Crystalline phases were identified through XRD analysis using a PANalytical

EMPYREAN diffractometer operating in Bragg–Brentano (θ–2θ) geometry. The instrument employed a Cu Kα radiation source (λ = 1.5406 Å) and an XCELERATOR detector capable of angular steps as fine as 0.0001°, yielding high fidelity diffraction patterns. Mineralogical assignments were performed using the Crystallography Open Database (COD), allowing robust discrimination of the crystalline constituents (Velez et al., 2025; Cadenbach et al., 2025; Moreno et al., 2026). To facilitate geochemical comparison and interpretation, all elemental data were recalculated to their corresponding oxide forms, incorporating atomic weights and stoichiometric equilibrium with oxygen (Rollinson, 2014).

Volcanic ash distribution

The preferred direction of ash-laden clouds of Ecuadorian volcanoes has been obtained by evaluating satellite images of active volcanoes in the period of September 1999 up to December 2025 from the data base of Global Forecast System / North American Model of the National Oceanic and Atmospheric Administration (NOAA, 2026). In this time frame five of the potential 19 active volcanic complexes demonstrated signs of volcanic unrest with visible and determined ash distributions in their surroundings. The five active volcanoes have been Sangay (higher, registered intensity in 2004-2011, 2013, 2016 and since 2020), Guagua Pichincha (1999-2001 and 2009), Reventador (since 2002), Tungurahua (1999-2016 with few interruptions) and Cotopaxi (2015 and 2022-2023) (Toulkeridis et al., 2015; NOAA, 2026). The ash movement or distribution model was realized by using rose-diagrams based on a known methodology of previous studies (Toulkeridis & Zach, 2017; Toulkeridis et al., 2025). Hereby, some 18805 satellite images were considered and evaluated as well as exhibited by months to capture potential anomalies during seasonal changes (Figure 5).

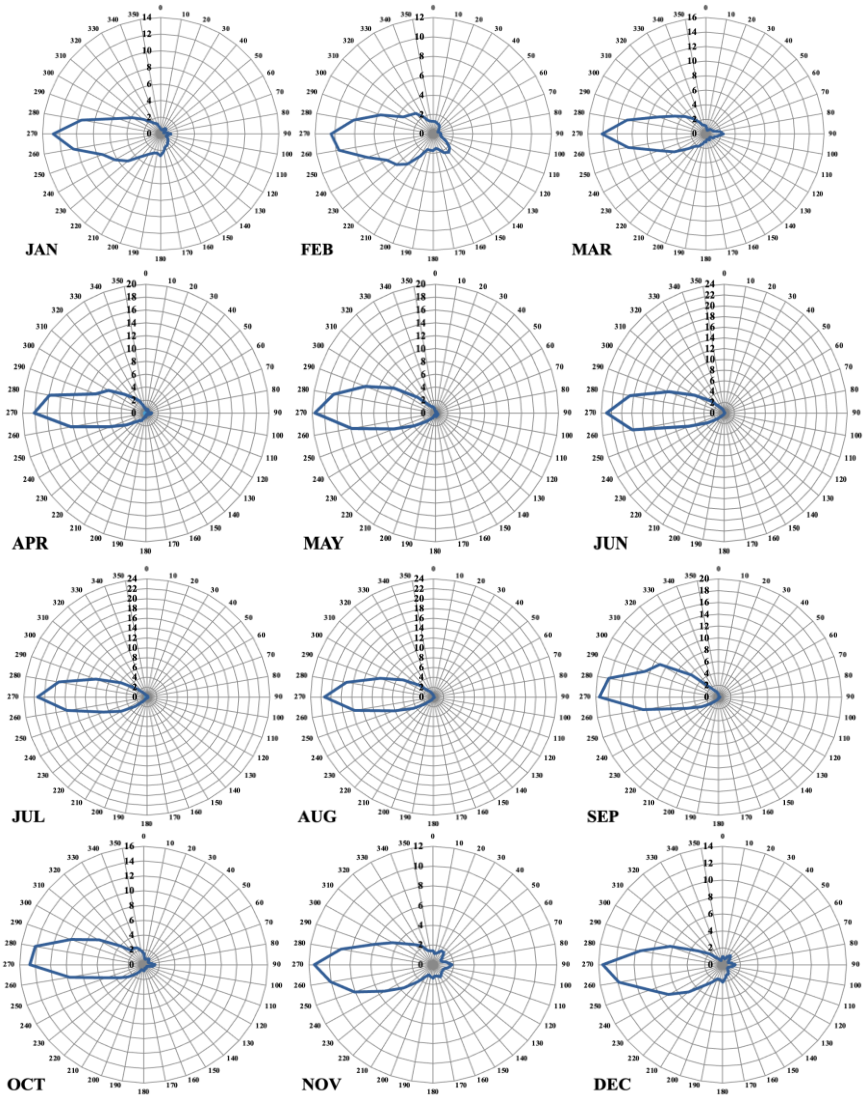

Figure 5. Wind directions of ash-containing clouds for the period September 1999 to July 2026, distributed by months. The graphs indicate the combined data of the five Ecuadorian volcanoes, which have been active in this time period. Information based on the data base of the Global Forecast System / North American Model of the National Oceanic and Atmospheric Administration (NOAA, 2026)

RESULTS AND DISCUSSION

Geochronology

Geochronological data based on charcoal separated from the prominent ash layer at the Papayita geosite yielded an age

of 3530 ±30 years (Páez-Barrera et al., 2024), being identical to the 3560 ±70 years BP, 3540 ±30 years BP and 3549 ±30 years BP ages of previous studies of the same deposit in different sites throughout the Ecuadorian area, being originated from the activity of the Pichincha Volcanic Complex (Zeidler, 1994, 2016; Robin et al., 2008, 2010). This age has been also revealed in tephra layers preserved in marine sediments reaching an age of 3516 years BP (Bablon et al., 2022). This was realized within the KAT18 core as the so-called ATAC-51 tephra, which was sampled just 75 km NW of the Papayita geosite without being associated with the same major event of the Pichincha Volcanic Complex.

Archeology

Upon examination in the field, it was clear that the area impacted by the backhoe exposed part of a larger site that was previously unknown in the Cerro Hojas-Jaboncillo archaeological area. The 15 m long by 2 m deep machine cut had revealed a stratigraphic sequence that indicated the existence of a cultural deposit, completely sealed off by other layers and capped by the contemporary surface which was being worked as a family-owned farming plot (Figure 6).

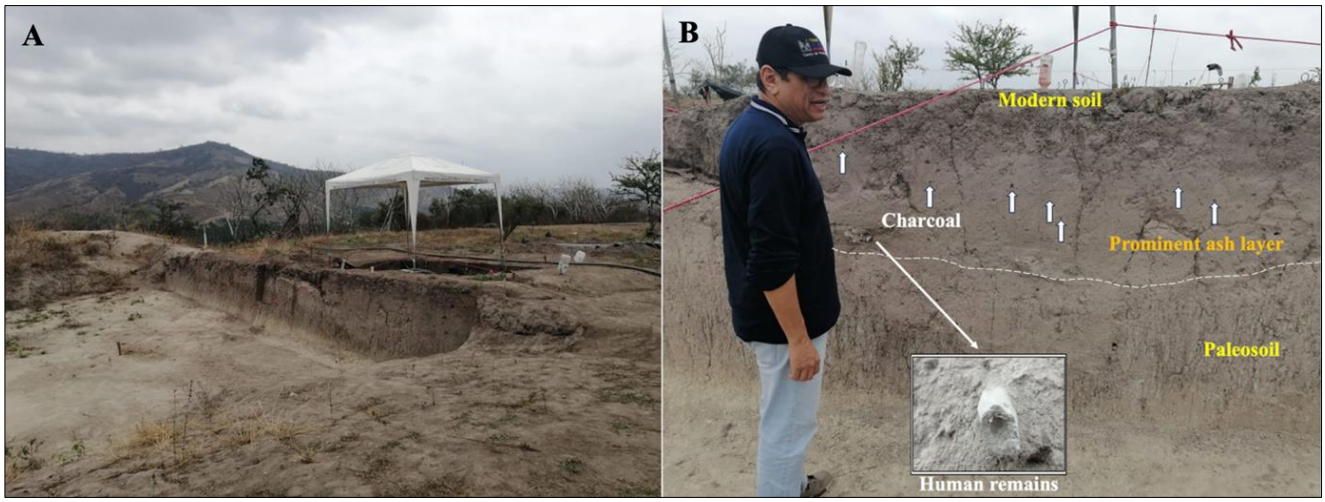

Figure 6. A: Initial excavation site at Papayita; B: Representative outcrop, with some fundamental parts of the excavation site; Both pictures were taken by Theofilos Toulkeridis on August 6, 2022

Since the backhoe cut provided a quite clear window into the stratigraphic configuration of the site, it was decided to clean this profile and then combine with narrow trenches to isolate a 4x4 m block that we would then remove using the different stratigraphic units as vertical guides. On the horizontal plane, we used as guides carefully delineated rectangular excavation sampling geometry units that ranged from 50 by 50 cm to 100 x 50 cm to carefully control the provenance of features and artifacts. This excavation process was carefully followed until each stratigraphic unit or context was extracted since it became apparent that we were excavating what appeared to be a domestic cultural context the encompassed different activity areas in evidence. From the very beginning of the findings, it was obvious that the ceramic material that the backhoe disturbed, and that we later examined on the field, pertained to a very late Valdivia component that suggested that it was best associated with the known data from Valdivia 7 and 8 phases. Once we started the excavation process and completed a few of the excavation units it became clear that we were dealing with a single component site.

The archaeological “living floor” had the artifacts within its context. This living floor was located on top of what appeared to be a paleosoil which in turn was preceded by a parent material. In other words, the Valdivia activity had taken place on virgin soil that had not been disturbed before the Valdivia settlement itself.

Excavated materials and features were varied although not very numerous. Among the recovered artifacts were utilitarian ceramics, some chipped stone tools, lithic debitage, animal bones (probably deer) and a small number of mollusk shells of marine origin. The features included a hearth, two possible offerings or ceremonial activity indications, one posthole, remains of what could be basketry artifacts or some organic material and two burials. In terms of the features which suggested activity areas the most obvious one was the hearth which contained some fragments of marine shells, as well as small fragments of charcoal and very few ceramic sherds. The base of the hearth was directly on the living floor context. Very near that hearth we found two lithic artifacts, one being a fragment of a cylindrical Mano (grinding stone) in a vertical position under rectangular brick-shaped lithic artifact with rectilinear incisions that may or may not have been some sort of abstract figurine. This latter artifact was placed horizontally on the top end of the vertically positioned Mano. The far end of the mano was resting on the living floor surface. Also on the living surface, a retouched flake tool with beaked/spurred working end, being likely for a graver/gouge function was found (Figure 7). The function of this configuration of artifacts, the cylindrical mano, and the brick like object, is not clear (Figure 7). They were obviously placed one on top of the other and they don’t seem to have been buried into the ash, rather they were buried by the ash while being on the living floor. A similar situation can be stated for the hearth which was clearly resting on the living floor. It was covered by the ashfall. Indeed, all the features and findings were essentially on the living floor, and they all appear to have been covered by the general ashfall event. The only feature that seems to have cut into the ash layer was Burial #1.

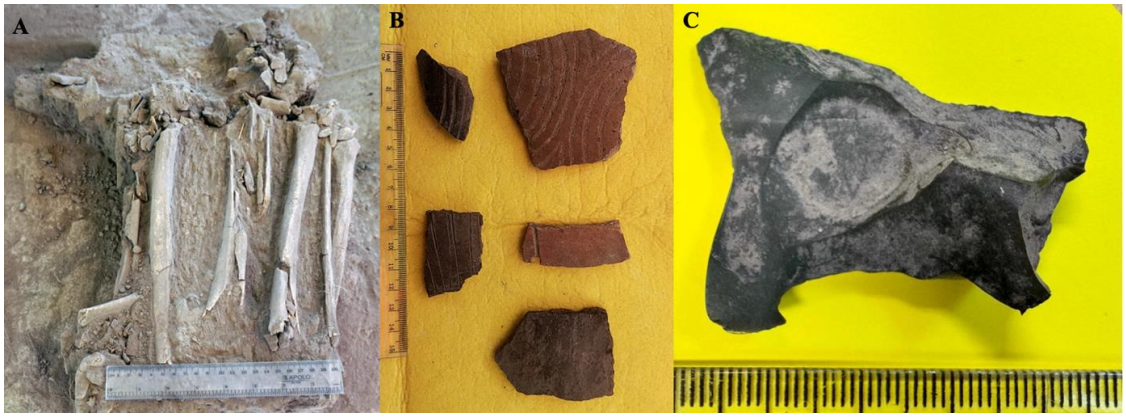

Figure 7. Excavated items of Papayita from the Valdivia culture: (A) Burial 1 exposed; (B) Valdivia Phase 8 ceramic sherds, mostly utilitarian ware; (C) cutting tool (knife) All pictures taken by Juan José Ortiz-Aguilú in December 2022

Burial #1 consists of human long-bone shafts arranged in a tight, sub-parallel cluster buried into the volcanic ash matrix, with little to no representation of axial elements (cranium, vertebrae, ribs) or pelvic components within the excavated block (Figure 7). The bone types represented and their spatial patterning are mainly robust limb long bones, in a mainly disarticulated position, and lacking anatomical continuity at the hip/pelvic region. Such content and configuration match well-documented indications of a reduced or secondary deposition, in which selected elements (often long bones) are intentionally collected and reinterred after decomposition elsewhere, rather than remaining in full articulation as in a primary burial (Bass, 2005; Buikstra & Ubelaker, 1994; Ubelaker, 1999). From a forensic standpoint, a configuration of long bones with absent or underrepresented axial/pelvic elements is repeatedly treated as a strong indicator of secondary mortuary handling, including bundle-type or redeposited remains (Rhodes et al., 2016; Ubelaker, 1999). While digging the *albarrada*, mechanical truncation appears to have removed the upper portion of the burial. The surviving long-bone–dominant pattern and the lack of clear hip articulation or pelvic concentration in situ are most consistent with a reduced/secondary long-bone deposit, pending confirmation through block excavation and inventory/MNI assessment.

As previously mentioned, sample of charcoal fragments contained in the burial matrix were submitted for C14 measurement for chronometric purposes, yielding a result of 3530 +/− 30 BP (ICA-14C-7129). This date aligns favorably with the current chronology for Late Valdivia. Therefore, Burial # 1 pit's context presents an interesting situation. Aside from the human remains described above, the burial soil content is indistinguishable from the pit's matrix. In other words, there is no contrast in texture, color, or particle size for example, between the soil inside the burial pit and the soil into which the pit was dug. They are both volcanic ash. That situation suggests that the burial pit was dug shortly after the ashfall and very likely at a moment where no pedogenesis had occurred and hence no dark topsoil existed. The absence of fill–matrix contrast is then consistent with a relatively short interval between ashfall and burial.

The analytical lens of Disaster Archaeology posits that sudden, high-magnitude natural events are primary drivers that can fundamentally alter the trajectory of civilizations. This perspective challenges the gradualist view of cultural change, emphasizing instead punctuated equilibrium—a concept borrowed from evolutionary biology by Eldredge & Gould (1972) and applied to social systems to explain abrupt "beginnings and endings" in the archaeological record (Torrence & Grattan, 2002). A disaster is not defined solely by the physical event, but by the social context in which it occurs. Hoffman & Oliver-Smith (2002) argue that disasters are "socially produced," occurring when a natural hazard meets a vulnerable population. The global archaeological record offers key parallels: Bawden & Reycraft (2000) have documented how the Moche state in Peru collapsed due to extreme El Niño (ENSO) events, while Payson Sheets (1992, 2002) illustrated at Joya de Cerén how volcanic eruptions can instantly entomb entire populations, creating a "time capsule" of domestic life interrupted by disaster. Even in modern times, events like the 1985 Armero tragedy in Colombia demonstrate how volcanism acts as a cultural "reset," altering landscapes and social memory permanently (Zeiderman, 2016). Studying these cataclysms allows archaeologists to measure "cultural resilience" (Redman, 2005) seeking to understand why some societies adapt to such abrupt changes, while others, facing a threshold of environmental stress, vanish.

Sealed deposits preserve short-term activity residues better than open stratified sequences. In the case of Papayita we have a scientifically exceptional site because it offers a closed Late Valdivia cultural system sealed by a geologically instantaneous ashfall, creating a rare opportunity to reconstruct behavior, chronology, and human–environment dynamics at unusually high resolution. It is, indeed, a near perfect stratigraphically integrated catastrophe-and-society case study.

Geochemistry and provenance analysis

Geochemical data of major elements of the sampled ash layer of the Papayita geosite may allow confirm its source to be the Pichincha Volcanic Complex or, however, to identify a different source by revealing a thorough provenance analysis involving other potential sources. Therefore, samples of ashes of a several volcanoes were taken, of which activities were expected to have occurred close the given timeframe some 3,5 ka ago. Those chosen volcanoes should have had also recorded volcanic events which may have been superior to a volcanic explosivity index (VEI) of 4, as this degree or higher, represents very strong impacts of pyroclastic material in even remote areas. This case is given in the Papayita geosite,

which in respect to the distance to any of the volcanoes of the Ecuadorian Andes is yielding that a very strong eruption was capable to deposit such quantities of ashes in this spot. Subsequently, the samples were taken from the Cuicocha, Pululahua, Niñahuilca, Quilotoa, Cotopaxi and Chalupas volcanoes. Furthermore, special emphasis was given on further samples for reason of comparisons of the Pichincha Volcanic Complex such as young, historic known layers, ashes of the 3,5 ka event of the volcano found on its western rim, ashes slightly older to the 3,5 ka event and much older ashes of the Rucu Pichincha sector of the Pichincha Volcanic Complex. Based on the chosen samples of the identified source and other potential sources, provenance analysis in form of ternary diagrams were realized. Provenance analysis may be realized with mineralogical assemblages, lithic compositions, isotopic pairs or geochemical data in combination of major, trace or rare earth elements (Toulkeridis et al., 1999; Toulkeridis et al., 2015; Toulkeridis et al., 1998; Toulkeridis et al., 2010; Seelos et al., 2021; Bryant et al., 2006; Willmes et al., 2018; Alvarado-Induni et al., 2026; Rollinson, 2014). In the current research, this occurred with the combination of the oxides of major elements of the more mafic constellation of SiO_2-((Na_2O-K_2O)*5)-Al_2O_3 (Figure 8a and 8b) The ternary diagrams were subdivided in the potential sources of the different, age-related ashes of the different volcanoes and to the different ashes of the Pichincha Volcanic Complex. Hereby, a very nice correlation was observed within the given ternary diagrams. There, clear distances revealed that the ash samples of the Papayita geosite were identical to the pyroclasts taken of the 3,5 ka event site, west of the Pichincha Volcanic Complex (Figure 8b). Furthermore, the other potential sources are quite distinct to the geochemical affinity of the sampled ashes of the Papayita geosite (Figure 8a).

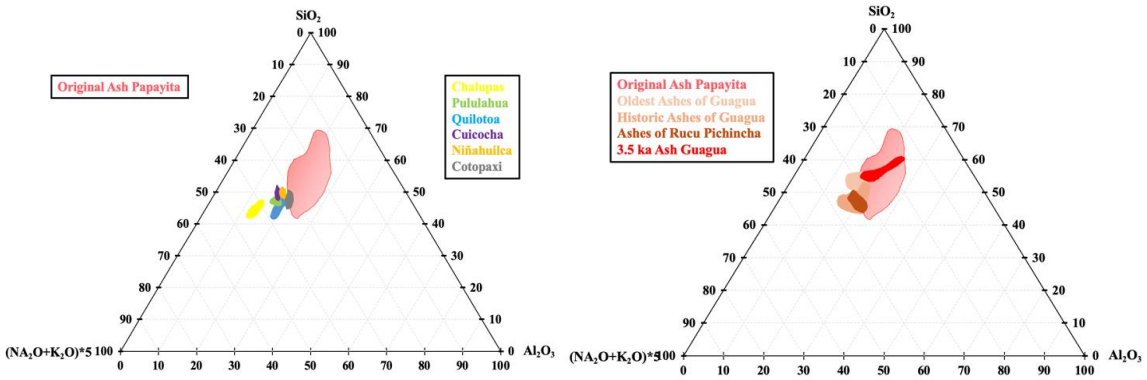

Figure 8a (left) and 8b (right). Ternary diagrams about the provenance analysis of the potential source of the studied prominent ash layer (explanation see text)

Wind direction of the ashes and magnitude of corresponding eruption

Based on the findings in several sites of the coastal area, where the prominent ash layer has been encountered, the determined thicknesses of the ash layer may reveal that the explosive event which occurred some 3,5 ky ago and distributed the mentioned tephra, resulted to have been directed towards the west to southwest direction of the Pichincha Volcanic Complex. This would most likely have occurred in the early months of the year, meaning around January to February, as these are the months where the ash-carrying eruptive clouds direction points to such course. Up to date, the extension of the magnitude of the eruptive cloud and the corresponding ash volume was not well documented, as only very few and mostly very thin layers were considered to calculate the resulting VEI of this catastrophic event. The method for calculating the minimum volume of tephra was based on the formula of Legros (2000), which calculated the volume based on a single isopach with the equation (Legros, 2000):

$$V_{min} = 3.69\ TA$$

where V_{min} is the minimum volume, T is the thickness (cm) of the isopach and A is the area (km^2) of the isopach. The data used have been of about 0.03 cm for T and $15*10^9$ for A. Unfortunately, these preliminary findings gave a way to incomplete idea of the extension of the disaster 3,5 ky ago as its calculation was demonstrating just a VEI of 4 (Vallejo Vargas, 2011). In order to compare such an event of modern times, a VEI of 4 occurred in Ecuador on November 3, 2002, when the El Reventador volcano erupted, some 90 km east of Quito (Ridolfi et al., 2008; Toulkeridis et al., 2022). Then, the westwards directing ash cloud precipitated some 2 mm of ash in Quito. The Papayita geosite is situated some 225 km southwest of the Pichincha Volcanic Complex and the prominent ash layer does have a thickness of at least 85 cm (Figure 9). This prominent ash layer has been found in many remote places within Ecuador, including Jama, Coaque, Julcuy, Mana besides many other sites and always having considerable thicknesses, being much higher in average than those reported in Vallejo Vargas (2011). Nonetheless, with the new findings, especially based on the thicknesses of the prominent ash layers at the Papayita geosite and also elsewhere, as mentioned previously, the newly calculated VEI is almost exponentially higher than that previously reported, as it yielded a VEI of 6, making this recorded event to one of the most devastating of the Ecuadorian active volcanism in the Holocene so far. Previously to the present study, it was documented that a massive volcanic eruption emanating from the Ecuadorian highlands blanketed a large swath of the western lowlands with a tephra mantle so thick that Early Formative lifeways were completely devastated and resident populations of northern Manabí were forced to either migrate or succumb to asphyxiation and/or famine (Zeidler & Isaacson, 2003). The footprint of this eruption was not well understood, but its effects have been well documented in the Jama Valley of northern Manabí, where the Piquigua Phase peoples abruptly disappeared and the valley was abandoned for over 600 years (Zeidler, 1994; Zeidler et al., 1998; Zeidler & Isaacson, 2003).

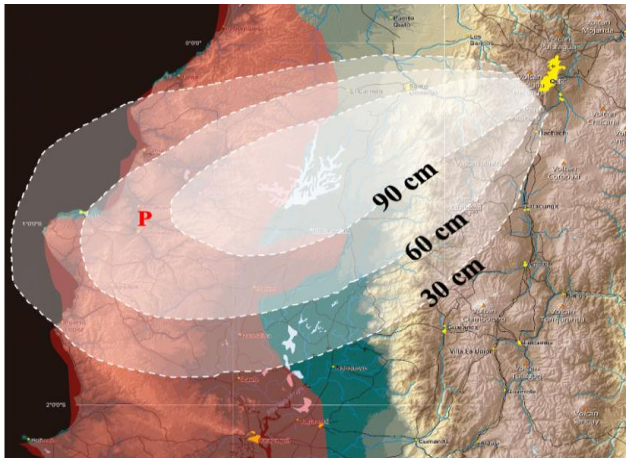

Figure 9. The morphological map of Ecuador with the potential ash distribution and corresponding isopachs of 30, 60 and 90 cm of the eruptive event of the Pichincha Volcanic Complex some 3,5 ka years ago (Páez-Barrera et al., 2024); The known distribution of the Valdivian culture in coastal Ecuador is illustrated in reddish color, while "P" points the study area of the Papayita geosite, based on Meggers & Evans, 1977; Meggers et al., 1965; Map of the Military Geographical Institute (IGM) of Ecuador

Figure 10a-b. Hypothetical, illustrative reconstruction of the triple mega-event in the Ecuadorian coast some 3,5 ka ago; Explanation see text. All images were generated by Artificial Intelligence

Reconstruction of the 3,5 ka mega-event, which destroyed the Valdivia culture

The new geo-archaeological discoveries in the Papayita geosite may allow to reconstruct and or reveal a triple mega-event that ended the flourishing of the Valdivia culture in the Manabí and Guayas area of coastal Ecuador. Close or on beach areas of Ecuador, several paleotsunami deposits have been encountered, which indicate the existence of severe marine quakes in the past, a behavior very well-known up to present day as demonstrated previously. These very strong seismic events have occurred in the recorded past along the south American continental margin, very magnitudes have reached up to 9.5 Mw on the Richter scale, destroying vast areas close to the epicenters due to the resulting long-lasting movements and due to the corresponding associated generation of devastating tsunamis (Cisternas et al., 2005; McCaffrey, 2008).

In the case of Ecuador, a new discovery includes a paleotsunami deposit in the San Pablo area in the Province of Santa Elena, some 120 km south of the Papayita geosite. There, a 18cm thick paleotsunami deposit dated an OSL age of 3,500±30 years, being identical to the charcoal separated from the ash deposit on the Papayita geosite (López Cadavid et al., 2019). This implies, that a strong earthquake occurred, which may have frightened some of the public of the Valdivia culture, without provoking major concerns, as at the ancient times more than a few landslides may be not to be expected in the coastal area of Ecuador. Landslides as well as liquefaction as result of earthquakes in the coastal morphology are quite common, as demonstrated in 2016 due to the 7.8 Mw earthquake, but these phenomena most likely lacked to provoke an extended harm as it did in present society with unprepared or less seismic resistant modern edifices with a high number of fatalities (Toulkeridis et al., 2017; Ortiz-Hernández et al., 2022a; 2022b; Avilés-Campoverde et al., 2020; Sennson & Beck, 1996).

Nonetheless, we simply speculate that shortly after the shaking due to the marine earthquake, an incoming wave certainly impacted the people who were elaborating fishing and other beach activities of the Valdivia culture (Figure 10a) bringing death and devastation close, on the beaches and sometime towards inland based on channeled rivers, deltas and estuaries. Volcanic activity of the Ecuadorian highlands may have been perceived and accompanied the Valdivian culture from time to time where some strong explosions may have been heard and some less amounts of ashes may have been precipitated upon the Valdivian villages (Figure 10b). It may be pure speculative but also potentially true, that such strong seismic movement, as previously explained, along the Ecuadorian coast may have triggered the volcanic activity of the Pichincha volcanic complex to generate an enormous eruptive power, leading to a VEI of 6, which precipitated rather quickly enormous amounts if fine-grained volcanic material towards the settlements of the Valdivian culture. Such active eruptive phase may have very fast not only covered a huge amount of land destroying in the agricultural sector the growing crops, the associated livestock and

related tasks. However, even worse, such amounts of ashes were leading to death by asphyxiation to animals and humans alike, as almost no opportunities existed to escape this deadly volcanic hazard as demonstrated in our study.

The surviving public migrated to other lands to escape the deadly ash-covered areas and for certainly many years unproductive lands. It may be pure coincidence, but exactly along this time, 3,5 ky ago, indigenous people entered Amazonian caves such as the Tayos cave may as a potential shelter of the described mega-triple event (earthquake-tsunami-volcanic explosion), as evidenced by archeological findings (Judson, 1976; Toulkeridis et al., 2025). Such "triple" mega-events are not unusual in human history as shown in the Greek Island of Santorini 3,6 ky ago, where (volcanic) earthquakes have led to the escape of the public from the volcanic island, which later erupted to form an enormous caldera, and shortly later to generate a deadly tsunami along the Aegean Sea (Bruins et al., 2009).

CONCLUSIONS

The multidisciplinary research that has been conducted at the Papayita site provides fundamental information about the abrupt termination of the Valdivia tradition in the central and north-central Manabí province. This study, by integrating archaeology, geochemistry, and volcanology, finds important conclusions. The analysis of the geochemical provenance links the ash deposits at Papayita site to the Pichincha Volcanic Complex. The stratigraphic profile identifies a tephra layer of approximately 85 cm, which, according to new calculations based on isopach distribution, can correspond to a VEI of 6.

This number puts this event as one of the most devastating within the Holocene. Simultaneously, geochronological data found within the tephra (3530 ±30 years BP, uncalibrated) indicates a direct temporal link between the Guagua Pichincha eruption and the terminal phase of the Valdivia Phase 8 culture (ca. 1600–1500 BC). The archaeological evidence at Papayita, specifically hearths and ceremonial offerings encased in ash, proves that the eruption occurred during active domestic occupation, when occurred immediate and permanent abandonment of the site.This study demonstrates an observed regional variation in human response to the disaster. While southern populations exhibited resilience through a gradual transition into the Machalilla phase, the central coast of Manabí suffered a total societal collapse followed by a 600-year hiatus of abandonment. This period of depopulation, lasting until the arrival of the Chorrera tradition, highlights that the magnitude of the ashfall rendered the structured agricultural systems of the Valdivia untenable in this specific region. This, however, can be related to the impact of the ash in the areas. Perhaps in Southern coast, the effect was a minimal to any, and thus, we can observe a steady transition between Valdivia and Machalilla traditions.

Investigations which information is presented here suggests in a purely speculative form, that this volcanic event may have been part of a larger compound disaster, potentially triggered by a high-magnitude earthquake and tsunami. Such geodynamic interaction is characteristic if the extreme vulnerability of the Ecuadorian coast, mainly due to the subduction and collision of the Nazca Plate with the continent. Finally, the Papayita area is established as an extraordinary archeological geosite of global importance. It is and works as a "time capsule" preserving a high-resolution record of the intersection between catastrophic natural hazards and social vulnerability. Hereby, it also serves as an indicator of a warning to modern society towards the recurrence of future catastrophic events with little to no warning.

Abstract: Karst areas have complex hydrogeological systems resulting from the dissolution of carbonate rocks, fracture networks, and the presence of underground rivers. Lo Cave and Bangi Cave, in South Malang, are located in the Wonosari Formation and are known as active underground river sites with potential for the development of karst geotourism, speleology, and water resources. However, to date, no study has combined geophysical and hydrochemical methods to provide information on underground river connectivity, karstification levels, and groundwater vulnerability at these sites. This study aims to understand the subsurface structure, flow patterns, and geochemical processes as a basis for geotourism development. This study was conducted in Kedungsalam Village, South Malang, Indonesia. This study used Self-Potential (SP), Induced Polarization (IP), and Hydrochemical analyses. SP data showed negative anomalies consistent with underground flow paths connecting the two caves. IP data identified loading zones at Lines 4, 6, and 7, which are suspected to be active cavities and water-filled channels. Hydrochemistry analysis showed that all samples had low mineralization (TDS 31-63 mg/L), neutral to slightly alkaline pH, and were dominated by Ca^{2+}–Mg^{2+}–HCO_3^- ions. Similar hydrochemical facies confirm that all water sources originate from a single, interconnected karst aquifer system. Integration of geophysical and hydrochemical methods reveals that Lo Cave and Bangi Cave form a hydrogeological system, with active channels and flow controlled by carbonate dissolution.

Keywords: carbonate rocks, cave, dissolution karst, geotourism development, geosite, hydrochemistry, induced polarization, karst aquifers, self potential, underground river

* * * * * *

INTRODUCTION

Karst areas are unique and complex landscapes due to the close relationship between geomorphology, geology, and (Cao et al., 2024; Faizal et al., 2025a; Ford & Williams, 2013). Karst hydrochemistry is a highly dynamic and heterogeneous system due to interactions between water and rocks (Pambudi et al., 2024; Tian et al., 2025). The main characteristic of karst areas is the dominance of carbonate rocks such as limestone and dolomite, which are readily soluble in water (Deng et al., 2022). The longterm dissolution process forms distinctive morphologies such as caves, dolines, sinkholes, and complex underground river networks. These structures make karst systems vital for storing and distributing groundwater, while also

making them vulnerable to environmental changes and human activities (Faizal et al., 2017; Jones & White, 2019). Groundwater dynamics in karst areas differ from those in aquifers in ordinary rocks. Groundwater movement is controlled by subsurface fractures, channels, and cavities that serve as primary flow pathways (Ma et al., 2022; Yang et al., 2024).

This makes groundwater flow patterns in karst areas highly complex and difficult to predict (Zhao et al., 2023). Consequently, karst groundwater systems are highly sensitive to hydrological changes, both natural and anthropogenic (Yang et al., 2026), such as water exploitation, land-use changes, and seawater intrusion in coastal areas. The Lo Cave and Bangi Cave complexes are part of a karst system that developed in southern Malang, East Java, Indonesia. This area was formed in the carbonate rock of the Wonosari Formation, which underwent intensive dissolution, resulting in distinctive cave, doline, and underground drainage systems related to local aquifer activity (Susanti et al., 2025; Utomo & Siregar, 2018). Based on previous research (Faizal et al., 2025) and field observations, these two caves have underground river flows that can meet domestic and agricultural water needs in the area. However, to date, scientific information explaining the geochemical processes, the direction of underground flow, and potential groundwater contamination in this area remains very limited.

Understanding the dynamics of karst aquifers at the research site requires integrating subsurface conditions and geochemical information. Hydrochemistry analysis is an important approach in tracing the dissolution process of carbonate rocks and the characteristics of groundwater evolution. Measuring major ions such as calcium (Ca^{2+}), magnesium (Mg^{2+}), sodium (Na^{+}), potassium (K^{+}), bicarbonate (HCO_3^{-}), sulfate (SO_4^{2-}), and chloride (Cl^{-}), it is possible to determine the extent to which carbonate dissolution dominates the chemical composition of groundwater and the importance of external influences such as anthropogenic activity or seawater intrusion (Alemdağ et al., 2025; Féraud et al., 2009; Zhao et al., 2023). The chemical composition of groundwater reflects the complex interactions between water, rocks, and the atmosphere, which are influenced by the depth of the aquifer, the water residence time, and local Hydrochemistry conditions (Liang et al., 2018; Ryzhenko & Sidkina, 2017). Riyanto & Cahyadi (2023) investigated the carbonate dissolution process in the Gunung Sewu karst springs, which are also located in the Wonosari formation, and found that the dominant ions in the springs are calcium ($Ca^{2+)}$ and bicarbonate, derived from bicarbonate limestone.

On the other hand, geophysical methods can provide information on karst subsurface features, such as cavities, fractures, and groundwater flow paths (Hussain et al., 2020; Wang, 2026; Zhou et al., 2002), and are non-intrusive and cost effective (Massinai et al., 2023). Various geophysical techniques have been used to support karst Hydrochemistry research, including Self Potential (SP) and Induced Polarisation (IP). The SP method is sensitive to the movement of conductive fluids and natural potential gradients, making it effective for detecting patterns and directions of underground water flow (Ammar et al., 2023; Boimau et al., 2023; Revil et al., 2004). In the Malang karst area, the SP and resistivity methods were used to map underground river flow, showing a good correlation between SP anomalies and water flow paths (Susilo et al., 2017). The study by Boimau et al. (2018) also showed that low potential values in SP data can be used to identify underground river paths in the karst area of South Malang. Meanwhile, the IP method can map chargeability zones indicative of carbonate rock dissolution or water-saturated zones (Lubang et al., 2023; Yang et al., 2023).

Research conducted by Wahid et al. (2022) using the IP method at Sendang Biru Beach, Malang Regency, successfully identified zones with high chargeability, which are generally associated with cavities or fractures filled with water.

Although several studies using Hydrochemistry or geophysical methods have been conducted in the karst area of South Malang, the results have not provided a comprehensive picture because they have used only a single approach. Integrated research using Hydrochemistry, SP, and IP methods has never been conducted, especially in the South Malang region. Therefore, this study combines these three methods to analyse the relationship between carbonate dissolution processes and groundwater characteristics around Lo Cave and Bangi Cave. The integration of the results from these three methods provides a more comprehensive understanding of the dynamics of karst aquifers and a scientific basis for water resource management and geotourism development in the South Malang region, Indonesia.

MATERIALS AND METHODS

Study area

This research was conducted in the Gua Lo and Bangi areas, Kedungsalam Village, Donomulyo District, Malang Regency, East Java Province. Geographically, it is located at coordinates 112.426°–112.427° East Longitude and 8.342°–8.345° South Latitude. The research area is located in the Wonosari Formation (Figure 1), which comprises carbonate rocks such as coral limestone, clay limestone, tuff limestone, and sandy limestone (Faizal et al., 2025; Labib et al., 2019; Susanti et al., 2025). Based on the results of research conducted by Sholichin & Prayogo (2019), the subsurface conditions around the research location consist of layers of sand, mud, clay, tuff, limestone, and andesite, which determine the storage capacity and quality of groundwater in the South Malang area. The dissolution process in these carbonate rocks produces a complex karst system both on the surface and below the surface, including dolines, karst hills, and horizontal and vertical cave networks, which often contain underground spaces (Labib et al., 2019; Sahrina et al., 2022).

Geophysical Methods

The geophysical methods used in this study were SP and IP. These two methods complement each other in identifying groundwater flow patterns, conductive zones, and karst rock characteristics that can form cavities or fractures beneath the surface. Data collection was conducted using eight lines adapted to the field topography, with a line length of 180 meters and electrode spacing of 10 meters (Figure 2).

The dipole-dipole configuration used was a resistivity instrument manufactured by PASI SRL, Turin, Italy.

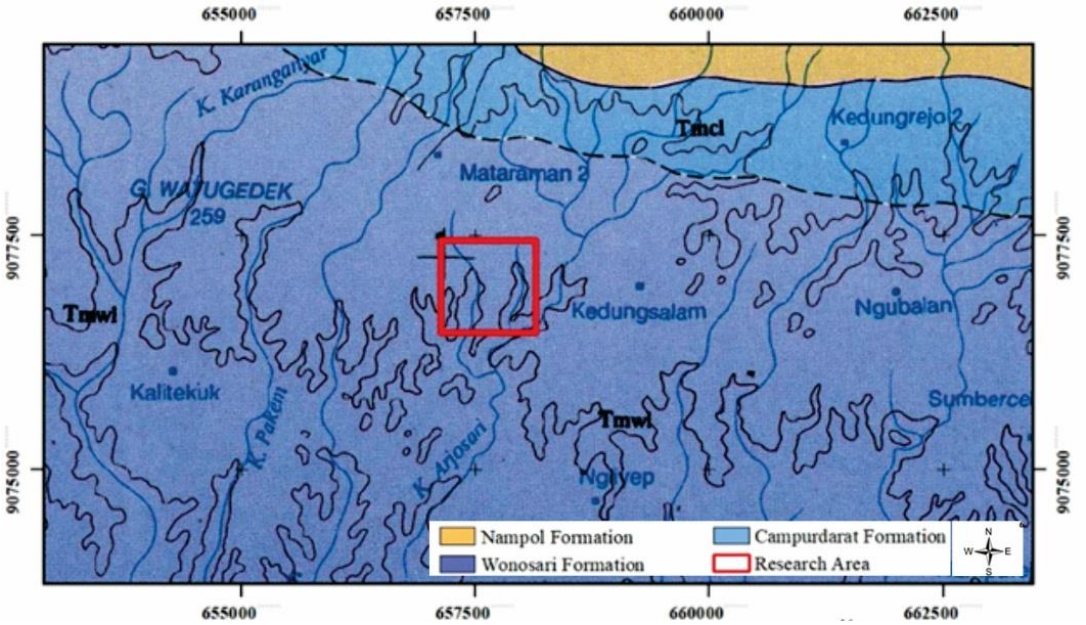

Figure 1. Geological map of the research area (Source: Developed by the authors, 2025)

SP measurements were conducted to detect natural potential variations arising from differences in electrokinetic gradients in the groundwater flow system. The obtained data were then processed using 2D inversion with a smoothness-constrained least-squares approach, and the results were plotted to display the distribution of potential contours.

The negative potential anomaly pattern was interpreted as a natural conduit or water-saturated zone, indicating the direction of underground river flow in the karst areas of Lo Cave and Bangi Cave. Meanwhile, the IP method was applied to analyse the electrical properties of subsurface rocks associated with cavities, fractures, and water-saturated zones.

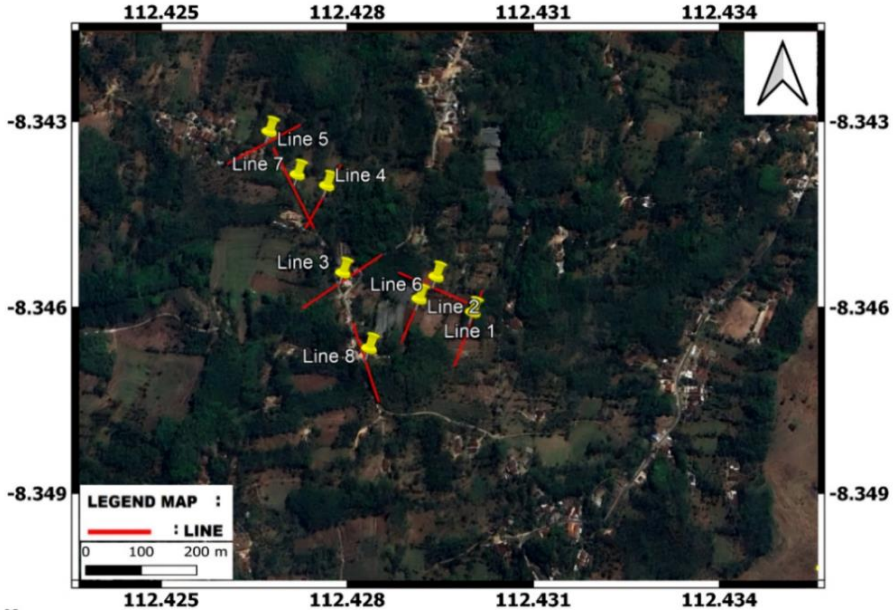

Figure 2. Research Location and Groundwater Sampling Points in the Lo Cave and Bangi Bangi Karst Areas, Kedungsalam Village, Malang Regency (Source: Developed by the authors, 2025)

Measurements were conducted in the time domain by injecting an electric current through a current electrode and observing the remaining potential difference after the current was turned off. The configuration used was a dipole-dipole with a resistivity meter. The main parameter analysed was chargeability. High chargeability values indicate a strong polarisation effect, which is generally associated with dissolved-carbonate rocks or groundwater-rich zones.

Hydrochemistry Method

Hydrochemistry methods were used to analyse the chemical characteristics of water reflecting the dissolution processes, flow dynamics, and aquifer types in the Lo Cave and Bangi Cave karst systems. Purposive sampling was used at strategic points, including the river flow within the caves and surface water sources around the Lo Cave and Bangi Cave areas (Figure 3).

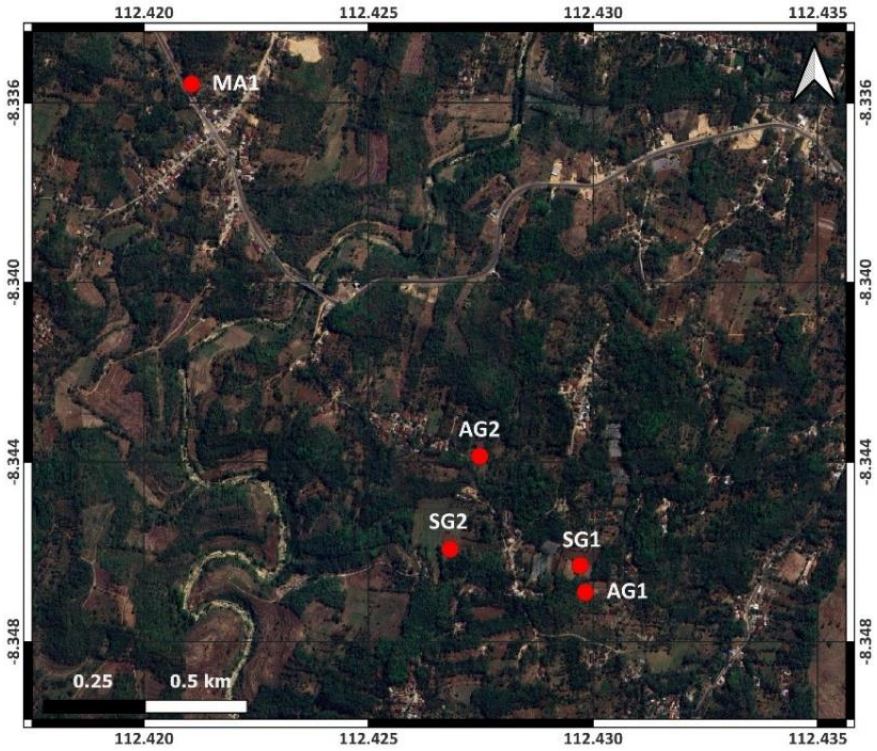

Figure 3. Groundwater Sampling Points in the Lo Cave and Bangi Cave Karst Areas, Kedungsalam Village, Malang Regency (Source: Developed by the authors, 2025)

The selection of chemical parameters was based on their relevance to the carbonate rock dissolution process and the possibility of external contributions, both from anthropogenic activities and seawater intrusion. The Hydrochemistry parameters analysed included the concentrations of major ions, namely calcium (Ca^{2+}), magnesium (Mg^{2+}), bicarbonate (HCO_3^-), sodium (Na^+), potassium (K^+), chloride (Cl^-), and total dissolved solids (TDS). The laboratory analysis data were then processed to determine the concentration of each ion and the total dissolved content. Ion balance analysis was performed on the main elements, namely Mg, Na, K, Ca, Cl, SO_4, CO_3, and HCO_3. Theoretically, the ion content of groundwater should be balanced between positive and negative ions (Atkinson, 2024; Lu et al., 2020; Megha et al., 2025; Sajil Kumar & James, 2019). This principle is the basis for hydrochemical evaluation by calculating the Charge Balance Error (CBE) of the main ion concentrations from laboratory analyses using Equation 1 (Domenico & Schwartz, 1997).

$$\text{CBE (\%)} = \frac{\sum \text{kation} - \sum \text{anion}}{\sum \text{kation} + \sum \text{anion}} \text{ x } 100 \qquad (1)$$

The calculation of the Charge Balance Error (CBE) is carried out by converting the ion concentration, both the ∑ cation component, which represents the total positively charged ions, and the ∑ anion component, which shows the total negatively charged ions, from milligrams per liter (mg/L) to milliequivalents per liter (meq/L).

The hydrochemical data are then plotted on a Piper diagram (Piper, 1944) to determine groundwater type and to interpret relationships among sources based on the dominance of their major cations and anions.

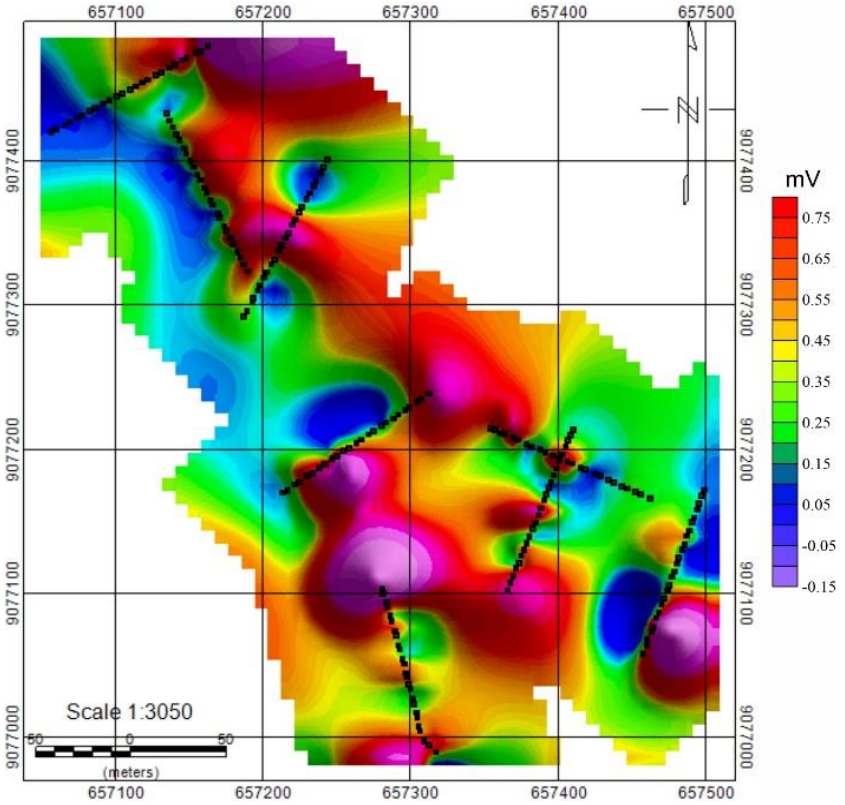
The geophysical interpretation results are integrated with hydrochemical analysis to provide a more complete picture of the subsurface structural characteristics, groundwater flow patterns, and geochemical processes controlling the aquifer system.

RESULTS

Results of the self potential method in the Lo Cave and Bangi Cave karst area

Figure 4 shows a contour map of SP anomalies in the Gua Lo and Gua Bangi karst areas. Negative potential values indicate conductive zones, while positive values characterize resistive zones. Negative SP anomalies, shown in blue to dark purple, are thought to represent groundwater flow pathways or active recharge zones. These zones are characterized by dissolution features, such as cracks, sinkholes, and epikarst development. SP values down to approximately -0.15 mV indicate high fluid movement intensity in the study area. The distribution of negative anomalies in the Lo Cave and Bangi Cave areas follows the morphological orientation of the karst hills, indicating that rainwater falling on the hilltops infiltrates and then flows through the fracture system to the lower zones. The presence of these negative anomalies also reflects ongoing speleogenesis, in which carbonate rock dissolution occurs continuously as water flows, carrying dissolved ions. The zone with strong negative anomalies in the central and southeastern parts of the map is thought to indicate an underground water channel connecting Lo Cave and Bangi Cave. The existence of this channel is not only crucial for understanding groundwater dynamics but also indicates ongoing active geological processes, such as carbonate rock dissolution and underground cavity formation. Meanwhile, positive SP anomalies, indicated by yellow to red colors (values

> 0.15 mV to > 0.75 mV) as more resistive areas, are thought to be related to relatively higher or drier topography that serves as a recharge area, as well as the presence of impermeable lithologies such as marl or carbonate mudstone.



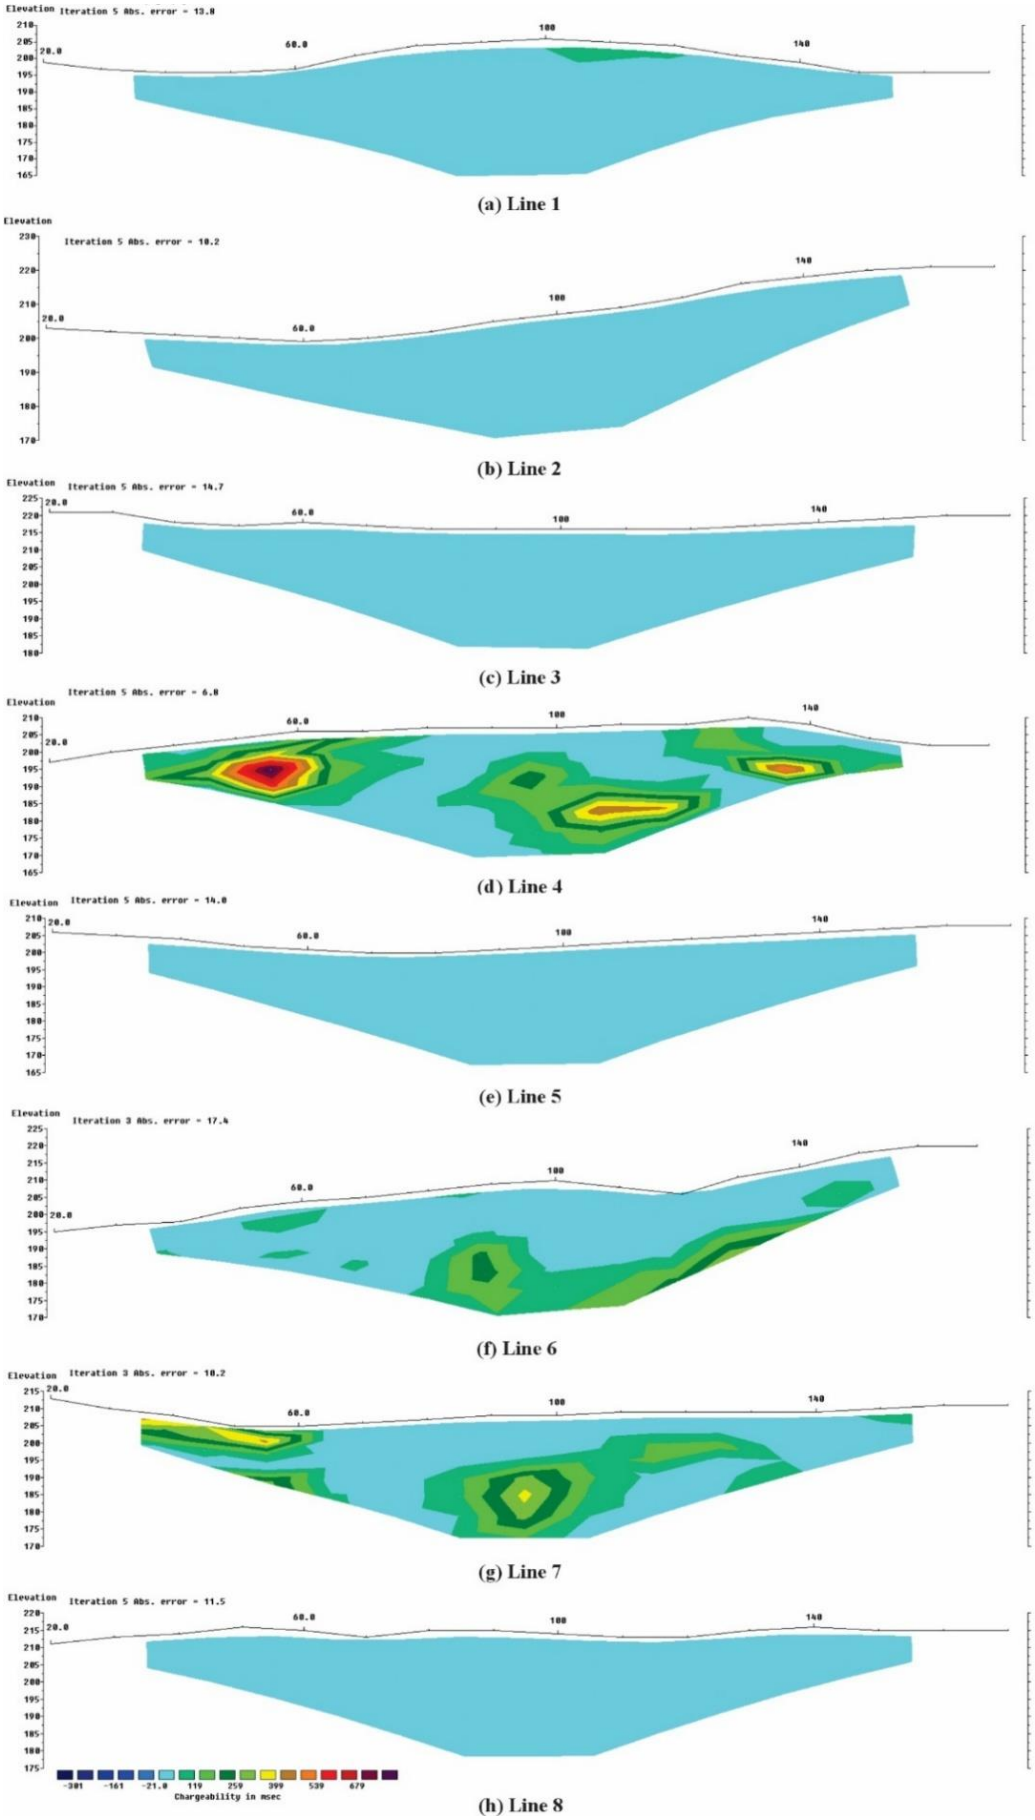


Figure 4. Contour map of Self Potential anomalies in the Lo Cave and Bangi Cave karst areas (Source: Developed by the authors, 2025)

Results of the induced polarization method in the Lo Cave and Bangi Cave karst areas

Figure 5 shows the results of 2D Induced Polarization modeling for eight lines (lines 1-8). The colors, from dark blue (low charge) to red (high charge), provide subsurface information on lithological conditions, dissolution rates, and the presence of conductive fluids. Line 1 (Figure 5a) shows a zone dominated by low to moderate values, with one green anomaly (~60-120 ms) at a depth of approximately 5-8 meters. The presence of moderately charged material is thought to be related to carbonate rocks that have undergone alteration or initial dissolution, which have not yet been filled with clay or water. This condition indicates the presence of shallow infiltration pathways (epikarst) that serve as initial channels for surface water movement into the subsurface. Based on field observations, a ponor serves as the primary entry point for surface water into the underground hydrological system at this location (Figure 6). The presence of this ponor is consistent with the IP anomaly in Line 1 and the SP pattern (Figure 4), both of which indicate active infiltration pathways.

Lines 2, 3, 5, and 8 (Figure 5) show low charge values (<40 ms) throughout most of the cross-section. This pattern indicates that these four lines are located within compact carbonate units with low dissolution rates. Therefore, these lines can be interpreted as part of a stable rock, as shown in the figure, or an anticline zone with little dissolution or fluid recharge at these depths. Line 4 (Figure 5d) shows a very prominent chargeability anomaly, characterized by a red to purple zone (>300 ms) on the left side of the cross-section. This zone indicates the presence of water-filled karst cavities or residual clay deposits trapped within dissolution channels. This high-value anomaly suggests intense hydrogeological activity, with fluid flow focused in the area. This pattern is consistent with SP results at the exact location, which identified laterally elongated underground flow paths. Thus, Line 4 can be considered the area with the most active karst aquifer dynamics in the study area. Line 4 (Figure 5d) shows the presence of a red to purple zone (>300 ms) on the left side of the line, indicating the presence of water-filled karst cavities or residual clay deposits trapped within dissolution channels. This anomaly indicates hydrogeological activity with focused fluid flow in the area. This pattern is consistent with SP results at the same location, which identified laterally extending underground flow paths. Lines 6 and 7 (Figures 5f and 5g) show several zones with moderate to high chargeability values at intermediate depths. Zones with chargeability values of 120–180 ms indicate the presence of cavities or conductive materials such as clay, and are surrounded by weathered carbonate rocks. Anomalies on both lines indicate isolated zones, characteristic of tropical karst systems in massive carbonate rocks. This pattern is consistent across Lines 6 and 7 and also suggests possible connectivity between cavities around Bangi Cave.

IP modeling results for lines 2, 3, 5, and 8 indicate resistive zones with low chargeability values, representing compact carbonate rocks with minimal dissolution activity. In contrast, Lines 4, 6, and 7 have zones with high chargeability values, indicating areas of intense dissolution, water-filled karst cavities, and accumulation of conductive materials. Overall, this pattern demonstrates subsurface heterogeneity in the Lo Cave and Bangi Cave karst systems.

Hydrochemistry facies analysis based on the Piper diagram

The results of groundwater sample analysis around Lo Cave and Bangi Cave show variations in the concentrations of major ions and differences in chemical characteristics between locations (Table 1). Sodium (Na) concentrations ranged from 9.87 to 21.83 meq/L, with the highest value in SG2 and the lowest in AG1. Potassium (K) content was relatively low in all samples, ranging from 0.13 to 0.23 meq/L. Calcium (Ca) was approximately between 1.25 and 1.79 meq/L, while magnesium (Mg) ranged from 0.54 to 1.34 meq/L. Bicarbonate (HCO_3^-) ranged from 1.53 to 2.74 meq/L, with the highest value in SG2 and the lowest in MA1. Chloride (Cl^-) content is very low, namely 0.0045–0.0062 meq/L, while sulfate (SO_4^{2-}) is between 0.62–0.85 meq/L, with the highest value in MA1. The pH value shows neutral to slightly alkaline conditions (6.8–7.8). Total dissolved solids (TDS) with values between 31–63 meq/L, with the highest value in MA1 and the lowest in AG2. In general, the analysis results show that groundwater in the study area has low mineralization, with Na^+, Ca^{2+}, and HCO_3^- ions dominating the hydrochemical system. The Charge Balance Error (CBE) for the 5 groundwater samples analyzed is below 10%, indicating that all samples are valid and can be used in further analysis.

Table 1. Physical and chemical parameters of groundwater in the Lo Cave and Bangi
Cave karst systems, Kedungsalam Village, Donomulyo District, Malang Regency (Source: Authors, 2025)

Sampel	Na (meq/L)	K (meq/L)	Ca (meq/L)	Mg (meq/L)	HCO3 (meq/L)	Cl (meq/L)	SO4 (meq/L)	pH	TDS
SG-1	14.33	0.21	1.79	0.80	2.42	0.0045	0.62	7.8	37
AG 1	9.87	0.13	1.60	1.07	2.47	0.0045	0.77	7.2	43
AG 2	12.26	0.20	1.25	0.81	2.25	0.0054	0.69	6.8	31
SG 2	21.83	0.15	1.29	1.34	2.74	0.0054	0.62	7.8	47
MA 1	12.89	0.23	1.32	0.54	1.53	0.0062	0.85	7.5	63

Figure 7 shows the hydrogeochemical facies classification using the Piper Diagram for five water samples around Lo Cave and Bangi Cave (SG1, SG2, AG1, AG2, MA1). In the cation triangle, all points are clustered in the area of relative Na^++K^+ dominance, with significant contributions from Ca^{2+} and Mg^{2+}. This pattern indicates a mixture of carbonate dissolution and ion exchange processes in the shallow aquifer. SG1, SG2, AG1, and AG2 occupy almost identical positions, suggesting that they originated from the same flow system. MA1 is slightly shifted towards Ca-Mg, which may reflect a longer water residence time and more intense water-rock interactions. The dominance of HCO_3^-+CO_3^{2-} across all samples is characteristic of limestone dissolution in tropical karst systems. MA1 is slightly shifted from the central cluster but remains within the HCO_3 domain, indicating no significant SO_4^{2-} or Cl^- presence.

This suggests that carbonation reactions are the primary chemical process controlling groundwater composition, despite the influence of surface water. Cave waters (AG1 and AG2) and well waters (SG1 and SG2) remain within the same cluster, reinforcing the interpretation that the karst system has high surface-subsurface connectivity. The combined dominance of Na^++K^+ (cation) and HCO_3^- (anion) maps all samples to the Na-HCO_3 zone in the centre of the diamond, indicating that all samples originate from the same hydrogeological system. The similarity of facies between the wells, cave waters, and springs suggests that the karst system in this area is hydrologically connected. Water flows through fractures and dissolution channels, resulting in similar chemical characteristics across all samples. None of the samples exhibited significant evaporite influence, seawater intrusion, or anthropogenic contamination. This consistent pattern aligns with the results of geophysical modelling (SP and IP), which identified a network of subsurface cavities and channels still actively conducting water.

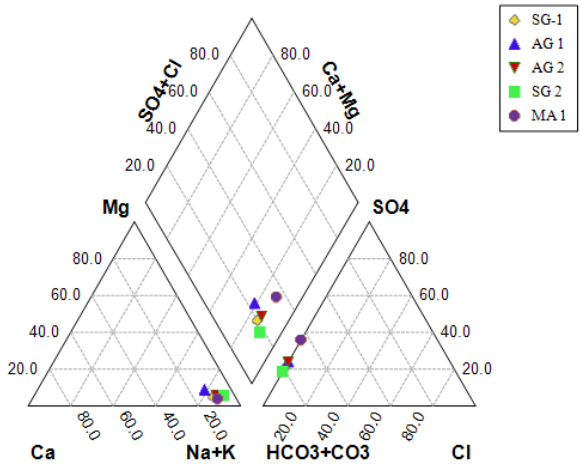

Figure 7. Piper diagram for hydrochemistry facies classification of groundwater around Lo Cave and Bangi Cave (Source: Authors, 2025)

DISCUSSION

The integrated SP, IP, and Hydrochemistry methods indicate that the karst aquifers around Lo Cave and Bangi Cave are connected. Hydrochemistry data confirm that the system is dominated by carbonate dissolution, producing $CaMgHCO_3$ water with low mineralization (TDS 31–63 meq/L) and a neutral to alkaline pH. According to the Piper diagram (Figure 7), the concentration of major ions and the position of all samples within the Na–HCO3 facies indicate that the groundwater is still in its natural state. The similarity in chemical properties of the well, cave water, and spring samples indicates that interconnected flow paths supply all of these locations. These conditions indicate rapid infiltration and short water residence times, characteristic of tropical karst aquifers. This interpretation is consistent with research by Hoaghia et al. (2021), Liu et al. (2022), and Gao et al. (2023), which states that young karst systems are generally controlled by the dissolution of calcite and dolomite, resulting in a dominance of Ca^{2+}–Mg^{2+}–HCO_3^- ions. At this study site, the very low Cl^- and SO_4^{2-} contents confirm the absence of saltwater intrusion, despite the area's coastal location.

This indicates that the coastal karst aquifer in South Malang remains Hydrochemistryly stable and has not been affected by external factors such as marine intrusion or anthropogenic activity. From the geophysical results, the elongated negative SP anomaly indicates an active underground flow path that serves as the main conduit for the karst system. This finding is reinforced by the high chargeability zones (>300 ms) in the IP results on Tracks 4, 6, and 7, which indicate the presence of water-filled cavities and fractures. The agreement between SP and IP patterns, and the uniform Hydrochemistry results, demonstrates that fluid flow through a network of interconnected dissolution channels results in the homogenization of water's chemical properties. This relationship aligns with the classical speleogenesis model, which explains that the development of karst conduits is controlled by the flow of calcium and bicarbonate-rich water (Ford & Williams, 2007).

One important finding is the high Na^+ concentration in SG2 and the highest TDS value in MA1. These small variations may result from localized flow with longer residence times or from interactions with non-carbonate lithologies surrounding the spring. The absence of elevated Cl- or SO42- concentrations suggests that these variations are caused by natural processes within the aquifer system rather than human contamination or seawater intrusion. Microscale ion exchange, common in shallow karst aquifers connected to residual clays, is another possibility. With good water quality and low contaminant levels, it is likely suitable for domestic use. However, open fractures in the aquifer make it vulnerable to land-use changes and to the intrusion of pollutants. The integration of geochemical and geophysical data provides new insights into the hydrogeological structure of karst that cannot be obtained from either method alone. The uniformity of Hydrochemistry facies in wells, cave water, and springs, in line with SP and IP results showing interconnected subsurface flow pathways, suggests that the Lo Cave and Bangi Cave aquifers form a single hydrogeological system.

Overall, this study improves our understanding of carbonate dissolution mechanisms and subsurface flow patterns in coastal tropical karst and provides a scientific basis for water resources management, mitigation of potential geological hazards, and sustainable geotourism development in the Gua Lo and Gua Bangi areas.

CONCLUSION

Based on SP, IP, and hydrochemical analysis data, it is known that the karst aquifer system in Gua Lo and Gua Bangi is influenced by carbonate dissolution processes and subsurface connectivity, with a Ca-Mg-HCO_3 facies and low mineralization, suggesting that the groundwater originates from a natural system relatively unaffected by marine intrusion or anthropogenic activity. Similarities in primary ion composition in dug wells, cave water, and springs indicate a single, connected flow system with rapid infiltration and short water residence times. The elongated negative SP anomaly and high-charge zone in the IP confirm the presence of an active underground river network.

While this study provides information that can inform geotourism planning and development in Gua Lo and Gua Bangi, it still has several limitations. The number of hydrochemical samples was limited, and data were collected only during one season. From a geophysical perspective, the limited number of lines does not provide extensive subsurface spatial information. Therefore, further research is needed, including geophysical surveys, such as ERT, to improve the resolution

in detecting subsurface cavities and fractures. In addition, to determine the response of karst systems to seasonal changes and anthropogenic influences, long-term hydrochemical and hydrological monitoring is required.

The role of digital leadership in shaping employees' digital mindset, agility, and adaptive performance in hotel enterprises. *Geojournal of Tourism and Geosites*, 67(3), 2386–2399. https://doi.org/10.30892/gtg.67349-1861

Abstract: The rapid digital transformation of the hospitality industry has intensified the need for leadership approaches that foster employees' adaptability and digital capabilities. In digitally intensive hotel environments, employees must continuously adjust their behaviors, adopt new technologies, and respond to evolving service demands. Drawing on Social Cognitive Theory (SCT), this study examines how digital leadership influences employees' adaptive performance by shaping two key mechanisms: digital mindset and digital agility. Specifically, the study aims to investigate the direct effects of digital leadership on adaptive performance, digital mindset, and digital agility, as well as the mediating roles of digital mindset and digital agility in the relationship between digital leadership and adaptive performance. Data were collected from 428 full-time employees working in five-star hotels in Egypt. The study employed a structured questionnaire using previously validated measurement scales. The proposed research model was tested using Partial Least Squares Structural Equation Modeling (PLS-SEM) with WarpPLS software to evaluate both measurement and structural relationships among the constructs. The findings reveal that digital leadership has significant positive effects on employees' adaptive performance, digital mindset, and digital agility. Furthermore, both digital mindset and digital agility positively influence adaptive performance. Mediation analysis indicates that digital mindset and digital agility partially mediate the relationship between digital leadership and adaptive performance, suggesting that digital leaders enhance employee adaptability not only directly but also by cultivating cognitive openness to digital technologies and the capability to respond quickly to technological change. These findings highlight the critical role of digital leadership in developing a digitally agile workforce capable of sustaining performance in rapidly evolving hospitality environments.

Keywords: digital leadership, digital mindset, digital agility, adaptive performance, hotel enterprises

INTRODUCTION

The rapid digitalization of the tourism and hospitality industry has fundamentally reshaped how hotel enterprises operate, compete, and deliver value (Al-Romeedy, 2026; Salama et al., 2025; Zeqiri, 2024). Advances in digital platforms, data-driven decision-making, and service automation have intensified environmental uncertainty while simultaneously raising expectations for responsiveness, personalization, and operational flexibility (Ghobakhloo et al., 2026). Within this evolving landscape, leadership has emerged as a decisive factor in determining whether digital technologies function merely as operational tools or as catalysts for sustained organizational adaptability (Khairy et al., 2026; Razzak et al., 2025). Digital leadership, in particular, has gained prominence as a form of leadership that transcends technical oversight by actively shaping how individuals perceive, interpret, and respond to digital transformation initiatives (Salih, 2024).

In hotel enterprises, where service encounters are dynamic and customer demands fluctuate continuously, adaptive performance has become a critical indicator of organizational effectiveness (Khairy & Salama, 2026; Elshaer & Saad, 2022). Employees are increasingly required to adjust their behaviors, learn new digital routines, and respond constructively to unexpected challenges (Hasanein & Metwally, 2025; Al-Shyyab et al., 2026). Digital leaders play a pivotal role in this process by establishing norms, role-modelling digital behaviors, and fostering environments that encourage experimentation and continuous learning (Zhu et al., 2025). Through these mechanisms, digital leadership is expected to exert a direct influence on employees' adaptive performance, while also shaping the psychological and behavioral foundations that enable adaptation in digitally intensive work settings (Salih, 2024; Ayad & Hasanein, 2025).

Beyond its direct influence on performance outcomes, digital leadership is instrumental in cultivating employees' digital mindset and digital agility (Pandey et al., 2023; Shen et al., 2025). A digital mindset reflects an individual's cognitive orientation toward digital technologies, encompassing openness to change, confidence in using digital tools, and a positive evaluation of technology-enabled work practices (Goldmann et al., 2025). Digital agility, in contrast, represents the behavioral manifestation of this mindset, capturing employees' capacity to rapidly apply digital knowledge, adjust work processes, and respond effectively to evolving technological demands (Goraya et al., 2026). Leaders who actively support digital learning, communicate a compelling digital vision, and legitimize adaptive experimentation are likely to strengthen both the cognitive readiness and the behavioral flexibility of their employees (Shahzad, 2024). The link between digital mindset, digital agility, and adaptive performance is particularly salient in hospitality contexts characterized by real-time service delivery and high levels of interpersonal interaction (Seraj et al., 2025; Li et al., 2024). Employees who possess a strong digital mindset are more inclined to interpret technological change as an opportunity rather than a disruption, which enhances their willingness to engage in adaptive behaviors (Solberg et al., 2020). When this mindset is coupled with digital agility, employees are better equipped to translate cognitive readiness into effective action, allowing them to modify routines, integrate new digital tools, and maintain service quality under changing conditions (Aldhi et al., 2025). Adaptive performance, therefore, emerges not as a spontaneous outcome, but as the result of an underlying cognitive–behavioral process shaped by leadership and enacted through digital capabilities (Jundt & Shoss, 2023). This study is theoretically anchored in Social Cognitive Theory, which emphasizes the reciprocal interaction between environmental influences, cognitive processes, and behavioral capabilities in shaping individual performance (Schunk & DiBenedetto, 2020). From this perspective, digital leadership constitutes a salient environmental stimulus that signals expected behaviors and acceptable norms within the organization (Salih, 2024).

Employees internalize these signals through the development of a digital mindset, which influences their self-efficacy, expectations, and interpretations of digital work demands (Liu & Kamioka, 2025). Digital agility, in turn, represents the behavioral capability through which cognitive orientations are enacted, ultimately enabling adaptive performance (Seraj et al., 2025). By adopting this lens, the study moves beyond deterministic views of technology adoption and highlights the human-centered mechanisms through which leadership drives adaptation in digital service environments.

Despite the growing scholarly attention to digital leadership within tourism and hospitality research, several important gaps remain in understanding how leadership-driven digital transformation translates into employees' adaptive behaviors. Previous studies have primarily examined digital leadership in relation to general innovation outcomes, organizational performance indicators, or technological adoption, often overlooking adaptive performance as a dynamic capability that reflects employees' ability to adjust behaviors, learn new approaches, and respond effectively to continuous technological change (Razzak et al., 2025; Palmucci et al., 2025). In service-intensive sectors such as hospitality, where operational environments are highly dynamic and customer expectations evolve rapidly, adaptive performance represents a critical dimension of organizational effectiveness that has received relatively limited attention in digital leadership research. A second limitation concerns the level of analysis adopted in prior studies. Much of the existing literature conceptualizes digital capabilities as organizational resources or technological infrastructures, emphasizing firm-level digital transformation while providing limited explanation of the individual-level mechanisms through which employees interpret leadership signals and translate them into adaptive behaviors (e.g., Held et al., 2025). This perspective leaves insufficient understanding of the cognitive and behavioral processes that shape how employees respond to digitally oriented leadership in daily work settings. Third, although concepts such as digital mindset and digital agility have emerged as important elements in contemporary digital transformation literature, these constructs have often been examined separately and rarely integrated within a unified theoretical framework that explains their mediating roles between leadership and employee outcomes. In particular, little empirical research has investigated how digital leadership fosters employees' digital mindset and agility, and how these factors subsequently enhance adaptive performance within hospitality organizations, where continuous learning, rapid problem-solving, and behavioral flexibility are essential for service delivery. To date, no empirical study has simultaneously examined how digital leadership shapes adaptive performance through both cognitive and behavioral mechanisms within a unified Social Cognitive Theory framework in hotel enterprises.

These gaps highlight the need for a more comprehensive framework that explains not only whether digital leadership influences employee performance, but also how and through which psychological and behavioral mechanisms such influence occurs. Addressing these limitations, the present study adopts Social Cognitive Theory as a theoretical lens to explain how leadership shapes employees' cognitive orientations and behavioral capabilities in digital work environments. Accordingly, the study pursues three main objectives. First, it examines the direct influence of digital leadership on adaptive performance, digital mindset, and digital agility within hotel enterprises. Second, it investigates the effects of digital mindset and digital agility on employees' adaptive performance. Third, it explores the mediating roles of digital mindset and digital agility in explaining how digital leadership translates into adaptive performance, thereby illuminating the cognitive–behavioral pathways through which leadership influences employee adaptability.

This study makes several theoretical and practical contributions. Theoretically, it extends the digital leadership literature by positioning adaptive performance as a key outcome of leadership-driven digital transformation in hospitality organizations. By integrating digital mindset and digital agility within a social cognitive framework, the study provides a deeper understanding of the micro-level mechanisms through which leadership influence is translated into adaptive employee behaviors. Empirically, the research contributes evidence from hotel enterprises, a context that remains relatively underexplored in digital leadership research despite its strong dependence on human adaptability and service innovation. Practically, the findings offer valuable insights for hotel managers and hospitality organizations by emphasizing the importance of cultivating employees' digital mindset and agility, rather than relying solely on technological investments, as essential drivers of adaptive performance in increasingly digitalized service environments.

LITERATURE REVIEW AND HYPOTHESES DEVELOPMENT

Digital leadership and adaptive performance

Adaptive performance has become increasingly important in digitally intensive hotel environments where employees must continuously adjust their behaviors, learn new digital practices, and respond to evolving service demands (Goraya et al., 2026; Huu, 2023). In such contexts, leadership plays a critical role in shaping how employees interpret and respond to technological change (Yin & Hoang, 2026). Digital leaders guide employees through digital transformation by clarifying expectations, modelling adaptive behaviors, and encouraging experimentation with digital tools (Imran et al., 2021; Chen & Zhao, 2024). From the perspective of Social Cognitive Theory, leadership behaviors function as environmental cues that influence how employees regulate their actions and respond to new challenges (Schunk & DiBenedetto, 2020). When leaders reinforce flexibility, learning, and proactive problem-solving, employees are more likely to adjust their work practices and develop stronger adaptive responses to changing service conditions (Breit et al., 2021; Razzak et al., 2025). Accordingly, digital leadership is expected to strengthen employees' adaptive performance in digitally evolving hotel enterprises. Accordingly, the following hypothesis is proposed:

H1: Digital leadership positively influences employees' adaptive performance.

Digital leadership and digital mindset

Employees' digital mindset reflects their cognitive orientation toward digital technologies, including their openness to technological change and confidence in using digital tools (Hamouche et al., 2026). The development of this mindset is strongly influenced by leadership signals that shape how employees interpret digital transformation within the organization. Digital leaders communicate the strategic importance of digitalization, demonstrate engagement with digital tools, and encourage employees to explore new technological solutions (Shahzad, 2024; Chowdhury, 2025). Within a social cognitive perspective, such leadership behaviors influence employees' beliefs, expectations, and perceived capabilities in digital work environments (Albannai et al., 2025). As employees observe and internalize these signals, they become more likely to view digital technologies as opportunities for learning and innovation rather than sources of uncertainty (Seraj et al., 2025). Consequently, digital leadership is expected to foster the development of employees' digital mindset. Based on this reasoning, the following hypothesis is advanced:

H2: Digital leadership positively influences employees' digital mindset.

Digital leadership and digital agility

Digital agility refers to employees' ability to respond quickly and effectively to technological changes by adapting digital work processes and service routines (Varshney, 2020). In hotel enterprises characterized by dynamic service environments, such agility enables employees to adjust digital tools and processes while maintaining service quality (Busulwa, 2020). Digital leadership contributes to the development of this capability by fostering work environments that support flexibility, decentralized decision-making, and experimentation with digital solutions (Zia et al., 2025; Wenten, 2025). According to Social Cognitive Theory, leadership behaviors influence employees' behavioral capabilities by shaping opportunities for action and reinforcing adaptive responses (Schunk & DiBenedetto, 2020). When leaders encourage initiative and support real-time problem solving, employees become more confident in modifying digital practices and responding effectively to changing operational demands (Busse & Weidner, 2020; Razzak et al., 2025). Therefore, digital leadership is expected to enhance employees' digital agility. Accordingly, the following hypothesis is proposed:

H3: Digital leadership positively influences employees' digital agility.

Digital mindset and adaptive performance

Employees' ability to perform adaptively in hotel settings is closely tied to how they interpret and mentally engage with digital change (Hasanein et al., 2026). When employees approach technology with curiosity rather than resistance, and with confidence rather than apprehension, they are better positioned to adjust their behavior as work demands evolve (Khanfar et al., 2026). A digital mindset shapes this interpretive process by influencing how employees evaluate new tools, assess situational challenges, and decide whether adaptation is necessary or worthwhile (Neeley & Leonardi, 2022). In practice, employees who possess a strong digital mindset tend to view unexpected service situations as manageable rather than disruptive. This orientation encourages proactive learning, experimentation, and cognitive flexibility, all of which are essential for modifying work practices in real time (Solberg et al., 2020; Smith & Beretta, 2021). Rather than relying on established routines, such employees are more inclined to reconsider existing approaches and identify digitally enabled alternatives that align with changing operational requirements (Salmela et al., 2022; Baiyere et al., 2020). Over time, this pattern of thinking translates into consistent adaptive performance. Employees who remain mentally receptive to digital innovation are more likely to recalibrate their responses, acquire new competencies, and maintain effectiveness under shifting conditions (Li & Long, 2025; Manroop et al., 2025). In dynamic hospitality environments, where adaptability is a continuous expectation rather than an occasional requirement, a digital mindset functions as a key psychological driver of sustained adaptive behavior (Meng et al., 2025; Al-Romeedy, 2026). Based on these arguments, the following hypothesis is proposed:

H4: Digital mindset positively influences employees' adaptive performance.

Digital agility and adaptive performance

Adaptive performance in hotel enterprises is ultimately realized through employees' capacity to adjust their actions as conditions change (Luo et al., 2021). While cognitive openness toward digital tools provides a foundation for adaptation, effective performance under dynamic circumstances depends on employees' ability to translate understanding into timely and

appropriate action (Jasim et al., 2024). Digital agility captures this action-oriented capability by reflecting how quickly and effectively employees can modify digital work processes, reconfigure tools, and respond to situational demands (Wiraeus & Creelman, 2019). Employees who demonstrate high levels of digital agility are better equipped to cope with operational disruptions, technology updates, and shifting service expectations. They can navigate multiple digital systems simultaneously, adjust service delivery methods on the spot, and implement alternative solutions when standard procedures become insufficient (Goraya et al., 2026; Kirjavainen & Jalonen, 2025). This behavioral flexibility allows them to maintain performance continuity even when faced with uncertainty, making adaptability an operational outcome rather than a reactive response (Karman, 2020). As digital work becomes increasingly embedded in hotel operations, agile behavior enables employees to sustain effectiveness across diverse and unpredictable service scenarios (Liu, 2025). The capacity to act swiftly, recalibrate workflows, and integrate digital resources as situations unfold enhances employees' ability to meet performance expectations under changing conditions (Omachi & Ajewumi, 2024). Consequently, digital agility serves as a critical driver of adaptive performance in digitally enabled hospitality environments. Accordingly, the following hypothesis is proposed:

H5: Digital agility positively influences employees' adaptive performance.

The mediation role of digital mindset

The influence of digital leadership on adaptive performance is unlikely to operate as an immediate or automatic effect, particularly in complex hotel environments where employees must interpret change before acting upon it (Jasim et al., 2024). Leadership initiatives related to digital transformation are first processed cognitively, as employees assess their relevance, feasibility, and implications for daily work (Trenerry et al., 2021). This interpretive stage plays a decisive role in determining whether leadership signals translate into adaptive behavior or remain superficial directives with limited behavioral impact (Enang et al., 2025; Al-Romeedy, 2026). Digital mindset represents the cognitive mechanism through which leadership influence is filtered and internalized. When digital leaders consistently frame technology as an enabler of effectiveness and professional growth, employees are more likely to develop a mindset that supports experimentation, learning, and flexibility (Shen et al., 2025; Brunner et al., 2023). This cognitive orientation shapes how employees perceive uncertainty, evaluate new digital demands, and decide whether to engage in adaptive responses (Yadav & Dhar, 2025). Without such a mindset, leadership-driven digital initiatives may fail to alter behavior, as employees may comply superficially while resisting deeper adaptation (Salih, 2024; Khairy et al., 2025). As employees' digital mindset strengthens, adaptive performance becomes more sustainable and self-reinforcing. A cognitively receptive orientation toward digital change allows employees to recalibrate their behavior proactively, learn from digitally mediated experiences, and respond constructively to evolving service conditions (Seraj et al., 2025). In this sense, digital mindset functions as the internal conduit through which digital leadership exerts its influence on adaptive performance, transforming external leadership cues into meaningful behavioral outcomes (Shen et al., 2025; Razzak et al., 2025). Accordingly, the following hypothesis is proposed:

H6: Digital mindset mediates the relationship between digital leadership and adaptive performance.

The mediation role of digital agility

In digitally enabled hotel operations, leadership influence becomes consequential only when employees can execute change under time pressure and service variability (Brunner et al., 2023). Digital leadership may introduce new systems, redefine workflows, or raise expectations for technology-mediated service delivery, yet these signals do not improve adaptive performance unless employees can respond with fast, situationally appropriate adjustments (Al-Romeedy, 2024). The practical bottleneck is rarely the strategic intent; it is the employee's ability to reconfigure digital work while the service is still unfolding (Salih, 2024). Digital agility offers that execution capacity. It is reflected in how employees switch between platforms, improvise alternatives when a system fails, adjust procedures to match updated digital requirements, and keep the guest experience stable while internal routines are being recalibrated (Salmela et al., 2022; Busulwa, 2020). When digital leaders grant discretion, remove procedural friction, and reinforce rapid problem resolution, employees are more likely to develop the kind of digitally fluent responsiveness that turns managerial direction into real-time adaptive behavior (Kupiek, 2021). Under these conditions, the effect of digital leadership on adaptive performance is expected to be transmitted through employees' digital agility. Leadership shapes the readiness to act; agility determines whether that action is feasible at the moment it is needed (Jasim et al., 2024; Wenten, 2025). Accordingly, the following hypothesis is proposed:

H7: Digital agility mediates the relationship between digital leadership and adaptive performance.

The theoretical framework of the study is illustrated below in Figure 1.

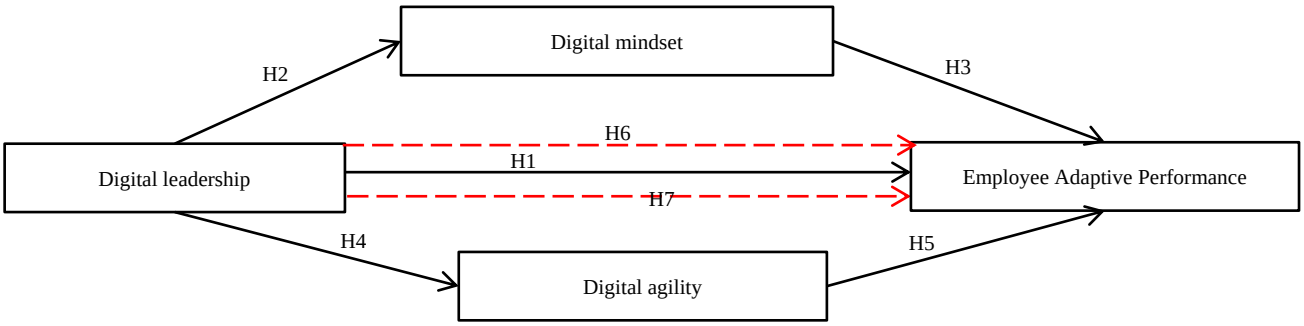

Figure 1. The theoretical framework of the study

METHODOLOGY

Survey Instrument and Measures

This study employed a structured questionnaire divided into two sections. The first section assessed the study's latent constructs using 42 measurement items (see Appendix A), while the second section collected demographic information, including gender, age, and educational attainment. All constructs were measured using previously validated scales adapted from the literature.

- Digital Leadership: Evaluated using a 7-item scale adapted from Claassen et al. (2021).
- Employee Adaptive Performance (EAP): Measured with ten items adapted from Hartline & Ferrell (1996).
- Digital Agility: Assessed via a 10-item scale adapted from Srivastava et al. (2023).
- Digital Mindset (DM): Captured using a 15-item scale derived from Valta et al. (2024).

All items employed a five-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree"). To ensure linguistic accuracy and conceptual equivalence, the questionnaire underwent a rigorous back-translation process. Additionally, academic scholars and hotel industry practitioners reviewed the instrument to confirm clarity, cultural relevance, and practical applicability prior to data collection.

Sampling and Data Collection

The study targeted full-time employees in five-star hotels located in Greater Cairo, Egypt. A judgmental sampling approach identified suitable hotels, while convenience sampling was used to select individual participants. This strategy was deemed appropriate given practical constraints, including access, time, and organizational approvals.

Data collection was conducted on-site following formal approval from hotel management and HR departments. Participation was voluntary, and respondents were informed of the study's objectives. Confidentiality and anonymity were emphasized to encourage candid responses, and all data were reported in aggregated form. A total of 600 questionnaires were distributed, with 428 returned and deemed usable, yielding a response rate of 71.3%. According to Hair et al. (2010), who recommend a minimum of 10 respondents per observed variable, the required sample size for 42 measurement items was 420, indicating that the final sample was sufficient for statistical analysis. Only employees with at least one year of work experience were included to ensure familiarity with organizational processes and culture (Morrison, 1993).

Analytical Strategy

Data were analyzed using Partial Least Squares Structural Equation Modelling (PLS-SEM) via WarpPLS version 8.0 (Kock, 2021). PLS-SEM is a robust multivariate technique suitable for testing complex models with multiple latent constructs, particularly when data may deviate from normality and sample sizes are small to medium (Hair et al., 2017; Ali et al., 2018).

The analysis proceeded in two stages:

1. Measurement model assessment – evaluated construct reliability, convergent validity, and discriminant validity.
2. Structural model assessment – tested the hypothesized relationships among the variables. This two-stage approach ensured both the robustness and validity of the results while accommodating exploratory and confirmatory objectives.

Assessment of Common Method Bias

Potential common method variance (CMV) was addressed using both procedural and statistical remedies. Procedurally, participants were assured of confidentiality and anonymity to minimize social desirability bias. Additionally, items measuring independent, mediating, and dependent variables were placed in separate sections of the questionnaire to reduce context and priming effects. Statistical analyses confirmed the absence of significant CMV. Harman's single-factor test indicated that no single factor accounted for more than 50% of the total variance. Moreover, Variance Inflation Factor (VIF) values for all constructs were below 3.3 (Table 2), further supporting the conclusion that CMV was unlikely to affect the study's findings.

RESULTS

Participants' profile

Table 1 presents the demographic characteristics of the 428 hotel employees who participated in the study. In terms of gender, the sample is predominantly male, with 264 respondents (61.68%), while females account for 164 participants (38.32%). This indicates a higher representation of male employees within the surveyed hotels.

Table 1. Participant's profile (N=428 hotel employees)

Demographics	Category	Frequency	Percent
Gender	Male	264	61.68
	Female	164	38.32
Age	18< 30 years	184	4.28
	30:<45 years	174	40.65
	45:60 years	70	16.36
Education	High school or below	84	19.63
	Undergraduate degree	282	65.89
	Postgraduate degree or above	62	14.49

Regarding age distribution, most participants fall within the 18 to below 30 years and 30 to below 45 years categories, with 184 (43.0%) and 174 (40.65%) respondents respectively, showing that the workforce is largely composed of young to

middle-aged adults. A smaller proportion of employees, 70 individuals (16.36%), are aged between 45 and 60 years, suggesting fewer older employees in the sample. With respect to educational attainment, the majority of respondents hold an undergraduate degree, representing 282 employees (65.89%). Those with a high school education or lower comprise 84 participants (19.63%), while 62 employees (14.49%) have obtained a postgraduate degree or higher. Overall, the table illustrates that the surveyed hotel employees are mostly male, relatively young, and generally well educated.

Table 2. Results of psychometric properties

Measurement model

Table 2 reports the psychometric evaluation of the study constructs, including indicator loadings, reliability measures, convergent validity, and collinearity diagnostics. Overall, the results demonstrate that all constructs meet the recommended thresholds, confirming the adequacy of the measurement model. For digital leadership, the indicator loadings range from 0.633 to 0.845, indicating acceptable to strong item contributions. The construct shows high internal consistency, with a composite reliability (CR) of 0.911 and Cronbach's alpha (CA) of 0.885. The average variance extracted (AVE) value of 0.597 exceeds the minimum recommended level of 0.50, supporting convergent validity. In addition, the variance inflation factor (VIF) of 3.027 remains within acceptable limits, suggesting no multicollinearity concerns. The employee adaptive performance construct demonstrates strong psychometric properties, with factor loadings between 0.701 and 0.844. Reliability is well established, as reflected by a CR of 0.919 and a CA of 0.893. The AVE value of 0.609 indicates that the construct explains a substantial portion of variance in its indicators. The VIF value of 2.017 further confirms that collinearity is not an issue for this construct. For digital agility, indicator loadings range from 0.636 to 0.830, which are generally acceptable. The construct exhibits high reliability, with a CR of 0.918 and a CA of 0.900. Although the AVE value is slightly lower at 0.529, it still exceeds the recommended threshold, supporting convergent validity. The VIF value of 3.142 is below the critical limit, indicating acceptable levels of collinearity. Finally, the digital mindset construct includes a larger number of indicators, with loadings ranging from 0.698 to 0.753. The reliability indices are strong, with a CR of 0.921 and a CA of 0.908, reflecting excellent internal consistency. The AVE value of 0.514 meets the minimum criterion for convergent validity, while the VIF value of 2.073 suggests that multicollinearity does not pose a concern. Although a small number of indicator loadings are slightly above the lower acceptable threshold (e.g., 0.633 and 0.636), they were retained because loadings above 0.60 are considered acceptable in PLS-SEM when composite reliability and AVE meet recommended criteria (Hair et al., 2017). In this study, all constructs demonstrate strong reliability and convergent validity, supporting the retention of these indicators to preserve the theoretical content validity of the measurement scales.

Table 3 presents the correlations among the latent variables along with the square roots of the average variance extracted (AVE) on the diagonal, in accordance with the Fornell–Larcker criterion. The diagonal values—0.772 for digital leadership, 0.780 for employee adaptive performance, 0.728 for digital agility, and 0.717 for digital mindset—represent the square roots of the AVEs for each construct. In all cases, these values are higher than the corresponding inter-construct correlation coefficients. The correlation results indicate moderate positive relationships among the constructs. Digital leadership is positively associated with employee adaptive performance (0.565), digital agility (0.621), and digital mindset (0.582). Employee adaptive performance also shows notable correlations with digital agility (0.527) and digital mindset (0.676), suggesting meaningful relationships among these variables. Additionally, digital agility and digital mindset are moderately correlated (0.537). Importantly, since the square root of each construct's AVE exceeds its correlations with other constructs, the results satisfy the Fornell–Larcker criterion. This confirms adequate discriminant validity, indicating that each construct is empirically distinct and captures a unique aspect of the conceptual model.

Table 3. Correlations among latent variables with the square root of AVEs

Construct	DL	EAP	DA	DM
Digital leadership (DL)	0.772			
Employee adaptive performance (EAP)	0.565	0.780		
Digital agility (DA)	0.621	0.527	0.728	
Digital mindset (DM)	0.582	0.676	0.537	0.717

Table 4 reports the results of discriminant validity assessment using the Heterotrait–Monotrait (HTMT) ratio of correlations. The HTMT values are evaluated against the recommended thresholds, where values below 0.90 indicate acceptable discriminant validity and values below 0.85 suggest a more stringent criterion. Overall, the results confirm that discriminant validity is well established for all constructs, as none of the HTMT ratios approach the critical cutoff values. This suggests that each construct measures a conceptually unique dimension within the research model.

Table 4. Discriminant validity (HTMT)

HTMT ratios (good if < 0.90, best if < 0.85)				
Construct	DL	EAP	DA	DM
Digital leadership (DL)				
Employee adaptive performance (EAP)	0.629			
Digital agility (DA)	0.706	0.582		
Digital mindset (DM)	0.657	0.742	0.590	

Model Fit

Appendix B summarizes the model fit and quality indices used to evaluate the robustness and adequacy of the proposed structural model. Overall, the results indicate that the model demonstrates a strong and acceptable fit according to the criteria suggested by Kock (2021). The average path coefficient (APC) is 0.455 and statistically significant at $p < 0.001$, confirming that the relationships specified in the model are meaningful. Similarly, the average R-squared (ARS) and average adjusted R-squared (AARS) values are 0.540 and 0.538 respectively, both significant at $p < 0.001$, indicating that the model explains a substantial proportion of variance in the endogenous constructs. Collinearity diagnostics further support the quality of the model. The average block variance inflation factor (AVIF) and the average full collinearity variance inflation factor (AFVIF) are 2.877 and 2.564 respectively, both well below the acceptable threshold of 5 and close to the ideal value of 3.3. These findings suggest that multicollinearity is not a concern in the model. In addition, the Tenenhaus goodness-of-fit (GoF) index is 0.536, which exceeds the benchmark for a large effect size, reflecting strong overall explanatory power. The remaining quality indices also meet or exceed recommended standards. The Sympson's paradox ratio (SPR), R-squared contribution ratio (RSCR), statistical suppression ratio (SSR), and nonlinear bivariate causality direction ratio (NLBCDR) all equal 1.000, which represents the ideal value for each criterion. Collectively, these results confirm that the model is statistically sound, free from major estimation issues, and suitable for hypothesis testing.

Structural model and hypotheses testing

Table 5 and Figure 2 present the results of the direct effects analysis, including path coefficients, significance levels, effect sizes, and hypothesis testing outcomes. The findings indicate that all hypothesized relationships are statistically significant and supported, highlighting the strength of the proposed structural model.

Table 5. Direct effects

H	Structural Paths	Path Coefficient (β)	P-values	Effect Size (f^2)	Result
H1	DL →EAP	0.19	<0.01	0.110	Supported
H2	DL →DM	0.61	<0.01	0.370	Supported
H3	DL →DA	0.85	<0.01	0.731	Supported
H4	DM →EAP	0.52	<0.01	0.352	Supported
H5	DA →EAP	0.10	<0.01	0.057	Supported
DM $R^{2:}$ = 0.37, DA $R^{2:}$ = 0.73, EAP $R^{2:}$ = 0.52					

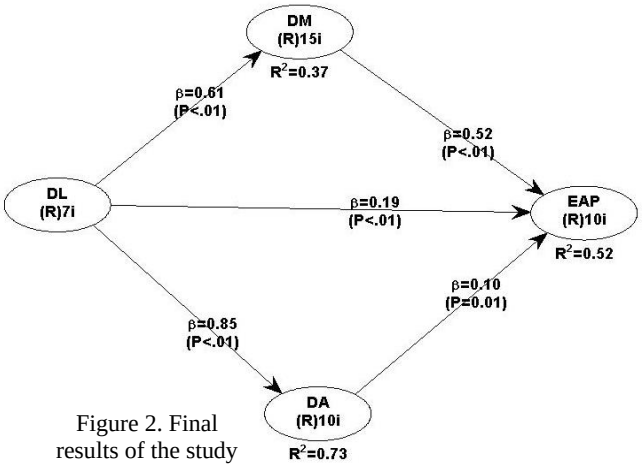

Figure 2. Final results of the study

Digital leadership has a positive and significant effect on employee adaptive performance ($\beta = 0.19$, $p < 0.01$), with a small to moderate effect size ($f^2 = 0.110$), supporting Hypothesis 1. In addition, digital leadership strongly influences digital mindset ($\beta = 0.61$, $p < 0.01$), exhibiting a large effect size ($f^2 = 0.370$), which confirms Hypothesis 2. The strongest relationship is observed between digital leadership and digital agility ($\beta = 0.85$, $p < 0.01$), with a very large

effect size ($f^2 = 0.731$), providing strong support for Hypothesis 3. Furthermore, digital mindset shows a substantial positive impact on employee adaptive performance ($\beta = 0.52$, $p < 0.01$), with a large effect size ($f^2 = 0.352$), supporting Hypothesis 4. Digital agility also has a positive and statistically significant influence on employee adaptive performance ($\beta = 0.10$, $p < 0.01$); however, its effect size is relatively small ($f^2 = 0.057$), which nonetheless supports Hypothesis 5.

Regarding the model's explanatory power, digital leadership accounts for 37% of the variance in digital mindset ($R^2 = 0.37$) and 73% of the variance in digital agility ($R^2 = 0.73$). Collectively, digital leadership, digital mindset, and digital agility explain 52% of the variance in employee adaptive performance ($R^2 = 0.52$). These results indicate that the model has strong predictive capability and that the proposed relationships meaningfully explain employee adaptive performance.

Table 6 presents the results of the mediation analysis using the bootstrapping approach recommended by Preacher & Hayes (2008). The analysis examines whether digital mindset and digital agility mediate the relationship between digital leadership and employee adaptive performance. Mediation is assessed based on the significance of indirect effects and the exclusion of zero from the 95% bootstrapped confidence intervals.

For Hypothesis 6, digital mindset is found to significantly mediate the relationship between digital leadership and employee adaptive performance. The indirect effect is 0.317, with a standard error of 0.033 and a t-value of 9.612, indicating strong statistical significance. The corresponding 95% bootstrapped confidence interval ranges from 0.253 to 0.382, which does not include zero, confirming the presence of partial mediation. This suggests that digital leadership enhances employee adaptive performance in part by fostering a stronger digital mindset among employees.

Similarly, Hypothesis 7 examines the mediating role of digital agility in the relationship between digital leadership and employee adaptive performance. The indirect effect is 0.085, with a standard error of 0.033 and a t-value of 2.576. The 95% bootstrapped confidence interval spans from 0.020 to 0.150, again excluding zero, thereby supporting the partial mediating effect. Although the magnitude of this indirect effect is smaller compared to that of digital mindset, it still indicates that digital leadership contributes to employee adaptive performance through improved digital agility.

Overall, the mediation analysis confirms that both digital mindset and digital agility serve as significant mediators between digital leadership and employee adaptive performance. These findings highlight the importance of internal cognitive and capability-based mechanisms in translating digital leadership into enhanced adaptive performance outcomes.

Table 6. Mediation analysis' Bootstrapped Confidence Interval

Hypo.	Indirect Path	Path a	Path b	Indirect Effect	SE	t-value	Bootstrapped Confidence Interval		Mediation
							95% LL	95% UL	
H6	DL→DM→EAP	0.610	0.520	0.317	0.033	9.612	0.253	0.382	Yes
H7	DL→DA →EAP	0.850	0.100	0.085	0.033	2.576	0.020	0.150	Yes

DISCUSSION

The findings of this study reinforce and extend emerging evidence on the pivotal role of digital leadership in shaping employee outcomes within dynamic work environments. Supporting Hypotheses H1–H3, digital leadership demonstrated significant positive effects on employees' adaptive performance, digital mindset, and digital agility. These results underscore that leaders with strong digital competencies are instrumental in enabling employees to navigate change and adopt new technologies—a conclusion echoed in hospitality research showing that digital leadership enhances operational performance through employee engagement and technology integration in five-star hotels (Hussein et al., 2024). Moreover, the observed impact of digital leadership on digital mindset and agility aligns with prior studies suggesting that digitally competent leaders cultivate a learning-oriented culture and promote adaptability, thereby strengthening staff readiness to meet evolving service demands (Hamouche et al., 2026). The positive relationships between digital mindset and adaptive performance (H4), and between digital agility and adaptive performance (H5), highlight the importance of employees' internal readiness and capability for effective adjustment to digital transformation. Contemporary research emphasizes that a growth-oriented mindset enhances digital self-efficacy, supporting performance in technology-intensive contexts (Liu & Kamioka, 2025).

Similarly, both organizational and individual agility underpin performance resilience in turbulent environments, particularly as digital strategies become central to service delivery (Alakaş, 2024). Together, these findings illustrate that employees' cognitive and behavioral adaptations are key mechanisms linking digital leadership to adaptive outcomes.

Although digital agility significantly influences adaptive performance, its effect size is smaller than that of digital mindset. This difference suggests that cognitive readiness toward digital technologies may play a more foundational role in shaping adaptive behavior. In other words, employees who possess a strong digital mindset are more likely to interpret technological change positively and engage in adaptive behaviors consistently, whereas digital agility reflects the situational execution of these behaviors during specific operational challenges. Mediation analyses (H6 and H7) further demonstrate that digital mindset and digital agility serve as psychological and capability-based pathways through which digital leadership influences adaptive performance. This mediating role aligns with recent theoretical developments emphasizing internal cognitive and behavioral processes as critical in explaining how leadership fosters performance amid digital disruption (Yang et al., 2025).

By revealing both direct and indirect effects, the results suggest a layered influence process: digital leaders not only provide strategic direction but also cultivate the internal capacities that enable employees to adapt, innovate, and excel.

The findings collectively underscore that digital leadership enhances employee adaptability through multiple mechanisms. Leaders influence organizational priorities and employee attitudes toward digital innovation, creating contexts in which staff feel empowered to experiment with new tools and processes—conditions that nurture agility and an open mindset, essential for thriving in dynamic service sectors (Sacavém et al., 2025). Consistent with Social Cognitive Theory, these outcomes reflect

active psychological and behavioral adaptations shaped by leadership cues (Al-Romeedy, 2026). By empirically linking digital mindset and agility to performance, the study extends prior work showing that employees' attitudes and capabilities enable them to manage uncertainty, innovate service delivery, and maintain high performance—insights particularly relevant to hospitality, where responsiveness and customization are paramount (Hasanein et al., 2026; Hussein et al., 2024).

Finally, the mediation results indicate that the effects of digital leadership on adaptive performance are not solely direct but also operate by enhancing employees' internal capacities (Albannai et al., 2026). This mechanism resonates with contemporary digital transformation literature, highlighting that leaders influence performance not only through strategic guidance but also by fostering learning and adaptive processes, emphasizing the interplay between leadership practices and individual dynamic capabilities (Wang et al., 2024).Overall, the results illustrate the multifaceted role of digital leadership in enabling workforce adaptability during digital transformation. By fostering a progressive digital mindset and strengthening agility, leaders empower employees to engage in adaptive behaviors essential in today's volatile, technology-driven hospitality landscape. This integrated perspective advances both theory and practice by identifying the cognitive and capability-based pathways through which leadership drives performance in digital contexts, offering actionable insights for managers aiming to cultivate resilient, adaptive, and high-performing teams.

THEORITICAL IMPLICATIONS

This study makes several substantive theoretical contributions by extending Social Cognitive Theory into the domain of digital leadership and adaptive performance within hospitality contexts. While Social Cognitive Theory has traditionally been employed to explain learning, self-regulation, and behavior in relatively stable environments, this research advances the theory by situating it within digitally volatile service settings characterized by constant technological change and operational uncertainty. By doing so, the study demonstrates that the theory remains highly relevant for explaining behavior under conditions of continuous digital disruption, rather than episodic change.

A key theoretical contribution lies in explicating the distinct yet complementary roles of cognitive orientation and behavioral capability in the leadership–performance relationship. Prior applications of Social Cognitive Theory have often emphasized either cognitive mechanisms or behavioral outcomes in isolation. This study advances the theory by empirically distinguishing digital mindset as a cognitive interpretive mechanism and digital agility as a behavioral enactment mechanism, thereby clarifying how leadership influence is cognitively internalized and behaviorally executed. This separation refines the theory's explanatory power by showing that cognition and behavior operate as sequential, rather than interchangeable, processes in digitally intensive work environments. Furthermore, the study extends Social Cognitive Theory by repositioning leadership as a dynamic environmental stimulus rather than a static contextual factor.

In this framework, digital leadership is not merely a background condition shaping behavior indirectly; it actively structures employees' sensemaking processes and action possibilities as digital conditions evolve. This perspective enriches the theory by highlighting leadership's role in continuously recalibrating cognitive expectations and behavioral repertoires, offering a more dynamic view of environmental influence aligned with modern digital work realities. Another important theoretical contribution concerns the conceptualization of adaptive performance. Rather than treating adaptive performance as a general or dispositional outcome, the study embeds it within a social cognitive process in which adaptation emerges from repeated cycles of interpretation and action. This reframing advances Social Cognitive Theory by demonstrating how adaptive performance can be understood as a cumulative behavioral outcome grounded in leadership-shaped cognition and agility-driven execution. As such, the study shifts adaptive performance from being an abstract capability to a socially constructed and theoretically traceable outcome. By empirically validating both direct and mediated pathways, the study also strengthens the internal coherence of Social Cognitive Theory in organizational research. The findings confirm that leadership influence does not dissipate when cognitive and behavioral mechanisms are introduced; instead, it operates through them. This reinforces the theory's core proposition that environmental, cognitive, and behavioral elements function interdependently rather than hierarchically. In doing so, the study provides robust empirical support for applying Social Cognitive Theory to complex organizational phenomena involving leadership, digital transformation, and performance adaptation.

Finally, the hospitality context itself contributes to theoretical enrichment. Much of the existing social cognitive literature has been developed in manufacturing, education, or generalized organizational settings. By demonstrating the theory's applicability within hotel enterprises—where service immediacy, emotional labor, and technological mediation intersect—the study broadens the contextual boundaries of Social Cognitive Theory. This extension underscores the theory's versatility and opens new avenues for its application in service-dominant and digitally enabled industries.

PRACTICAL IMPLICATIONS

The findings of this study provide clear execution-oriented implications for hotel organizations seeking to enhance adaptive performance in digitally dynamic environments. Given the confirmed direct effect of digital leadership on adaptive performance, hotel executives should reconceptualize digital leadership as a core operational capability rather than a support function. Practically, this can be implemented by incorporating digital leadership competencies into leadership development programs, including digital adaptation indicators in managerial performance appraisal systems, and requiring department managers to lead periodic digital problem-solving meetings during operational briefings. This requires embedding digital leadership responsibilities into managerial roles, performance evaluations, and daily supervisory practices, ensuring that leaders consistently demonstrate adaptive responses to digital disruptions rather than merely endorsing digital initiatives at a strategic level. The positive effects of digital leadership on employees' digital mindset and digital agility indicate that leadership influence must be enacted simultaneously at cognitive and behavioral levels. From an execution standpoint, hotel

managers should deliberately structure leadership interactions to shape how employees think about digital change while enabling immediate action. For example, managers can integrate short digital learning discussions into daily shift briefings, assign employees rotating responsibility for resolving minor digital service disruptions, and encourage supervisors to openly analyze digital challenges encountered during operations. This can be operationalized by integrating digital decision-making responsibilities into frontline roles, encouraging leaders to openly discuss digital challenges during operations, and legitimizing on-the-spot adjustments to digital workflows when service conditions require rapid adaptation.

The direct influence of digital mindset on adaptive performance suggests that managing digital transformation as a mindset-shaping process is critical. Practically, hotel organizations should move beyond technology-centered training and introduce structured reflection mechanisms that allow employees to reinterpret digital challenges as solvable and manageable. This can be implemented through brief "digital reflection sessions" incorporated into shift handovers, where employees discuss recent digital service issues and identify alternative responses for similar future situations. Embedding brief digital debriefings into shift handovers or post-service reviews can systematically reinforce constructive digital interpretations, strengthening employees' readiness to adapt when conditions change.

Similarly, the confirmed effect of digital agility on adaptive performance underscores the importance of redesigning work systems to support rapid execution. Hotel managers should critically assess procedural rigidity, approval layers, and digital task dependencies that slow adaptive responses. In practice, organizations can establish simplified digital escalation protocols, empower frontline employees to resolve routine digital service disruptions without managerial approval, and implement quick-response guidelines for handling technology-related service interruptions. Reducing bureaucratic constraints, granting situational autonomy in digitally mediated service tasks, and simplifying escalation protocols enable employees to translate leadership intent into immediate adaptive action during live service encounters.

The mediating roles of digital mindset and digital agility further imply that leadership-driven improvements in adaptive performance unfold through identifiable internal mechanisms rather than instant outcomes. For practitioners, this means that the success of digital leadership initiatives should be evaluated not only through performance indicators but also through intermediate signals such as changes in employees' digital attitudes and responsiveness. Organizations can operationalize this monitoring process by incorporating short internal surveys measuring digital confidence and agility into quarterly employee assessments, allowing managers to track cognitive and behavioral readiness for digital adaptation. Regular monitoring of these indicators allows organizations to adjust leadership practices before performance consequences fully materialize.

Finally, the results highlight the need for alignment across human resource systems. Recruitment criteria, leadership development programs, and performance appraisal frameworks should explicitly prioritize cognitive openness to digital change and behavioral responsiveness in digital contexts. To support implementation, hotel organizations can include digital adaptability scenarios in recruitment interviews, introduce leadership workshops focused on managing digital change in service environments, and integrate digital agility metrics into employee performance reviews. Training programs should emphasize scenario-based simulations that require employees to adapt digital tools under realistic service pressures, reinforcing the link between leadership influence, agile execution, and adaptive performance. Such alignment ensures that digital leadership is institutionalized as a driver of sustained adaptability rather than dependent on individual managerial discretion.

CONCLUSION

This study examined the influence of digital leadership on employees' adaptive performance in hotel enterprises through the mediating roles of digital mindset and digital agility, drawing on Social Cognitive Theory. The findings demonstrate that digital leadership directly enhances employees' adaptive performance while simultaneously fostering a stronger digital mindset and greater digital agility. Furthermore, both digital mindset and digital agility positively influence adaptive performance and partially mediate the relationship between digital leadership and adaptive performance, confirming that leadership promotes employee adaptability through both cognitive and behavioral mechanisms.

The study contributes to the digital leadership literature by providing an integrated Social Cognitive Theory framework that explains how leadership translates into adaptive employee behaviors in digitally intensive hospitality environments.

By distinguishing digital mindset as a cognitive mechanism and digital agility as a behavioral capability, the research offers a more comprehensive understanding of the processes through which digital leadership enhances workforce adaptability. These findings also emphasize that successful digital transformation depends not only on technological investments but also on leadership practices that cultivate employees' digital readiness and responsiveness.

From a managerial perspective, the results suggest that hotel organizations should invest in developing digitally competent leaders who encourage continuous learning, strengthen employees' digital mindset, and create work environments that support agile responses to technological change. Such efforts are likely to improve employees' adaptive performance and enhance organizational resilience in increasingly dynamic hospitality settings. Overall, this study provides robust empirical evidence that digital leadership is a critical driver of adaptive performance and highlights the importance of developing employees' cognitive and behavioral capabilities to achieve sustainable success during digital transformation.

Limitations and Future Research

Despite its contributions, this study entails several limitations that warrant consideration and offer meaningful directions for future research. First, the cross-sectional nature of the research design limits the ability to capture the temporal processes through which digital leadership shapes employees' cognitive orientations and behavioral capabilities. Adaptive performance in digitally intensive environments is inherently dynamic, suggesting that longitudinal or time-lagged designs could provide richer insights into how digital mindset and digital agility develop and interact over time as leadership

practices and technological conditions evolve. Second, the empirical focus on hotel enterprises, while theoretically appropriate, suggests caution in generalizing the findings to other service sectors with different operational characteristics. The hospitality context is distinguished by high levels of customer interaction, real-time service delivery, and emotional labor, which may amplify the influence of digital leadership on adaptive behavior. Future research could test the proposed framework across other digitally enabled service sectors, such as healthcare, logistics, or financial services, to assess the robustness of the identified mechanisms under different organizational and task environments.

Third, the reliance on self-reported data introduces the potential for perceptual bias and common method variance, despite the use of validated measurement instruments and rigorous analytical procedures. Employees' evaluations of leadership behavior, mindset, and performance may be shaped by subjective interpretations or situational factors beyond the scope of the current model. Subsequent studies could enhance empirical rigor by incorporating multi-source data, including supervisor assessments or objective indicators of digitally adaptive behavior, to strengthen causal inference and measurement validity.

Additionally, the study models digital mindset and digital agility as mediators operating independently between digital leadership and adaptive performance. While this approach clarifies their distinct explanatory roles, future research may benefit from exploring more complex process configurations. For example, reciprocal or reinforcing relationships between mindset and agility could be examined to determine whether adaptive behavior feeds back into cognitive readiness over time, thereby capturing adaptation as an iterative rather than linear phenomenon. Finally, although the theoretical framework is grounded in Social Cognitive Theory, future research could extend the explanatory scope by integrating complementary perspectives. The incorporation of theories related to role identity, job demands and resources, or paradox management may further illuminate how employees navigate competing expectations and technological pressures in digitally transformed service environments. Such extensions would not detract from the social cognitive foundation established in this study, but rather deepen understanding of adaptive performance as a multifaceted organizational outcome.

Appendix (A) measurement scales

Digital leadership (DL)	DL1	I am involved in decisions that affect my work and my digital work environment
	DL2	My digital literacy is encouraged by my manager.
	DL3	When there is a need for questions about digitalization, I receive support from my manager.
	DL4	I get regular feedback on the quality of my digital work.
	DL5	I get all the information I need to do my digital job.
	DL6	I am supported by my manager to better understand and use digital applications.
	DL7	In my department, digital working methods are encouraged.
Employee Adaptive performance (EAP)	EAP.1	I knows that every customer requires a unique approach
	EAP.2	I can easily change to another approach when he or she feels that his or her approach is not working
	EAP.3	I like to experiment with different approaches
	EAP.4	I do not change his or her approach from one customer to another (–)
	EAP.5	I is very sensitive to the needs of his or her customers
	EAP.6	I find it difficult to adapt his or her style to certain customers (–)*
	EAP.7	I varies his or her approach from situation to situation
	EAP.8	I try to understand how one customer differs from another
	EAP.9	I feel confident that he or she can effectively change his or her approach when necessary
	EAP.10	I treat all customers pretty much the same (–)
Digital agility (DA)	DA1	I can quickly adapt and respond to the changing digital landscape
	DA2	I can leverage digital tools and technologies to automate manual tasks
	DA3	I can leverage digital tools and technologies to enable collaboration across teams
	DA4	I can quickly learn and adapt to new technologies, processes, and best practices
	DA5	I can support institutions to remain competitive and enhance student experiences
	DA6	I can quickly shift to online or hybrid learning models
	DA7	I can experiment with new technologies and teaching methods
	DA8	I take the shortest possible time to develop my skills, adjust to new environment, and collect information
	DA9	I take a personal interest in collecting information about my organization and other related organization
	DA10	I have the potential to transform the way we teach and learn
Digital Minset (DM)	DM1	I am aware of the high growth potential of IT
	DM2	I always think of the future growth of IT as an exponential curve
	DM3	I always have the long-term exponential growth projections of IT in mind
	DM4	When using IT, I always think about what else I could use it for besides its intended functions
	DM5	I always see potential new use cases for IT that go beyond the intended use
	DM6	I enjoy developing or using IT that is generic and versatile
	DM7	If I developed IT, I would always provide possibilities for alternative use cases
	DM8	I often think about how IT can be combined in a way similar to a modular IT
	DM9	I enjoy recombining IT from existing components of a variety of technology fields to create new things
	DM10	I always notice that digital products consist of different (digital) components
	DM11	I always think about combining different IT when solving problems
	DM12	I always see potential for digital products or services to transform entire markets
	DM13	I always recognize how IT could replace established solutions
	DM14	I always see potentials for existing business models being replaced by disruptive IT
	DM15	I regularly think about how the business model of my company/employer could be replaced by a more effective unexpected IT

Appendix (B): Model fit and quality indices (Kock, 2021)

	Assessment	Criterion	Mark
Average path coefficient (APC)	0.455, P<0.001	P<0.05	√
Average R-squared (ARS)	0.540, P<0.001	P<0.05	√
Average adjusted R-squared (AARS)	0.538, P<0.001	P<0.05	√
Average block VIF (AVIF)	2.877	acceptable if ≤ 5, ideally ≤ 3.3	√
Average full collinearity VIF (AFVIF)	2.564	acceptable if ≤ 5, ideally ≤ 3.3	√
Tenenhaus GoF (GoF)	0.536	small ≥ 0.1, medium ≥ 0.25, large ≥ 0.36	√
Sympson's paradox ratio (SPR)	1.000	acceptable if ≥ 0.7, ideally = 1	√
R-squared contribution ratio (RSCR)	1.000	acceptable if ≥ 0.9, ideally = 1	√
Statistical suppression ratio (SSR)	1.000	acceptable if ≥ 0.7	√
Nonlinear bivariate causality direction ratio (NLBCDR)	1.000	acceptable if ≥ 0.7	√

Abstract: Spa treatments in Hungary are covered by social security; however, actual utilization of these services is influenced not only by formal financing frameworks but also by social, economic, and regional factors. The aim of the research was to explore the socio-demographic characteristics of patients receiving spa treatments covered by social security in the Northern Great Plain region, as well as the attitudes, financial, and time constraints associated with the use of these services. The study was based on primary, questionnaire-based data collection, which took place between June and December 2025 at eight thermal spas in the Northern Great Plain region. A total of 405 patients receiving balneotherapy treatments covered by social security participated in the study. The data were analyzed using IBM SPSS Statistics. During the analysis, we employed descriptive statistics, the chi-square test, the Kruskal–Wallis test, and ordinal logistic regression to identify correlations and regional differences. Based on the results, the majority of respondents were women, belonged to an older age group, and had a secondary or higher education. A significant correlation was found between educational attainment and the subjective assessment of financial status: a higher proportion of those with lower educational attainment reported a sense of financial constraint. In terms of regional breakdown, financial and time constraints were more pronounced in Szabolcs-Szatmár-Bereg and Jász-Nagykun-Szolnok counties, while more favorable access conditions were identified in Hajdú-Bihar county. The results suggest that formal access provided by social security alone does not eliminate regional and social inequalities in access to balneotherapy services in health tourism in the Northern Great Plain in Hungary.

Keywords: balneotherapy, medicinal spas, health tourism, territorial inequalities, access

INTRODUCTION

Medicinal activities associated with spas constitute an integral part of the healthcare system in numerous European countries (Oliveira et al., 2023; Walczak & Kowalska, 2025). Accordingly, in several European countries—such as France, Italy, Spain, Turkey, and Hungary—the number of scientific studies related to balneotherapy has increased significantly in recent decades (Protano et al., 2023; Protano et al., 2024), especially research analyzing the results of balneotherapy procedures used in the treatment of chronic diseases (Gutenbrunner et al., 2010; Varga et al., 2019).

Numerous empirical studies have confirmed that balneotherapy has a beneficial effect on various health conditions, especially when used in the treatment of chronic diseases (Pittler et al., 2006; Santos et al., 2016; Antonelli et al., 2018; Antonelli & Donelli, 2018). In Hungary, balneotherapy – linked to physiotherapy and rehabilitation services – is institutionalized and embedded in the social security-funded healthcare system (Géher, 2013; Hojcska, 2022). In Hungary, some spa treatments are covered by health insurance, typically on medical grounds, which reinforces the interpretation of these services as healthcare (Bender, 2014; Hinek et al., 2019; Hojcska, 2019).

According to data from the National Health Insurance Fund Administration of Hungary (Hungarian acronym: NEAK), there were a total of 200 healthcare providers with valid contracts for social security reimbursement in Hungary in 2022 (Table 1). From a territorial perspective, the distribution of service providers shows substantial disparities: the highest number operated in Hajdú-Bihar County (20), while only two were located in Nógrád County. In the Northern Great Plain region, a total of 42 providers financed by the NEAK were available, representing more than one-fifth of the total national capacity. The number of service providers and the size of the population are not always proportional: while Budapest and Pest County have a particularly high population, the number of service providers is more moderate, whereas in some counties – such as Heves or Jász-Nagykun-Szolnok – the presence of service providers is more favorable in relation to the population.

The use of subsidized balneotherapy services in Hungary has been declining in recent years (HCSO, 2024), but at the same time, in line with findings in the international literature, marked regional differences can be identified in terms of both the number of treatments and the distribution of social security subsidies (Helmeczi & Láczay, 2025). Analyses based on

the NEAK financing database provide an opportunity to empirically explore these spatial inequalities and to interpret access conditions and the fairness of the healthcare system. According to an analysis by Varga et al. (2020), the number of spa treatments subsidized by social security showed a downward trend between 2009 and 2016, reaching its highest value in 2009 and its lowest in 2012. In territorial terms, the amount of support per 10,000 inhabitants was highest in Csongrád, Hajdú-Bihar, and Győr-Moson-Sopron counties, while it was lowest in Nógrád, Zala, and Szabolcs-Szatmár-Bereg counties. Usage increases in the 60–69 age group, then declines. Furthermore, women over the age of 40 used treatments at a higher rate than men in all age groups. Jóna & Fedor (2025) similarly explained differences in access to healthcare services by the impact of spatial inequalities as well as gender differences in health behavior.

Table 1. Regional distribution of healthcare providers financed by social security and population size in Hungary (Source: NEAK, 2022; HCSO, 2024)

County[1]	**Number of service providers (NEAK, 2022)**	**Population, 2024 (HCSO, 2024)**

The literature highlights that the function and social significance of medicinal spa use vary considerably across regions. While in Western Europe medicinal spas primarily appear within the framework of wellness and recreational tourism (Csirmaz & Pető, 2015), in Central and Eastern Europe—especially in countries where balneotherapeutic treatments are available with social insurance support—spas are more closely integrated into the healthcare system (Dryglas & Salamaga, 2017; Woźniak-Holecka, 2017; Derco et al., 2020).

Owing to its geographical endowments, Hungary has gained international recognition for its natural healing factors—particularly its medicinal waters—which interdisciplinarily link the fields of geography, balneology, and tourism, and, alongside the growing emphasis on health, play an increasingly prominent role within health tourism, especially in the context of therapeutic tourism trips aimed at health preservation (Hojcska & Szabó, 2021; Kővári-Tóth et al., 2024).

In addition to their health benefits, more and more research is emphasizing the tourism and spatial dimensions of balneotherapy services. Spas are not only health institutions, but also complex service locations that simultaneously fulfill therapeutic, recreational, and tourism functions (Smith & Puczkó, 2014; Widawski, 2017; Diekmann, 2020; Walczak, & Kowalska, 2025; Smith, 2025). This dual role – in health and tourism – makes spa tourism particularly suitable for examining social inequalities, access barriers, and regional differences.

In recent years, research on balneotherapy and health tourism has increasingly moved beyond traditional clinical efficacy studies and shifted toward spatial, social, and health policy dimensions. Among these approaches, spatial studies have become particularly prominent, analyzing the geographical distribution of natural therapeutic factors and the services built upon them, as well as inequalities in access to care. In Hungary, significant differences can be observed in this regard: the geographical concentration of institutions and natural resources based on thermal water influences not only the availability of services but also their utilization (Hojcska, 2021; Szabó, 2023).

The social dimension of research is also receiving increasing attention. Köbli (2021) points out that the development of Hungarian spa towns is closely linked to the implementation of sustainability and ecological considerations. According to his findings, environmental sustainability and the active involvement of the local community and economy play a key role in the long-term competitiveness of spa towns, which aligns well with a complex, systemic understanding of health tourism.

An examination of health policy dimensions further nuances this picture. Research by Ádám Ruszinkó and colleagues (2024) highlights that the macroeconomic environment and health insurance financing mechanisms play a decisive role in the accessibility and sustainability of medical treatments. Financing structures and policy decisions thus have a direct impact on the operation and development potential of medical tourism services.

[1] NUTS 3 level administrative unit in Hungary

MATERIALS AND METHODS

The aim of this research was to explore the characteristics of patients receiving spa treatments covered by social security benefits and their experiences with the service in a primary questionnaire survey.

The primary data collection took place in the Northern Great Plain region of Hungary, which includes Hajdú-Bihar, Jász-Nagykun-Szolnok, and Szabolcs-Szatmár-Bereg counties. The research took place at eight thermal spas offering balneotherapy treatments covered by social security between June and December 2025. Figure 1 shows the geographical location of the study sites within Hungary and broken down by county.

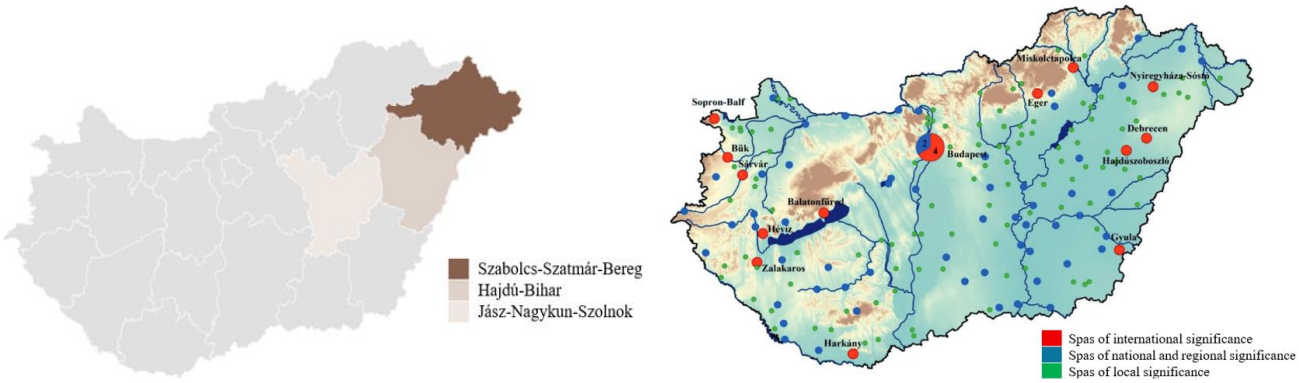

Figure 1. Research location and the classification and location of spas in Hungary (Source: Own compilation; Köbli, 2021)

Following the review of the literature, data collection was carried out using a structured questionnaire designed by the authors during the primary research. The target group of the study consisted of patients receiving spa treatments covered by Hungarian social security, who were available at the spas during the treatment period. Accordingly, data collection was carried out in person using paper-based questionnaires at eight spas in the Northern Great Plain Region. Data collection took place between June and December 2025, during which a total of 405 people participated in the research and completed the questionnaire (Figure 2). The sample cannot be considered representative, as respondents participated in the survey on a voluntary basis and completed the questionnaire while undergoing balneotherapy treatments. As a result, the findings cannot be generalized to the entire population, but they do reflect trends and correlations within the target group studied.

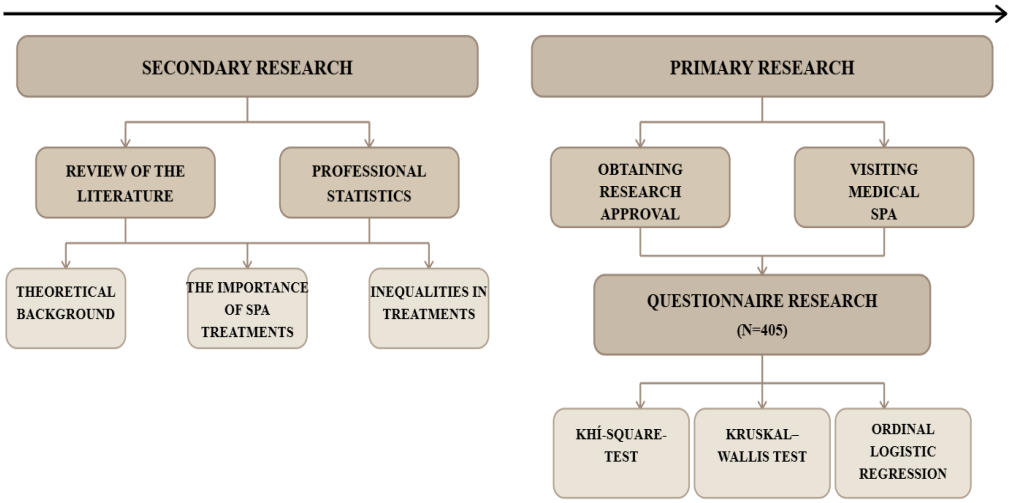

Figure 2. Research process (Source: Own compilation)

Applied Research Methods

Among the applied methods, this study draws on insights obtained from secondary sources, including the analysis of data from the HCSO, the NEAK, and providers of balneological treatments, examined both at the national level and by regional breakdown. The coding, cleaning, and statistical analysis of the primary research data was performed using the IBM SPSS Statistics software package. The analyses were conducted in several steps, in line with the research questions and the measurement levels of the variables. We used descriptive statistics to present the socio-demographic characteristics of the respondents, in the form of absolute and relative frequencies (number of persons, %).

We used a chi-square test to examine the correlations between socio-demographic factors and subjective assessments of financial status, interpreting the strength of the correlations using Cramer's V index. We also used a chi-square test to analyze the subjective financial burden of using balneotherapy services by region.

Attitudes toward health tourism based on medicinal waters and the use of spa treatments were measured using six statements on a five-point Likert scale (1 = strongly disagree; 5 = strongly agree). The questions concerned the need for

relaxation, financial and time constraints, the tourist nature of spa tourism, the requirement for a doctor's recommendation, and visiting new spas. We used the Kruskal–Wallis test to reveal differences between counties.

To explain the significant regional differences, we estimated ordinal logistic regression models, in which county, gender, educational attainment, economic activity status, and age were included as explanatory variables. Hajdú-Bihar county, female gender, higher education, and active status were defined as reference categories.

In the analyses, we considered a 5% significance level to be relevant ($p < 0.05$).

Description of the Questionnaire Content

The questionnaire was compiled by integrating several sources in order to ensure that the measurement tool was well-founded in terms of both content and methodology. The questions were developed using relevant elements from partially standardized, validated measurement tools, questions used in previous empirical research, and items developed in-house.

The measurement tools used included relevant elements of the SF-36 quality of life questionnaire, questions from the European Health Interview Survey (EHIS), and adapted questions from previous PhD research (Hojcska, 2022; Szabó, 2015). These were supplemented by questions developed in-house and tailored to the objectives of the research and the specific characteristics of balneotherapy treatments. Prior to finalizing the questions, professional consultations were held with a specialist working at a spa and a spa manager, which contributed to the professional soundness and comprehensibility of the questions and their suitability for spa medical practice. The consent of the spas concerned and the approval of the Regional Research Ethics Committee were required to carry out the research.

RESULTS

Socio-demographic characteristics of respondents

Table 2 summarizes the socio-demographic characteristics of the respondents participating in the survey by gender, age, educational attainment, place of residence, and subjective income status.

Table 2. Socio-demographic characteristics of respondents (Source: Own compilation)

Characteristics of respondents		Person	%
Gender	Male	124	30.6%
	Female	281	69.4%
Classification by age	18-24	5	1.2%
	25-34	15	3.7%
	35-44	35	8.6%
	45-54	76	18.8%
	55-64	84	20.7%
	65-74	135	33.3%
	75+	55	13.6%
Classification by educational attainment	Low (Less than 8 years of elementary school; 8 years of elementary school; Vocational school, vocational training	72	17.8%
	Secondary (with vocational secondary school leaving certificate; high school; secondary school leaving certificate, technical college)	165	40.7%
	Higher education (college, university)	168	41.5%
Classification by place of residence	Capital	16	4.0%
	County seat	124	30.6%
	City	167	41.2%
	Village	98	24.2%
Income distribution	No, because I live comfortably and am able to save regularly	89	22.0%
	No, because I live on my income and am rarely able to save	189	46.7%
	Yes, because my income just covers my expenses	103	25.4%
	Yes, I often have financial difficulties	18	4.4%
	I do not have my own income	6	1.5%

Based on the socio-demographic characteristics of the 405 participants in the study, it can be concluded that the gender composition of the sample was heavily skewed towards women: 69.4% of respondents were women, while 30.6% were men. This ratio is consistent with the gender distribution characteristic of the population using balneotherapy treatments.

Looking at the age structure, it can be seen that the majority of the sample consisted of older age groups (Figure 3). 67.6% of respondents were over 55 years of age, with the largest proportion being those aged 65–74 (33.3%). The proportion of age groups under 45 is low, which can be explained by the more frequent occurrence of musculoskeletal complaints with age. In terms of educational attainment, the vast majority of respondents had secondary or higher education (82.2% in total). The proportion of those with higher education (41.5%) slightly exceeded that of those with secondary education (40.7%), while the proportion of those with low educational attainment was 17.8%. The results suggest that the more educated social groups are overrepresented among those who use balneotherapy treatments (Figure 3).

Based on the distribution by place of residence, the sample is typically urban. Of the respondents, 41.2% lived in cities, 30.6% in county seats, while the proportion of those living in villages and farms was 24.2%. The proportion of those living in the capital is low (4.0%), which is consistent with the geographical location of the region under study.

Based on their subjective assessment of their income situation, nearly half of respondents (46.7%) said that they could live on their income, but were rarely able to save (Table 1). Twenty-two point zero percent reported a stable financial situation and regular savings opportunities. At the same time, more than a quarter of the sample (25.4%) indicated that their income barely covers their expenses, while 4.4% experience regular financial difficulties. The proportion of respondents without independent income is low (1.5%) (Figure 4).

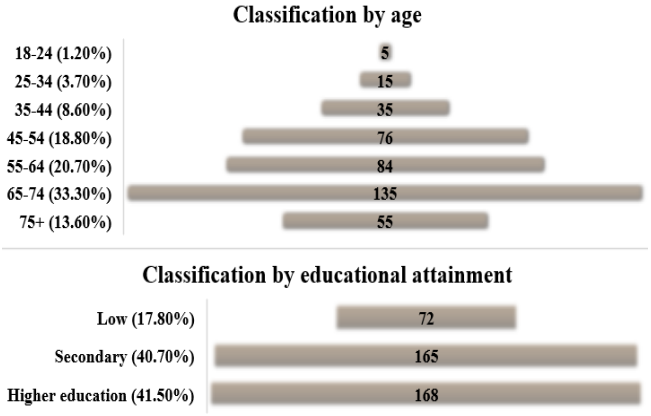

Figure 3. Classification by age and educational attainment (N=405) (Source: Own compilation)

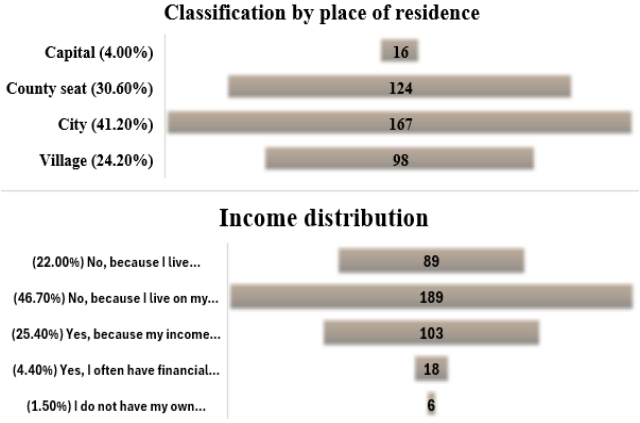

Figure 4. Classification by place of residence and income distribution (N=405) (Source: Own compilation)

Relationships between financial situation and socio-demographic factors

Table 3 shows the distribution between educational attainment and subjective assessment of financial situation, which indicates that higher educational attainment is associated with a more favorable assessment of financial situation.

Table 3. Respondents' educational attainment and subjective assessment of their financial situation (number of respondents, %) (Source: Own compilation)

	Is it difficult for you to use services in your situation?					Total
School education	**No, because I live comfortably and am able to save regularly**	**No, because I live on my income and am rarely able to save**	**Yes, because my income just covers my expenses**	**Yes, I often have financial difficulties**	**I do not have my own income**	
Low	7	30	31	3	1	72
	9.7%	41.7%	43.1%	4.2%	1.4%	100.0%
Secondary school education	24	80	45	13	3	165
	14.5%	48.5%	27.3%	7.9%	1.8%	100.0%
Higher education	58	79	27	2	2	168
	34.5%	47.0%	16.1%	1.2%	1.2%	100.0%
Total	89	189	103	18	6	405
	22.0%	46.7%	25.4%	4.4%	1.5%	100.0%

We used a chi-square test to explore the correlations between the socio-demographic characteristics of respondents and their subjective assessment of their financial situation. A statistically significant correlation was found between educational attainment and respondents' subjective assessment of their financial situation ($\chi^2 = 45.03$; df = 8; $p < 0.001$). The Cramer's V value indicating the strength of the relationship was 0.236, which indicates a small to medium effect size. Respondents with lower levels of education were more likely to report financial difficulties, while those with higher education were more likely to assess their financial situation as favorable. Table 4 shows the subjective financial burden of using balneotherapy services broken down by county among respondents.

Table 4. Financial burden of using balneotherapy services broken down by region (Source: Own compilation)

	Is it difficult for you to use services in your situation?					Total
	No, because I live comfortably and am able to save regularly	**No, because I live on my income and am rarely able to save**	**Yes, because my income just covers my expenses**	**Yes, I often have financial difficulties**	**I do not have my own income**	
Szabolcs-Szatmár-Bereg	52	82	46	6	5	191
	27.2%	42.9%	24.1%	3.1%	2.6%	100.0%
Jász-Nagykun-Szolnok	12	41	37	10	0	100
	12.0%	41.0%	37.0%	10.0%	0.0%	100.0%
Hajdú-Bihar	25	66	20	2	1	114
	21.9%	57.9%	17.5%	1.8%	0.9%	100.0%
Total	89	189	103	18	6	405
	22.0%	46.7%	25.4%	4.4%	1.5%	100.0%

A statistically significant correlation was found between the location (county) where spa treatments were used and the respondents' subjective assessment of their financial situation ($\chi^2 = 32.41$; df = 8; $p < 0.001$).

The Cramer's V value indicating the strength of the relationship was 0.200, which indicates a small to medium effect size. The proportion of patients who considered their income to be financially limited was highest in the spas of Jász-Nagykun-Szolnok County (47.0%), while respondents reporting a stable financial situation were overrepresented in Hajdú-Bihar County (79.8%). In the spas of Szabolcs-Szatmár-Bereg County, the proportion of responses indicating financial constraints (27.2%) fell between the values of the other two counties.

Attitudes towards health tourism based on medicinal waters

Attitudes toward health tourism based on medicinal waters and the use of balneotherapy treatments were examined in a separate set of questions. Respondents could express their level of agreement with each statement on a five-point Likert scale (1 = strongly disagree; 5 = strongly agree). With regard to the ordinal measurement level, we used the Kruskal–Wallis test to reveal differences between counties (Table 5). Based on the results of the analysis, statistically significant differences were found between counties for several of the statements examined.

A significant difference was found for the statement “I don’t have enough money to use spa services as often as I would like” (H = 14.372; p = 0.001), while a particularly strong regional difference was observed in the case of the statement "I am unable to take long trips or vacations due to my work" (H = 64.297; p < 0.001).

Table 5. Examination of attitudes related to the use of spa services by county (Kruskal–Wallis H test) (Source: Own compilation)

Test Statistics[a] (Kruskal Wallis Test),b (Grouping Variable: Vármegye)						
	Due to our hectic lives, it is often necessary to relax.	I don't have enough money to use spa services as often as I would like to.	Due to my job, I don't have the opportunity to travel for long periods of time or relax.	I try to combine spa treatments with getting to know a particular region.	I only use spa services on medical advice.	I always try to visit new spas.
Kruskal-Wallis H	1.359	14.372	64.297	7.661	6.478	0.520
df	2	2	2	2	2	2
Asymp. Sig.	0.507	**<0.001**	**<0.001**	**0.022**	**0.039**	0.771

There was also a significant difference in the assessment of the tourist nature of spa treatments (H = 7.661; p = 0.022) and in terms of the requirement for a doctor's recommendation (H = 6.478; p = 0.039). The results suggest that the assessment of financial, time and attitude factors related to balneotherapy treatments varies regionally among patients receiving treatment at spas in the Northern Great Plain region. We used ordinal logistic regression to identify the explanatory factors for the regional differences revealed by the Kruskal–Wallis test (Table 6). In the models, Hajdú-Bihar county, female gender, higher education, and active status served as reference categories.

Table 6. Significant results of ordinal logistic regression models of attitudes toward spa use (Source: Own compilation)

Age	–	–	–	–	–	–	–

Based on the results, respondents in Szabolcs-Szatmár-Bereg and Jász-Nagykun-Szolnok counties were significantly more likely to indicate financial constraints and lack of time as barriers to using balneotherapy services. Educational attainment also proved to be a decisive factor: those with lower and secondary education were more likely to feel financially constrained and less likely to view spa treatments as recreational activities.

Inactive respondents were significantly less likely to perceive lack of time as a limiting factor. Gender and age did not have a significant effect on any of the attitudes examined. The results of the ordinal logistic regression analysis

confirm that attitudes and constraints related to the use of balneotherapy services are not determined solely by individual demographic characteristics, but are also significantly influenced by regional and structural factors.

Based on the results of the model, financial constraints and lack of time are more likely to appear in the perceptions of respondents in Szabolcs-Szatmár-Bereg and Jász-Nagykun-Szolnok counties, even when the analysis controls for educational attainment, economic activity, gender, and age. This suggests that social security support alone cannot compensate for regional inequalities in access to spa treatments.

Presumably, we can speak of a complex, multifactorial mechanism of effects in which the factors mutually influence one another, and where the utilization of services is simultaneously shaped by individual characteristics as well as the social and physical environment (Moravcsik-Kornyicki & Fedor, 2021). The impact of educational attainment also shows a consistent and interpretable pattern. Respondents with lower and intermediate levels of education were more likely to report feeling financially constrained and less likely to view spa treatments as a form of recreation or relaxation. This result is consistent with approaches that suggest that the use of health and health tourism services is influenced not only by formal access to care, but also by individuals' socioeconomic resources and interpretive frameworks. In this sense, spa tourism is not merely a therapeutic service, but an experience with different meanings for different social groups.

The impact of economic activity status—particularly in terms of perceived lack of time—further reinforces the structural interpretation. Inactive respondents were significantly less likely to cite lack of time as a limiting factor, which logically follows from their lack of time constraints related to work. This result highlights that the use of spa treatments is significantly influenced not only by financial conditions but also by time resources related to labor market position.

It is noteworthy that neither gender nor age had a significant effect on individual attitudes. This suggests that the differences examined are not primarily linked to biological or demographic characteristics, but rather stem from differences in the functioning of territorial and socio-economic structures. Overall, the results of the model suggest that, even with formal access provided by social security support, there remain "hidden" financial and time constraints that differentially affect actual access to and interpretation of balneotherapy services.

DISCUSSION

The results of this study confirm that attitudes toward and barriers to accessing balneotherapy services are complex, with individual socio-demographic characteristics and regional characteristics both playing a decisive role. The differences identified among patients treated in spas in the Northern Great Plain region with social security support and on medical grounds indicate that, even with formal access provided by funding, financial and time constraints remain that influence the actual use of services.

Based on an analysis of regional differences, financial constraints and lack of time were significantly more common in Szabolcs-Szatmár-Bereg and Jász-Nagykun-Szolnok counties than in Hajdú-Bihar county. This result is consistent with previous analyses of NEAK's financing and service provider capacities, which suggest that the spatial distribution of service providers and regional socio-economic conditions together shape access conditions (Varga, 2019; Hojcska, 2022). The results of the regression models show that these regional differences remain even when individual demographic factors are taken into account in the analysis. The effect of educational attainment showed a consistent pattern in both the assessment of financial constraints and the interpretation of the therapeutic, recreational, and tourist role of spa treatments. Respondents with lower and intermediate levels of education were more likely to report feeling financially burdened and less likely to view spa treatments as a form of recreation and relaxation. This result is consistent with approaches that suggest that the use of health and health tourism services is influenced not only by formal access to care, but also by individuals' socioeconomic resources, cultural capital, and interpretive frameworks (Rezapour et al., 2024).

The impact of economic activity status—particularly in terms of perceived lack of time—further complicates the interpretation of access barriers. Inactive (retired, unemployed) respondents were less likely to cite lack of time as a limiting factor, which is logical given their lack of work-related time constraints. This result highlights that the use of spa treatments is significantly influenced not only by financial conditions but also by time resources related to labor market position (Andersen, 1995). It is noteworthy that neither gender nor age had a significant effect on the attitudes examined. This suggests that the differences identified are not primarily related to biological or age characteristics, but rather stem from differences in the functioning of territorial and socio-economic structures. In this context, spa treatment is not only a form of healthcare, but also a socially embedded service with different meanings.

The limitations of the research include the fact that the sample is not representative and that data collection was conducted exclusively among patients who actually used balneotherapy treatments. Nevertheless, the results provide valuable empirical insight into regional patterns of attitudes and access barriers related to spa services covered by social security, and lay the foundation for further studies based on extended data collection.

CONCLUSIONS

Based on the results of the research, it can be concluded that access to spa treatments covered by social security benefits cannot be considered homogeneous in the Northern Great Plain Region. Despite the existence of formal financing frameworks, significant regional, social, and structural differences influence the actual interpretation of services.

The analyses showed that in Szabolcs-Szatmár-Bereg and Jász-Nagykun-Szolnok counties, financial and time constraints are more strongly reflected in patients' perceptions than in Hajdú-Bihar county, even when controlling for individual socio-demographic factors. Educational attainment and economic activity also play a decisive role in shaping attitudes, while gender and age were found to have no significant effect. The results of the research suggest that inequalities

in access to spa treatments cannot be interpreted solely as a health policy or financing issue, but are closely linked to regional socio-economic characteristics and individual resources. In this sense, spas fulfill both a health and health tourism function, the interpretation and utilization of which varies from one social group to another.

The study contributes to expanding the empirical basis for research on balneotherapy and health tourism, and highlights that regional and social inequalities should be taken into account when developing spas and planning services.

One of the methodological limitations of the research is that the primary data collection covered only those patients who personally participated in balneotherapy treatment during the data collection period, so the sample does not represent the entire range of potential users. As a result, the study primarily reflects the experiences and perceptions of patients currently receiving care. In order to expand the scope of the study, supplementary online data collection will also be launched, based on the basic structure of the questionnaire, using a database built on snowball sampling techniques via social media. This data collection provides an opportunity to include in the analysis the opinions and experiences of people who are unfamiliar with balneotherapy treatments, have used them in the past, or plan to use them in the future.

The data from the external sample can later serve as a control group, the inclusion of which can contribute to confirming the results of the present study and to a more nuanced interpretation of those results, with particular regard to the correlations between health status, financial situation, and regional access.

Citation: Dağ, K. (2026). The effect of online destination brand experience on behavioural intentions: The mediating role of destination brand authenticity. *Geojournal of Tourism and Geosites*, 67(3), 2409–2418. https://doi.org/10.30892/gtg.67351-1863

Abstract: This study examines the effects of online destination brand experience on destination brand authenticity, affective commitment, and behavioural intention within the context of cultural tourism destinations. As digital interactions increasingly shape tourists' destination perceptions before and during their travel experiences, understanding the role of online brand experiences has become essential for destination marketing research. Accordingly, this study contributes to the destination branding literature by investigating the mediating role of destination brand authenticity in the relationship between online destination brand experience and affective commitment. The study population consists of visitors who experienced the cultural tourism destinations of Zeugma and Gaziantep in Türkiye. Quantitative data were collected using a structured questionnaire administered to destination visitors, and the proposed conceptual model was analysed through Partial Least Squares Structural Equation Modelling (PLS-SEM) using SmartPLS. The empirical findings demonstrate that online destination brand experience has significant positive effects on destination brand authenticity, affective commitment, and behavioural intention. Furthermore, destination brand authenticity significantly mediates the relationship between online destination brand experience and affective commitment, indicating that authentic brand perceptions strengthen tourists' emotional attachment to the destination. These findings provide both theoretical and practical implications by emphasising the strategic importance of creating engaging and authentic online destination experiences to enhance tourists' emotional bonds and encourage favourable behavioural intentions. The study also offers valuable insights for destination marketing organisations seeking to strengthen destination competitiveness through effective digital branding strategies.

Keywords: online destination brand experience, destination brand authenticity, affective commitment, behavioural intentions, Zeugma

INTRODUCTION

The perception of a destination as a brand is shaped by a set of associations and values that distinguish it from competitors and promise visitors unique and memorable experiences (Srivastava et al., 2022). Destination brand experience, in a physical context, emerges through tourists' direct visits to the destination (Candrea et al., 2025). However, when tourists interact with a destination through online channels such as official destination websites prior to travel, an online destination brand experience is formed, constituting a key component of the destination's experiential simulation process (Lin et al., 2024). In today's digitalized tourism market, destination marketing organizations (DMOs) increasingly use internet technologies to engage target audiences and promote their brands. Accordingly, online destination brand experience (ODBE) refers to the internal and subjective responses that arise during tourists' interactions with platforms such as official destination websites. These online experiences play a critical role in shaping perceptions of destination brand authenticity (DBA) (Khan & Fatma, 2021; Lalicic et al., 2020; Jimenez-Barreto et al., 2020; Napoli et al., 2016).

Many destinations emphasize authenticity and employ technologies such as virtual reality to establish stronger connections with tourists (Chen et al., 2020; Dağ et al., 2024). Immersive technologies, including AR and VR, are reported to enhance tourists' perceptions of destination brand authenticity by offering engaging and exciting experiences that exceed expectations (Gao et al., 2022). Consequently, destination brand authenticity has become a critical factor in tourism decision-making, as authenticity positively influences tourism experiences and related emotions (Chen et al., 2021). In this sense, perceiving a destination as authentic significantly affects destination choice and tourists' behavioral intentions (Zhou et al., 2023; Genc & Genc, 2023). Tourists' desire to escape the technological complexity and artificiality of everyday life further increases their demand for genuine and authentic experiences (Chen et al., 2020).

As a result, the search for authentic experiences has positioned destination brand authenticity (DBA) at the center of visitors' decision-making processes. DBA reflects the extent to which a destination is perceived as honest, value-driven, and supportive of visitors' self-expression. In this process, destination websites function as experiential simulations in the pre-visit stage by virtually presenting cultural and promotional elements, thereby playing a critical role in

constructing authenticity perceptions (Khan & Fatma, 2021). Understanding how the relationship between ODBE and DBA influences behavioral intention is therefore essential. Prior studies demonstrate that unique experiences delivered through online interactions and multimedia content enhance authenticity perceptions, which in turn strengthen tourists' intentions to visit and recommend destinations (Khan & Fatma, 2021; Chen et al., 2020; Jimenez-Barreto et al., 2020).

CONCEPTUAL FRAMEWORK

Online Destination Brand Experience (ODBE)

Representing a preliminary stage, unlike traditional offline experiences, where tourists gather information and increase their motivation before making a decision, ODBE is expressed as the internal and subjective responses that occur during a tourist's interaction with a destination's official website or other digital platforms (Kumar & Kaushik, 2018; Choi et al., 2018; Zhang et al., 2018; Khan et al., 2016). ODBE, as a whole of sensory, emotional, cognitive, and behavioral responses, arises as a result of visitors' interaction with the destination brand in the digital realm (Lonardi et al., 2024; Grosso et al., 2024). This whole set of responses actually represents an experience that potential visitors have remotely lived through and formed in their minds via digital content before visiting the destination (Candrea et al., 2025). This digitally represented experience is considered a significant factor in decision-making and planning stages, positively influencing physical visits and behavioral intentions (Jimenez-Barreto et al., 2020).

Destination Brand Authenticity (DBA)

The increasing demand for authenticity in the tourism industry is considered important within the technological complexity of modern societies and is treated as a fundamental understanding for a genuine experience (Shi et al., 2022; Kososki & Prado, 2017; Yeh et al., 2025). DBA becomes an important structure at this point, responding to tourists' search for authentic experiences and representing a fundamental role with increasing importance in destination marketing. DBA is defined as the degree to which tourists perceive how honest a destination brand is in fulfilling its promises, and how "authentically" it represents its values and origins (Kumail et al., 2022). Therefore, authenticity includes elements such as the destination brand being honest with the tourist, being responsible, and helping the tourist find their own identity. Essentially, DBA is considered a subjective judgment about the authenticity and accuracy of a brand's image (Beverland & Farrelly, 2010; Newman & Dhar, 2014; Khan & Fatma, 2021; Can et al., 2025).

Affective Commitment (AC)

Affective commitment, reflecting visitors' desire to maintain a long-term relationship with a business or brand and their strong emotional responses to the destination brand, manifests itself through positive emotions and carries personal meaning. Affective commitment is a consumer's or tourist's emotional attachment to a brand and a sense of belonging based on identification with that brand (Iglesias et al., 2019; Brakus et al., 2009). Therefore, for visitors, this emotional commitment is more than just a rational choice for that destination; it carries a strong personal meaning (Zhong et al., 2017). This emotional commitment manifests itself through the happiness, pride, and strong positive emotions visitors feel while experiencing the destination. In other words, it is considered a strong sense of belonging to the destination and the destination having a personal meaning (Yew, 2008; Tang et al., 2021).

Behavioural Intentions (BI)

Behavioral intention is referenced to better understand marketing efforts and to provide a focal point for tourism managers in decision-making. Behavioral intention is considered a critical variable that determines the potential of a tourism experience to translate into future actions. Behavioral intention is defined as an individual's conscious and planned inclination or willingness to engage in future behaviors. In other words, it provides insight into the tourist's future interactions with the destination (Wong et al., 2020; Yeh et al., 2025). Behavioral intentions always focus on the expected outcome in future behavior and comparison with overt behavior, enabling tourism managers to better understand how to improve marketing efforts to create an attractive image for the destination and maximize resource utilization (Matiza & Kruger, 2021; Zatori et al., 2018).

THEORETICAL FRAMEWORK

Online Destination Brand Experience and Destination Brand Authenticity

Tourists, influenced by multiple visual and auditory stimuli, transform the experiences they perceive through these online platforms into lasting impressions. The function of destination websites is to present the cultural and promotional features of a destination to tourists before their visit, creating a perception that the destination is real and authentic. This is because tourists, overwhelmed by the complex routines of modern life, increasingly desire more interactive, value-oriented, and self-respecting experiences (Jimenez-Barreto et al., 2020; Mura et al., 2017). This desired authenticity is formed as a result of the internal and subjective interactions that visitors have with various experiences and stimuli. Therefore, the sensory and cognitive processes triggered during interaction with a website form a judgment about the authenticity of that destination brand (Moulard et al., 2016). Online experiences, especially those with a high level of emotional intensity, lead tourists to perceive the destination as more authentic and genuine (Jim´enez-Barreto et al., 2020). Consequently, online destination brand experience is considered a fundamental antecedent that constructs tourists' perception of destination authenticity (Khan & Fatma, 2021; Jimenez-Barreto et al., 2020; Chen et al., 2022; Jin et al., 2020). Based on this information, the following hypothesis is proposed:

H1. Online destination brand experience positively influences destination brand authenticity.

Online Destination Brand Experience and Behavioural Intentions

Online experiences offered by destinations through their official websites positively influence tourists' intentions to visit and recommend them to others. Sensory, cognitive, and emotional stimuli offered on these platforms create a positive destination image in the minds of tourists, strengthening behavioral intentions and encouraging digital interactions to translate into physical visits (Jimenez-Barreto et al., 2020). The enhancement of authenticity perception by online brand experience also has significant effects on destination selection and future behavioral intentions (Chen et al., 2022; Zhu et al., 2023). Previous studies have shown that a positive online experience directly increases visit intention and recommendation behavior (Bilgihan et al., 2016; Illouz & Illouz, 2017; Li et al., 2023; Wang et al., 2023; Candrea et al., 2025). Accordingly, the following hypothesis is proposed:

H2. Online destination brand experience positively influences behavioral intention.

Online Destination Brand Experience and Affective Commitment

Experiences delivered through online and interactive brand content generate strong emotional responses among tourists, thereby strengthening affective commitment and a sense of belonging toward the brand (Brakus et al., 2009; Iglesias et al., 2019). Interactive and value-laden digital experiences offered by destinations address not only visitors' rational needs but also their emotional needs, which enhances commitment (Li et al., 2023). In this context, stimuli presented through platforms such as destination websites (e.g., multimedia content) are reported to have significant effects on affective commitment. Prior studies consistently demonstrate that online destination brand experience (ODBE) has a direct and positive effect on tourists' affective commitment (Khan & Fatma, 2021). Accordingly, the following hypothesis is proposed:

H3. Online destination brand experience positively affects affective commitment.

Destination Brand Authenticity and Affective Commitment

When tourists perceive a destination brand's promises as honest, genuine, and faithful to its core values, destination brand authenticity (DBA) reinforces perceptions of strong values and originality, thereby increasing tourists' tendency to develop a strong affective commitment toward the brand (Sallaku & Vigolo, 2024; Yin & Dai, 2021). Moreover, DBA functions as a bridging mechanism in the relationship between online experiences and affective commitment, exerting a positive influence on tourists' emotional attachment to the destination (Manthiou et al., 2018; Kim & Song, 2020; Khan & Fatma, 2021). Accordingly, the following hypothesis is proposed:

H4. Destination brand authenticity positively affects affective commitment.

Affective Commitment and Behavioural Intentions

Affective commitment toward a destination brand positively influences tourists' behavioural intentions. Tourists who develop a strong emotional bond are more likely to recommend the destination, provide positive feedback, and exhibit brand loyalty (Brakus et al., 2009; Jimenez-Barreto et al., 2020; Donthu & Gustafsson, 2020; Khan & Fatma, 2021). Experiences delivered through digital environments and destination websites foster affective commitment, thereby strengthening long-term behavioural intentions (Hosany & Gilbert, 2010; Khan & Fatma, 2021). In this context, interactive and high-quality digital experiences enhance visit intentions and encourage positive online behavioural outcomes, such as favourable reviews and recommendations (Lalicic et al., 2020; Choi et al., 2018). Accordingly, the following hypothesis is proposed:

H5. Affective commitment positively affects behavioural intention.

The Mediating Role of Destination Brand Authenticity

DBA plays a strategic bridging role in tourism marketing by functioning as a critical mediator between various marketing stimuli and destination brand experience, acting as both an influencing and an influenced construct. In particular, destination brand authenticity has been confirmed to exert direct positive effects on revisit and recommendation intentions, thereby strengthening the link between brand experience and commitment (Zhou et al., 2023; Chen et al., 2020). In the relationship between ODBE and tourists' attitudes toward the destination, DBA occupies a central position. Its mediating role is especially grounded in tourists' efforts to reduce information asymmetry and make sense of virtual experiences, thereby serving an important interpretive function (Jimenez-Barreto et al., 2020). Prior studies indicate that destinations perceived as authentic foster positive emotions during brand interactions and increase tourists' likelihood of recommending the destination when their need for authenticity is fulfilled (Gilmore & Pine, 2007; Eggers et al., 2013; Schallehn et al., 2014). Moreover, brand authenticity positively influences tourists' affective commitment, brand engagement, and satisfaction, which ultimately shape behavioural outcomes (Carreira et al., 2022; Chen et al., 2022).

Sensory experiences generated by online multimedia content are considered sufficient to form judgments about destination authenticity, and such perceptions enhance affective commitment and subsequently strengthen behavioural intention (Khan & Fatma, 2021; Sallaku & Vigolo, 2024). Authenticity deepens tourists' interest in destination-related activities and reinforces their affective commitment (Yeh et al., 2025). In this process, DBA is described as a psychological bridge that enables marketing stimuli to resonate with tourists' minds and emotions (Can et al., 2025). While authenticity can directly influence visitor behaviour, it may also exert indirect effects through commitment (Meng & Luo, 2024), indicating that authenticity can generate multiple behavioural outcomes (Fu, 2019; Chen et al., 2020). Empirical findings further confirm the mediating role of DBA in the relationship between ODBE and affective commitment (Khan & Fatma, 2021; Can et al., 2025; You et al., 2015; Hasanein et al.,2026). Accordingly, the following hypothesis is proposed:

H6. Destination brand authenticity mediates the relationship between online destination brand experience and affective commitment.

MATERIALS AND METHODS

Data were collected from participants using a survey-based approach and an appropriate participant sample. The questionnaire was administered face-to-face in September 2025 and was completed by consumers who used the platform. Prior to responding to the survey, participants were asked to browse Zeugma's (Gaziantep) official online promotional platform(https://zeugma.org.tr/sanal-muze/). Accordingly, data were obtained from a sample of 515 users who had visited the cultural tourism destinations of Zeugma and Gaziantep in Türkiye and were familiar with the destination through its online promotional platforms. This procedure ensured that respondents had both actual destination experience and exposure to online destination-related content. Due to the large size of the research population, it was not possible to reach the entire population; therefore, a representative sample was selected by considering time and cost constraints. According to Krejcie & Morgan (1970), for populations exceeding 10,000, a sample size of 387 is sufficient at a 5% significance level and a 5% sampling error. Accordingly, the study aimed to reach at least 387 participants. Data were collected using a convenience sampling method through a pre-tested structured questionnaire. A five-point Likert scale was employed in the survey instrument.

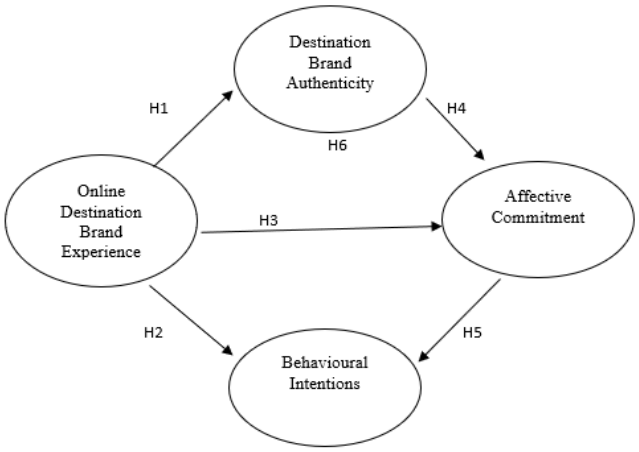

Figure 1. Research Model

RESULTS AND DISCUSSION

Demographics

The demographic characteristics of the participants are as follows (Table 1). Of the participants, 28.5% were between the ages of 25 and 34. The sample consisted of 47.2% males and 52.8% females. Regarding marital status, 41.6% of the participants were married, while 58.4% were single. In terms of education level, 44.5% of the respondents held a bachelor's degree. With respect to income level, 17.3% of the participants reported very low income, whereas 11.5% reported very high income.

Table 1. Demographic Characteristics of the Respondents

Demographic Characteristics		**n**	**%**
Age	18-24	84	16.3
	25-34	147	28.5
	35-44	134	26.1
	45-54	63	12.2
	55-64	41	8.0
	65 ≤	46	8.9
Gender	Male	243	47.2
	Female	272	52.8
Marital status	Married	214	41.6
	Single	301	58.4
Education	Primary education	23	4.5
	High school	44	8.5
	Associate degree	122	23.7
	Bachelor's degree	229	44.5
	Master's degree/Ph.D.	97	18.8
Perception of income status	Very low	89	17.3
	Low	132	25.6
	Average	173	33.6
	High	62	12.0
	Very high	59	11.5

Data Analysis

Data analysis was conducted using the SmartPLS software. SmartPLS enables the assessment of both measurement and structural models (Hair et al., 2014; Çavuşoğlu, 2021). In evaluating the measurement model, reliability was

assessed using Cronbach's alpha (CA) and rho_A, while internal consistency was examined through composite reliability (CR). Convergent validity was evaluated based on factor loadings and average variance extracted (AVE).

Discriminant validity was tested using the Fornell–Larcker criterion and the Heterotrait–Monotrait (HTMT) ratio. For the structural model, multicollinearity was examined using the inner variance inflation factor (VIF) prior to hypothesis testing. Subsequently, R^2 values were calculated to assess explained variance, and f^2 values were computed to determine effect sizes. Finally, path analysis was performed to test the proposed hypotheses.

External Model Results

Reliability and validity tests of the scale were conducted for the measurement model. For reliability and validity, the CA, rho_A, and CR values are expected to be greater than 0.70 (Nunnally & Bernstein, 1994), while factor loadings and average variance extracted (AVE) values are expected to exceed 0.50 (Kaiser, 1974). According to the results of the analyses, the reliability coefficients (CA and rho_A) and CR values were found to be above the threshold of 0.70, and both factor loadings and AVE values exceeded the recommended cutoff levels (Table 2 and Figure 2).

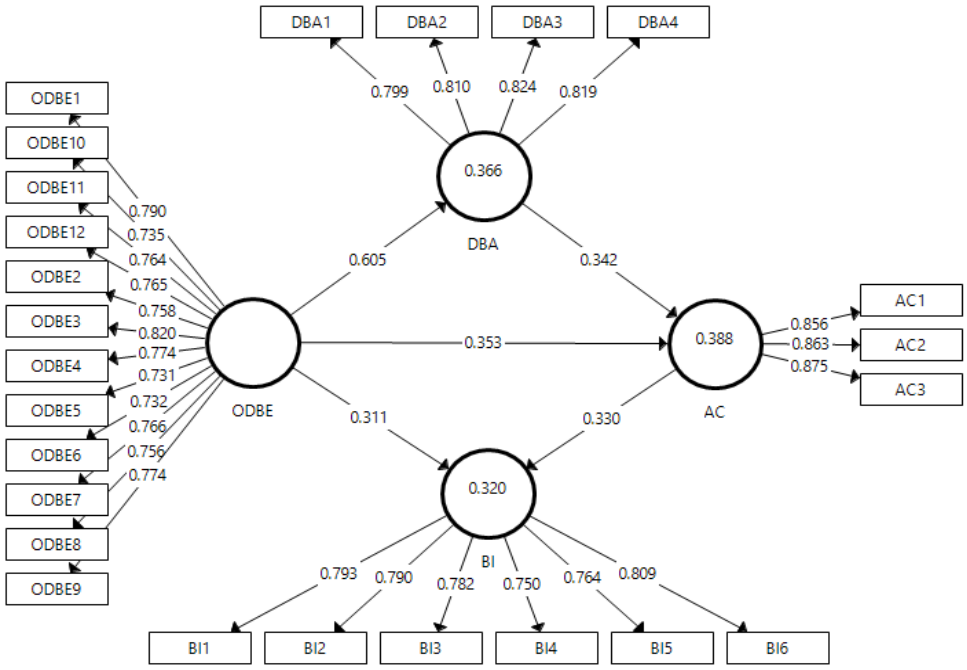

Figure 2. Average Variance Explained

The Fornell–Larcker criterion was applied to assess the discriminant validity of the scales (Fornell & Larcker, 1981). The results of the analyses indicate that the square roots of all AVE values on the diagonal in Table 3 are greater than the corresponding inter-construct correlation coefficients, thereby confirming discriminant validity.

Table 2. Reliability and Validity

Variables	CA	CR	rho-A	AVE
ODBE	0.935	0.944	0.936	0.584
DBA	0.829	0.886	0.831	0.661
BI	0.873	0.904	0.874	0.611
AC	02.831	0.899	0.832	0.747

Table 3. Fornell-Larcker Results

Variables	1	2	3	4
ODBE	**0.764**			
DBA	0.605	**0.813**		
BI	0.495	0.373	**0.782**	
AC	0.560	0.556	0.504	**0.864**

In addition, HTMT values were calculated to assess discriminant validity (Hair et al., 2016). HTMT values are expected to be below 1.00 (Voorhees et al., 2016). The results of the analyses indicate that all HTMT values are below this threshold (Table 4). The goodness-of-fit indices of the variables in the research model were used to assess the measurement model. SRMR and NFI values were analyzed using SmartPLS. The results indicate that the SRMR value is 0.039, which is below the critical threshold of 0.08 (Hu & Bentler, 1999). For the NFI, Hair et al. (2013) suggest that values close to 1 indicate good model fit. Accordingly, the NFI value was found to be 0.925. Overall, these results demonstrate that the research model meets the recommended goodness-of-fit criteria.

Table 4. HTMT Results

BI	0.547	0.438		
AC	0.634	0.667	0.592	

Internal Model Results

In evaluating the structural model, inner VIF, R^2, f^2, and path coefficients were considered. All inner VIF values were below 3, indicating that multicollinearity among the constructs was not a concern (Diamantopoulos & Siguaw, 2006). Examination of the R^2 values shows that online destination brand experience explains 36% of destination brand authenticity, 32% of behavioural intention, and 38% of affective commitment (Table 5).

Table 5. R^2 Results

Construct		R^2		
Destination Brand Authenticity		0.36		
Behavioural Intention		0.32		
Affective Commitment		0.38		

These values exceed the commonly accepted threshold of 0.20 in consumer research (Marmaya et al., 2019). Furthermore, the f^2 analysis conducted to assess the explanatory power of the independent variables revealed that all effect size values were above 0.02 (Cohen, 1988). Based on these findings, all assumptions of the structural model were satisfied, and hypothesis testing was subsequently conducted.

Table 6. Hypotheses Results
p <0.001***, p <0.01**, p <0.05*; ODBE: Online Destination Brand Experience,
DBA: Destination Brand Authenticity, BI: Behavioural Intentions, AC: Affective Commitment

Hypotheses		ß	S.D.	t value	p value	VIF	f^2
H_1	ODBE >>> DBA	0.605	0.028	21.601	0.000***	1.000	0.578
H_2	ODBE >>> BI	0.311	0.045	6.958	0.000***	1.457	0.097
H_3	ODBE >>> AC	0.353	0.045	7.893	0.000***	1.578	0.129

H_5	AC >>> BI	0.330	0.044	7.495	0.000***	1.457	0.110

The results of the analyses indicate that online destination brand experience has a positive effect on destination brand authenticity, behavioural intention, and affective commitment. The structural model and standardized path coefficients are presented in Figure 3. Accordingly, hypotheses H1, H2, and H3 are supported (Table 6).

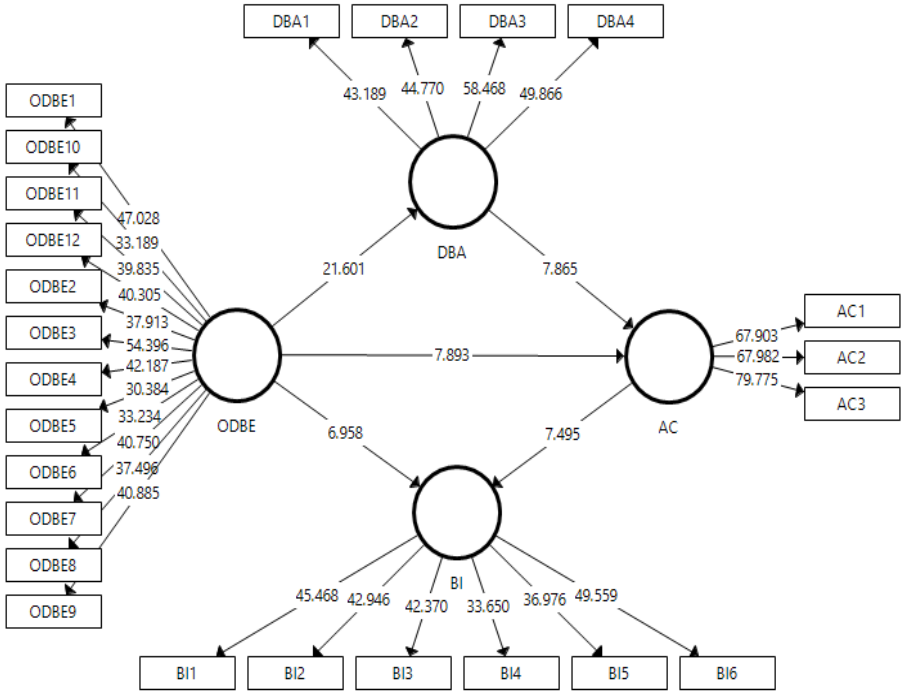

Figure 3. Structural Equation Modeling

Moreover, destination brand authenticity was found to have a positive effect on affective commitment, and affective commitment similarly exerted a positive effect on behavioural intention. Therefore, hypotheses H4 and H5 are also supported (Table 6). Finally, the mediating effect of destination brand authenticity in the relationship between online destination brand experience and affective commitment was examined. The mediation analysis revealed that destination brand authenticity significantly mediates this relationship. Accordingly, hypothesis H6 is supported (Table 7).

CONCLUSION

The study examines the effects of online destination brand experience on destination brand authenticity, affective commitment, and behavioural intention, while also investigating the mediating role of destination brand authenticity.

The findings indicate that all proposed hypotheses are supported.Specifically, the hypotheses proposing that online destination brand experience positively influences destination brand authenticity, affective commitment, and behavioural intention are supported. These results are consistent with prior studies in the literature (Khan & Fatma, 2021; Jimenez-Barreto et al., 2020; Chen et al., 2022; Jin et al., 2020; Illouz & Illouz, 2017; Bilgihan et al., 2016). In addition, the hypothesis suggesting that destination brand authenticity positively affects affective commitment is supported in line with previous research (Manthiou et al., 2018; Kim & Song, 2020; Khan & Fatma, 2021). Similarly, the hypothesis proposing that affective commitment positively influences behavioural intention is also consistent with the literature (Brakus et al., 2009; Khan & Fatma, 2021; Jimenez-Barreto et al., 2020; Donthu & Gustafsson, 2020; Lalicic et al., 2020; Choi et al., 2018). Finally, the mediation analysis reveals that destination brand authenticity plays a significant mediating role in the relationship between online destination brand experience and affective commitment.

The findings make several important theoretical contributions to the destination branding literature. This study theorizes that online destination brand experience (ODBE) is not merely a tool for information search, but also a fundamental cognitive and sensory process that constructs perceptions of destination brand authenticity (DBA).

While authenticity has traditionally been associated with physical visitation in the literature, the findings provide theoretical support for the notion that authenticity perceptions can also be effectively triggered in digital environments through multimedia content and virtual experience simulations delivered via destination websites (Liu et al., 2017; Jimenez-Barreto et al., 2020). Accordingly, online brand experience is suggested to enhance users' intentions to physically visit the destination, extending its role beyond pre-visit information provision to a key determinant of travel motivation (Li et al., 2023). Another important contribution of the study is the demonstration that ODBE exerts direct effects on behavioural intentions, such as visit intention and recommendation (Suhud et al., 2024). The psychological mechanism operating through DBA indicates that online experiences are transformed into enduring loyalty outcomes only when they pass through a filter of authenticity or perceived genuineness (Khan & Fatma, 2021). This finding suggests that interaction with a website alone does not directly generate commitment; rather, such interaction first constructs a perception of authenticity in tourists' minds, which subsequently triggers affective commitment. Furthermore, the internal and subjective responses experienced by tourists during their interaction with a destination website provide a sufficient basis for forming judgments about whether the destination is genuine and honest. This process, in turn, fosters the development of positive psychological attitudes toward the destination (Phat et al., 2025).

The findings also provide several practical implications for destination marketing organisations (DMOs). Official destination websites should be designed not merely as sources of information, but as experience simulation platforms. High-quality videos, high-resolution visuals, and interactive content that appeal to users' senses can enable tourists to develop strong evidence of a destination's authenticity before visiting. DMOs should therefore be more willing to use authenticity as a strategic mediator, as interactive experiences offered without first constructing authenticity perceptions are likely to be insufficient in generating long-term outcomes such as commitment and recommendation (Khan & Fatma, 2021). Accordingly, DMOs need to better examine and systematically build authenticity perceptions so that the destination brand is perceived as genuine by tourists. Destinations perceived as artificial or insufficiently authentic may face long-term strategic losses. In this regard, co-branding and joint promotional efforts with national tourism brands or partner brands possessing high authenticity values may yield positive results by transferring authenticity perceptions from strong to weaker brands, thereby directly enhancing visit and behavioural intentions.

At the same time, maintaining a balance between authenticity and technology is critical, as excessive technology may be perceived as intrusive or risky and could ultimately undermine authenticity (Gardiner et al., 2022).

Similarly, ODBE should be viewed not only as a promotional tool in destination marketing, but also as a mechanism for brand recovery and reputation management. While effectively managed online destination brand experiences can enhance tourists' visit intentions and brand loyalty through social media content, poorly managed digital experiences may lead to significant economic and reputational damage for destinations (Shah et al., 2025). To further strengthen behavioural intentions, tourists' regulatory focus orientations should be taken into account. For tourists who are risk-averse and security-oriented, authenticity functions as a safety signal, making this aspect particularly important. Marketing communications targeting this segment should emphasize the destination's traditional values, honesty, and ability to deliver on its promises. Ultimately, a high-quality digital experience not only directly increases behavioural intentions but also indirectly strengthens recommendation intentions by reinforcing perceptions of authenticity.

Abstract: The emergence of agentic artificial intelligence (AI), systems capable of autonomous reasoning, decision-making, and cross-functional execution, represents a paradigm shift from traditional predictive analytics to autonomous decision-makers in hotel revenue management (RM). Drawing upon the Meta-Unified Theory of Acceptance and Use of Technology (Meta-UTAUT), this study investigates the factors influencing the adoption of agentic AI among revenue managers in the Egyptian hospitality industry. A quantitative research design was employed, collecting primary data from 213 hotel revenue management managers across major Egyptian tourism destinations, including Cairo, Alexandria, Hurghada, and Sharm El-Sheikh. An extended Meta-UTAUT model was developed to examine the relationships between performance expectancy, effort expectancy, social influence, facilitating conditions, attitude toward use, and behavioural intention. Structural Equation Modelling (SEM) was utilised to test the formulated hypotheses and determine the strength and significance of these relationships. The results indicate that all nine direct hypotheses and four mediating hypotheses were supported, demonstrating that performance expectancy, effort expectancy, social influence, and facilitating conditions significantly influence both behavioural intention and attitude toward use, while attitude toward use plays a significant mediating role in the adoption process, demonstrating that performance expectancy, effort expectancy, and social influence significantly affect both behavioural intention and attitude toward use, while facilitating conditions positively impact attitude toward use. The results confirm that attitude toward use serves as a crucial mediating variable in the adoption process, providing empirical validation for the extended theoretical framework in the context of autonomous AI systems.

Keywords: agentic AI, hotel revenue management, extended Meta-UTAUT, technology adoption, Egypt

INTRODUCTION

Artificial intelligence (AI) is rapidly reshaping hotel decision-making, moving the industry beyond rule-based automation toward agentic AI, systems that can plan, reason, and act autonomously across multi-step tasks to achieve goals (e.g., monitoring demand signals, testing rate strategies, coordinating channel actions, and learning from outcomes). While UTAUT/Meta-UTAUT has been extensively applied to hospitality technology adoption, and AI in revenue management has been widely discussed (Kadagidze & Ugrelidze, 2023), agentic AI adoption in hotel RM, particularly among Egyptian revenue managers, remains empirically undertested (Surianingsih et al., 2024).

In practice, hotels already rely on revenue management systems (RMSs) for forecasting and price optimisation, but these systems are often perceived as "black boxes", which can reduce managerial trust and willingness to follow algorithmic recommendations. A recent study in *tourism economics* highlights that explainable AI (XAI) may be critical for RM because interpretability can reduce mistrust and improve acceptance of AI-supported pricing and forecasting decisions, especially among expert stakeholders who must justify decisions internally (Salem et al., 2024). Despite the operational promise, adoption of agentic AI in hotel RM is not a purely technical issue, it is fundamentally behavioural and organisational.

Revenue managers must believe that agentic tools improve performance, are usable under time pressure, fit existing workflows, and are socially and institutionally supported (Huang, 2025). The broader hospitality technology-adoption literature consistently emphasises that adoption outcomes depend on users' perceptions of usefulness/benefits, ease of use, normative pressures, and enabling infrastructure. A recent meta-analysis synthesising hotel-context UTAUT/UTAUT2 evidence (2021–2025) found that core UTAUT constructs, performance expectancy, effort expectancy, social influence, and facilitating conditions, show reliable positive relationships with behavioural intention in hotel technology settings, while also varying by user type (operators vs. guests) and technology context (Kamal & Kamarulzaman, 2025).

At the same time, agentic AI introduces new psychological and governance dynamics that can strengthen the role of user attitudes. Unlike traditional decision-support tools, agentic systems can proactively initiate actions, negotiate trade-offs, and optimise over time, features that may amplify perceived risk, loss of control, and accountability concerns in RM

(Dwivedi et al., 2026). In hospitality and tourism, recent research agendas on AI agents highlight both opportunities (efficiency, personalisation, and sustainability) and challenges (reliability, ethical risks, transparency, and responsibility allocation), reinforcing the need to examine adoption with attention to users' evaluative responses and trust-related judgements. These characteristics provide a strong rationale for extending the UTAUT logic using a Meta-UTAUT framing that explicitly incorporates attitude toward use as a proximal driver of behavioural intention, particularly when the technology is perceived as autonomous and high-stakes (Venkatesh et al., 2012). Supporting this approach, Meta-UTAUT has recently been applied in hospitality contexts (e.g., advanced service technologies), demonstrating its usefulness for explaining acceptance mechanisms beyond the classic UTAUT paths (Ibrahim & Islam, 2024).

The relationship between facilitating conditions and attitude toward use represents a critical yet often underexplored dimension in the adoption of agentic AI for hotel revenue management. Facilitating conditions, encompassing the organisational and technical infrastructure, availability of resources, training programmes, and ongoing support systems, can significantly shape users' attitudes by either reducing psychological barriers or amplifying concerns about implementation challenges (Venkatesh et al., 2003; Rahman et al., 2024). When revenue managers and hotel executives perceive that adequate technological infrastructure, expert assistance, and institutional support mechanisms are in place, their apprehension about transitioning from traditional rule-based systems to autonomous AI agents diminishes, fostering more favourable dispositions toward the technology (Oliveira et al., 2016; Koenig, 2025). This relationship operates through both cognitive and affective pathways: cognitively, strong facilitating conditions signal organisational commitment and resource adequacy, which users interpret as validation of the technology's legitimacy and viability (Tamilmani et al., 2021); affectively, the presence of comprehensive support structures reduces anxiety and uncertainty associated with complex AI systems, particularly given the autonomous decision-making capabilities that distinguish agentic AI from conventional automation (Dwivedi et al., 2019; Raheem & Hossain, 2025).

The study provides evidence-based strategies for technology adoption in emerging market hospitality settings, emphasising the importance of demonstrating performance benefits, ensuring system usability, leveraging social influence mechanisms, and establishing robust technological infrastructure. This study makes several distinctive contributions: (1) it extends Meta-UTAUT theory to the novel context of agentic AI, distinguishing autonomous, decision-making AI systems from generative AI tools, in hospitality revenue management; (2) it provides the first empirical investigation of autonomous AI adoption within the Egyptian hotel industry, addressing a significant gap in developing economy hospitality technology research; and (3) it validates attitude toward use as a critical mediating mechanism in agentic AI acceptance. In the Egyptian hospitality context, where hotels demonstrate varying degrees of technological preparedness and organisational competency, the strength of facilitating conditions becomes especially influential in shaping initial attitudes, as properties with limited prior experience in advanced analytics may view robust support infrastructure as essential for building confidence in AI-driven revenue management (Baabdullah et al., 2019).

Moreover, the heterogeneity across luxury Red Sea resorts, boutique Cairo hotels, and business properties suggests that facilitating conditions may differentially impact attitude formation depending on organisational resources and existing technological capabilities (Alalwan et al., 2017). However, research indicates that while facilitating conditions primarily predict behavioural intention and actual use through perceived behavioural control mechanisms, their indirect influence on attitude should not be underestimated, particularly during the critical early adoption phases when users are forming fundamental evaluative judgements about whether agentic AI represents an opportunity or threat to their professional roles and operational effectiveness (Venkatesh et al., 2012).

To strengthen the theoretical grounding of this study, the present research explicitly positions agentic AI adoption within the intersection of three converging streams of literature: (1) technology adoption theories, particularly the Meta-UTAUT framework; (2) artificial intelligence adoption in hospitality and tourism contexts; and (3) AI-driven revenue management and decision-support systems. While prior studies have extensively applied UTAUT and its extensions to general hospitality technologies (e.g., mobile services, service robots, and AI-enabled customer interfaces), relatively limited attention has been given to autonomous, agentic AI systems in operational decision-making domains such as revenue management. Moreover, some existing studies focus on general AI awareness or digital transformation, rather than directly addressing the behavioural mechanisms underlying the adoption of AI-driven decision-support tools. Therefore, this study refines the theoretical alignment by integrating recent and domain-specific literature on AI adoption in hospitality, algorithmic decision-making, and revenue management systems, ensuring that all cited works directly contribute to explaining how and why revenue managers adopt agentic AI technologies.

LITERATURE REVIEW

To ensure conceptual clarity, this study operationalises agentic AI as autonomous, goal-oriented artificial intelligence systems capable not only of generating recommendations but also of initiating, executing, and adapting revenue management actions with limited human intervention. In the context of hotel revenue management, agentic AI systems extend beyond traditional analytics or decision-support tools by continuously monitoring market conditions (e.g., demand fluctuations, competitor pricing, and booking pace), generating optimised pricing and inventory strategies, and autonomously implementing these decisions across distribution channels. For example, an agentic AI system may dynamically adjust room rates in real time, apply length-of-stay restrictions, reallocate inventory across online travel agencies, and refine its strategies based on observed performance outcomes. This operational definition distinguishes agentic AI from conventional revenue management systems, which typically require human validation before execution, and from generative AI tools, which primarily assist in content generation rather than operational decision-making.

Theoretical foundation and literature alignment

This study is grounded in the Meta-UTAUT framework, which extends the original Unified Theory of Acceptance and Use of Technology by incorporating additional psychological and contextual mechanisms, particularly attitude toward use as a mediating construct. The selection of this framework is justified by its strong empirical support in explaining technology adoption in organisational and hospitality contexts, especially when technologies involve uncertainty, complexity, and perceived risk. To ensure theoretical alignment, the literature review focuses on four closely related domains.

First, research on artificial intelligence adoption in hospitality highlights how AI technologies, such as service robots, predictive analytics, and intelligent systems, are increasingly shaping operational and strategic decision-making. These studies emphasize perceived usefulness, trust, and organizational readiness as key drivers of adoption.

Second, literature on AI-driven revenue management systems demonstrates the growing role of machine learning and automation in pricing, forecasting, and demand optimization. Unlike traditional decision-support systems, recent AI-based RM tools incorporate adaptive learning and real-time decision-making, making them more complex and requiring higher levels of user acceptance and trust.

Third, emerging research on agentic AI introduces a new paradigm in which systems act autonomously rather than merely supporting human decisions. This shift raises important behavioural and organizational questions about control, accountability, and transparency that are not fully addressed in traditional technology adoption studies.

Finally, prior applications of UTAUT and Meta-UTAUT in hospitality provide a strong theoretical basis for examining adoption behaviour, but many of these studies focus on customer-facing technologies rather than professional decision-making tools. By integrating these four streams, the present study ensures that the theoretical framework is both conceptually robust and directly relevant to the adoption of agentic AI in hotel revenue management.

Agentic AI and the shift from decision support to autonomous action in hospitality

Hospitality scholarship increasingly distinguishes between conventional "AI-enabled decision support" and agentic AI, where systems can plan, coordinate, and execute multi-step actions with limited human intervention (Chatti & Argoubi, 2025). In tourism and hospitality, agentic AI is framed as a step change because it redistributes decision rights, introduces new accountability pathways, and requires hotels to manage human-AI collaboration, governance, and risk controls more explicitly than earlier automation waves did. Complementing this macro view, work on algorithmic management in hotels shows that as algorithmic systems become more embedded, managerial roles evolve toward "translation," facilitation, and coaching, helping teams understand and operationalize algorithmic outputs while maintaining motivation, coordination, and service quality (Jianu et al., 2025). This emerging stream implies that adoption of agentic AI is not merely "technology acceptance," but acceptance of algorithmic agency in domains where decisions have visible performance consequences (Ngo, 2025).

AI in hotel revenue management and the importance of transparency and trust

Revenue management is a natural use case for AI because it depends on high-frequency analysis of demand signals, competitor pricing, distribution constraints, and inventory controls, complementing broader evidence on AI's synergy with hotel financial management functions (Milton, 2024). However, hospitality research also notes that AI in RM can face resistance when recommendations are perceived as non-transparent, difficult to justify, or misaligned with managerial expertise and accountability requirements (Mullapudi, 2025). This matters even more for agentic RM systems than for advisory revenue management. When an AI system shifts from recommending to acting (e.g., implementing rate changes or restrictions), the adoption calculus becomes more complex: users evaluate not only predictive accuracy but also reliability under unusual market conditions, integration with workflows, escalation logic, and auditability. The wider hospitality employee-focused AI literature supports this view (Agrawal et al., 2024).

Technology adoption models in hospitality: from UTAUT to Meta-UTAUT extensions

To explain why professionals, adopt advanced technologies, hospitality research frequently builds on UTAUT/UTAUT2 (Venkatesh et al., 2003, 2012) while adapting constructs to sector realities such as service experience, operational constraints, and multi-stakeholder pressures. Recent hospitality meta-evidence supports the continued relevance of the core UTAUT predictors. At the same time, hospitality scholars increasingly rely on Meta-UTAUT approaches that incorporate additional psychological and contextual factors (e.g., trust, anthropomorphism, aesthetics, privacy) and elevate attitude as a mechanism linking beliefs to intention in emerging technology contexts. Although much of this evidence is guest-facing (e.g., robots), it is theoretically informative for professional settings: when technologies introduce uncertainty, perceived agency, or accountability concerns, users' global evaluations (attitude) become more diagnostic than any single belief (Godolja et al., 2025).

Performance expectancy and behavioural intention

Performance expectancy, defined as the belief that using a technology will improve of job performance and the provide actual benefits, is one of the most powerful factors in technology adoption across a range of settings (Rahi et al., 2019). Performance expectancy in the context of agentic AI in hotel revenue management includes perceptions of the system's capacity to optimize pricing policies, improve forecast accuracy, increase revenue growth, decrease the amount of manual work, and enable higher-quality decision-making (Tamilmani et al., 2021). In RM, PE is likely to include expectations about improved forecasting, faster reaction to demand, better price optimization, and reduced manual workload, benefits that become stronger when AI is positioned as continuously learning and executing (Naghavi et al., 2024). The agentic AI is autonomous, continuously learning from the market and independently adjusting its strategies without necessarily needing human intervention, which may enhance performance expectations as users expect more than traditional revenue

management systems can provide (Hosseini & Seilani, 2025). The strong correlation between performance expectancy and behavioral intention has been proven in empirical studies in various areas of technology (Baabdullah et al., 2019; Sair & Danish, 2018). Therefore, the suggested hypothesis is as follows:

H1: Performance Expectancy has a significantly positive effect on Behavioural Intention

Effort expectancy and behavioural intention

Effort expectancy takes on special importance in the context of agentic AI in hotel revenue management as these devices are sophisticated, and the machines that apply machine learning algorithms involve technical complexity, making the transition to AI-assisted or AI-independent systems associated with a learning curve (Morosan & Dursun-Cengizci, 2024). The relationship between effort expectancy and behavioural intention has been well documented in the context of technological applications in organizational settings. Studies have consistently shown that once users believe that technologies are simple to use and do not involve much effort or investment, their adoption and continuance intentions toward the systems rise to high levels. The latter relationship is particularly strong in the early stages of adoption, as users form initial judgments of system usability based on demonstrations, training, or early interactions (Gunesekera et al., 2019). The urgency of decision-making in revenue management, where professionals are required to process information quickly and make price adjustments to reflect market conditions, makes effort expectancy crucial, as cumbersome or cognitively challenging systems could slow decision-making effectiveness rather than improve it (Hayes et al., 2021). Therefore, the suggested hypothesis is as follows:

H2: Effort Expectancy has a significantly positive effect on Behavioural Intention

Social influence and behavioural intention

Social influence refers to the degree of perception among individuals that important others think they ought to use a given technology, which is indicative of social pressure, normative beliefs, and interpersonal forces within technology adoption decisions. The basic acknowledgment of social influence is that adoption decisions on technologies are not always made in isolation, but rather have a societal aspect where the opinions, suggestions, and actions of peers, supervisors, industry leaders, and personal networks play a major role in influencing individuals' intentions and actions. SI is salient in hotels due to cross-functional interdependence (sales, marketing, operations, GM/ownership) and strong normative pressures tied to competitive benchmarking and brand standards (Figueroa-Armijos et al., 2023).

Social influence has various channels in organizational technology adoption situations which include direct suggestions by colleagues whom one has high regard for, adoption behaviour by other similar organizations, industry association promotion, management pressure to adopt technology, and symbolic sense of being viewed as technologically advanced or innovative (Al-Adwan et al., 2024). Hotel revenue management professionals work in communities of professionals who are closely connected with each other and whose best practices are spread as people gather in industry associations, presentations by technology vendors, peer discussions, and competitive practices as people observe. As industry leaders or reputable individuals in the hotel industry switch to the use of agentic AI systems and share positive experiences, normative pressures develop that other hotels should also switch to stay within the same level of competition and professionalism (D'Emidio, 2025). Therefore, the suggested hypothesis is as follows:

H3: Social Influence has a significantly positive effect on Behavioural Intention

Facilitating conditions and behavioural intention

The spirit behind facilitating conditions is that adoption intentions and positive attitudes cannot always be effectively translated into actual use unless they are properly supported by structures, provision of resources, and environmental facilitators (Priyastomo et al., 2025). In agentic RM, FC should be interpreted broadly to include reliable data pipelines, connectivity across PMS/RMS/channel manager/BI systems, governance policies (approval thresholds, audit logs), and training for human-AI collaboration (Winskowski & Homölle, 2022). With respect to the adoption of agentic AI in the hotel revenue management process, the conditions of facilitation include availability of excellent internet connection and computing infrastructure, presence of quality training programs that lead to the development of AI literacy and system competence, availability of consistent technical support in addressing implementation challenges, compatibility of agentic AI systems with current property management systems or revenue management processes, and organizational commitment via resource allocation and management support that justifies time investment in learning and using the new technologies (Sun et al., 2025). Therefore, the suggested hypothesis is as follows:

H4: Facilitating Conditions have a significant positive effect on Behavioural Intention

Performance expectancy and attitude toward use

According to Rahi et al. (2019), the effects of performance expectancy are not limited to behavioural intention but also include the formation of attitudes that mediate technology acceptance. Whereas the traditional UTAUT framework places performance expectancy as a direct antecedent of behavioural intention, the Extended Meta-UTAUT framework acknowledges that performance beliefs also mediate attitudinal inclinations toward technologies, which, in turn, mediate intentions and behaviour. Attitudes reflect more or less enduring positive or negative judgments of things, actions, or concepts, formed by information-integration processes in which beliefs about consequences are evaluated against outcome valuations.

The performance expectancy-attitude toward use relationship operates through both cognitive and affective channels. On the cognitive level, positive associations with the technology form around expectations of good performance, as people are likely to realize desired goals and results with its use. Emotionally, performance expectations may have an impact, such as enthusiasm, confidence, and optimism about future performance, especially when projected performance improvements cover

existing pain points or professional ambitions (Wang & Chen, 2025). Therefore, the suggested hypothesis is as follows:

H5: Performance Expectancy has a significantly positive effect on Attitude Toward Use

Effort expectancy and attitude toward use

The role of effort expectancy in shaping technology acceptance has both attitudinal mediation effects and behavioural intentions. The Extended Meta-UTAUT framework acknowledges that ease or difficulty perceptions of technology use are related to general evaluative orientations about technology usage, which lead people to develop positive or negative attitudes (Chatterjee et al., 2023). When people have a sense that agentic AI systems will be simple to master, user-friendly, and require minimal cognitive effort to use successfully, such ease perceptions will contribute to positive attitudes toward the technology overall. On the other hand, negative attitudes, such as trepidation, unwillingness, or cynicism, are created by expectations of steep learning curves, complex interfaces, or cognitively challenging interactions (Hsieh & Lee, 2024).

The connection between effort expectancy and attitude toward use takes place through several psychological processes applicable to agentic AI adoption in hotel revenue management (Kukanja & Planinc, 2025). This decrease in negative experiences that are anticipated leads to higher positive attitudinal orientations (Zampetakis et al., 2016). The possibility of agentic AI systems making the work processes of revenue management professionals simpler instead of more complex is also a source of positive attitudes in situations where they already face significant analytical demands and time constraints (Hughes et al., 2025). Therefore, the suggested hypothesis is as follows:

H6: Effort Expectancy has a significantly positive effect on Attitude Toward Use

Social influence and attitude toward use

To a greater extent, social influence not only affects technology acceptance by directly influencing behavioural intentions but also through the process of attitude formation, as social contexts and interpersonal relations are found to influence not only what people intend to do but also how they feel and evaluate technologies (Trivedi et al., 2022). When revenue management professionals see respected peers talk about agentic AI in a positive way, suggest its usage, or show interest in its functionality, the social cues shape their own attitude development, thereby leading to a positive or negative orientation based on the valence of the social messages they obtain (Akter & Ahmed, 2025).

The interaction between social influence and attitude toward use operates through informational and normative processes. Informationally, social influence offers vicarious learning experiences, in which one develops an attitude on the basis of what other people report, their opinions, and what they demonstrate (Maity et al., 2019). Whenever hotel revenue managers learn that associates in other properties are enjoying positive experiences with agentic AI, improved revenue performance, increased decision confidence, or less workflow burden, they have been influenced by such testimonies to form attitudes, as they offer social evidence of the value of the technology and dispel doubts about what it entails (Hodari et al., 2020). When the adoption of agentic AI is linked to progressive, innovative, or professionally advanced hotel operations in industry networks, revenue management professionals could form positive attitudes toward the technology in part by identifying with these desirable features and the urge to conform to the professional norms that arise in their reference groups (Gass & Seiter, 2022). Therefore, the suggested hypothesis is as follows:

H7: Social Influence has a significantly positive effect on Attitude Toward Use.

Facilitating conditions and attitude toward use

The interaction between facilitating conditions and attitude toward use is a significant but subtle process in technology adoption (Or, 2024). Once users appreciate that sufficient resources, training, and technical support are in place, their fears will diminish, and their attitude toward the technology will improve. This association works both directly and indirectly: on the one hand, the presence of strong facilitating conditions can lead to positive correlations with the technology itself; on the other hand, perceived ease of use is positively affected, and anxiety is negatively affected, which in turn influences attitude (Zhou et al., 2019). The facilitating conditions-attitude toward use relationship, although a less explored UTAUT relationship compared to other relationships, encompasses significant theoretical implications regarding the effects of environmental facilitators in influencing the psychological orientations toward technologies (Dwivedi et al., 2019). On the other hand, when facilitating conditions are considered weak or absent, skeptical or negative attitudes are likely to emerge, where people perceive the technology as not well supported, incongruent with organizational realities, or unlikely to be given the long-term investment it may require to be successfully implemented (Clark et al., 2016).

Though the intensity of this relationship can vary by degree of user experience, beginner users tend to be more attitudinally responsive to facilitating conditions than experienced users, who already have internal resources and competency (Hornbæk & Hertzum, 2017). Also, in circumstances where use is mandatory, the conditions of facilitation do not necessarily have a significant impact on attitude formation, as users are required to use the technology whether they feel it or not; however, with sufficient support, negative attitudes do not develop. It is argued that although facilitating conditions are the most direct predictors of behavioral intention and actual use (especially through perceived behavioral control) (Khechine & Lakhal, 2018). Therefore, the suggested hypothesis is as follows:

H8: Facilitating Conditions have a positive and significant effect on Attitude Toward Use.

Attitude toward use and behavioral intention

Agentic AI changes the psychological object of adoption from "a tool I use" to "an actor I delegate to." In such settings, attitude provides a compact evaluation that integrates perceived usefulness, effort, risk, and control into an overall stance toward the technology. Hospitality AI research supports the importance of attitudinal and trust-related pathways: for

example, customer-facing AI adoption studies show that perceived benefits and trust mechanisms help explain behavioral intentions in AI-adopting hotels (Kamal & Kamarulzaman, 2025). Evidence from Meta-UTAUT applications in hospitality further supports the model of attitude as a mediator between expectancy beliefs and intention. In the International Journal of Hospitality Management, the Meta-UTAUT robot study found that attitude mediates the relationships between PE/EE and behavioral intention (Aikins & Dimitrijevska-Markoski, 2026; Marghany et al., 2025). Translating this to agentic RM, attitude can capture whether revenue managers feel comfortable with AI autonomy, whether they perceive agentic actions as aligned with RM logic, and whether they believe the system's outputs are defensible to stakeholders (e.g., GM/ownership). Therefore, the suggested hypothesis is as follows:

H9: Attitude Toward Use has a significantly positive effect on Behavioural Intention

Contextualizing adoption in Egypt: Digital readiness and emerging-market constraints

Empirically, the focus on Egyptian hotel revenue managers is well motivated because emerging-market hospitality environments often exhibit wider variance in data maturity, integration quality, and resource availability,conditions that directly map onto facilitating conditions. Egypt-focused work on technology transformation highlights the benefits and challenges of digital transformation in Egyptian hotels, including partial readiness and department-level constraints (Noby et al., 2024). Broader empirical evidence from Egypt's travel and hospitality sector also shows that AI/automation adoption decisions are shaped by factors such as compatibility, data security, external pressures, and organizational readiness (Ismail et al., 2025).

Research gap and study contribution

Across top-tier and emerging hospitality/tourism journals, three points converge. First, hospitality research anticipates a shift toward agentic systems that require stronger governance and human-AI collaboration (Ali & Ali, 2025; Dwivedi et al., 2026). Second, RM-focused AI work highlights that transparency and explainability are essential to make AI outputs usable and defensible in practice (Akhtar et al., 2024). Third, Meta-UTAUT models have proven effective in explaining hospitality technology adoption, particularly when attitude serves as a mediating mechanism between expectancy beliefs and behavioural intention (Hasanein et al., 2025). However, despite these advances, empirical research on agentic AI adoption in hotel revenue management, particularly among revenue managers in emerging markets such as Egypt,remains limited. This study addresses this gap by developing and testing an extended Meta-UTAUT framework that examines how performance expectancy, effort expectancy, social influence, and facilitating conditions influence both attitude toward use and behavioural intention in the context of agentic AI adoption for hotel revenue management among Egyptian revenue managers. In contrast to earlier studies that relied on broadly related or cross-domain technology adoption literature, this review prioritizes recent and context-specific research on artificial intelligence in hospitality, revenue management systems, and AI-driven decision support. This ensures that each theoretical construct within the Extended Meta-UTAUT model is supported by evidence directly related to the study context. By aligning the cited literature with the specific characteristics of agentic AI,such as autonomy, continuous learning, and decision execution,the study enhances both the theoretical precision and empirical relevance of the proposed model. After reviewing the previous studies, the suggested hypotheses are as follows:

H10: Attitude toward use mediates the relationship between performance expectancy and behavioural intention

H11: Attitude toward use mediates the relationship between effort expectancy and behavioural intention

H12: Attitude toward use mediates the relationship between social influence and behavioural intention

H13: Attitude toward use mediates the relationship between facilitating conditions and behavioural intention

Research model

Having established the theoretical model (illustrated in Figure 1) and proposed hypotheses, the following section outlines the research methodology for empirically testing the proposed relationships, including the research design, sampling procedure, data collection methods, and analytical approach.

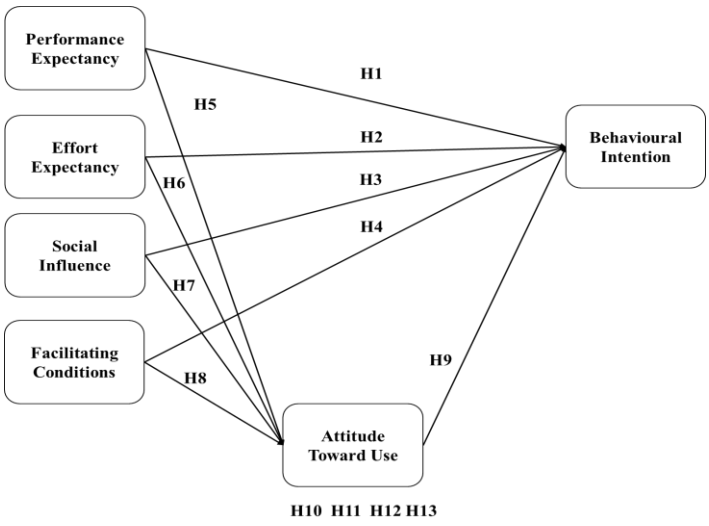

Figure 1. Research Model (Source: Dwivedi et al., 2019)

METHODOLOGY

To ensure a consistent understanding of agentic AI among respondents, a brief standardized explanation was provided at the beginning of the questionnaire. The definition described agentic AI as autonomous revenue management systems capable of analysing market data, generating pricing decisions, and automatically implementing these decisions across hotel systems with minimal human intervention. In addition, respondents were given practical examples (e.g., automatic price adjustments, real-time inventory control, and self-optimizing revenue strategies) to contextualize the concept within their daily operational environment. This approach was adopted to reduce ambiguity and ensure that participants evaluated the constructs based on a shared, contextually relevant understanding of agentic AI rather than general perceptions of artificial intelligence.

Research design and philosophical approach

The paper uses a quantitative research design, adopting a positivist epistemology to inform research inquiry into the adoption of agentic artificial intelligence in hotel revenue management in the Egyptian hospitality industry. The quantitative method was chosen due to its ability to test theoretical relationships systematically, measure latent constructs using validated measures, and produce findings that apply to the study's entire population. The research is informed by positivist philosophical assumptions that the phenomena of technology adoption are objectively measurable, that relationships among constructs exist independently of the researcher, and that empirical observation based on structured data collection is valid for making inferences about the determinants of adoption (Shibly et al., 2022). The deductive character of this study begins with theoretical hypotheses grounded in the Extended Meta-UTAUT model and proceeds to empirical validation through testing, consistent with the existing traditions of research on technology acceptance (Razzak & Jassem, 2021).

Population and sampling

The research population will be hotel revenue management professionals employed in establishments within the largest Egyptian cities, who will be the main decision-makers and influencers in the hotel agentic AI adoption decisions. The sampling procedure followed a purposive (judgmental) sampling approach, targeting hotel professionals directly involved in revenue management decisions. Eligible participants included revenue managers, revenue analysts, assistant revenue managers, and senior managers responsible for pricing and demand management functions. These roles were selected to ensure that respondents possessed relevant knowledge and practical experience with revenue management systems and emerging AI technologies. Participants were identified through multiple sources, including industry directories, professional networks, hotel contact databases, and tourism-related associations. Data collection was conducted across four major Egyptian tourism destinations (Cairo, Alexandria, Hurghada, and Sharm El-Sheikh) to capture variability in hotel types and operational contexts. The selection process prioritized medium-to-large-sized hotels where formal revenue management practices are more likely to be established. To reduce selection bias, invitations were distributed across different hotel categories (e.g., business hotels, resorts, and chain-affiliated properties), ensuring diversity in organizational size, market segment, and technological maturity. This approach enhances the representativeness of the sample within the constraints of a non-probability sampling design commonly used in organizational technology adoption studies.

These cities together account for a large share of the total number of hotel rooms in Egypt and encompass a diverse array of operational settings, including urban business hotels, beach resorts, cultural tourism properties, and mixed-use establishments. The sampling frame was established through consultation with the Egyptian Hotel Association, tourism ministry databases, and industry directories to select hotels with revenue management functions, given the notion that small properties might not have dedicated revenue management functions and that larger hotels tend to have many revenue management employees. Since the target population is specialized and it is not feasible in an emerging market setting to obtain full sampling frames, a purposive sampling strategy was used to ensure representation of pertinent respondent attributes.

Revenue analysts, senior managers, revenue managers, assistant revenue managers, and revenue managers were identified as suitable respondents, as they had first-hand experience evaluating revenue management technology, making decisions on technology adoption, and using systems. To determine a sufficient sample size for structural equation modeling, guidelines for the minimum sample size required in SEM were used. Then, based on the standard rule of the number of observations per estimated parameter (10-15) and the complexity of the Extended Meta-UTAUT model with eight hypothesized paths and measurement model parameters, the target was set at 200 respondents. The last sample of 213 respondents exceeds this threshold, providing sufficient statistical power to estimate parameters and test hypotheses using SEM procedures. The sample size calculation can be expressed as:

$$\frac{1.645^2 * 0.50\ (1-0.50)}{0.1^2} = 68$$

where Z = 1.645 is the critical Z-value corresponding to a 90% confidence level (a dimensionless standard normal deviate); p = 0.5 is the estimated population proportion of the target attribute (dimensionless), selected at its most conservative value to maximize the required sample size; (1 - p) = 0.5 is the complement of that proportion; and e = 0.1 is the maximum acceptable margin of error, set at 10% (i.e., ±0.10 on a 0-1 proportion scale). Applying these values yields a minimum required sample of 68 respondents per group or stratum.

The final sample size of 213 respondents is considered adequate for Partial Least Squares Structural Equation Modelling (PLS-SEM) analysis. Following the "10-times rule," the minimum required sample size should be at least ten times the maximum number of structural paths directed at any construct in the model. In this study, the most complex construct (behavioural intention) has four incoming paths, suggesting a minimum sample size of 40. Additionally, recent

methodological guidelines recommend larger samples (e.g., >200) to ensure statistical power and model stability. Therefore, the sample size of 213 exceeds these thresholds and is sufficient for reliable estimation and hypothesis testing.

Data collection instrument

The measurement instrument was developed based on previously validated scales from the technology adoption literature, particularly studies applying UTAUT and Meta-UTAUT frameworks. Items measuring performance expectancy, effort expectancy, social influence, facilitating conditions, behavioural intention, and attitude toward use were adapted from established sources (e.g., Venkatesh et al., 2003; 2012; Tamilmani et al., 2021; Chatterjee et al., 2023), with wording modified to fit the context of agentic AI in hotel revenue management. All items were measured using a five-point Likert scale ranging from "strongly disagree" to "strongly agree." To ensure content validity, the questionnaire was reviewed by academic experts in hospitality and information systems, as well as industry professionals in revenue management. A pilot test was conducted with a small group of respondents to assess clarity, relevance, and wording. Construct validity and reliability were evaluated using PLS-SEM measurement model assessment procedures, including indicator loadings, composite reliability (CR), average variance extracted (AVE), and discriminant validity (HTMT criterion). All constructs met the recommended thresholds, confirming the measurement instrument's adequacy.

Data collection procedure

Data collection was implemented over a four-month period, from September 2024 to December 2024, which will allow sufficient time to cover the target population, which is geographically spread, while ensuring consistent timing between responses. Several distribution channels were used to achieve the highest response rates and sample representativeness. The distribution was mostly online, via survey platforms (via email), where revenue management professionals were contacted based on hotel contacts, industry association membership, and professional network contacts.

The online platform enabled effective data collection across different cities, in addition to offering capabilities such as progress indicators, response validation, and automated data collection, which improved data quality. Regarding professional experience, respondents spanned a wide range, from less than 5 years to more than 10 years in hospitality and revenue management. This diversity enhances the robustness of the findings by incorporating perspectives from both relatively new and highly experienced professionals. In terms of organizational context, respondents were drawn from different types of hotels, including luxury resorts, business hotels, and chain-affiliated properties, primarily located in Cairo, Alexandria, Hurghada, and Sharm El-Sheikh. This diversity reflects variations in operational environments, technological readiness, and market dynamics within the Egyptian hospitality industry.

Additional distribution was made via face-to-face delivery at industry conferences and professional gatherings, where revenue management practitioners met and offered a chance to interact with them in person, clarify questions, and build relationships, which might have added to the motivation to respond. Ethical issues were addressed by making the data collection protocol focus on voluntary participation, informed consent, and confidentiality guarantees to help participants be honest and considerate in their responses. Respondents were informed of the purpose of the research, the intended use of the data collected, and their rights to terminate their participation or refuse to provide detailed answers to certain questions.

Data analysis techniques

Data analysis was conducted using Partial Least Squares Structural Equation Modelling (PLS-SEM) with SmartPLS version 3. This approach was selected due to its suitability for exploratory research, complex models with multiple constructs, and prediction-oriented objectives. PLS-SEM is also appropriate for studies with relatively moderate sample sizes and non-normal data distributions, to confirm the properties of measurement, and test hypotheses on structural relationships stipulated in the Extended Meta-UTAUT framework. The first analysis was conducted through data screening to detect missing data patterns, outliers, and potential data entry errors. The analysis of missing data revealed that missing values accounted for less than 5 percent of the data set and were not systematically present; instead, they were randomly distributed, allowing the application of expectation-maximization algorithms to impute missing data.

The Mahalanobis distance calculation reads were used to detect outliers in the sample, with some of the multivariate outliers being reviewed separately; those that represented a valid extreme response were included in the analysis, whereas those that seemed to be due to an apparent data entry error or a poor response to the question were eliminated. All measured variables were summarized using descriptive statistics (means, standard deviations, skewness, kurtosis) to describe the sample and evaluate distributional characteristics for future multivariate analysis. Structural Equation Modelling (SEM) was the primary technique used in the analysis: it is a complex multivariate method that estimates the parameters of measurement models (relationships between latent constructs and their indicators) and structural model parameters (relationships between latent constructs). AVE values greater than 0.50, and Composite Reliability (CR) values greater than 0.70 also provided further convergent validity evidence. Discriminant validity was tested by comparing squared correlations between constructs with AVE values. AVE greater than squared correlation, there are constructs that represent more variance on their indicators than they overlap with other constructs. The model fit was assessed as a series of fit indices that offer various measures of model adequacy, i.e. the chi-square test of exact fit, incremental fit measures such as Comparative Fit Index (CFI) and Tucker-Lewis Index (TLI), absolute fit measure such as Root Mean Square Error of Approximation (RMSEA) and residual-based fit measure Standardized Root Mean Square Residual (SRMR). The standard measures, such as CFI and TLI values of above 0.90, RmseA below 0.08, and SRMR below 0.08, were used to determine the acceptable model fit. After developing sufficient properties for the model of measurement, structural model analysis was used to estimate path coefficients that depicted the proposed relationships between constructs. The estimation

was carried out using maximum likelihood when the sample size was sufficient, and the data were approximately normal. Path coefficients were interpreted in terms of magnitude, direction, and statistical significance; path coefficients with critical ratios (t-values) greater than 1.96 were considered statistically significant at the $p < 0.05$ level.

The analysis followed a two-step approach: (1) assessment of the measurement model and (2) evaluation of the structural model. The measurement model was assessed using indicator loadings, composite reliability (CR), average variance extracted (AVE), and discriminant validity using the heterotrait-monotrait (HTMT) ratio. The structural model was evaluated based on path coefficients (β), significance levels (p-values), coefficient of determination (R^2), predictive relevance (Q^2), and effect sizes where applicable. Bootstrapping with 5,000 resamples was employed to test the statistical significance of path coefficients and mediation effects. This non-parametric procedure provides robust estimates of standard errors and confidence intervals, ensuring reliable hypothesis testing. Unlike covariance-based SEM (CB-SEM), PLS-SEM does not rely on maximum likelihood estimation or global goodness-of-fit indices but instead focuses on maximizing explained variance and prediction accuracy. Therefore, all reported results are consistent with PLS-SEM guidelines.

Assessment of methodological biases

Given the use of self-reported questionnaire data, several procedural and statistical measures were implemented to minimize potential methodological biases. First, to reduce common method bias (CMB), respondents were assured of anonymity and confidentiality, and the questionnaire items were carefully structured to minimize ambiguity and social desirability effects. Second, a statistical assessment of common method bias was conducted using Harman's single-factor test. The results indicated that a single factor did not account for the majority of the variance, suggesting that common method bias is unlikely to be a serious concern in this study. Additionally, variance inflation factor (VIF) values were examined, and all values were below the recommended threshold of 5, further indicating the absence of significant common method bias.

Third, non-response bias was assessed by comparing early and late respondents, following established survey-based research procedures. The comparison showed no significant differences in key variables, suggesting that non-response bias is not likely to affect the results. These steps provide confidence that the findings are not substantially influenced by methodological biases.

RESULTS

Table 1 presents the measurement model assessment results. CR = Composite Reliability; AVE = Average Variance Extracted; α = Cronbach's Alpha; VIF = Variance Inflation Factor. All factor loadings exceed the recommended threshold of 0.70, indicating adequate convergent validity.

Table 1. Measurement Model Assessment (PLS-SEM) (Source: Based on SmartPls v.3 Analysis)

Variable	Code	Outer Loading	CR	AVE	CA	VIF
Performance Expectancy	PE1	0.915	0.906	0.708	0.858	1.122

Effort Expectancy	0.873	0.863	-			
Facilitating Conditions	0.749	.628*	0.740	-		
Performance Expectancy	0.856	0.852	0.856	0.730	-	
Social Influence	0.592	0.630	0.721	0.460	0.603	-

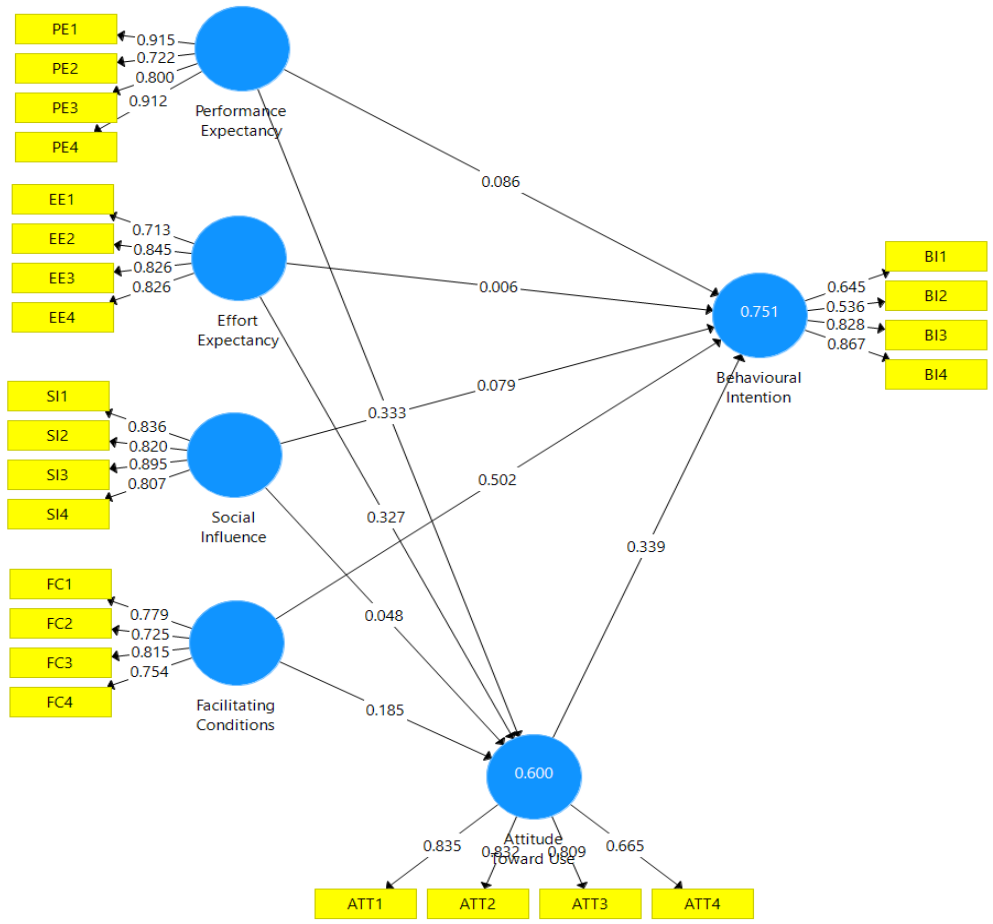

Figure 2. Structural Model Results (PLS-SEM Path Coefficients and Significance Levels) (Source: Based on SmartPls v.3 Analysis)

CR values exceed 0.80 and AVE values exceed 0.50 for all constructs, confirming internal consistency and convergent validity. Cronbach's Alpha values exceed 0.70, demonstrating reliability. VIF values below 5.0 indicate acceptable multicollinearity levels (Kim, 2019). Table 2 presents the HTMT discriminant validity results. Social Influence shows the strongest discriminant validity, with all HTMT values ranging from 0.460 to 0.721, well below the threshold. Facilitating Conditions also demonstrates adequate discrimination (0.628* to 0.749), with one value marked with an asterisk that may warrant attention. This is theoretically plausible given that these constructs are conceptually related, but researchers should consider whether items need refinement or if multicollinearity could affect subsequent structural model results. The measurement model shows adequate indicator loadings, with most items loading above 0.70 on their respective constructs, supporting convergent validity. The relationships suggest that, in this context, social factors and perceived ease of use shape users' attitudes, which, in turn, drive their behavioral intentions to adopt the technology. The weak direct paths from PE and EE to BI, contrasted with the strong R^2 value, underscore the importance of the attitudinal mediation pathway in this model.

Table 3. Structural Model Results and Hypothesis Testing (PLS-SEM) (Source: Based on SmartPls v.3 Analysis)

	Original Sample (O)	**β**	**P Values**
Attitude Toward Use -> Behavioural Intention	0.339	0.048	0.000
Effort Expectancy -> Attitude Toward Use	0.327	0.068	0.000
Effort Expectancy -> Behavioural Intention	0.275	0.054	0.000
Facilitating Conditions -> Attitude Toward Use	0.185	0.045	0.000
Facilitating Conditions -> Behavioural Intention	0.502	0.040	0.000
Performance Expectancy -> Attitude Toward Use	0.333	0.064	0.000
Performance Expectancy -> Behavioural Intention	0.232	2.701	0.007
Social Influence -> Attitude Toward Use	0.710	0.080	0.000
Social Influence -> Behavioural Intention	0.079	0.037	0.033
Mediating			
Effort Expectancy -> Attitude Toward Use -> Behavioural Intention	0.111	0.028	0.000
Facilitating Conditions -> Attitude Toward Use -> Behavioural Intention	0.063	0.018	0.001
Performance Expectancy -> Attitude Toward Use -> Behavioural Intention	0.113	0.027	0.000
Social Influence -> Attitude Toward Use -> Behavioural Intention	0.304	0.115	0.009

Figure 2 illustrates the path coefficients and significance levels for the hypothesised relationships, and as shown in Table 3, all nine direct hypotheses are supported ($p < 0.05$). Social Influence → Attitude Toward Use shows the strongest

relationship (β = 0.710), indicating social factors are the primary driver of user attitudes. Facilitating Conditions → Behavioural Intention (β = 0.502) is the second strongest path, suggesting that resource availability directly impacts adoption decisions. Performance Expectancy (β = 0.333) and Effort Expectancy (β = 0.327) demonstrate moderate effects on attitude formation. There's a notable inconsistency between the table and the structural model diagram. The table shows EE → BI (β = 0.275) and PE → BI (β = 0.232), while the diagram displays these as 0.006 and, 0.232 respectively. This requires verification of which results are correct. All the mediation hypotheses are supported. Attitude Toward Use significantly mediates the relationships between EE → BI (β = 0.111), FC → BI (β = 0.063), and PE → BI (β = 0.113), all at $p < 0.001$. However, Social Influence → ATU → BI mediation is also supported (β = 0.115, p = 0.009), suggesting SI's effect on intention operates primarily through its direct path rather than through attitude formation.

The hypothesis testing results confirm that all nine direct relationships (H1–H9) are statistically significant at $p < 0.05$, indicating strong empirical support for the proposed structural model. Specifically, performance expectancy, effort expectancy, social influence, and facilitating conditions significantly influence both behavioural intention and attitude toward use, while attitude toward use also has a significant positive effect on behavioural intention. In addition, all four mediation hypotheses (H10–H13) are supported, confirming that attitude toward use plays a significant mediating role in the relationships between performance expectancy, effort expectancy, social influence, facilitating conditions, and behavioural intention. These findings provide strong support for the Extended Meta-UTAUT framework in explaining agentic AI adoption in hotel revenue management.

Table 3. Model Fit (Source: Based on SmartPls v.3 Analysis) SRMR: 0.074, d_ULS: 1.655, d_G: 1.258, Chi-Square: 1803.478, NFI : 0.689

	SSO	SSE	Q^2 (=1-SSE/SSO)	R Square	R Square Adjusted
Attitude Toward Use	1376.000	874.101	0.365	0.600	0.595
Behavioural Intention	1376.000	837.977	0.391	0.751	0.747

Table 4 reports the predictive accuracy and overall model fit of the structural model. The Q2 values for Attitude Toward Use (0.365) and Behavioural Intention (0.391) are both well above zero, confirming that the model possesses satisfactory predictive relevance for both endogenous constructs (Hair et al., 2017). The R2 values of 0.600 and 0.751, respectively, indicate that the model explains a substantial proportion of variance in each construct, with Behavioural Intention reaching a level conventionally regarded as strong in PLS-SEM applications (Hair et al., 2019).

The adjusted R^2 figures (0.595 and 0.747) are virtually identical to the unadjusted values, suggesting that model complexity is well justified by the data. Regarding overall fit, the SRMR of 0.074 falls below the recommended threshold of 0.08, reflecting an acceptable discrepancy between the observed and implied correlation matrices (Henseler et al., 2016). Taken together, these indices support the adequacy of the model for hypothesis testing.

DISCUSSION

This study provides comprehensive empirical support for the proposed Extended Meta-UTAUT framework, with all 13 hypotheses (9 direct relationships and 4 mediating effects) being statistically supported.

The findings confirm that performance expectancy, effort expectancy, social influence, and facilitating conditions significantly shape both attitude toward use and behavioural intention, while attitude toward use serves as a central mediating mechanism linking these determinants to adoption intention.

These results reinforce the importance of considering both direct and indirect pathways in technology adoption, particularly in the context of agentic AI, where users evaluate not only functional benefits but also broader psychological and organizational implications of delegating decision-making to autonomous systems. In total, the study proposes thirteen hypotheses, including nine direct relationships (H1–H9) and four mediation hypotheses (H10–H13). The results of the research correspond significantly with the existing literature on technology adoption and provide some new information about agentic AI incorporated in the Egyptian hospitality setting. The positive relationship between the performance expectancy and the behavioural intention (β = 0.232) and the attitude toward use (β = 0.333) is confirmed, which is consistent with the initial propositions of UTAUT put forward by Venkatesh et al. (2003) and supported in various technological settings by Dwivedi et al. (2019) and Baabdullah et al. (2019).

These findings align with the trends in studies on technology adoption in the hospitality industry by Pillai et al. (2020), who also reported that perceived performance benefits are strong predictors of adoption intentions for automated systems. Nonetheless, the medium size of the performance expectancy-behavioural intention contingency in this study is in contrast with other Western-based studies, where the relationship usually appears as the most powerful predictor, which indicates that instrumental rationality can be used in addition to the more powerful social and organisational factors in emerging market hospitality environments.

The strong impact of effort expectancy on attitude toward use (β = 0.327) replicates the results of García de Blanes Sebastián et al. (2022) with AI virtual assistants, which substantiates the idea that regardless of the level of sophistication of the autonomous systems, the perceived ease of use is the key to positive technological dispositions, especially at the initial stages of adoption, when users develop a primary evaluative judgement.

The fabulously large social influence effect on attitude towards use (β = 0.710) is a notably interesting result that is larger than the standard magnitude of the effect that has been reported in individualistic societies but coincides with the literature of collectivistic societies and hierarchical organisations that Graf-Vlachy et al. (2018) and Al-Adwan et al. (2024) provided. This observation echoes the fact that Granić (2024) found that the cultural dimensions were a strong moderator of

social influence processes, so the professional networks, hierarchical management system, and the focus on competitive benchmarking in the Egyptian hospitality industry generate high normative pressure that is more likely to influence technology attitudes than in individualistic societies. The strong direct impact of the facilitating conditions on the behavioural intention (β = 0.502) is not limited to the conventional UTAUT model and confirms the situational prominence of the organisational infrastructure in the face of emerging markets, as the resource availability and technical support gain the decisive role in the technology acceptance decision despite the wide range of organisational technological maturity, as it was revealed by Rahman et al. (2024) and Oliveira et al. (2016). The strength of this relationship in the Egyptian context justifies the arguments of Alalwan et al. (2017) regarding the differentiating power of facilitating conditions in environments unequally prepared in terms of technology across organisational environments.

The mediation analysis demonstrates that attitude toward use is a key psychological process, where expectancy constructs and facilitating conditions affect behaviour intentions, which is a result of the theoretical extensions of the Extended Meta-UTAUT framework as compared to the original model. Theoretical arguments are confirmed by the significant indirect impacts via attitude expectancy of performance (β=0.113), effort expectancy (β=0.111), and enabling conditions (β=0.063) in the processes of technology acceptance by Rahi et al. (2019) and Tamilmani et al. (2021). [Theoretical and Practical Implications relocated here, into the Discussion section, per reviewer comment]

As an academic study, this research has numerous significant theoretical implications for the body of literature on the adoption of technology. First, it applies the UTAUT theory to the agentic AI, a category of autonomous intelligent systems that are significantly different from the traditional information technologies that are discussed in the majority of the prior adoption studies. The fact that the constructs of UTAUT are still applicable to agentic AI justifies the theoretical generalisability of the framework and creates an opportunity to explore the possibility of autonomous technologies posing specific adoption factors not originally considered in the framework. Second, introducing the concept of attitude toward use as a mediating variable in the Extended Meta-UTAUT paradigm offers a more detailed explanation of the process of adoption compared to models that are built on the behavioural intention alone. The strong correlations among various constructs and attitudes, as well as attitudinal intention, support the notion that attitudinal pathways deserve a direct theoretical and empirical consideration when developing technology adoption models.

Thirdly, the study adds to the sparse yet increasingly notable growing body of technology adoption literature operating in the context of the emerging economies. The ability to prove all hypotheses in the sector of hospitality in Egypt gives confirmation that the mechanisms of foundational adoption are not limited to geographic and economic conditions, and the particular pattern and the intensity of the relationships contribute to understanding how the contextual factors could regulate these universal processes. This contribution responds to longstanding requests to have more geographically heterogeneous adoption research studies that transcend the Western-centric bias that characterizes much of the extant research.

The findings of this study offer several actionable implications for hotel managers, revenue management professionals, and technology providers seeking to implement agentic AI in real-world settings.

First, the strong effect of performance expectancy suggests that successful adoption depends on clearly demonstrating tangible business value. Hotel managers should prioritize pilot implementations and performance benchmarking to show how agentic AI can improve key metrics such as RevPAR, occupancy forecasting accuracy, and pricing responsiveness.

Second, the importance of effort expectancy indicates that ease of use and system usability remain critical, even for advanced AI technologies. Therefore, organizations should invest in user-friendly interfaces, intuitive dashboards, and comprehensive training programs to reduce resistance and accelerate adoption. In practice, this means integrating agentic AI tools seamlessly with existing property management systems (PMS), revenue management systems (RMS), and channel managers to avoid workflow disruption.

Third, the strong influence of social influence highlights the need for internal change management strategies. Hotel organizations can facilitate adoption by identifying "AI champions" within revenue management teams, encouraging knowledge sharing, and leveraging success stories from early adopters. Industry-level influence, such as benchmarking against competitors or adopting technologies endorsed by major hotel chains, can also play a critical role.

Fourth, facilitating conditions emerged as a key determinant of both attitude and behavioral intention, emphasizing the importance of organizational readiness. For practical implementation, hotels should ensure the availability of reliable data infrastructure, system integration capabilities, and ongoing technical support.

This includes establishing governance mechanisms, such as approval thresholds, audit trails, and human override options, to maintain managerial control over autonomous decisions. From an operational perspective, agentic AI can be integrated gradually rather than through full automation. Hotels may begin by deploying AI systems in advisory mode (decision support), then transition to semi-autonomous execution (e.g., automated pricing within predefined limits), and eventually adopt fully agentic systems for real-time decision-making. This phased approach allows organizations to build trust, reduce perceived risk, and align AI capabilities with organizational maturity.

Overall, the results suggest that the successful integration of agentic AI in revenue management requires not only technological investment but also organizational alignment, user acceptance, and strategic change management.

CONCLUSION

This study has been able to conduct systematic research on the factors that define the acceptance of agentic artificial intelligence in hotel revenue management within the hospitality industry in Egypt using an Extended Meta-UTAUT framework. All eight hypothesised relationships have strong empirical backing based on the results of the 213 revenue management professionals in major cities in Egypt as well as the structural equation modelling, which was based on the results

acquired. The findings affirm that the expectancy of performance, expectancy of effort, and their influence on behavioural intention to adopt agentic AI systems have strong impacts and moderate relations on attitude towards use, a key mediating psychological condition. Furthermore, the facilitating conditions occur as an influential factor of the attitudes to agentic AI adoption. All these findings provide an insight into the complexity of technology adoption decisions within the hospitality setting, in which cognitive assessments of performance advantages and usability interface with social processes and organisational support systems to determine the degree of attitudinal stances as well as behavioural intentions.

The findings of this study provide important insights into the behavioral and organizational dynamics underlying agentic AI adoption in hotel revenue management. One of the most notable results is the strong influence of social influence on attitude toward use, which suggests that adoption decisions in the hospitality context are highly socially embedded. This can be explained by the collaborative and hierarchical nature of hotel operations, where decisions are often shaped by managerial expectations, peer practices, and competitive benchmarking. This finding is consistent with prior hospitality research emphasizing the role of normative pressures and industry networks in shaping technology adoption.

The significant impact of facilitating conditions on both behavioral intention and attitude toward use highlights the critical role of organizational readiness in emerging market contexts. Unlike more technologically mature environments, hotels in developing economies may face constraints related to infrastructure, technical expertise, and system integration. Therefore, the availability of resources, training, and support becomes a decisive factor in determining whether advanced technologies such as agentic AI can be successfully adopted. This result aligns with previous studies that emphasize the importance of organizational and technological infrastructure in AI adoption.

Performance expectancy and effort expectancy were also found to significantly influence both attitude and behavioral intention, confirming their central role in technology acceptance models. However, their effects were relatively moderate compared to social influence and facilitating conditions, suggesting that in the context of agentic AI,where systems are autonomous and potentially disruptive,organizational and social factors may outweigh purely functional considerations.

Finally, the strong mediating role of attitude toward use indicates that adoption is not driven solely by rational evaluations of usefulness and ease of use, but also by broader psychological judgments regarding trust, control, and perceived compatibility with professional roles. This reinforces the relevance of extending traditional UTAUT models to better capture the complexities of adopting autonomous AI systems in high-stakes decision-making environments such as hotel revenue management.

Limitations and Future Research

Despite its contributions, this study has several limitations that should be acknowledged. First, the use of a cross-sectional research design limits the ability to capture changes in perceptions and adoption behavior over time. Future research could employ longitudinal designs to examine how trust, experience, and reliance on agentic AI evolve as users gain familiarity with autonomous systems. Second, the study relies on self-reported data, which may be subject to perceptual bias despite the procedural and statistical controls applied. Future studies could incorporate objective performance data, system usage metrics, or experimental designs to validate the behavioral implications of agentic AI adoption. Third, the empirical context is limited to the Egyptian hospitality industry, which, while valuable for understanding emerging market dynamics, may limit the generalizability of the findings to other regions.

Comparative studies across different countries, levels of technological maturity, and hotel categories would provide deeper insights into contextual differences in AI adoption. Fourth, although the Extended Meta-UTAUT framework captures key determinants of adoption, it does not explicitly incorporate agentic AI–specific constructs such as trust in autonomy, perceived loss of control, explainability, and accountability concerns. Future research should extend the model by integrating these variables to better reflect the unique characteristics of autonomous AI systems.

Finally, future studies could explore the organizational and performance outcomes of agentic AI adoption, such as revenue optimization, pricing efficiency, and decision quality, as well as potential unintended consequences, including over-reliance on automation or resistance from employees. Such research would further strengthen the practical and theoretical understanding of agentic AI in hospitality revenue management.

Abstract: Relief and hydrography have constituted, since the earliest times, the main axes delimiting civilization. The two natural factors, through their specific characteristics, can represent either favorable or restrictive factors in the development of human settlements. Consequently, the configuration of the relief and the presence of watercourses have influenced the choice of locations for settlements, the development and type of economic activities, while also serving as reference points for the creation and development of routes of access and communication. Moreover, these factors influenced the development of Roman roads, often built along valleys and natural corridors that facilitated the movement of flows. The Roman roads of Antiquity represent one of the models applied by the Romans, demonstrating that hydrography played a very important role in their creation. Thus, in the territory of Transylvania we have two major axes: the Someș and the Mureș. Based on the course of these waters and on all the factors involved in hydrography, the Roman roads and their settlements were concentrated around these two major axes and their tributaries. The result of this research was the delineation of the axes of the Roman roads, which are closely linked to the natural relief and the hydrographic network. The axes received a measurable and quantifiable identity: The Defensive Axis of Dacia Porolissensis based on the natural course of Someș tributaries, The Someș Limes Axis – a defensive axis on the northern frontier of Dacia Porolissensis, The Someș Limes Axis – a Defensive Axis on the Northern Frontier of Dacia Porolissensis, The Mureș Limes Axis – a southern Carpathian barrier. All four limes axes presented in this article have territorial connectivity and form a road system which, although initially built for military and administration, today represents an important point of economic development, preserving its connectivity function up to the present day.

Keywords: axes, hydrography, Limes, roman road, river valleys, territorial organization, Transylvania

INTRODUCTION

The earliest information regarding the waters of Romania and their hydrological regime dates back to ancient times, when the inhabitants of these lands began to use them for various practical and economic purposes. Evidence indicates that as early as the Geto-Dacian period, the waters of the Danube were used for navigation, while the remains of military fortifications discovered along the river demonstrate that these sites also functioned as ports. Archaeological excavations have revealed clay water pipes dating from the period of Roman rulinge in Dacia (Ujvári, 1972).

Romania's geographical position within the temperate continental climate zone, and the presence of the Carpathian arc at its center of the country, strongly influence the hydrographic network. Rivers constitute the most important category of water resources. They are closely linked to the Carpathian and Subcarpathian mountain regions, as this is where most rivers originate and where the main characteristics of liquid runoff are defined.

While the Carpathian arc gives the hydrographic network a radial-divergent configuration, the Danube acts as the collector of approximately 97.8% of the country's surface area. These characteristics allow Romania's rivers to be considered Carpathian in origin and Danubian–Pontic in terms of drainage. The total length of watercourses recorded in Romania's water cadastre is 66,029 km, with a total number of 4,295 rivers.

A major axis dominating the central part of Transylvania is the Mureș River. Its axis crosses the depression from south to north over a length of 71.5 km and includes 55 tributaries. The longest tributaries originate near mountain passes along the surrounding mountain frame, such as the Toplița River near the Mesteacăn (or Creangă) Pass, and the Jolotca and Ditrău rivers near the Ditrău Pass (Pop, 2016). The Mureș River rises in the Eastern Carpathians, in the Hășmașul Mare Mountains, at an altitude of approximately 850 m. The Mureș hydrographic basin covers a total area of 29,289 km², of which 28,310 km² lie on Romanian territory (including the Ier Canal), representing 11.7% of the country's total surface area. The river flows largely on Romanian territory, covering 761 km of its total length of 766 km, with only a short section flowing through Hungary. The cadastral hydrographic network within the Mureș basin

comprises 758 watercourses with a total length of approximately 10,800 km. The Mureș hydrographic basin encompasses all major relief forms. The landscape displays considerable diversity, ranging from plains to mountains. The minimum altitude is approximately 80 m at the point where the river exits the country into the Western Plain, while the maximum altitude reaches 2,509 m in the Retezat Mountains.

Approximately 25% of the basin area is mountainous, 55% consists of hills and plateaus, 15% comprises valleys and floodplains, and 5% is made up of plains. Figure 1 presents the hydrographic basin of the Mureș River.

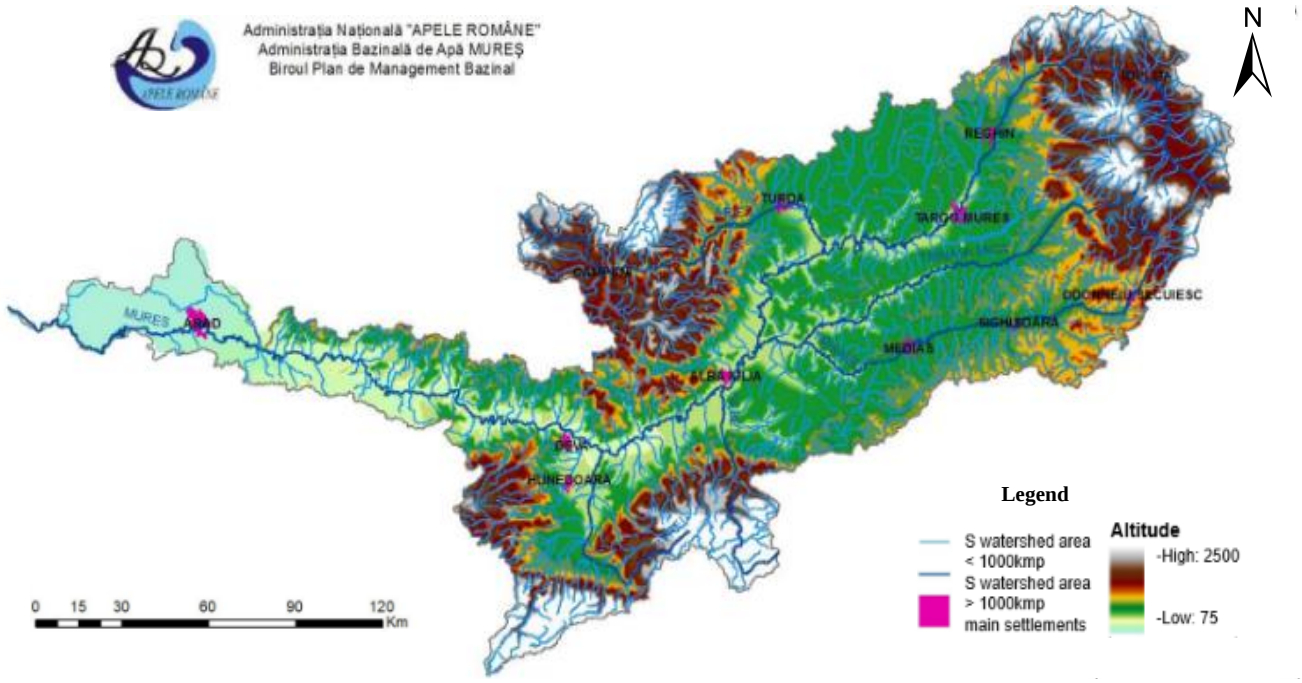

Figure 1. The main landforms in the Mureș River basin

Located in the west-central part of the country, the Arieș River flows through an area rich in natural resources and picturesque landscapes, while also benefiting from a climate favorable to the development of human communities.

The hydrographic basin from which the river collects its waters covers an area of 2,970 km², making it one of the medium-sized rivers in the country. Along its west-to-east axis, the Arieș crosses all three landform types, passing successively through mountainous, hilly, and then plain terrain.

The Arieș hydrographic basin belongs mainly to Alba County to the southwest and Cluj County to the northeast, with a smaller share in Arad, Bihor, and Hunedoara counties to the west and in Mureș County to the east (Dîscă, 2022).

The Mureș Corridor has represented an important communication zone throughout all historical periods. The Mureș Corridor is defined by several essential characteristics. First, the elevation difference between the corridor and the two neighboring geographical units is approximately 150 m. Second, the course of the Mureș River (with the exception of the area near Târgu Mureș) developed extremely close to the southern boundary of the Transylvanian Plain, forming a cuesta zone that is still visible today in many places. As a result, areas suitable for settlement developed primarily on the left side of the corridor, where the floodplain is well developed, reaching a width of approximately 3 km.

These important hydrographic characteristics have led, over time, to the valorization of this geographical potential, as reflected by the high density of settlements during various historical periods, including the Roman era (Fodorean, 2004). A second major hydrographic axis is the Someș Valley axis. The Someș hydrographic area is located in the northern and northwestern part of Romania, bordered to the north by the Tisza River basin—partially located in Ukraine—to the west by the border with Hungary, and within the country by the Siret Basin to the east, the Mureș Basin to the south, and the Crișuri Basin to the southwest. From an administrative perspective, the Someș hydrographic area covers the territory of seven counties: Cluj, Sălaj, Bistrița-Năsăud, Maramureș, Satu Mare, Alba, and Bihor.

The contribution of the latter two is insignificant. The degree of industrialization of the hydrographic basin's territory is relatively high, reflected in numerous economic branches, of which the following activities hold the greatest weight: ore extraction and processing, machine building, metallurgy, the construction materials industry, the chemical industry, the textile industry, the food industry, and timber exploitation and processing (Sofronie, 2000)

The name of the Someș River originates from the Dacian word Samus. It belongs to a group of geographical names dating from the Dacian period, which also includes Alutus (Olt), Crisus (Criș), Istros (Danube), Maris (Mureș), and Tyras (Dniester). Approximately 150–160 basic words from the Dacian language have been preserved, primarily in the form of toponyms and hydronyms. Within this geographical framework, the valleys of the Mureș and Someș rivers functioned as natural axes that facilitated the development of Roman roads and settlements. The positioning of forts and communication routes within the Roman province of Dacia was closely related to these hydrographic corridors, which offered both strategic advantages and access to natural resources. Figure 2 presents the hydrographic basin of the Someș River.

Figure 2. Someș River Basin

There was a fairly extensive system of Roman roads in Transylvania, and the location of these roads is directly related to natural factors, their permissibility and utility. The Romani roads in the Bârgăului Mountains are directly influenced by the accessibility of valleys and natural corridors, being linked to existing hydrographic networks (Bâca, 2012).

Main watercourses, or hydrographic axes, have represented early areas of population concentration, while their characteristics have provided favorable conditions for development. As areas of long-standing settlement, they benefit from significant archaeological potential. For example, the ISTER project focuses on promoting the cultural potential of the Danube region. The project aims to promote Roman roads as coherent transnational elements, an approach considered useful and beneficial for sustainable territorial development (ISTER, 2022). The potential and usefulness of such an approach is also argued by other studies (Jovanović et al., 2022; Amato et al., 2026).

River valleys play a crucial role in the location of tourist centres, representing a linear-nodal territorial structure of tourism (Dunets et al., 2024).The aim of this article is to analyze the relationship between the axes of Roman roads in Transylvania and the major hydrographic corridors represented by the Mureș and Someș rivers. Cultural heritage and archaeological legacy exist along the course of these rivers, therefore it must be highlighted. These historical routes create a tourism potential for the development of this sector and it shapes territorial connectivity for future development of archaeotourism and cultural tourism in region of Transylvania. One of the major objective of this research is to interpret the natural corridors given by hydrographic axes and archaeological heritage as a potential relevance in tourism.

MATERIALS AND METHODS

The study of geographical axes in the specialized literature has attracted the interest of many researchers and has led to much more concrete knowledge in this field. The theory of the geographical axis can be found in several studies that focus on the economic, geographical, and social image of Europe. Laitin, Moortgat & Robinson (2012) test the continental axis theory advanced by Diamond (1997), according to which east–west expansion facilitates the diffusion of agricultural innovations, technologies, and cultural homogenization, whereas north–south expansion preserves cultural diversity due to greater climatic and ecological variation. In addition to providing empirical support for these hypotheses, the authors also examine the economic trends and the geographical and historical implications shaping cultural identity. The main historical implication of this research is that continental axes, understood as geographical factors, have played a crucial role in shaping history and continue to influence contemporary cultural diversity, which in turn generates significant social, economic, and political consequences. The present research is based on a geographical and geo-archaeological approach that analyzes the relationship between Roman road networks and the major hydrographic corridors of Transylvania. The study focuses on identifying the spatial relationship between Roman roads, military forts, and the natural hydrographic framework represented mainly by the valleys of the Mureș and Someș rivers.

Various categories of data from all the fields addressed were used. Among them are data on history and archaeology, geographical and cartographic data to which are added data on tourism in the study area but also relevant information on the current transport infrastructure as well as that of antiquity. The current research involved the use of quantitative and qualitative methods, all scientifically validated to determine the geographical, archaeological and tourist approaches.

The concept of geographical axes has been studied over time from the perspective of territorial organization, transport networks, and the influence of natural factors on the development of human settlements. Iurea & Brăghină (2012) describe development axes as corridors of concentration and diffusion of population, goods, capital, and information flows generated by development poles, mainly along major communication routes. These axes support the urban-rural relationship by facilitating the spatial diffusion of development from urban centers to nearby rural settlements, and underpin polycentric networks capable of attracting investment and reducing disparities between developed and peripheral areas. Given their recognized role in spatial development policy, integrating this perspective

into the valorization of the axes proposed in this study becomes necessary. These concepts were later adapted to the study of historical road networks, especially Roman roads, due to their importance in structuring the territory of Dacia.

The development of historical roads is closely linked to geographical axes, which are often determined by natural features, trade routes, political boundaries, and cultural connections. Geographical axes—such as mountain chains, rivers, valleys, and coastlines—have historically influenced the direction and layout of roads.

Geographical axes refer to natural or human-defined lines that guide movement and connectivity. These axes have often determined the alignment of historical roads through natural features:

- rivers served as natural axes for transport and trade, and roads often developed along river courses to facilitate movement and access to water.

Campbell (2012) addresses the main themes that made river courses strategic and economic elements in the development of Roman roads. The most suitable examples of hydrographic axes were the Danube, Rhine, Nile, and Tiber, which were used as trade routes, functioning as "natural highways" facilitating the circulation of goods and people. Roman settlements were designed, located, and aligned along river axes to ensure high connectivity and access to resources.

Horden & Purcell (2000) argue that rivers were essential resources and transport routes, and many types of settlements shaped their economic activities along them. Rivers were interpreted as geographical axes because they acted as linking poles, being vital axes for trade that connected areas and territories.

Whittaker (1994) succinctly presents how geographical-type axes influence the development of Roman frontiers. In this case, attention is focused on hydrographic axes, which had a military and defensive purpose, as well as a strategic role in connectivity and facilitating the circulation of goods throughout the empire. Remaining within the same framework, Wilson (2019) explains how rivers played a crucial role in the economy of the Roman Empire and fulfilled their role as "natural highways" and economic axes. The Romans invested heavily in water-related infrastructure, including the construction of bridges, canals, ports, and storage facilities. The author's article addresses the relationship between hydrographic axes and Roman roads, as Roman roads were built along rivers to connect settlements and facilitate trade.

The information taken in this research comes from the study of specialized literature found in scientific articles in national and international journals of specific interest, current publications but also from the last century in the field of geography and history and numerous monographic research.

Based on the previous information, the elements that characterize the study area were identified. The spatial framework in which I place the research was analyzed based on current geographical information and outdated research that still presented nuances of topicality. The historical data research was based on both ancient historical sources and the results of modern archaeology. Also within these sources, we placed cartographic and geospatial data thanks to the maps taken. The tourism infrastructure was analysed through digital sources provided by the National Institute of Statistics and validated through field study. The method of observation and field research involved the analysis of the accessibility and current state of conservation of archaeological sites. The quantitative method supports and validates scientific knowledge and allows for the analysis of the identified phenomena with high accuracy.

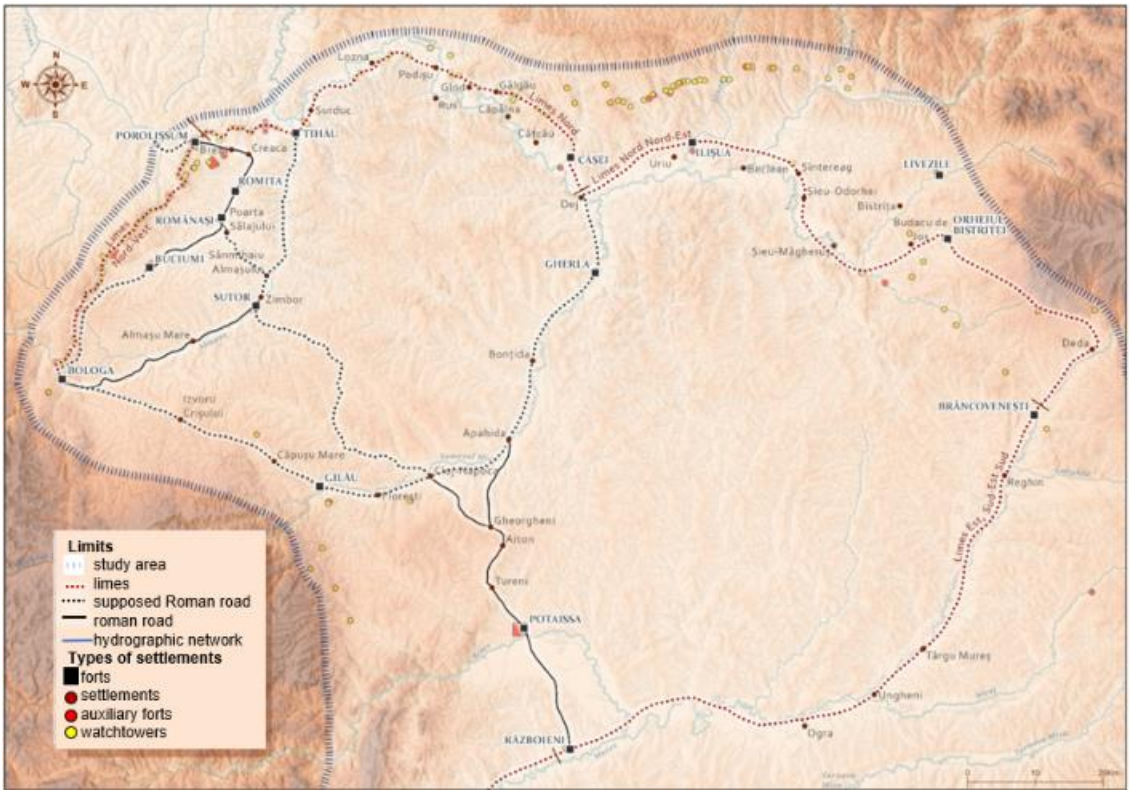

Figure 3. The northern limes route of Dacia Porolissensis (Source: Authors)

RESULTS AND DISCUSSION

These axes are the result of an accumulation of archaeological sites generated by the construction of Roman military structures, closely linked to the natural relief, hydrographic networks, and strategic positioning within the territory.

The placement of the forts was conditioned by factors such as visual dominance over the landscape, control of waterways, and proximity to circulation corridors and administrative centers. Figure 3 presents the location of the northern limes of Dacia Porolissensis.

Thus, the proposed axes function as territorial organisms with economic, social, and residential roles.

The tracing and delimitation of these axes pursue several objectives: the reconstruction of the Roman military structure, the highlighting of the tourism and spatial valorization potential of the heritage, and the demonstration of the current relevance of Roman roads and settlements. Starting with the network of forts on the northern Limes and continuing with those inside the Roman province, located along the main imperial roads, geo-archaeo-touristic axes with their own geomorphological specificity are proposed.

Within this chapter, the following geo-archaeo-touristic axes are proposed: the defensive axis of the western forts of Dacia Porolissensis; the Someș Limes axis, a defensive axis on the northern frontier of Dacia Porolissensis; the intra-Carpathian Limes axis from the Meseș Mountains to the barrier of the Eastern Carpathians; and the urban-imperial axis Potaissa – Napoca – Porolissum. Based on these axes, initiatives can be substantiated to integrate historical research into a modern tourism framework, in line with current trends in regional and cultural development at the European level.

The Defensive Axis of Dacia Porolissensis based on natural course of Someș tributaries

The mountainous area of Sălaj County is located in the southern part of the county, comprising two major ridges: the Meseș and Plopiș ridges (600-900 m). The hilly area—the largest in extent—belongs to a highly complex unit known as the Someș Plateau; the most significant part is the Sălaj Plateau, which is bordered by the Meseș ridge to the east, the Plopiș Mountains to the south, the Baia Mare Depression to the north, and the Western Plain.

This landform unit has an average elevation of 150-300 m, consisting of gentle hills, mostly deforested and cultivated, and is crossed by the wide valleys of the Barcău, Crasna, and Sălaj rivers In the eastern part of Sălaj County lies the Almaș Depression, drained by the Almaș Valley, and the Gârbou Depression, located along the Someș Valley.

The three main plains in Sălaj County are the Someș, Crasna, and Barcău Plains. They are small in extent and appear as elongated strips along the riverbanks, formed from alluvial deposits. The hydrographic network of Sălaj County is evenly distributed, with a high density (0.7-0.9 km/km²). The Someș River crosses the county for approximately 70 km, with its main tributaries being the Almaș and Crasna rivers. Other rivers in the county, such as Agrij, Barcău, Sălaj, and Valea Zalăului, are of local importance, with higher flow rates only during snowmelt and heavy rainfall.

The delimitation of this axis begins with the fort at Bologa and ends at the military complex of Porolissum. The natural framework to which this axis belongs has a coherent morphological and functional impact. This corridor within the Limes of Dacia Porolissensis capitalized on mountainous relief, largely formed by the Meseș Mountains, and on a hydrographic network based on the courses of the Almaș and Agrij valleys. The Agrij River rises in the Apuseni Mountains, in the Meseș Mountains area, where it gathers all its tributaries. It flows northward, discharging into the Someșul Mare at Jibou, running parallel to the Meseș Mountains. The chain of hills east of the Agrij separates its valley from the Almaș Valley, which flows parallel to the Agrij and empties into the same area near Jibou. These two valleys thus form two corridors that penetrate deep into the province of Dacia (Matei & Bajusz, 1997).

Almaș and Agrij are secondary rivers, but they have proven to be vital within the segments of this axis. This sector of the Limes also represents a natural barrier between the Transylvanian Plateau and the Tisza Plain, once again demonstrating the appropriate choice made by the Romans in creating roads and erecting forts.b These two axes represent two geo-archaeological corridors that integrate natural elements of relief and hydrography, as well as anthropogenic military elements such as Roman roads and forts. The scale and historical load present along these corridors represent the development potential of tourist circulation flows.

The Someș Limes Axis – a Defensive Axis on the Northern Frontier of Dacia Porolissensis

The geographical positioning of this defensive axis is set within the natural framework of the Transylvanian Depression, a terrain that has favored, since Antiquity, the development of military roads and Roman forts. The northern limes of Dacia Porolissensis surrounds the geographical core of this depression with a well-branched hydrographic network, especially centered on the main river, the Someș. The river crosses the proposed axis from west to east, longitudinally, creating a corridor that links the Transylvanian Depression with the mountainous area of the Carpathians. The Someș Limes axis includes the Roman roads that connect the forts: Porolissum – Tihău – Cășeiu – Ilișua – Orheiul Bistriței.

The Roman forts within this geographical space are closely connected to the main hydrographic axis. The fort at Tihău is located at the contact between the Meseș Mountains and the western extremity of the Someș corridor; the fort at Cășeiu is placed on a high terrace of the Someș; the fort at Ilișua lies on the floodplain of the Someș; and the fort at Orheiul Bistriței is positioned in the area where the route exits the intra-Carpathian space toward the Bistrița corridor.

The Transylvanian Depression area was identified by the Romans and later validated by specialized literature as a space of balance and convergence. The Someș Limes axis can acquire significant tourist value, as it fits into a landscape that still preserves traces of Roman presence from Antiquity. This network of fortifications is not accidental, but rather the result of a coherent strategy for managing the northern frontier. The Someș corridor, oriented west–east, functioned as a natural corridor for transport and migration, but also as a potential invasion route. Its control was a military necessity for the Romans.

The Mureș Limes Axis – A southern Carpathian Barrier

The Mureș area represented an important community area in all historical periods, its corridor being defined by several essential characteristics, characteristics that favored the geographical potential it had to offer especially in the Roman area (Fodorean, 2015). The archeological excavations carried out in the county led to discovery of material and intangible evidence of human traces on the main geographical axis.

As in our days, the Mureș River valley was a great important transport and communication route in historical Transylvania. The oldest evidence of transport traces is given by Roman roads (Berecki et al., 2013). The chronological setting of the roads is difficult to identify, but at the level of the Mures valley in Mures County, some traces of the presence of Roman roads can be found. Figure 4 presents the location of archaeological components along the Mureș Axis, in Mureș County. The Mureșului Corridor is located at a level difference between the two neighboring geographical units of about 150 meters, making this course extremely close to the southern line of the Transylvanian Plain. This fact facilitated the more pronounced development on the left side of the corridor where the long one is better developed with approximately 3 kilometers wide (Fodorean, 2015). The geographical and hydrographic characteristics of this area led to the exploitation of a Roman traffic road since Prehistory.

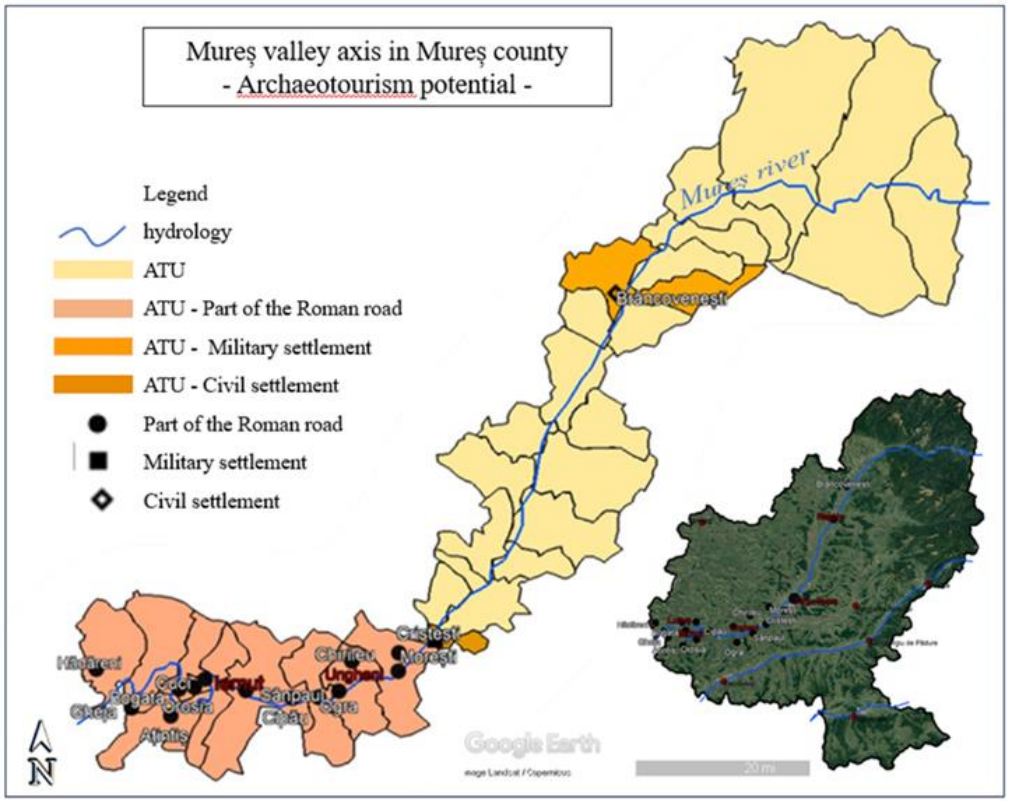

Figure 4. Villages with archaeotouristic discoveries on the Mureș Valley in Mureș County
(Source: http://www.eemj.icpm.tuiasi.ro/pdfs/vol23/no1/3_550_Gudea_23.pdf)

Beyond their historical and geographical significance, the axes identified in this research also present important potential for cultural and heritage tourism. The concentration of Roman forts, settlements, and road segments along the hydrographic corridors of the Mureș and Someș rivers creates the conditions for the development of thematic tourism routes based on Roman heritage. These geo-archaeological corridors combine natural landscapes with archaeological remains, offering opportunities for the interpretation of historical landscapes and for the valorization of the Roman presence in Transylvania.The spatial continuity of these axes allows them to be interpreted as archaeotouristic corridors that connect several important archaeological sites. Roman forts such as Porolissum, Tihău, Cășeiu, Ilișua, and other settlements located along the hydrographic valleys form a network of sites that can be integrated into cultural tourism itineraries. The presence of natural corridors, accessible valleys, and historically documented routes facilitates the creation of thematic trails that combine archaeological heritage with the natural landscape.

From a territorial perspective, the valorization of these historical axes can contribute to the development of sustainable tourism in the regions crossed by the Mureș and Someș valleys. The Roman road and the identified prehistoric remains overlap, at county level, with the Mureș Valley axis, highlighting its role as an important natural corridor for movement and territorial connectivity. The Roman road and prehistoric remains overlap with the Mureș Valley axis, highlighting its role as a natural corridor of movement and connectivity. This relationship can support archaeotourism along the Mureș Valley and contribute to the sustainable development of the territory (Gudea et al., 2024).

The integration of Roman archaeological sites into tourism circuits could support the diversification of tourism activities, promote local heritage, and strengthen the cultural identity of the region. In this context, the Roman road axes

can be interpreted not only as historical communication routes but also as elements of contemporary territorial development, contributing to the promotion of archaeotourism and cultural tourism in Transylvania.

CONCLUSION

The road network analyzed in this article represents one of the most durable and influential transport systems developed in Antiquity. In synergy with physical geography—relief and hydrography—Roman infrastructure was strategically designed to meet the military, administrative, and economic needs of the province of Dacia. Roman roads connected forts and urban centers with one another and with frontier points, being constructed with considerable technical rigour, maximum visibility, territorial control, and easy access to natural resources.

This network not only physically endured in the landscape but has also preserved its relevance and influence up to the present day, directly or indirectly shaping the routes of modern roads. Roman roads can be regarded as generators of territorial development axes. Urban settlements that formed in the vicinity of these roads experienced accelerated urbanization, many of them being elevated to the status of municipium or colony.

All limes axes presented in this article have territorial connectivity and form a road system which, although initially built for military and administration, today represents an important point of economic development, preserving its connectivity function up to the present day. The geographical axes that acquire a historical role in the case of Roman roads are reliable elements of sustainable development through the existing archaeological heritage.

The concentration of Roman archaeological sites, including forts and settlements located along these hydrographic corridors, creates opportunities for their interpretation as geo-archaeological routes. From a tourism perspective, the integration of Roman archaeological sites located along the Mureș and Someș valleys into thematic tourism routes could contribute to the promotion of historical heritage and to the diversification of tourism activities in Transylvania. Such initiatives could strengthen the connection between archaeological research, landscape interpretation, and sustainable territorial development. In this context, the Roman road axes identified in this study represent not only elements of the historical organization of space but also potential resources for the development of cultural and heritage tourism.

Local hydrography together with the geographic factor greatly influenced the construction of the Roman roads, which leads to the conclusion that they were not an obstacle but the foundation from which the shape of the road network originated. The Mureș and Someș corridors were natural axes from the very beginning. The optimal geomorphological conditions imposed within the landscape of the hydrographic structure the Roman military infrastructure, which has been preserved to this day and has become axes with economic, infrastructural, and communication value.

Abstract: Protected areas increasingly depend on tourism to support biodiversity conservation and local development; however, conflicts over governance, resource access, and benefit-sharing continue to challenge sustainability outcomes. The Makuleke Contractual National Park (MCNP) in South Africa, established through a landmark land restitution agreement, provides a valuable context for examining the relationship between co-management and tourism-resource conflict. This study aimed to investigate how co-management arrangements shape governance processes, access to tourism benefits, and sustainability outcomes within MCNP. A qualitative case study approach was employed, drawing on 23 semi-structured interviews conducted between January and March 2025 with community members, traditional leaders, South African National Parks officials, Communal Property Association representatives, and tourism stakeholders. Data were analysed using Braun and Clarke's six-phase thematic analysis framework. Three key themes emerged: governance and participation, unequal benefit-sharing, and sustainability implications. Findings indicate that although the Makuleke community regained ownership of the land through restitution, meaningful decision-making authority remains limited, while concerns over unequal benefit distribution and inadequate transparency persist. Participants perceived these challenges as undermining trust, community support for conservation, and long-term tourism sustainability. The findings suggest that legal ownership alone does not guarantee empowerment or equitable access to tourism benefits. The study concludes that strengthening co-management requires transparent governance, inclusive participation, equitable benefit-sharing mechanisms, and sustained capacity-building initiatives to enhance conservation outcomes and support the long-term sustainability of community-based tourism in protected areas.

Keywords: tourism resources, conflict, sustainability, Makuleke Contractual National Park, co-management, benefit-sharing, protected areas

INTRODUCTION

Tourism in protected areas is widely recognised as a tool for biodiversity conservation and socio-economic development, particularly in rural regions where it generates revenue, employment, and incentives for conservation (Eagles et al., 2002; Balmford et al., 2015; Weaver & Lawton, 2017). However, tourism development can also generate conflict when local communities experience exclusion from decision-making, access to resources, and benefit-sharing (Adams & Hutton, 2007; Anthony & Szabo, 2011). In South Africa, conservation has historically been linked to forced removals and racialised land dispossession, prompting post-apartheid land restitution initiatives to restore rights to affected communities (Beinart & Delius, 2014; Kepe, 2008; Walker, 2024). The Makuleke community represents a prominent restitution case, regaining ownership of approximately 24,000 hectares within Kruger National Park in 1998 under a co-management agreement with SANParks that retained conservation and tourism objectives (Ramutsindela, 2001; Fabricius & de Wet, 2002; Spenceley, 2008; Bvuma, 2023). Although the arrangement was designed to balance conservation and community development, it created a complex governance system characterised by shared authority and unequal power relations (Büscher & Ramutsindela, 2016). Protected areas are geographically designated spaces established to conserve biodiversity, natural resources, and cultural heritage while supporting ecosystem services and sustainable human use (Chardonnet, 2019). The International Union for Conservation of Nature (IUCN) defines a protected area as a clearly defined space managed through legal or effective means to achieve the long-term conservation of nature, ecosystem services, and cultural values (Dudley, 2008). These areas range from strictly protected reserves to multiple-use landscapes, reflecting varying management objectives and degrees of human intervention (Chardonnet, 2019).

Beyond biodiversity conservation, protected areas play an important role in maintaining ecosystem processes, protecting endangered species, supporting sustainable livelihoods and ecotourism, and serving as sites for research and education (Gandiwa et al., 2013; McCool & Spenceley, 2014). Globally, protected and conserved areas now cover

approximately 17.6% of terrestrial and inland waters and 8.4% of marine areas, reflecting substantial growth in conservation efforts over recent decades (UNEP-WCMC & IUCN, 2024). Despite this expansion, concerns regarding management effectiveness, governance quality, and equity continue to challenge the achievement of the Kunming-Montreal Global Biodiversity Framework Target 3, which seeks to conserve 30% of the planet by 2030 (UNEP-WCMC & IUCN, 2024). Consequently, there is increasing recognition that spatial expansion alone is insufficient without effective governance and equitable management systems (UNEP-WCMC & IUCN, 2021; UNEP-WCMC & IUCN, 2024).

Contemporary conservation policy increasingly emphasises co-management and participatory governance approaches that seek to involve local and Indigenous communities more directly in conservation and tourism decision-making (Fabricius & de Wet, 2002; Ramutsindela, 2004; UNEP-WCMC & IUCN, 2024).

This shift aligns with broader sustainability objectives, including Sustainable Development Goal 15, and promotes social inclusion, climate resilience, and ecological connectivity (Dudley, 2008). However, conservation interventions frequently generate conflict when restrictions on land use, limited access to resources, and unequal tourism benefit-sharing intersect with local livelihood needs (Brockington & Igoe, 2006; Domínguez & Luoma, 2020). Recent studies indicate that community participation often remains consultative rather than transformative, with limited transfer of decision-making authority to local stakeholders (Jánová et al., 2025; Siltanen et al., 2025).

In South Africa, these governance challenges are further shaped by colonial and apartheid legacies of land dispossession, which resulted in many protected areas being established on ancestral land (Kepe et al., 2005; DeMotts & Swatuk, 2012). Post-apartheid conservation, therefore, operates within a dual mandate of biodiversity protection and social justice through land restitution (Ramutsindela, 2004). The Restitution of Land Rights Act facilitated the creation of contractual national parks, such as the Makuleke Contractual National Park (MCNP), in which communities regained ownership while maintaining conservation objectives through co-management agreements, reflecting South Africa's broader land reform programme aimed at redressing historical dispossession, strengthening tenure security, promoting equitable access to land, and advancing rural development (Steenkamp & Uhr, 2000; Hall & Kepe, 2017; Cousins, 2022; Du Plessis et al., 2023). The Manyeleti land claim provides another important example of the complexities associated with restitution in protected areas, including disputes over claimant representation, verification processes, and expectations regarding future benefits from the claim (Tesselaar, 2021). Although this model represents a significant shift toward participatory governance and benefit-sharing, implementation challenges remain, including limited access to resources, contested tourism benefits, and persistent governance inequalities (McCool & Spenceley, 2014; Matiku et al., 2020; Domínguez & Luoma, 2020). Studies conducted within the Makuleke context have identified enduring power asymmetries within governance structures, limited community influence over strategic decision-making, and the continued dominance of conservation agencies despite institutional reforms (Steenkamp & Uhr, 2000; Maluleke, 2018; Makuleke Contractual National Park Management Plan, 2021). These challenges continue to undermine community trust and contribute to resource conflicts, highlighting the importance of transparent governance, equitable benefit-sharing, enforceable decision rights, and accountable co-management systems (Jánová et al., 2025; Siltanen et al., 2025).

Despite extensive research on protected area governance, community participation, and land restitution, limited research has examined how governance arrangements, tourism benefit-sharing, and stakeholder experiences interact to shape tourism resource conflicts and sustainability outcomes within the Makuleke Contractual National Park. Therefore, this study investigates how co-management arrangements influence governance processes, access to tourism benefits, and sustainability outcomes in the Makuleke Contractual National Park.

Conflict and Co-Management in Protected Areas

Conflicts in protected areas arise when multiple stakeholders compete for access to land, natural resources, and decision-making authority, often creating tensions between conservation objectives and local livelihoods (Eagles et al., 2002). These conflicts are frequently linked to conservation policies that restrict traditional land-use practices, limit access to livelihood resources, alter land-tenure arrangements, and distribute tourism benefits unevenly (Anthony & Szabo, 2011; Thondhlana & Cundill, 2017). Tourism can further intensify inequalities when benefits accrue to elites or external operators, while local communities bear social and environmental costs (Brockington & Igoe, 2006; Snyman & Bricker, 2021; Snyman et al., 2023). In response, co-management emerged as a collaborative governance approach through which state agencies and local communities share responsibility for protected area management (Berkes, 2009; Borrini-Feyerabend et al., 2012; Fedreheim & Blanco, 2017). Supported by international frameworks such as the Durban Accord, co-management aims to promote participation, equity, and conservation effectiveness (IUCN-The World Conservation Union, 2005). In South Africa, this approach has been closely linked to land restitution, particularly in contractual national parks such as the Makuleke Contractual National Park (MCNP), where communities regain ownership while conservation status is maintained (Steenkamp & Uhr, 2000; Maluleke, 2018; Makuleke JMB/GKSDP, 2021).

Despite its promise, evidence suggests that co-management often delivers mixed outcomes, with decision-making authority remaining concentrated within state institutions and private tourism operators, resulting in symbolic rather than meaningful participation (AWARD, 2020; Maluleke, 2018; Scheyvens & van der Watt, 2021). Similar findings from other countries indicate that effective co-management requires sustained engagement, accountability, and genuine power-sharing (Thomlinson & Crouch, 2012; UNEP-WCMC, 2024). In the Makuleke context, historical displacement, land-use restrictions, unresolved tenure concerns, and unequal access to tourism benefits continue to generate conflict despite formal co-management structures (Thondhlana et al., 2016; Matiku et al., 2020). SANParks' retention of significant authority and

the dominance of private concessionaires further constrain community influence over tourism development and revenue distribution (Chaderopa, 2016). Human-wildlife conflict, including crop damage and livestock losses, further reinforces community dissatisfaction with conservation initiatives (Gandiwa et al., 2013; Salerno et al., 2020).

Collectively, the literature demonstrates that protected-area conflicts are fundamentally governance and justice issues rooted in historical inequalities and power asymmetries, highlighting the need for transparent governance, equitable benefit-sharing, enforceable decision rights, and accountable co-management systems (Dube, 2018; Borrini-Feyerabend et al., 2012; Jánová et al., 2025; Siltanen et al., 2025). Political Ecology provides the primary theoretical lens for this study by explaining how power relations, historical inequalities, and governance structures shape access to tourism resources, environmental decision-making, and the distribution of conservation benefits and costs (Blaikie & Brookfield, 1987; Robbins, 2012). The theory argues that tourism and conservation conflicts are rooted in unequal control over land, resources, participation, and development opportunities rather than ecological concerns alone (Aastrup, 2020; Di Marzo & Espinosa, 2023; Darwis et al., 2025). In the context of the Makuleke Contractual National Park (MCNP), Political Ecology is particularly relevant because land restitution restored ownership rights while governance arrangements continue to influence access to tourism opportunities, participation, and development decisions (Akampurira, 2023; Mthimkhulu & Nel, 2024; Turner, 2004; Turner, 2006). The theory further highlights the importance of transparency, accountability, equitable benefit-sharing, and meaningful stakeholder participation in achieving sustainable tourism outcomes (Heslinga et al., 2017; Soliev et al., 2021; Ramukumba, 2021; McKercher, 2025). To strengthen the analysis, the study also draws on Stakeholder Theory (Freeman, 1984), which examines stakeholder interests and interactions; Conflict Theory, which explains tensions arising from unequal access to power and resources; and the Triple Bottom Line framework (Elkington, 1997), which assesses sustainability across environmental, social, and economic dimensions.

More than two decades after restitution, challenges relating to governance, tourism benefit-sharing, community participation, and sustainability remain evident, raising concerns about the extent to which co-management arrangements have addressed historical inequalities and delivered meaningful benefits to local communities (Balint & Mashinya, 2006; Thondhlana & Cundill, 2017; Derman et al., 2017). Table 1 provides a synthesis of key literature on co-management and protected area governance. It highlights major trends, limitations, and research gaps relevant to tourism resource conflicts and sustainability in the Makuleke Contractual National Park.

Table 1. Literature Synthesis on Co-management and Protected Area Governance (Source: Authors' own creation)

Author(s)	Year	Study Focus/Location	Methodology	Key Findings	Limitations	Research Gap/Relevance to MCNP
Ramutsindela	2004	Conservation and land restitution (South Africa)	Conceptual analysis	Restitution introduces new governance challenges in protected areas	Limited empirical evidence	Does not examine tourism governance and stakeholder perceptions in contractual parks
Kepe	2008	Land restitution and conservation conflicts (South Africa)	Case study	Conservation and community rights often remain contested after restitution	Site-specific findings	Limited focus on tourism benefit-sharing and sustainability outcomes
Spenceley	2012	Tourism in protected areas (South Africa)	Literature review	Tourism can support conservation and livelihoods when benefits are equitably distributed	Broad focus	Limited attention to restituted contractual parks
Thondhlana & Cundill	2017	Community participation in conservation (South Africa)	Qualitative study	Participation often remains limited despite co-management arrangements	Focus on community perceptions	Limited examination of tourism finance and governance processes
Maluleke	2018	Co-management in MCNP	Case study	Power asymmetries persist despite restitution and co-management	Historical focus	Limited assessment of current governance arrangements and sustainability outcomes
Matiku et al.	2020	Restitution and conservation governance (South Africa)	Qualitative analysis	Land restitution does not automatically guarantee resource access or empowerment	Limited stakeholder perspectives	Does not examine tourism-related conflicts in detail
Snyman & Bricker	2021	Benefit-sharing (Southern Africa)	Literature synthesis	Transparency and fair benefit-sharing enhance community support	Not specific to restituted parks	Limited understanding of transparency and conflict in contractual parks
Ntuli et al.	2021	Governance and poaching (Southern Africa)	Empirical study	Governance exclusion contributes to resistance and illegal resource use	Cross-sectional study	Limited evidence on long-term sustainability impacts
Scheyvens & van der Watt	2021	Tourism empowerment (Global)	Conceptual review	Participation often remains symbolic	No empirical testing	Need for empirical evidence from restituted South African parks
Snyman et al.	2023	Revenue-sharing programme (Rwanda)	Longitudinal review	Fair benefit-sharing reduces conflict	Different governance context	Limited application to co-managed contractual parks
Jánová et al.	2025	Participation in governance	Systematic review	Genuine participation requires enforceable decision rights	Few restitution cases	Need for evidence from South African restitution contexts
Siltanen et al.	2025	Protected-area governance	Standards synthesis	Equity and accountability are central to governance success	Normative guidance	Limited empirical assessment of stakeholder experiences

Recent studies indicate that co-management in restituted protected areas often fails to transform underlying power relations significantly. Although governance structures and benefit-sharing mechanisms are formally established, communities frequently have limited decision-making authority, while inadequate transparency in tourism revenues and financial management undermines trust and accountability (Snyman & Bricker, 2021; Maluleke, 2018; Jánová et al., 2025). Evidence further shows that perceptions of unfair benefit distribution, weak accountability, and limited community influence can reduce local support for conservation and contribute to conflict (Ntuli et al., 2021; Snyman et al., 2023). While the literature consistently identifies power imbalances, limited participation, and unequal benefit-sharing as key challenges, most studies examine these issues in isolation and offer limited insight into how they interact to shape resource conflicts and sustainability outcomes in restituted protected areas (Matiku et al., 2020; Snyman & Bricker, 2021). Consequently, there remains a need to understand better how governance arrangements, tourism finance, and stakeholder experiences shape conflict and sustainability within contractual national parks such as the Makuleke Contractual National Park.

Governance and Land Restitution in South Africa

Conflict in protected areas arises when multiple stakeholders compete over access to land, natural resources, tourism opportunities, and decision-making authority, often creating tensions between conservation objectives and local livelihood needs (Eagles et al., 2002; Anthony & Szabo, 2011; Thondhlana & Cundill, 2017). In many contexts, conservation policies have restricted traditional land-use practices and resource access, while tourism development has intensified disputes over benefits perceived as unevenly distributed among stakeholders (Brockington & Igoe, 2006; Domínguez & Luoma, 2020; Snyman & Bricker, 2021). These conflicts are frequently rooted in broader governance challenges, including unequal power relations, limited participation, inadequate transparency, and exclusion from decision-making processes (Jánová et al., 2025). From a Political Ecology perspective, such conflicts reflect historical and structural inequalities that shape access to resources and influence over environmental governance rather than merely technical management failures (Aastrup, 2020; Akampurira, 2023). In response to the limitations of exclusionary conservation approaches, co-management emerged as a collaborative governance model that shares responsibility and decision-making between conservation authorities and local communities (Berkes, 2009; Borrini-Feyerabend et al., 2012; Fedreheim & Blanco, 2017). Co-management is intended to promote local participation, strengthen legitimacy, integrate indigenous knowledge, and improve benefit-sharing while maintaining conservation objectives (AWARD, 2020; IUCN-The World Conservation Union, 2005).

However, empirical evidence suggests that co-management outcomes remain mixed, as decision-making power often remains concentrated within state institutions and private tourism operators, resulting in symbolic rather than substantive participation (Maluleke, 2018; Scheyvens & van der Watt, 2021; Jánová et al., 2025). Across Africa and South Africa in particular, studies consistently show that power asymmetries, limited community influence, and unequal access to tourism benefits continue to undermine trust, generate conflict, and constrain sustainable conservation outcomes even within formally co-managed protected areas (Kepe, 2008; Matiku et al., 2020; Ntuli et al., 2021). Consequently, the literature suggests that successful co-management depends not only on the establishment of participatory structures but also on meaningful community influence, transparent governance, equitable benefit-sharing, and accountable decision-making processes.

The Makuleke settlement is widely recognised as a landmark example of balancing land restitution, biodiversity conservation, tourism development, and community livelihood enhancement within a protected area (Maluleke, 2018; Bvuma, 2023). However, recent scholarship suggests that while restitution restored legal ownership, it did not necessarily translate into meaningful empowerment, equitable decision-making, or control over tourism resources (Chitonge, 2022; Abdullateef, 2024). Across South Africa, claimant communities often regain ownership of land while remaining subject to conservation frameworks that limit their influence over land use and development decisions (Bezerra & Paphitis, 2021; Mthimkhulu & Nel, 2024). Although tourism has been promoted as a key mechanism for generating socio-economic benefits through employment, revenue generation, and local economic development (Matiku et al., 2020), studies continue to highlight challenges related to unequal benefit-sharing, limited participation, governance constraints, and restricted community influence within co-management arrangements (Chitonge, 2022; Appiah-Boateng et al., 2025).

Similar concerns have been identified in other restitution and co-management contexts, including leadership disputes, social conflict, persistent inequalities, and tensions that undermine conservation and tourism outcomes (Krüger et al., 2016; Tsawu, 2025). Furthermore, communally owned protected areas may simultaneously restore ownership rights while reproducing new forms of exclusion through conservation territorialisation and restrictive governance systems (Mthimkhulu & Nel, 2024). Consequently, despite being frequently presented as a successful conservation-restoration model (Ramutsindela & Shabangu, 2013), important questions remain regarding the extent to which co-management arrangements have fostered meaningful participation, equitable benefit-sharing, and sustainable tourism outcomes.

This study addresses this gap by examining stakeholder perspectives on governance, participation, benefit-sharing, and tourism-related resource conflicts within the Makuleke Contractual National Park.

Sustainability and Community Participation

Sustainability in protected areas extends beyond biodiversity conservation to include social equity, effective governance, and economic benefits (McCool & Spenceley, 2014). Community participation remains a critical component of sustainable tourism development in protected areas because governance arrangements and institutional structures influence the extent to which local communities benefit from tourism and conservation initiatives (Lekgau & Tichaawa, 2019; Strydom et al., 2019). Research shows that while community participation is widely promoted in co-management arrangements, it often remains consultative rather than transformative, with communities having limited influence over

decision-making and benefit distribution (Berkes et al., 2000; Maluleke, 2018; Domínguez & Luoma, 2020). These governance challenges can undermine trust, community support, and long-term conservation outcomes (Musakwa et al., 2020; Setokoe & Ramukumba, 2022). Evidence further suggests that equitable benefit-sharing, transparent governance, and inclusive decision-making are essential for sustainable protected area management (Ntuli et al., 2021; Chidakel & Child, 2022; Vandermale & Mason, 2024). Despite formal co-management structures in the Makuleke Contractual National Park, concerns regarding limited participation, unequal benefits, and inadequate transparency persist (Maluleke, 2018; Snyman & Bricker, 2021). Although previous studies have examined restitution, conservation governance, and community participation, limited research has explored how governance arrangements, tourism benefit-sharing, and resource conflicts interact to shape sustainability outcomes. This study addresses this gap by examining stakeholder perspectives on these issues within the Makuleke Contractual National Park (Borrini-Feyerabend et al., 2012; Spenceley & Rylance, 2021).

METHODOLOGY

This study employed a qualitative case study design to explore tourism resource conflicts and their implications for sustainable tourism management within the specific context of MCNP. Highlighting this context emphasises the study's importance for understanding conflict dynamics in co-managed protected areas, thereby clarifying the research scope. The qualitative methodology aimed to gather in-depth insights into stakeholder perceptions, experiences, and interactions within their real-life contexts (Yin, 2018; Creswell & Creswell, 2017). The approach allowed for a comprehensive examination of MCNP as a bounded system, suitable for exploring 'how' and 'why' questions involving multiple stakeholders and complex social phenomena (Hennink et al., 2020; Islam & Aldaihani, 2022). This design facilitated a detailed understanding of conflicts surrounding tourism resources and the sustainability dynamics of co-managed protected areas. The Makuleke Contractual National Park is located in the northern part of Kruger National Park in Limpopo province, South Africa.

Figure 1 illustrates the location of the Makuleke Contractual National Park within Kruger National Park and the surrounding Makuleke communities. Figures 2 and 3 present tourism facilities and tourism infrastructure observed during fieldwork, providing contextual information regarding tourism development within the study area.

Figure 1. Shows the location of the Makuleke Contractual National Park within
Kruger National Park and the three villages of the Makuleke community (Source: Du Plessis, 2023)

Figure 2. Tourism facilities at Makuleke Contractual National Park: (a) Return Africa Pafuri Camp along the Luvuvhu River, northern Kruger National Park, South Africa (Source: Photos taken by the author during fieldwork, February 2025)

Figure 3. Entrance signage to Makuleke Contractual Park and The Outpost Lodge, northern Kruger National Park, South Africa (Source: Taken by the author during fieldwork, February 2025)

It was chosen for this study because of its unique status as the first co-managed protected area within the country's land restitution framework (Ramutsindela, 2004; Fabricius & De Wet, 2002; Qwatekana & Mazibuko, 2020). The park covers approximately 24,000 hectares and is jointly managed by the Makuleke community and South African National Parks (SANParks) through a Joint Management Board (JMB). The park boasts high biodiversity conservation value and features various tourism enterprises, including The Outpost Lodge, Return Africa Pafuri Camp, and Pel's Post Lodge (du Plessis, 2023).

Primary data were collected through semi-structured interviews conducted between January and March 2025, targeting key stakeholder groups, including traditional leaders, Makuleke community members from the villages of Makuleke, Mabiligwe, and Makahlule, SANParks officials, and private tourism operators. The interview guide was developed following an extensive literature review, designed to obtain detailed information regarding stakeholder perceptions of conflict drivers, sustainability concerns, governance challenges, and potential solutions.

The semi-structured format allowed participants to express nuanced views while maintaining a consistent thematic focus across interviews (Bhalla et al., 2023). A total of 23 interviews were conducted until thematic saturation was achieved, ensuring a depth of information and a broad coverage of perspectives (Boddy, 2016; Braun & Clarke, 2021).

Purposive sampling was employed to intentionally select informants with specific knowledge and experience related to MCNP governance and tourism activities (Taherdoost, 2016). Efforts were made to ensure diverse representation across age, gender, roles, and affiliations, enhancing the richness of the dataset. To analyse the interview transcripts, a thematic analysis was conducted using Braun and Clarke's six-step approach (Braun & Clarke, 2006).

This rigorous and systematic process involved familiarisation with the data, generating initial codes, searching for themes, reviewing those themes, defining and naming them, and finally producing the report. This method provided a reliable foundation for identifying core conflict issues, stakeholder perceptions, and governance challenges relevant to MCNP's sustainability, fostering confidence in the findings.

RESULTS AND DISCUSSIONS

This section presents the study's findings based on semi-structured interviews with key stakeholders involved in the Makuleke Contractual National Park. The analysis used thematic analysis, which enabled the identification of recurring patterns and key themes related to tourism resource conflicts and sustainability. The results are presented in two parts: first, the demographic profile of participants to provide contextual background, and second, the thematic findings that capture stakeholder perspectives on the causes, nature, and impacts of tourism resource conflicts in the study area.

Participant Profile

The participant profile provides important contextual information for understanding the range of perspectives represented in the study. By categorising participants according to their stakeholder affiliation and social position, the analysis captures how experiences of tourism resource conflicts and co-management may differ across groups. Examining the views of community members, traditional leaders, tourism operators, SANParks officials, and the CPA representative enables a more nuanced understanding of the interests, power relations, and governance dynamics shaping tourism and conservation outcomes within MCNP.

Furthermore, the demographic composition of participants provides a basis for exploring variations in perceptions across gender and age groups, which are often overlooked despite their influence on participation, benefit-sharing, and decision-making processes. Table 2 summarises the demographic and stakeholder characteristics of the participants and provides the foundation for the thematic analysis that follows.

Table 2 presents the demographic and stakeholder characteristics of the 23 interview participants. Community members constituted the largest stakeholder group (61%; n = 14), reflecting the study's emphasis on local experiences of tourism governance, conservation, and benefit-sharing. Other participants included tourism operators (4%; n = 1), Lodge

managers (13%; n=3), SANParks officials (9%; n = 2), traditional leaders (9%; n = 2), and one CPA representative (4%; n = 1). Participants were drawn from Makuleke, Makahlule, and Mabiligwe villages, as well as neighbouring communities. The sample included both male (61%) and female (39%) participants.

It was dominated by respondents aged 41 years and older (78%), indicating a strong representation of individuals with long-standing experience of land restitution, conservation, and co-management processes. The diversity of stakeholder affiliations and community positions enabled comparison of convergent and divergent perspectives regarding governance, participation, benefit-sharing, and sustainability within MCNP.

Thematic Analysis

This study aimed to examine how co-management influences governance, access to tourism benefits, and resource conflicts within the Makuleke Contractual National Park (MCNP). Data generated from 23 semi-structured interviews with community members, traditional leaders, a CPA representative, SANParks officials, and tourism operators were analysed thematically. Three interrelated themes emerged from the analysis: Governance and Participation, Unequal Benefit-Sharing, and Sustainability Implications.

These themes provide a framework for understanding stakeholder experiences and perceptions of co-management within MCNP. By exploring the long-term outcomes of restitution and co-management, the study contributes to ongoing debates on the extent to which legal ownership translates into effective governance, economic inclusion, and sustainable conservation outcomes. The findings and discussion are presented under the three themes below.

Theme 1: Governance and Participation

A dominant theme across stakeholder groups was the perception that legal ownership had not translated into equivalent decision-making authority within the co-management arrangement. Although structures such as the Joint Management Board (JMB), Communal Property Association (CPA), and community consultation forums were intended to facilitate shared governance, participants frequently reported that strategic and operational decisions remained concentrated within SANParks and private concessionaires. As Community Member 9 explained:

"Consultation is there, but decisions come from above."

This distinction between consultation and influence was a recurring concern, with participants questioning whether engagement processes translated into meaningful authority over employment, development priorities, and park management decisions. Similar concerns were reflected in Community Member 4's observation that SANParks often sought to "do things their way," reinforcing perceptions of centralised decision-making. Operational stakeholders also identified communication challenges as a governance concern. As Lodge Manager 1 noted:

"There are consultation structures in place, but communication between stakeholders is not always consistent, which can create misunderstandings about how decisions are made."

These communication gaps were linked to broader tensions regarding stakeholder priorities. For example, Lodge Manager 3 argued:

"The community is on everything, but SANParks only cares more about conservation. They don't care about the business... So this is where the CPA or the community must play a role here to make sure that we have common grounds with SANParks and us."

Together, these views suggest that governance tensions in MCNP stem not only from decision-making authority but also from communication challenges and competing stakeholder priorities. Similar findings have been reported in transfrontier conservation areas, where institutional arrangements and protected area policies create barriers to meaningful community participation in wildlife tourism and decision-making processes (Lekgau & Tichaawa, 2019). Traditional leaders similarly emphasised the need for a more balanced partnership based on shared responsibility and mutual benefit. As Traditional Leader 1 noted:

"We need to work until we strike that balance so we can move in the same direction."

These perceptions suggest that restitution created expectations of shared governance that many participants felt had not been fully realised in practice. Importantly, governance concerns were not limited to community stakeholders. SANParks officials also acknowledged shortcomings in stakeholder engagement and communication, with SANParks Official 1 stating:

"We need to conduct stakeholder engagement sessions; currently, we do not have that platform."

While community members interpreted these shortcomings as evidence of unequal authority, SANParks officials tended to frame them as operational and communication challenges. This divergence highlights how governance tensions are understood differently by stakeholders, despite a shared recognition that current engagement mechanisms are insufficient.

Overall, participants associated governance challenges with limited influence over decision-making, weak communication, and uncertainty regarding stakeholder roles within the co-management system.

These findings extend earlier work by Maluleke (2018), which identified unequal power relations and limited community influence during the early implementation of the agreement. More than two decades after land restitution, similar concerns persist, suggesting that the central challenge is no longer the restoration of ownership rights but the effective translation of those rights into meaningful governance authority. The findings therefore reinforce broader evidence that formal participation structures do not necessarily guarantee substantive participation, particularly where institutional authority and decision-making power remain unevenly distributed.

The findings corroborate concerns regarding the implementation of benefit-sharing mechanisms. While the MCNP Management Plan prioritises socio-economic development through employment creation, tourism partnerships, and community benefits, participants highlighted perceived inequalities in the distribution of these benefits.

From a Political Ecology perspective, these findings demonstrate that land restitution and formal co-management structures do not necessarily transform underlying power relations. Although the Makuleke community regained legal ownership of the land and is represented within governance structures, participants perceived that substantive decision-making authority remains concentrated within SANParks and other institutional actors. This supports Political Ecology's contention that formal reforms may coexist with persistent inequalities in resource governance and control. Furthermore, the findings extend Stakeholder Theory by illustrating that stakeholder representation alone does not guarantee meaningful participation. While community members are included in consultation processes, participants perceived limited influence over strategic decisions affecting tourism development, conservation management, and benefit distribution. The findings therefore suggest that effective co-management requires not only stakeholder inclusion but also genuine decision-making authority and accountability mechanisms that enable stakeholders to influence outcomes.

Theme 2: Unequal Benefit-Sharing

Participants widely perceived tourism benefits as unevenly distributed despite community ownership of the land. Concerns centred on concession agreements, employment opportunities, revenue transparency, and limited participation in tourism-related economic benefits. As Community Member 6 explained:

"Even though Makuleke owns the land, the kind of business we entered does not allow us to have much benefit. We are not part of the profits."

The same participant further noted:

"The concessionaires brought capital. We only brought land, so we get a concession fee and nothing from the profits."

These accounts suggest that stakeholders perceived a disconnect between land ownership and economic influence within tourism operations, a concern also highlighted in studies examining the livelihood outcomes of the Pafuri Triangle Agreement among the Makuleke community (Bvuma, 2023). While previous studies have examined co-management and benefit-sharing in the Makuleke region, the present findings indicate that tourism governance has become a key site of contestation, with concerns extending beyond revenue distribution to include concession arrangements, employment opportunities, and financial accountability. This suggests that tourism governance functions as an important mechanism through which power, inclusion, and economic benefits are negotiated in restituted protected areas. Similar concerns have been reported in protected-area tourism, where benefit-sharing outcomes are shaped by partnership structures and the degree of community participation in decision-making processes (Snyman & Bricker, 2019; Spenceley & Snyman, 2017; Qwatekana & Mazibuko, 2020). Moreover, benefit-sharing extends beyond direct financial transfers to include employment, local procurement, enterprise opportunities, and skills development, which may explain why dissatisfaction persists despite the existence of some economic benefits (Ramukumba, 2021; Kegamba et al., 2021).

The findings support Conflict Theory by demonstrating how unequal access to tourism revenues, employment opportunities, and decision-making authority contributes to tensions among stakeholders despite formal co-management arrangements. Participants perceived that although the Makuleke community regained ownership of the land, economic benefits associated with tourism remain unevenly distributed. From a Political Ecology perspective, this reflects broader power relations that shape who controls tourism revenues, information, and development opportunities. The findings therefore suggest that benefit-sharing is not merely an economic issue but also a governance and justice concern.

Concerns regarding transparency and accountability further emerged as a significant source of tension. Participants frequently questioned the accuracy of reported tourism revenues and the adequacy of existing reporting mechanisms. As Community Member 8 stated:

"We do not trust the figures they provide, suspecting they may not reflect the real amounts being earned."

These perceptions indicate that limited access to financial information was associated with reduced accountability and weakened trust in tourism governance. Although this study did not examine audited financial records and cannot verify these claims, participant concerns reflect broader evidence that limited transparency can undermine stakeholder trust, whereas clear and accountable revenue-sharing mechanisms strengthen legitimacy and community support (Spenceley & Snyman, 2017).

A Lodge Manager 3 explained:

"The communities closer to the park, such as Bennde-Mutale, feel that they live closer to an orange tree that they cannot even pick the oranges to enjoy".

The metaphor of an "orange tree" reflects feelings of exclusion among neighbouring communities who perceive tourism benefits as inaccessible despite their proximity to the park. These perceptions suggest that benefit-sharing tensions extend beyond financial returns and include questions of fairness, recognition, and access to employment opportunities. Similar findings have been reported in protected-area tourism studies where perceived inequities contribute to stakeholder dissatisfaction and conflict (Snyman & Bricker, 2019).

The findings also revealed considerable variation in how benefits were experienced across communities. Neighbouring communities, particularly Bennde-Mutale, perceived themselves as excluded from tourism opportunities despite their proximity to the park and exposure to conservation-related costs. Community Member 14 noted:

"Jobs go to Makuleke only; we are also here and are not considered."

This concern was echoed by a tourism operator, who observed:

"The communities closer to the park, such as Bennde-Mutale, feel that they live closer to an orange tree that they cannot even pick the oranges to enjoy."

The convergence of views across stakeholder groups suggests broad recognition of uneven benefit distribution. Consistent with previous studies, participants perceived access to tourism benefits as shaped by institutional relationships, beneficiary status, and proximity to tourism opportunities rather than geography alone (Bennett et al., 2021; Kegamba et al., 2023; Mutanga et al., 2017). Importantly, perceived inequities extended beyond financial returns to include employment, information access, representation, and participation opportunities, reinforcing benefit-sharing as a broader governance issue and a significant source of tension within the MCNP co-management arrangement. The findings corroborate concerns regarding the implementation of benefit-sharing mechanisms. While the MCNP Management Plan prioritises socio-economic development through employment creation, tourism partnerships, and community benefits, participants highlighted perceived inequalities in the distribution of these benefits.

These findings provide strong support for Conflict Theory, which explains how unequal access to resources, opportunities, and benefits can generate tensions among social groups. Participants consistently perceived that tourism revenues, employment opportunities, and economic benefits were distributed unevenly despite community ownership of the land. Such perceptions contributed to dissatisfaction, mistrust, and contestation regarding tourism governance arrangements. From a Political Ecology perspective, the findings further demonstrate that benefit-sharing is not merely an economic issue but also a question of power and control over resources. The ability to influence concession agreements, access financial information, and participate in revenue-allocation decisions was viewed as equally important as the benefits themselves. Consequently, the findings suggest that tourism resource conflicts emerge not only from limited benefits but also from perceived inequalities in governance and access to decision-making processes.

Theme 3: Sustainability Implications

Participants frequently associated governance challenges, limited participation, and perceived inequities in benefit-sharing with broader concerns regarding conservation, tourism development, and community well-being. Across stakeholder groups, respondents viewed governance quality as closely connected to the long-term sustainability of the park. However, these accounts reflect stakeholders' perceptions and experiences rather than objectively verified ecological, social, or economic outcomes.

A recurring concern was that limited access to tangible benefits weakened community support for conservation initiatives. Participants argued that when local communities do not experience visible improvements in livelihoods, their willingness to support conservation efforts may decline. Community Member 11 explained:

"If there are no visible economic benefits or rewards for the neighbouring communities, they are not going to cooperate and protect the environment."

A similar view was expressed by a SANParks official. SANParks Official 1 stated:

"If people do not benefit, they stop caring about conservation and become resentful."

The convergence of perspectives between community members and SANParks officials suggests a shared recognition that perceptions of fairness and inclusion may influence attitudes towards conservation. Participants also linked exclusion from tourism opportunities and limited employment prospects to broader frustrations in community–park relations. For example, Community Member 12 remarked:

"We go into the park to poach because we need to eat. We are hungry and unemployed."

Similarly, Community Member 13 explained:

"We closed the gate because we were angry and we are not getting jobs in the park."

These accounts illustrate how some participants interpreted poaching and protest actions through the lens of unemployment, exclusion, and unmet livelihood expectations. Similar patterns have been reported in community–conservation studies, where perceived economic marginalisation is associated with declining conservation support and increased conflict (Carius & Job, 2019; Gidebo, 2022; Ghaderi et al., 2022; Koricha & Adem, 2024; Nugroho & Numata, 2020; Wei et al., 2024). However, these perceptions should not be interpreted as evidence of a direct causal relationship, as illegal resource use and conservation outcomes are shaped by complex interactions among socio-economic, governance, institutional, and contextual factors (Huber et al., 2023; Zhang et al., 2024; Zhang et al., 2025).

Lodge Manager 3 observed:

A recurring concern was that limited access to tangible benefits weakened community support for conservation initiatives. Participants repeatedly linked conservation support to the visible benefits derived from tourism. For instance, Lodge Manager 3 stated:

"If those communities are not seeing any benefits from the park, it's not going to help at all".

This observation suggests that stakeholders perceive a direct relationship between community benefits and conservation attitudes. Participants argued that when local people do not experience tangible improvements in their livelihoods, support for conservation initiatives may diminish. These findings align with studies showing that equitable benefit-sharing can strengthen conservation support, whereas perceived exclusion may contribute to resistance and conflict (Ntuli et al., 2021; Snyman et al., 2023).

The findings reinforce the relevance of the Triple Bottom Line framework by demonstrating the interconnected nature of environmental, social, and economic sustainability within the MCNP. Participants perceived that governance challenges and inequitable benefit-sharing negatively influenced all three dimensions simultaneously.

Social sustainability was affected through declining trust and strained stakeholder relationships; economic sustainability was constrained by limited employment and livelihood opportunities; and environmental sustainability was perceived to be vulnerable where local support for conservation weakened. The findings therefore suggest that sustainability outcomes cannot be achieved through conservation objectives alone but depend on balancing environmental protection with social equity and economic inclusion.

From a Stakeholder Theory perspective, the results further indicate that long-term sustainability is more likely when stakeholders perceive governance processes as fair, transparent, and responsive to their interests.

Overall, the findings suggest that visible livelihood benefits, meaningful participation, and perceptions of economic inclusion are important elements in sustaining community support for conservation and tourism development. Participants also perceived governance tensions as a potential threat to future tourism development. Community members, traditional leaders, and tourism stakeholders expressed concerns that persistent mistrust, uncertainty, and unresolved disputes could weaken collaboration and constrain investment opportunities.

Although the study did not assess actual tourism performance or investment trends, these findings indicate that stakeholders view governance quality as central to the long-term viability of tourism and conservation. More broadly, participants consistently linked exclusion from decision-making and perceived inequities in benefit-sharing to declining trust, weakened conservation support, and strained community–park relations. These findings highlight the interconnected nature of governance, conflict, and sustainability, suggesting that effective conservation outcomes depend not only on ecological management but also on governance legitimacy, meaningful participation, and equitable benefit-sharing.

The findings reinforce the Triple Bottom Line framework by demonstrating that social, economic, and environmental sustainability are interconnected and cannot be pursued independently.

CONCLUSION

The Makuleke Contractual National Park illustrates both the potential and challenges of land restitution and co-management in South Africa. While the model has created opportunities for conservation, tourism development, and community benefits, persistent governance challenges, unequal power relations, limited participation, and concerns over benefit-sharing continue to constrain sustainability. The findings suggest that legal ownership alone does not guarantee meaningful influence over decision-making or equitable access to tourism benefits.

The study highlights that sustainable tourism depends on inclusive governance, transparent decision-making, equitable benefit-sharing, and meaningful stakeholder participation. Strengthening accountability, dialogue, and collaborative management arrangements can reduce conflict and improve trust among stakeholders. The study also contributes theoretically by demonstrating the complementary value of Political Ecology, Stakeholder Theory, Conflict Theory, and the Triple Bottom Line framework in understanding tourism resource conflicts in restituted protected areas.

Political Ecology explains how historical inequalities and power relations continue to shape governance outcomes; Stakeholder Theory highlights the importance of meaningful participation; Conflict Theory explains tensions arising from unequal access to benefits; and the Triple Bottom Line framework illustrates how governance and benefit-sharing affect environmental, social, and economic sustainability simultaneously. Together, these perspectives provide a more integrated explanation of how tourism resource conflicts emerge and persist within co-managed protected areas.

The study also contributes theoretically by demonstrating the value of Political Ecology, Stakeholder Theory, Conflict Theory, and the Triple Bottom Line framework in explaining tourism resource conflicts in restituted protected areas. The findings show that co-management and land restitution do not automatically result in equitable power-

sharing, meaningful participation, or sustainable outcomes. Despite formal land ownership, the Makuleke community continues to experience limited influence in decision-making and benefit-sharing processes, reflecting the persistence of historical power inequalities. The study highlights that stakeholder influence is shaped by access to resources, expertise, and institutional authority rather than ownership alone. These findings suggest the need for stronger alignment between land restitution and conservation policies to promote transparency, accountability, and equitable benefit-sharing.

To enhance sustainability, co-management arrangements should strengthen community participation in governance structures, improve transparency in the allocation of tourism revenue, and implement participatory monitoring and decision-making processes. Capacity-building initiatives in governance, tourism management, financial literacy, and entrepreneurship should also be prioritised. Furthermore, regular stakeholder engagement forums and independent conflict-resolution mechanisms can improve trust and collaboration.

Ultimately, sustainable conservation and tourism outcomes depend on transforming legal restitution into genuine empowerment through inclusive governance, equitable benefit-sharing, and meaningful stakeholder participation.

Citation: Shao, Y. (2026). Landscape urbanism supports sponge city development in the Hangzhou Asian Games Village. *Geojournal of Tourism and Geosites*, 67(3), 2457–2468. https://doi.org/10.30892/gtg.67355-1867

Abstract: This study investigates the influence of landscape urbanism design and green infrastructure on the performance of sponge cities, an increasingly vital approach to sustainable urban water management in rapidly urbanizing contexts. Focusing on the Asian Games Village in in Hangzhou as a case study, the research explores the mediating role of stormwater management efficiency and the moderating effect of government policy support in this relationship. A quantitative method was employed, utilizing data from structured questionnaires completed by 296 urban development professionals. The hypothesized relationships were analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM). The findings confirm that both landscape urbanism design and green infrastructure significantly and positively impact sponge city performance. Stormwater management efficiency was identified as a crucial mediator in these relationships. Furthermore, the results revealed that government policy support acts as a moderator, strengthening the positive effects of landscape urbanism and green infrastructure on stormwater management. This research contributes a comprehensive conceptual model that integrates ecological design principles, operational performance, and governance frameworks. It provides practical guidance for urban planners and policymakers by highlighting the necessity of a systemic approach that combines innovative design with robust policy to create resilient and effective sponge cities, thereby advancing both theory and practice in sustainable urban development.

Keywords: landscape urbanism, sponge city, green infrastructure, stormwater management efficiency, government policy support

INTRODUCTION

Urbanization and global climate change heightened stormwater management and prevention of urban flooding concerns within cities around the world, especially in developing Asian cities (Abhijith et al., 2025) The "sponge city" is a desirable approach to maximizing urban resilience via encouraging natural absorption, storage, and purification of rainwater in cities (Chen, 2023). Sponge city planning promotes the use of green infrastructure and ecological design principles in urban planning in an effort to minimize surface runoff, remove flood threats, and enhance water quality (Chikhi et al., 2024).

Landscape urbanism, which concerns itself with merging ecological systems with urban planning, provides an interesting model for addressing the challenges of sponge cities through the creation of multifunctional spaces for human and environmental advantage (Balon et al., 2023). Specifically, planning of mass event villages, like the Asian Games Village, presents a chance to implement landscape urbanism as an integrated method in developing resilient and sustainable cities capable of managing water and enhancing human health (Aderyani et al., 2025; Daniels & Tichaawa, 2025). Research on major Chinese cities further indicates that metropolitan development is shaped by interacting economic, political, infrastructural, social, and cultural forces (Li & Dawood, 2016a). A substantial body of evidence underscores the efficacy of landscape urbanism in enhancing urban ecological performance, particularly in stormwater management. Core principles of landscape urbanism, such as ecological zoning and multifunctional landscapes, play a vital role in reducing impervious surface cover and increasing infiltration capacity—both of which are critical for effective stormwater retention and filtration.

Green infrastructure components such as bioswales, rain gardens, and green roofs further complement this approach by significantly reducing runoff volumes and improving water quality. Empirical studies from Chinese cities, for example, report up to 60% reductions in stormwater runoff during heavy rainfall events following green infrastructure implementation.

These strategies collectively contribute to improving sponge city performance by strengthening natural hydrological cycles and mitigating urban flood risks. Furthermore, stormwater management efficiency has emerged as a key mediating factor, influencing the relationship between ecological urban design strategies and overall sponge city outcomes. High-performing stormwater systems enhance the regulation of flow rates, pollutant loads, and water recycling capabilities. Government policy support also plays a moderating role, with financial incentives and regulatory frameworks significantly shaping the adoption and success of sustainable water management practices (Abhijith et al., 2025; Carranza, 2024; Grabowski et al., 2023; Grichting & Salama, 2024; Huang et al., 2025; Khoshhalshaghaji et al., 2025; Kurniawan et al., 2023; Ling et al., 2024; Mao

et al., 2025; Mendes et al., 2025; Štrbac et al., 2023). More broadly, resource-efficient innovation has been identified as a pathway toward sustainable development under technological and market turbulence (Iqbal et al., 2021).

Despite the widening knowledge base, several gaps exist in understanding the complex interactions among landscape urbanism design, green infrastructure implementation, and sponge city performance (Su & Tan, 2023; Tang et al., 2025; Zammit, 2025). First, much research to date focuses on these variables individually or considers green infrastructure technology without much consideration of the principles of landscape urbanism generally (Mendes et al., 2025). This fragmented approach restricts the fulfillment of comprehensively knowing how multifunctional urban typologies interact with stormwater systems and collectively contribute to urban resilience (Mao et al., 2025; Zhixin et al., 2025). Secondly, the mediating role of stormwater management efficiency in connecting ecological design strategies and sponge city outcomes remains insufficiently investigated, especially concerning massive-scale, transient urban complexes like the Asian Games Village (Wang et al., 2025). This gap highlights the need for empirical models to explicitly measure the way through which stormwater management acts as an avenue for design interventions to manifest into functional performance upgrades (Grichting & Salama, 2024; Liu, 2023). In addition, the moderating role of the support of government policy towards landscape urbanism and green infrastructure performance is still not adequately addressed in current studies (Balon et al., 2023). Although policy frameworks are well-documented to be key enablers, hardly any empirical studies have been conducted to examine how varying levels of policy strength and enforcement influence the relationship between design implementation and the effectiveness of stormwater management (Adedeji & Lenz, 2023; Kim, 2025; Mendes et al., 2025). This is particularly salient in the Asian context where governance arrangements in urban areas and policy environments vary considerably and impact the scalability and sustainability of sponge city initiatives (e Ali & Bashir, 2024). Closing these gaps is vital to constructing more robust, context-related frameworks that can advise on integrated urban water management strategies and help drive sustainable urban change in mega-event settings and other locales.

This article attempts to explore the complex relationships between landscape urbanism design, green infrastructure uptake, stormwater management efficacy, and sponge city performance, while highlighting the moderating role of government policy support in the context of the Asian Games Village in Hangzhou. The key objectives are: (1) to assess the direct relationships between landscape urbanism and green infrastructure and sponge city performance; (2) to examine the mediating role of stormwater management efficiency in these relationships; (3) to look at government policy support as a driver of the magnitude of these relationships. This study contributes to practice and theory significantly by providing a common model that integrates ecological design, infrastructural technology, and policy intervention in order to optimize sponge city performance. In its examination of the Asian Games Village a mega urban development project with high profile this study offers valuable information on the implementation of principles of landscape urbanism to problem conditions in the city in which sustainability and resilience are critical (Carranza, 2024). The results are anticipated to enlighten urban planners, policymakers, and environmental managers on the integral role of integrated design and governance interventions in ensuring appropriate management of stormwater and urban resilience, respectively. In addition, the research is bridging significant knowledge gaps, specifically in mediating and moderating factors influencing urban water management outcomes, thereby adding value to sustainable urbanism as a research field across Asia and the world (Suits et al., 2025).

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Landscape Urbanism Design and Sponge City Performance

Landscape urbanism planning is a planning and design approach that introduces ecological processes and landscape systems into the urban environment (Balon et al., 2023). Ecological zoning, one of its central principles, is based on the separation of city space by natural elements and environmental functions and multifunctional space that has several functions, including recreation, habitat provision, and stormwater management (Carranza, 2024). These design principles are responsible for the development of robust urban environments that enhance natural hydrological processes, biodiversity, and human well-being (Hoover et al., 2023; Mamirkulova et al., 2025). Sponge city performance, in this article, evaluates the capacity of the urban environment to capture, retain, and filter rainwater, thus barring the possibilities of flooding and water usage sustainability (Chikhi et al., 2024). Ecological zoning can minimize impervious surface flow through safeguarding natural water retention areas and preventing development from advancing to vulnerable areas (Ji & Rao, 2023). Multifunctional space, for example, parks with wetlands or retention basins, both control stormwater effectively and increase city and community appeal (Liu, 2023). Studies in various Asian cities confirmed that sites designed based on landscape urbanism principles have higher infiltration capacity and greater resilience during heavy rainfalls (Jensen & Cureton, 2024). Evidence supports the assumption that sponge city performance is positively affected by landscape urbanism design through the incorporation of ecological health and urban efficiency (Liang & Li, 2023; Liu et al., 2025).

H1: Landscape urbanism design significantly contributes to sponge city performance.

Green Infrastructure Application and Sponge City Performance

Green infrastructure refers to a decentralized network of natural systems that are designed to manage stormwater at the source (Grichting & Salama, 2024). Filter- and runoff-conveying bioswales, rain gardens for rainwater storage and infiltration, and green roofs for mitigating surface runoff by harvesting rainfall are the primary elements (Hapriyanto & Azmi, 2025). The elements support sponge city performance through enhanced infiltration, peak runoff attenuation, and improved water quality. Green infrastructure also contributes to cooling urban areas, maintaining biodiversity, and promoting greater environmental sustainability, and is therefore a major method for cities to combat dealing with climate change as well as metropolitan pressure (Khoshhalshaghaji et al., 2025). There is ample empirical evidence which bears witness to the fact that green infrastructure allows sponge city to function effectively (Kim, 2025). There are reported

consultations of sizeable runoff reductions and consultations of pollutant loads in urban spaces where rain gardens and bioswales have been implemented, especially in spaces with high intensity rainfall events (Ling et al., 2024). Green roofs, among other structures, have been reported to decrease runoff volume by up to 70%, with other thermal insulation properties (Mendes et al., 2025). Singaporean and Chinese urban case studies offer insights into the ways in which the massive deployment of green infrastructure results in the control of floods and improved urban microclimates (Štrbac et al., 2023). They form the basis of theory that green infrastructure development is a significant driver of improved sponge city performance, thus being a real-world, scalable means of sustainable urban water management.

H2: Effective implementation of green infrastructure contributes positively and significantly to sponge city performance.

Efficiency of Stormwater Management and Sponge City Performance

The efficiency of stormwater management systems and processes to treat precipitation volume and quality during and following rainfall is referred to as stormwater management effectiveness (Yadav et al., 2025). It involves features like peak flow control, enhanced infiltration, and cleaning of pollutants prior to runoff into natural water bodies (Wang et al., 2025). Appropriate stormwater management in sponge cities is important, and the challenge is to replicate the natural hydrology to alleviate flooding, recharge groundwater, and sustain urban ecological balance (Suits et al., 2025). Key performance indicators are decreased volume of runoff, decreased concentration of pollutants, and increased groundwater recharge rates (Stinshoff et al., 2025). The more sophisticated stormwater controls of more advanced cities such as detention basins, permeable pavements, and constructed wetlands have significantly lower urban flooding and water pollution rates (Mendes et al., 2025). Asian cities in their research have established that the improvement of stormwater management measures reduces surface runoff volumes by significant quantities, thus decreasing the burden on drainage infrastructure (Mao et al., 2025). These results verify the premise that the effectiveness of stormwater management positively influences the performance of sponge cities by regulating the urban system's capacity to sustain rainfall and reduce risks.

H3: The efficiency in stormwater management has a direct positive effect on the performance of the sponge city.

Stormwater Management Efficiency as Mediator

Landscape urbanism design prioritizes logical location of ecological and multifunctional spaces to enhance urban sustainability and resilience (Mao et al., 2025). The most important variables include the aspects of the design, such as ecological zoning, green corridors, and multifunctional landscapes, which enhance natural water flow and retention. Stormwater management performance refers to the degree to which urban infrastructure handles runoff volume, flow rates, and pollutant loads by functioning (Khoshhalshaghaji et al., 2025). The performance of the sponge city serves as an indicator of how well the city performs in recycling and holding back stormwater and thereby reduces flood risk and sustains ecological balance (Ma et al., 2023). The mediating role of stormwater management efficiency reveals that the advantages of landscape urbanism design in sponge city performance are primarily driven by improved capacity to handle stormwater (Liu, 2023). For instance, multifunctional landscapes in ecological zoning reduce impervious cover and increase infiltration and runoff regulation accordingly (Liu et al., 2025). Studies on Asian cities support that stormwater infrastructure incorporated in landscape urbanism planning optimizes peak flow reduction and water quality improvement benefits, and achieves effective stormwater management (Baghersad et al., 2025).

H4: The relationship between landscape urbanism design and sponge city performance is mediated by stormwater management efficiency.

Green infrastructure installation consists of integrating stormwater locally treated nature-based solutions, including bioswales, rain gardens, and green roof systems, within the urban setting. They enhance infiltration, reduce runoff, and enhance pollutant removal (Huang et al., 2025). The effectiveness of stormwater management, here used as a mediating variable, describes the extent to which such green infrastructure components maximize control of water quality and runoff in an efficient manner and thus affect citywide sponge city performance, where the urban system's capability to absorb, store, and reuse stormwater in a sustainable way is quantified (Kong et al., 2025). Thousands of studies have established that green infrastructure improves stormwater management efficiency through detrainment and filtration of contaminants and reduction and filtration of runoff peaks, respectively (Zhu et al., 2023). For instance, in an urban landscape, bioswales and rain gardens reduce volume runoff and retard peak discharge, thus improving the hydrologic capacity of urban catchments to absorb stormwater (Zhixin et al., 2025). In addition, green roofs have runoff reduction and thermal management benefits too, which supports improved hydrological performance additionally. These results show that the beneficial role of green infrastructure on sponge city performance primarily exists through its optimizing effectiveness of stormwater management (De Montis et al., 2024). Thus, stormwater management takes the functional bridge role to facilitate applications of green infrastructure to achieve its resultant benefit in sustainable urban water management.

H5: Stormwater management efficiency mediates the relationship between green infrastructure implementation and sponge city performance.

Government Policy Support as Moderator

Government policy support involves the policies, regulations, incentives, and financing instruments that make and promote sustainability-oriented approaches towards urban development (Alanazi et al., 2025; Ziari & Mosleh, 2025). Some of the most critical variables include policy interventions like zoning codes, environmental policies, fiscal policy incentives, and planning requirements that promote the use of landscape urbanism design principles (e Ali & Bashir, 2024). Whether or not stormwater management is successful serves as a proxy measure of the performance or effectiveness of how urban systems succeed in regulating and maximizing stormwater flow and quality (Kurniawan et al., 2023). Government

policy support as the moderating variable means that the positive impact of landscape urbanism design in enhancing stormwater management efficiency is more pronounced when it is supported vigorously by policies (Su & Tan, 2023). Empirical evidence indicates the requirement for policy environments to allow landscape urbanism to play its maximum possible role in urban water management (Baghersad et al., 2025). For example, cities with integrated green urban policy measures are bound to experience higher degrees of stormwater management and less flooding since they benefit from enhanced ecological zoning as well as multifunctional landscapes (Huang et al., 2025). Studies conducted in China and Singapore highlight how supportive policy settings facilitate cross-sector collaboration, allocate resources to landscape projects, and implement standards that enhance stormwater performance (Khodadad et al., 2023; Mendes et al., 2025; Zarei & Shahab, 2025). These findings validate the hypothesis that government policy support strengthens the relationship between landscape urbanism design and the effectiveness of stormwater management by providing the institution and funding necessary to overcome practical barriers and scale up successful interventions.

H6: Government policy support moderates the relationship between landscape urbanism design and stormwater management efficiency.

The deployment of green infrastructure involves mixing bioswales, permeable pavements, rain gardens, and green roofs in urban areas with a goal of managing stormwater in an environmentally friendly manner (Mao et al., 2025). Support in government policy through mixes of enabling tools such as environmental standards, finance schemes, technical specifications, and societal campaigns promoting the uptake of green infrastructure (Stinshoff et al., 2025). The efficiency of stormwater management measures the strength of cities to manage runoff volume, peak discharge, and pollutant load. The policy support moderation role indicates that this enhancing role of green infrastructure in stormwater management efficiency is intensified once the government provides substantial support and promotes it (Kong et al., 2025). Research has indicated that well-planned government policies are at the forefront in the proper implementation and functioning of green infrastructure in urban water management (Huang et al., 2025). For example, a policy incentive is stormwater fee credits and tax rebates, which have been shown to accompany higher rates of installation and maintenance of green infrastructure. In addition, planning regulations and regulatory requirements ensure that green infrastructure is incorporated in urban development plans in time to optimize its hydrological effectiveness (Zarei & Shahab, 2025). Portland and Seoul are examples or case studies demonstrating how policy support is correlated with enhanced stormwater performance, such as minimized flooding and better water quality.

H7: Government policy support moderates the relationship between green infrastructure implementation and stormwater management efficiency.

Theoretical Framework Supporting the Research

This research is grounded on the socio-ecological systems theory and urban thinking about resilience, which involves the dynamic interaction between human-built infrastructure and nature with a view to the development of resilient urban areas. Landscape urbanism design and green infrastructure are practiced as the focal ecological treatments that mimic the natural hydrological processes and thus enhance the efficiency of stormwater management a core process through which the performance of sponge cities is optimized (Jensen & Cureton, 2024). Theory suggests that urban systems work best when policy, design, and ecological elements are integrated into harmony with each other, emphasizing the government policy support function as a moderating variable in enhancing implementation and performance of green infrastructure and landscape urbanism interventions (Owojori & Erasmus, 2025). Moreover, stormwater management effectiveness serves as a mediating variable to convert design and investment in infrastructure into quantifiable impacts on sponge city performance because theories of environmental governance propose the interconnection between environmental and technological efficacy and institutional support. Such integrated planning offers a strong framework for understanding the intricate interdependencies of urban water governance and stresses the importance of integrating ecological planning, technological implementation, and policy instruments for the purpose of achieving sponge cities that are adaptive and resilient. The conceptual model of these postulated relationships is found in Figure 1, the direct effects of landscape urbanism planning and green infrastructure implementation on the performance of sponge cities, mediated by stormwater management effectiveness, and moderated by government policy support.

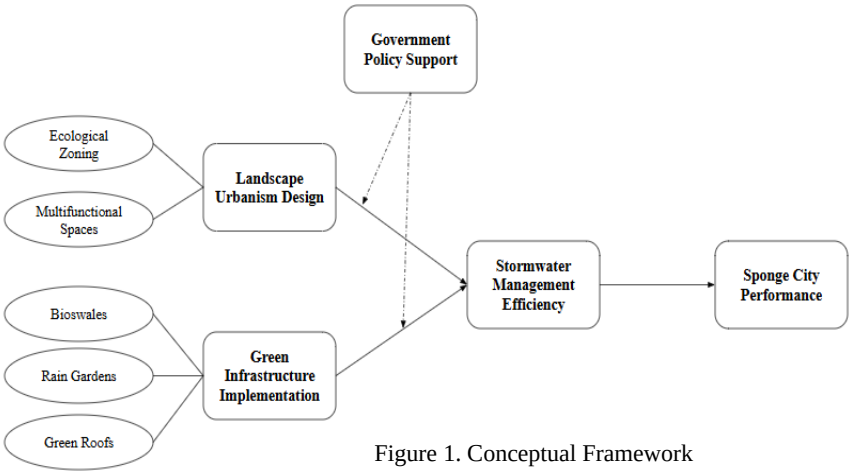

Figure 1. Conceptual Framework

METHODOLOGY

Research Design

In this research, a quantitative study design was used in an attempt to test hypothesized relationships between the main variables of sponge city performance in the context of the Asian Games Village 19th Hangzhou. More precisely, a cross-sectional survey design was used in collecting data from key stakeholders at one point in time. The application of quantitative methodology facilitated the empirical measurement of constructs such as landscape urbanism design, green infrastructure adoption, stormwater management effectiveness, and government policy enablement. Such a design facilitated the implementation of sophisticated statistical analyses to investigate direct, mediating, and moderating effects in the conceptual model proposed, hence conducting comprehensive empirical testing to corroborate or falsify the research hypotheses.

Population

The target population for this research consisted of individuals who were directly engaged in planning, designing, implementing, and governing the urban development projects of the Asian Games Village. They formed the group consisting of urban planners, landscape architects, civil and environmental engineers, sustainability advisors, and municipal policy makers possessing expert knowledge or experience in the context of sponge city initiatives, ecological urban design, and stormwater management practices. Such people have the necessary knowledge to give educated answers regarding the technical, design, and policy implications of sponge city development.

Sample Size and Sampling Technique

A purposive sampling method was utilized to choose respondents who were either directly engaged in the design, planning, or implementation of sponge city infrastructure within the Asian Games Village or possessed significant professional experience in related disciplines like landscape urbanism, environmental planning, or urban water management. The inclusion criterion demanded that participants: (1) work full-time in the fields of urban planning, landscape architecture, civil or environmental engineering, sustainability consulting, or local government, and (2) possess professional experience working on green infrastructure or stormwater management projects, preferably large-scale urban development. A list of organizations concerned, such as municipal departments, environmental departments, and private planning companies engaged in the Asian Games Village or comparable ventures, was made to select eligible respondents. 350 professionals were approached from this list, and 296 usable responses were obtained, giving an effective response percentage of 84.6%. The sample size is above the suggested limit for PLS-SEM, and it provides sufficient statistical power for analyzing complex

Data Collection

The data collection for the study was through a standardized, self-completed questionnaire that was meant to measure perceptions and experiences on landscape urbanism design, implementation of green infrastructure, effectiveness in stormwater management, government policy support, and performance of sponge cities. All the measurement items were taken from established instruments used in previous studies to ensure construct validity and reliability. Prior to the main data collection, a pilot test was applied to a sample of 15 urban planners, civil engineers, and sustainability consultants. Feedback from them was used to eliminate ambiguity in the questionnaire's language for contextualization and professional suitability, so that questions were both professionally suitable and comprehensible. Online and offline methods were adopted for data collection. The online questionnaire was circulated through email and professional platforms like LinkedIn to reach those associated with urban development and ecological infrastructure projects in China. Meanwhile, questionnaires based on paper were sent out during professional seminars, workshops of stakeholders, and project meetings concerning the development of sponge city in Hangzhou and surrounding areas. The three-month period for collecting data was used to cater to the diversified availability of professionals and provide adequate response time. The survey instrument included items measuring landscape urbanism design, green infrastructure implementation, stormwater management efficiency, government policy support, and sponge city performance, all rated on a five-point Likert scale (1 = strongly disagree to 5 = strongly agree).

Data Analysis

Data analysis was conducted using SmartPLS 4.0, a software tool designed for Partial Least Squares Structural Equation Modeling (PLS-SEM). The analysis followed a two-step approach: assessment of the measurement model and evaluation of the structural model. The measurement model was first tested to confirm reliability (using Cronbach's alpha and composite reliability) and validity (through convergent validity via Average Variance Extracted and discriminant validity using the Fornell-Larcker criterion). Once the measurement model was validated, the structural model was analyzed to test the hypothesized relationships, including direct, mediating, and moderating effects. Bootstrapping with 5,000 subsamples was employed to evaluate the significance of path coefficients. Additionally, the model's explanatory power was assessed using R^2 values, and model fit was verified through the SRMR index. This rigorous analytical process ensured robust empirical testing of the conceptual framework and hypotheses. PLS-SEM has also been applied in Chinese urban research to evaluate multiple drivers of city development (Li & Dawood, 2016b).

RESULTS

Table 1 and Figure 2 shows the reliability and validity measures of the major latent constructs in the study. All the constructs are highly reliable, as evidenced by Cronbach's alpha levels above the cut-off of 0.70. The values are between 0.774 for sponge city performance to 0.893 for landscape urbanism design, implying acceptable to exemplary reliability.

Table 1. Variables reliability and validity

	Cronbach's alpha	CR	AVE
Green Infrastructure Implementation	0.882	0.913	0.677
Government Policy Support	0.878	0.911	0.674
Landscape Urbanism Design	0.893	0.922	0.702
Sponge City Performance	0.774	0.846	0.527
Stormwater Management Efficiency	0.861	0.900	0.643

Composite reliability (CR) scores also attest to this internal consistency with all the constructs having a score greater than the acceptable value of 0.70, ranging from 0.846 to 0.922.

In the area of convergent validity, the average variance extracted (AVE) for all the constructs exceeds the recommended value of 0.50, thereby asserting that a high percentage of variance is explained by the indicators. Most importantly, landscape urbanism design bears the largest AVE at 0.702, showing robust construct representation by its measurement items. The findings uphold the reliability and convergent validity of the measurement model.

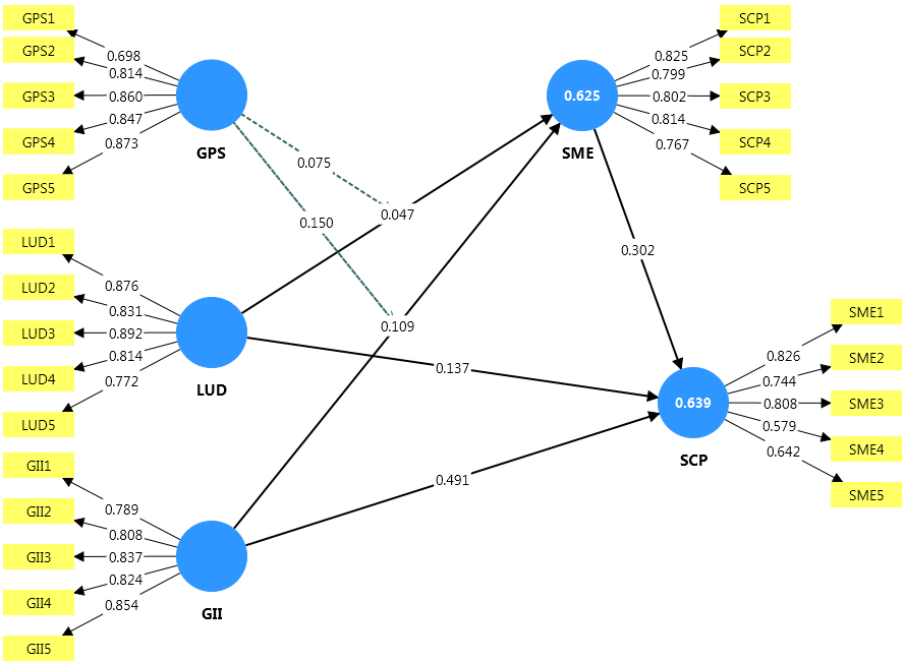

Figure 2. Estimated Model

Table 2 presents the outer loadings and variance inflation factor (VIF) values of all the measurement items for the five constructs. Outer loadings largely surpass the threshold of 0.70, depicting high item reliability and establishing that individual indicators noticeably contribute to their respective latent variables. One exception is SME4 for stormwater management efficiency, with a loading of 0.579, just below the desired cutoff but also in acceptable range for exploratory research. VIF values for all items are less than the critical value of 5, showing no serious multicollinearity problem among indicators. The set of VIF values (1.495 to 3.274) also attests to the fact that there is no possibility of collinearity to jeopardize the estimation process, and hence the measurement model is robust.

Table 2. Outer Loading and VIF

Variables	Items	Outer Loading	VIF	Variables	Items	Outer Loading	VIF
Green Infrastructure Implementation	GII1	0.789	2.724	Sponge City Performance	SCP1	0.825	2.064
	GII2	0.808	3.065		SCP2	0.799	1.811
	GII3	0.837	2.514		SCP3	0.802	1.916
	GII4	0.824	2.786		SCP4	0.814	1.980
	GII5	0.854	3.274		SCP5	0.767	1.793
Government Policy Support	GPS1	0.698	1.634	Stormwater Management Efficiency	SME1	0.826	2.247
	GPS2	0.814	2.158		SME2	0.744	1.772
	GPS3	0.860	2.609		SME3	0.808	1.888
	GPS4	0.847	2.543		SME4	0.579	1.495
	GPS5	0.873	2.800		SME5	0.642	1.696
Landscape Urbanism Design	LUD1	0.876	2.775				
	LUD2	0.831	2.167				
	LUD3	0.892	3.122				
	LUD4	0.814	2.124				
	LUD5	0.772	1.748				

Table 3. Discriminant Validity

	GII	GPS	LUD	SCP	SME
Green Infrastructure Implementation					
Government Policy Support	0.528				
Landscape Urbanism Design	0.631	0.697			
Sponge City Performance	0.838	0.787	0.815		
Stormwater Management Efficiency	0.532	0.704	0.634	0.762	

Table 4. R-square statistics Model Goodness of Fit Statistics

	R-square	R-square adjusted	Q2	SRMR
Sponge City Performance	0.639	0.636	0.631	0.074
Stormwater Management Efficiency	0.625	0.621	0.62	

Table 3 reports the Heterotrait-Monotrait (HTMT) ratios to test discriminant validity between the constructs. All HTMTs are far below the conservative value of 0.85 and indicate that every construct is empirically different from the others. For instance, the HTMT ratio for green infrastructure implementation versus stormwater management efficiency is 0.532, whereas the highest ratio attained is 0.838 between green infrastructure implementation and sponge city performance—still within an acceptable level. These results affirm that the constructs have strong discriminant validity, and they support the strength of the measurement model.

Table 4 presents the model's explanatory power and overall fit statistics. The R-square for sponge city performance is 0.639, reflecting that about 63.9% of the variance in this outcome is explained by the model variables. In a similar vein, R-square for stormwater management effectiveness is 0.625, indicating high predictive power. Adjusted R-square figures are slightly lower but above 0.60, again proving the model to be strong. The Q^2 figures for both endogenous constructs are more than 0.60, showing high predictive relevance. The SRMR value of 0.074 is less than 0.08, ensuring that the model meets an acceptable level of global fit. Collectively, these figures support the validity of the model to explain and predict the results of interest.

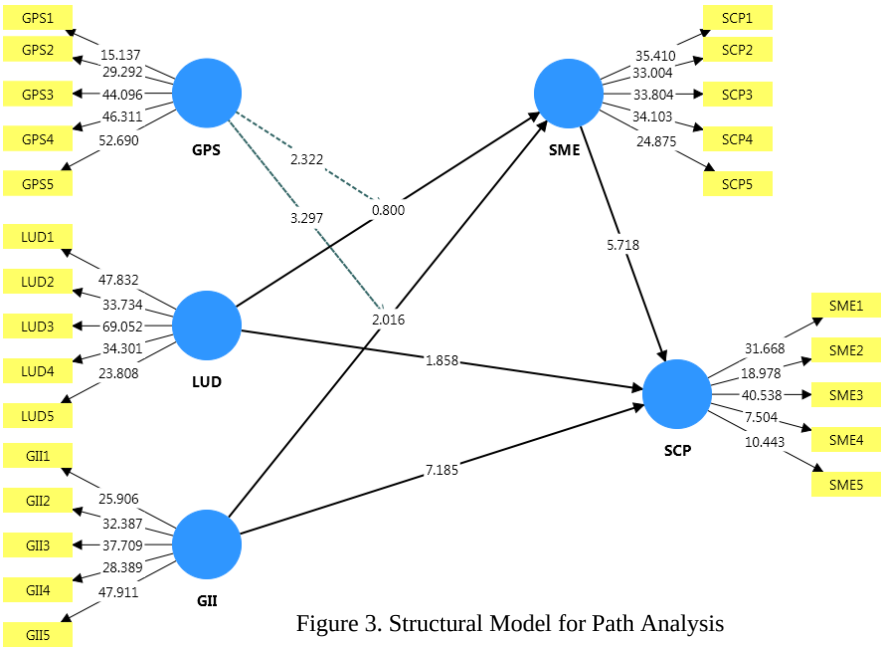

Figure 3. Structural Model for Path Analysis

Table 5 shows the outcome of the structural path analysis testing the direct, mediating, and moderating effects between the study constructs. The statistical significant path from landscape urbanism design (LUD) to sponge city performance (SCP) has a beta coefficient of 0.137, a t-value of 1.858, and a p-value of 0.032. This reflects a small but significant direct impact of landscape urbanism practice on the overall performance of sponge cities. Green infrastructure implementation (GII) reflects a high and highly significant direct impact on sponge city performance, with a beta of 0.491, t-value of 7.185, and p-value less than 0.001, indicating that green infrastructure has an important role in promoting ecological and hydrological performances in urban systems. Stormwater management effectiveness (SME) also illustrates a strong direct correlation with sponge city performance ($\beta = 0.302$, $t = 5.718$, $p < 0.001$), further establishing it as a critical working mechanism for connecting design and infrastructure with urban resilience. The mediating role of SME between LUD and SCP is statistically significant ($\beta = 0.023$, $t = 1.967$, $p = 0.025$), which indicates that stormwater efficiency partially conveys the impact of landscape design onto urban outcomes. Likewise, SME noticeably mediates green infrastructure to sponge city performance as evidenced by the beta of 0.207, t-value of 4.922, and p-value < 0.001. These findings confirm the dual mediating effect of stormwater efficiency in the hypothesized model. Additionally, government policy support (GPS) also has a significant moderating effect on the relationship between landscape urbanism and stormwater efficiency ($\beta = 0.075$, $t = 2.322$, $p = 0.010$), meaning that when policy support is high, the positive effect of landscape urbanism on

stormwater results is also heightened. The relationship between green infrastructure and GPS is also stronger ($\beta = 0.150$, $t = 3.297$, $p < 0.001$), indicating that support for policy increases the efficiency of green infrastructure implementation to enhance stormwater efficiency greatly. Generally, path analysis verifies the conceptual framework, offering empirical evidence supporting hypothesized direct, mediating, and moderating relations in the sponge city development model.

Table 5. Path Analysis

	Beta	T value	P value
LUD -> SCP	0.137	1.858	0.032
GII -> SCP	0.491	7.185	< 0.001
SME -> SCP	0.302	5.718	< 0.001
LUD -> SME -> SCP	0.023	1.967	0.025
GII -> SME -> SCP	0.207	4.922	< 0.001
GPS x LUD -> SME	0.075	2.322	0.010
GPS x GII -> SME	0.150	3.297	< 0.001

DISCUSSION

With the challenges of mounting urbanization and climatic volatility, the ability of cities to adapt, absorb, and regenerate characteristics embodied by the sponge city philosophy has never been more essential. The research was conducted within the vibrant setting of the Asian Games Village, which is a flagship development that features the latest urban resilience strategies. By means of an extensive examination of design paradigms, environmental infrastructure, operation mechanisms, and institutional settings, this study aimed at unearthing the ways through which integrated city planning principles are realized as quantifiable environmental performance. The subsequent discussion interlaces the empirical findings extracted from the tested hypotheses, providing an extended interpretation of landscape urbanism's multi-level relationships with green infrastructure, stormwater management, and policy support. All accepted hypotheses not only legitimize current theoretical assumptions but also shed light on new avenues for designing and managing resilient, hydrologically smart city spaces. The results of this research offer good empirical evidence in support of hypothesis 1, which verifies that landscape urbanism design does have a strong positive effect on the performance of sponge cities. This outcome is consistent with earlier research indicating that combining landscape architecture with ecological processes does augment hydrological functionality within cities (Mohebbi & Tahbaz, 2023).

In the Asian Games Village, the integration of landscape urbanism concepts enabled improved flood management, increased infiltration, and ecological connectedness. The composition of vegetated areas and permeable surfaces would have aided natural runoff infiltration and hence alleviated the load on traditional stormwater infrastructure. These findings confirm the potential of landscape urbanism as a design philosophy for generating robust city water cycles in demonstrating the validity of the argument that multifunctional landscape design can be both effective in fulfilling aesthetic and hydrological purposes in high-density urban settings (Grichting & Salama, 2024).

Further, this research adds to the theoretical basis of the socio-ecological systems framework by revealing that highly integrated urban landscape design interventions can be vital drivers of environmental performance and resilience, particularly within large-scale, high-profile developments like event villages.

The analysis also verifies hypothesis 2, and it is revealed that the implementation of green infrastructure has a strong positive impact on the performance of sponge cities. This is consistent with available literature highlighting green infrastructure as an effective nature-based solution for urban water problems (Hapriyanto & Azmi, 2025). In the Asian Games Village, the intentional use of green infrastructure increased stormwater uptake, lessened surface runoff, and filtered pollutants, thus strengthening the city's adaptive capacity to severe rain events. Such effects imply that engineered green systems interact synergistically with natural processes to alleviate urban flooding, manage microclimates, and enhance urban biodiversity all of which are aligned with the overall objective of sponge cities. The findings extend previous research by demonstrating that the technical effectiveness of green infrastructure is also spatial and systemic, especially when implemented coherently in a vast development area. In addition, the apparent gains in performance underscore the value of embracing decentralized water management strategies, wherein various green infrastructure components scattered across a city work in concert as a networked system (Zhang et al., 2025). From both policy and planning considerations, this makes the case for requiring green infrastructure in urban design codes and incorporating it into city-wide stormwater plans.

The evidence for hypothesis 3, which posits that stormwater management efficiency plays a significant role in determining sponge city performance, highlights the importance of effective water regulation systems to the realization of the benefits of interventions based on both design and infrastructure. This interaction proves that without efficient management strategies like flow regulation, sediment control, and retention measures, the hydrological and ecological benefits of landscape urbanism and green infrastructure can never be realized (Baghersad et al., 2025). Within the framework of the Asian Games Village, efficient stormwater management resulted from synergy between structural means (e.g., underground detention tanks, smart drainage systems) and ecological measures (e.g., vegetated swales, retention ponds), together providing the site with the capability to adapt dynamically to changeable weather conditions. The strong effect of stormwater management efficiency confirms its position as an operational center of sponge city function. It also improves our knowledge of the ways in which green technologies and spatial design help to build the resilience of cities. Theoretically, the results support the mediating role of hydrological efficiency in the socio-technical landscape of urban sustainability and indicate that it is not just the existence of green features or good design that is crucial, but also how well these elements are managed and connected to the city's larger water system (Stinshoff et al., 2025). This understanding is

especially applicable for engineers and urban planners, who need to see that stormwater infrastructure is not only environmentally integrated but technically optimized to accommodate climate variability as well as urban expansion stresses.

The findings are strongly in favor of hypothesis 4, which argued that stormwater management effectiveness mediates the impact of landscape urbanism design on sponge city performance. This conclusion outlines the essential process by which the spatial and ecological codes of landscape urbanism convert into measurable hydrologic benefits. While landscape urbanism injects permeable surfaces, ecological corridors, and multifunctional open spaces, it is the stormwater management systems in the end that control, direct, and put to use this spatial arrangement for water retention and absorption (Wang et al., 2025). The empirical evidence supporting this mediating relationship proves that design interventions are not enough unless supplemented by technically appropriate, operationally effective stormwater mechanisms. These findings are in line with systems-thought orientations towards sustainable urban planning, where it is held that performance results depend on the interaction between form (urban design) and function (infrastructure efficiency) (Balon et al., 2023). Landscape urbanism for the Asian Games Village was not cosmetic but functional in allowing efficient water capture, filtration, and slow release through skillfully aligned stormwater systems. Theoretically, this further justifies the case for integrated planning, under which spatial planning and hydrological engineering have to be balanced to produce the best sponge city results. It also emphasizes the importance of having urban design based on performance criteria, especially for flood-prone and high-density areas. Evidence in favor of hypothesis 5, which explored whether stormwater management effectiveness mediates the linkage between implementing green infrastructure and sponge city performance, also continues to expand knowledge on how ecological technologies perform within urban water cycles.

Although green infrastructure like bioswales, rain gardens, and green roofs are implemented to catch and treat stormwater at its origin, they perform better when part of a comprehensive, well-designed stormwater system. The mediating effect observed in the present study illustrates that the performance of green infrastructure is not merely dependent upon its existence but upon the manner in which it is managed, sized, and integrated into the general urban water infrastructure grid. This observation is aligned with previous studies that have established fragmented or degraded green infrastructure does not achieve intended stormwater control objectives (Huang et al., 2025). Within the Asian Games Village context, the green infrastructure elements were an integrated part of a greater, intelligently governed system that coordinated overflow management, sediment control, and water flow. Hence, the mediation effect validates the requirement for a hybridized model one that integrated soft ecological interventions with hard infrastructural controls (Yadav et al., 2025). Theoretically speaking, this discovery does support resilience-oriented models of urban water management, which promote adaptive systems that can function under changing conditions with ecological balance and service supply maintained.

The validation of hypothesis 6, where government policy support moderates the impact of landscape urbanism design on stormwater efficiency, supports the role of institutional and regulatory systems in ensuring efficient urban water management. The findings show that in settings where policy support is strengthened through financial rewards, planning requirements, and technical information the beneficial impacts of landscape urbanism on stormwater efficiency are greatly increased. This result resonates with the contention of (Adedeji & Lenz, 2023), who noted that the success of ecologically-oriented urban designs is highly contingent upon political will and regulative consistency. For the Asian Games Village, robust policy support allowed coordinated planning among urban designers, engineers, and environmental agencies such that landscape design was deliberately aligned with stormwater performance goals. The policy support moderating effect implies that even the most advanced landscape plans can fail without institutional support to guarantee implementation fidelity and cross-cutting integration (Tang et al., 2025). This also indicates that governance plays a part in turning sustainability principles into working realities. Theoretically, this finding highlights the usefulness of socio-institutional approaches to understanding urban resilience where governance is both driver and facilitator of ecological performance in complex urban systems.

Lastly, the hypothesis 7 confirmation to see if government policy support moderates the association between green infrastructure implementation and stormwater management effectiveness strengthens the argument further for policy as a strategic tool in the pursuit of sponge city objectives. The analysis indicates that when active support from local government, for example, subsidies for green roof construction, enforcement of permeable surface codes, or technical education for stormwater technicians is given, the effect of green infrastructure on stormwater effectiveness is more notable (Wang et al., 2023). This is in line with studies that emphasize policy as key in determining urban ecological change and overcoming institutional resistance. In the Asian Games Village, not only were there policies that required some of these green infrastructure components, but their correct maintenance and integration were also made possible through multi-agency coordination (Liang & Li, 2023). The moderating effect confirms that technical solutions alone cannot achieve dramatic changes unless the correct enabling environment is in place. It also supports the importance of cities following a governance-based perspective when incorporating green technologies. From a theoretical standpoint, the finding adds to adaptive governance discussion with a focus on responsive, collaborative, and strategically aligned policy systems as a necessary condition to scale up green infrastructure and realize long-term hydrological resilience in sponge cities.

In conclusion, the results for all seven hypotheses yield strong support for a multi-dimensional model in which spatial design, ecological infrastructure, operational efficiency, and policy alignment interact to define the success of sponge cities. Landscape urbanism and green infrastructure were found to directly and indirectly contribute to sponge city performance, through stormwater management efficiency as the mediating factor, and government policy support as the moderating factor. These cumulative interactions underscore that urban resilience is not the product of discrete interventions but of systemic thinking, integrative planning, and joined-up governance. The research reaffirms that cities need to transcend the reliance on piecemeal solutions and adopt a holistic approach one that acknowledges the interdependencies between form, function, and institution. By doing this, the likes of the Asian Games Village can be

living laboratories that exhibit how forward-looking urban design can balance with environmental demands and institutional requirements to create cities that are not just livable but adaptable and future-fit.

CONCLUSION

This research probed the complex dynamics of landscape urbanism and green infrastructure toward sponge city performance using the Asian Games Village as a case study. By empirically verifying seven hypotheses, the study confirmed that landscape urbanism design and green infrastructure implementation decisively improve sponge city performance, especially when facilitated by stormwater management efficiency and underpinned by effective government policy measures. The results highlight the importance of taking a systems-thinking approach one that is aware of the interdependency between spatial planning, ecological infrastructure, operational functionality, and institutional support. In affirming the mediating and moderating mechanisms involved, the research not only enriches the theoretical discussion on urban resilience and sustainable hydrological design but also provides actionable advice for practitioners and policymakers seeking to future-proof their cities against climate-driven water risks. The Asian Games Village is an example of best practice in that it shows how visionary urban planning, supported by policy and effective infrastructure, can also bring environmental and social returns. In the process, this study adds a solid conceptual and empirical basis for pushing the sponge city agenda forward, emphasizing integration, coordination, and innovation in building adaptive, resilient, and ecologically harmonious cities.

Implications

The results of this research provide crucial practical information for urban planners, city governments, architects, and environmental engineers engaged in sustainable city planning, especially in flood-affected and high-density areas. Most importantly, the proven effectiveness of landscape urbanism and green infrastructure in augmenting sponge city capability signifies the importance of their incorporation into urban master planning models right from the beginning, as opposed to afterthoughts or stand-alone green elements. As an example, rapidly developing or redeveloping cities can implement multifunctional green areas, ecological corridors, and rain gardens both to enhance the beauty of urban streets but to realize stormwater management and flood resilience. Additionally, the major mediating effect of stormwater management efficiency highlights the necessity of investing in technical capacity, smart drainage, and maintenance procedures in order for ecological design to reflect on actual hydrological performance. Local governments must also appreciate the significance of strong policy support, which was discovered to promote the effectiveness of landscape design and green infrastructure deployment. Through the provision of regulatory requirements, economic incentives, and interdepartmental cooperation, policymakers can establish an empowering environment in which sponge city measures can flourish. The Asian Games Village, being a flagship case, offers a replicable template to other city developments in striking a balance between aesthetics, livability, and climate resilience through nature-based solutions and integrated infrastructure planning.

Theoretically, the research adds to the expanding field of sustainable urbanism, urban hydrology, and environmental governance through the provision of an integrated conceptual model that relates spatial design, ecological infrastructure, functional performance, and institutional moderation. Results confirm and generalize socio-ecological systems and urban resilience theories by empirically illustrating how physical interventions (such as landscape urbanism and green infrastructure) are mediated by operational dynamics (efficiency of stormwater management) and moderated by governance variables (policy support) to yield sustainable results. Through their revelation of these nested relationships, the research contributes to theoretical knowledge on how design and infrastructure are channeled to environmental performance in complex urban systems. The established mediation and moderation effects enrich urban sustainability literature by implying that neither design nor technology operates autonomously both must be politically enabled and systemically regulated for them to be effective. Moreover, the study emphasizes the benefit of employing hybrid models that connect technical and social theories, situating cities as dynamic systems influenced by both built environment decisions and institutional pressures. These theoretical developments can guide future studies examining resilience frameworks, adaptive infrastructure planning, and governance structures in the context of climate-responsive urban development.

Limitations and Future Directions

Although this research provides useful insights into the interactions between landscape urbanism, green infrastructure, efficiency of stormwater management, and sponge city performance, some limitations must be noted. To begin with, the study is contextual, targeting the Asian Games Village as an isolated case study, which might restrict generalizability of findings to other cities with varying climatic, geographical, or regulatory conditions. The results might differ in lower resourced cities or cities without well-established policy frameworks. Second, the research was based mainly on cross-sectional data, limiting the capacity to measure long-term impacts and temporal variations in stormwater performance or infrastructure resilience. Longitudinal research could give more in-depth insights into the development and sustainability of sponge city systems over time. Third, although the model had included policy support as a moderating factor, it had not broken down the various policy dimensions (e.g., financial incentives vs. enforcement mechanisms) that might have different effects on implementation outcomes. Comparative analyses across multiple cities, incorporation of longitudinal or real-time monitoring data, and examination of further contextual factors like community engagement, maintenance practices, or public-private partnerships could be investigated in future research. Additionally, the incorporation of qualitative methods, i.e., stakeholder interviews or policy analysis, would provide an enriched understanding of institutional dynamics and implementation constraints. Such future directions would streamline and expand the theoretical model developed in this research as well as yield more in-depth strategies for sustainable urban water management.

Abstract : Medical tourism has emerged as a rapidly expanding sector within the global healthcare industry, intensifying competition among countries seeking to attract international patients. Although Jordan has established itself as a prominent regional destination for medical tourism, limited empirical research has examined the key determinants influencing international medical tourists' purchasing intentions toward Jordanian hospitals. In particular, the role of medical staff competence within the relationship between medical service quality and patients' behavioral intentions remains insufficiently explored. Accordingly, this study investigates the impact of medical service quality on international tourists' purchase intentions while examining the direct and mediating role of medical staff competence. A quantitative research design based on the descriptive–analytical approach was employed. The study population consisted of international medical tourists who visited Jordanian private hospitals for treatment, totaling approximately 92,500 patients during the first half of 2025. Using simple random sampling, 383 valid responses were collected through a structured questionnaire developed from prior literature. The data were analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM) to test the proposed hypotheses. The findings reveal that medical service quality has a significant positive effect on international tourists' purchase intentions and significantly influences medical staff competence. However, medical staff competence did not demonstrate a direct effect on purchase intention nor a mediating role in the relationship between service quality and purchase intention. This study contributes theoretically by integrating healthcare service quality and human resource competence within a unified framework to explain international patients' behavioral intentions in the medical tourism context. Practically, the findings provide strategic insights for hospital administrators and policymakers by emphasizing the importance of service quality enhancement and patient experience management in strengthening Jordan's competitiveness as a global medical tourism destination.

Keywords: service quality, purchase intention, medical staff, international tourist, medical tourism, Jordan

INTRODUCTION

In recent decades, the medical tourism sector has experienced significant expansion at both regional and global levels, largely driven by the growing demand for specialized healthcare services and increasing public awareness of health and wellness (Zhong et al., 2021). This growth has been further accelerated by structural deficiencies in healthcare systems in several countries, particularly with regard to high treatment costs, long waiting times, and inconsistencies in service quality (Karsana & Murhadi, 2021). As a result, medical tourism has progressively transformed from a peripheral activity into a well-established global industry. Beyond its healthcare dimension, the sector has become an important economic driver for many destinations due to the substantial direct and indirect revenues it generates, as well as its contribution to strengthening the international reputation and competitiveness of health destinations (Al-Nsour, 2020).

Recent market estimates highlight the rapid expansion of this industry. In 2025, the global medical tourism market was valued at approximately USD 273 billion, with an annual growth rate of 10.4%, while the number of international medical tourists reached nearly 21.1 million worldwide (Market.us Media, 2025). In addition to direct revenues generated by healthcare services, the sector has produced considerable spillover effects on the broader economy. In the same year, medical tourism contributed nearly USD 100 billion in indirect economic activity, increased government revenues by approximately 25%, supported employment growth of around 15%, and stimulated infrastructure investments estimated at USD 500 million (Market.us Media, 2025). At the national level, the sector generated direct revenues exceeding USD 1

billion by attracting approximately 224.8 thousand medical tourists in 2024, representing an estimated 0.4% share of the global medical tourism market (MOTA, 2025). These figures underscore the growing strategic importance of medical tourism as a driver of economic diversification and international competitiveness within the healthcare sector (Demir et al., 2025).

However, in an increasingly competitive global marketplace, the ability of destinations to attract international medical tourists is no longer determined solely by the availability of medical services (Choi et al., 2020). Instead, patients' decisions are strongly influenced by their perceptions of healthcare service quality, which plays a central role in shaping health-related behaviors and medical travel choices (Elgarhy & Alharethi, 2024). From this perspective, healthcare service quality has emerged as a critical determinant of international patients' evaluation of their treatment experience (Meng et al., 2022).

This is largely due to the multidimensional nature of healthcare quality, which encompasses technical, functional, and interpersonal components, including the safety of medical procedures, the accuracy of diagnosis, and the effectiveness of treatment outcomes (Demir, 2025). Furthermore, the patient experience is significantly influenced by relational aspects of care, such as the level of attention provided, the clarity of communication, and the degree of respect and transparency demonstrated by healthcare professionals throughout the treatment journey (Ye et al., 2011).

Collectively, these dimensions shape patients' overall perceptions of service quality and ultimately influence their satisfaction, trust, and willingness to engage in medical travel. In the context of medical tourism, purchase intention refers to the behavioral willingness of international patients to select a particular hospital or medical destination for treatment. This intention extends beyond the initial decision to seek medical services and encompasses the likelihood of revisiting the destination for future treatment as well as recommending it to others (Al-Nsour, 2017). From a theoretical perspective, purchase intention is widely recognized as a strong predictor of actual behavior, as suggested by the Theory of Planned Behavior, which posits that behavioral intentions reflect an individual's level of confidence and commitment toward performing a particular action (Rahman et al., 2022). Within medical tourism, such intentions are particularly significant because healthcare decisions typically involve high levels of perceived risk, uncertainty, and personal involvement. Existing empirical research consistently demonstrates that perceived healthcare service quality exerts a direct and positive influence on international patients' purchase intentions. High-quality medical services enhance patients' willingness to select a medical destination, revisit the facility, and recommend it to other potential medical tourists (Choi et al., 2020).

Nevertheless, although service quality remains a fundamental determinant of behavioral intentions, relying solely on a direct relationship between these variables may not sufficiently explain the complexity of international patients' decision-making processes. Medical tourism involves not only clinical outcomes but also interpersonal interactions and trust-building processes, which play a crucial role in shaping patient perceptions and behavioral responses (Al-Nsour, 2022).

In this regard, the competence of medical staff emerges as a critical contextual factor that may influence how perceived service quality translates into purchase intention. Medical professionals—through their clinical expertise, professional experience, and communication abilities—serve as the primary interface between healthcare institutions and international patients (Alawneh et al., 2025). Consequently, their performance represents a key element in shaping patients' perceptions of service quality and their overall healthcare experience (Farid et al., 2025). Contemporary literature suggests that medical staff competence extends beyond technical proficiency and professional qualifications (Fetscherin & Stephano, 2016). It also includes relational capabilities such as the ability to build trust, communicate effectively, demonstrate empathy, and manage interactions with patients from diverse linguistic and cultural backgrounds (Zhong et al., 2021).

Empirical studies further indicate that international patients' perceptions of medical staff competence significantly enhance their trust in healthcare providers (Park et al., 2021). Such trust contributes to higher levels of patient satisfaction, which in turn strengthens behavioral intentions, including the willingness to revisit medical destinations and recommend them to others (Khan et al., 2023). Despite the growing body of research on medical tourism, however, a review of the literature reveals a notable gap concerning the explanatory mechanisms linking healthcare service quality to purchase intention. In particular, limited attention has been devoted to examining the moderating role of medical staff competence in this relationship, especially within the context of Arab and developing countries (Al-Nsour, 2022).

Moreover, much of the existing research has predominantly focused on mediating variables such as satisfaction and destination image, while offering limited insight into how and why service quality translates into behavioral intentions. Accordingly, this study seeks to address this gap by proposing an integrated explanatory model that examines the moderating role of medical staff competence in the relationship between healthcare service quality and the purchase intention of international medical tourists. By doing so, the study contributes to advancing the theoretical understanding of international patients' behavioral decision-making while also providing practical implications for healthcare and tourism policymakers seeking to enhance the competitiveness and attractiveness of medical tourism destinations.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Medical Tourism in Jordan

The global medical tourism market has experienced sustained expansion over the past two decades and is projected to continue its upward trajectory in the coming years. Recent estimates suggest that the global medical tourism market will reach approximately USD 41.8 billion in 2024 and may expand to nearly USD 160 billion by 2032 (World Travel & Tourism Council, 2025). Within this expanding global landscape, the Middle East and North Africa (MENA) region—particularly the Arab Gulf states—has emerged as a major source market for international medical travel. Countries within the Gulf region collectively spend nearly USD 20 billion annually on healthcare services abroad, accounting for approximately 7% of the global medical tourism market (www.Alarabiya, 2025). This substantial outbound demand has contributed significantly to the development of regional medical tourism destinations, among which Jordan has established

a prominent position. The origins of medical tourism in Jordan can be traced back to the 1970s, when the country began attracting patients from neighboring states due to the availability of qualified medical professionals and relatively advanced healthcare services. Since then, Jordan has experienced remarkable progress in its healthcare sector, enabling it to become one of the leading medical tourism destinations in the region. In 2024, Jordan received approximately 224,000 medical tourists, generating revenues estimated at nearly USD 1 billion. This represents a notable increase compared to approximately 191,500 medical tourists in 2022 and 202,600 in 2023. The upward trend has continued into 2025, with approximately 92,800 medical tourists visiting Jordan by May 2025 alone, reflecting a 16.5% increase compared with the same period in 2024 (Ministry of Health, 2024). These figures highlight the growing importance of medical tourism as a strategic sector contributing to Jordan's economic development. Jordan has become a preferred medical destination for patients from several neighboring countries, particularly those within the Gulf Cooperation Council and the wider Middle East region. The country attracts a large number of patients from Saudi Arabia, Iraq, Palestine, Syria, Yemen, and Libya (Ministry of Health, 2025). This reputation is largely attributed to the long-standing development of Jordan's healthcare system and the country's history of medical achievements. For instance, Jordan performed its first open-heart surgery in 1970 and its first kidney transplant in 1972, marking important milestones in the development of advanced medical care in the region. More recently, specialized institutions such as the King Hussein Cancer Center have achieved internationally recognized clinical outcomes. In 2022, the center performed approximately 250 bone marrow transplant procedures with a success rate of around 85%, exceeding many global benchmarks. Reflecting these achievements, the United Nations World Tourism Organization recognized Jordan in 2023 as a regional hub for medical tourism, reporting that the country received nearly one million medical tourists from 71 countries during the past five years (UNWTO, 2025).

Jordan's competitiveness in medical tourism is further strengthened by its ability to combine high-quality healthcare services with relatively affordable treatment costs. Research indicates that the cost of medical procedures in Jordan is approximately 40% lower than in the United States and many European countries. Moreover, when compared with other major international medical tourism destinations—such as India, Singapore, and Thailand—Jordan remains highly competitive, with price differences generally ranging between 5% and 10% (World Travel & Tourism Council, 2025).

In addition to cost advantages, the country benefits from the availability of natural therapeutic resources that contribute to the overall attractiveness of its medical tourism offerings. Locations such as the Dead Sea, situated approximately 400 meters below sea level, are globally recognized for their mineral-rich waters and therapeutic properties, with salinity levels reaching nearly 33%. Similarly, the Ma'in hot springs, where mineral-rich waters can reach temperatures of up to 60°C, are widely used for therapeutic treatments related to skin conditions, joint diseases, and circulatory disorders (Ministry of Tourism and Antiquities, 2025). The strength of Jordan's healthcare system also plays a crucial role in supporting the growth of medical tourism. The country currently hosts approximately 121 hospitals and medical centers, including 71 private healthcare facilities and 47 public hospitals. Many of these institutions hold internationally recognized accreditations from organizations such as the Joint Commission International and the Jordanian Health Care Accreditation Council, ensuring adherence to global standards of patient safety and healthcare quality (Ministry of Health, 2025). Prominent private hospitals include the Jordan Hospital, Abdali Hospital, Al-Kindi Hospital, Ibn Al-Haytham Hospital, the Arab Medical Center, and the King Hussein Cancer Center. At the same time, major public facilities such as Al-Hussein Medical City and Al-Bashir Hospital also serve a large number of international patients.

In addition to modern healthcare infrastructure, Jordan benefits from a highly skilled medical workforce comprising more than 30,000 physicians and medical specialists. These professionals provide a wide range of advanced medical treatments, including cardiovascular surgery, oncology care, orthopedic procedures, and fertility treatments. The absence of long waiting lists for many procedures, combined with the widespread availability of English-speaking medical personnel, further enhances international patients' confidence and comfort during their treatment journeys (Abd Manaf et al., 2015). Beyond its healthcare benefits, medical tourism represents an important pillar of Jordan's national economy.

The sector contributes significantly to job creation and stimulates growth across multiple supporting industries, including hospitality, transportation, and wellness services (Chuang et al., 2014). Studies suggest that medical tourists typically spend three to five times as much as conventional tourists, owing to longer stays and the need for additional healthcare and accommodation services (Gholipour et al., 2023). Jordan's well-developed hospitality sector plays a complementary role in supporting this industry. As of April 2025, the country hosts approximately 357 classified hotels, 73 unclassified hotels, and 176 hotel apartments and suites, providing a diverse range of accommodation options suitable for patients and their accompanying companions (Ministry of Tourism and Antiquities, 2025). Furthermore, research indicates that between 2008 and 2022, revenues generated from medical tourism significantly contributed to the expansion of healthcare sectors across 49 emerging and developed economies, suggesting that increasing investment in medical tourism can further strengthen national healthcare systems and broader economic development (Gholipour & Esfandiar, 2025).

Medical Service Quality

Medical service quality is widely recognized as one of the most complex constructs in service management literature, given its direct association with human health and life, which inherently entails higher perceived risk and uncertainty than most other services (Gao et al., 2024). Over time, the conceptualization of healthcare service quality has evolved from traditional medical frameworks toward more comprehensive perspectives that integrate marketing and service management approaches. These perspectives emphasize the patient not merely as a passive recipient of healthcare but as an active participant in the service delivery process (Han et al., 2021). One of the most influential theoretical frameworks for evaluating healthcare quality is Donabedian's (1988) model, which conceptualizes quality through three interrelated

dimensions: structure, process, and outcomes. The structural dimension refers to the material, human, and organizational resources available within healthcare institutions, such as the competence of physicians, the availability of medical equipment, and health information systems. The process dimension concerns how healthcare services are delivered, including diagnostic accuracy, adherence to treatment protocols, and communication between healthcare providers and patients (Mo et al., 2025). The outcome dimension focuses on the outcomes of healthcare services, including improvements in patients' health status, reductions in complications, and patient satisfaction (Al-Nsour, 2013). Despite the emergence of several alternative approaches, the Donabedian model continues to provide a fundamental theoretical foundation for evaluating healthcare quality, particularly in studies that integrate medical and service management perspectives (Al-Nsour, 2024).

Complementing this medical perspective, service management scholars have highlighted the experiential and perceptual dimensions of healthcare service quality. Grönroos (1984) introduced the technical and functional quality model, which distinguishes between the quality of clinical outcomes received by patients (technical quality) and the service quality delivery processes (functional quality). Technical quality concerns the effectiveness of treatment, diagnostic accuracy, and professional competence. In contrast, functional quality encompasses interpersonal aspects of care, such as communication, empathy, responsiveness, and the manner in which healthcare services are delivered. Contemporary research increasingly conceptualizes perceived healthcare quality as a multidimensional construct comprising technical, human, organizational, and psychological components that shape the overall healthcare experience of international patients (Fetscherin & Stephano, 2016). In medical tourism, the perceived quality of healthcare services is particularly critical, as international patients evaluate medical destinations not only on clinical outcomes but also through a comprehensive assessment of their overall treatment experience. Empirical studies indicate that international patients assess healthcare service quality through several indicators, including treatment safety, efficiency of medical procedures, reliability of outcomes, and the level of empathy and personalized care provided by medical staff. Trust in healthcare providers and the ability of medical personnel to communicate effectively across cultural and linguistic barriers also play crucial roles in shaping perceptions of healthcare quality (Elgarhy & Alharethi, 2024). Consequently, medical tourists' decisions are influenced by a broader evaluation of the healthcare environment in the host destination, including perceptions of safety, transparency of medical information, ease of procedures, respect for patient privacy, and treatment costs (Aboalganam, 2024; Rauf et al., 2024). High levels of perceived service quality have been shown to enhance trust, reduce perceived risks, and ultimately influence patients' behavioral intentions, including destination selection, revisit intentions, and recommendations to others (Khan et al., 2023).

In this regard, healthcare service quality represents a fundamental pillar in strengthening Jordan's competitive position as a leading destination for medical tourism at both regional and international levels (Gao et al., 2024). Over the past decades, Jordan has developed a strong reputation in the healthcare sector due to the presence of highly qualified medical professionals, advanced healthcare infrastructure, and the adoption of internationally recognized accreditation standards by many hospitals and medical centers. These factors have significantly enhanced the credibility of Jordanian healthcare institutions and increased the confidence of both domestic and international patients in the quality of services provided.

The literature consistently emphasizes that healthcare service quality is among the most influential determinants shaping patients' decisions when selecting medical tourism destinations, as perceptions of care quality and the professional competence of healthcare providers directly affect patient satisfaction and trust in healthcare institutions (Rahman et al., 2022). Jordan's healthcare sector has undergone significant development, supported by a highly skilled medical workforce, continuous technological advancement in medical equipment, and the expansion of specialized hospitals and healthcare facilities. Moreover, many Jordanian hospitals have obtained international accreditation from globally recognized organizations such as the Joint Commission International (JCI) and the Health Care Accreditation Council (HCAC), which strengthens international confidence in the quality and safety of healthcare services provided in the country (Al-Ababneh, 2020). Importantly, healthcare service quality extends beyond clinical competence to include broader dimensions of patient-centered care, such as effective communication between healthcare providers and patients, responsiveness to patient needs, the efficiency of nursing services, and the provision of a safe therapeutic environment (Abdul-Rahman et al., 2023).

These elements collectively enhance the patient experience, increase patient satisfaction, and encourage positive behavioral outcomes, such as repeat visits and referrals to other medical tourists (Abdullah et al., 2023). The relatively high quality of therapeutic services in Jordan, combined with treatment costs that are competitive with those of many developed healthcare systems, has played a crucial role in attracting international patients, particularly from the Middle East and North Africa. Patients travel to Jordan to receive specialized medical treatments across various fields, including cardiac surgery, orthopedic procedures, ophthalmology, cosmetic surgery, and rehabilitation medicine.

Empirical evidence suggests that the high level of medical expertise and the quality of healthcare services available in Jordan are among the most influential factors shaping patients' decisions to select the country as a preferred medical tourism destination (Shriedeh & Ghani, 2019). Accordingly, therapeutic service quality represents a central determinant of Jordan's competitiveness within the global medical tourism market.

Recent statistics further confirm Jordan's sustained attractiveness as a medical tourism destination. The Jordan Tourism Board reports that the number of medical and wellness tourism visitors reached approximately 224,740 in 2024, and 52,500 were recorded during the first half of 2025, reflecting continued demand for therapeutic services in regional markets (TTN Worldwide, 2025). In terms of healthcare capacity, the Jordanian health system comprises approximately 120 hospitals with nearly 15,999 beds, including 70 private hospitals with 5,529 beds, providing a robust operational base for serving international patients (Ministry of Health, 2024). Furthermore, the expansion of international accreditation within the healthcare sector—where seven hospitals have obtained Joint Commission International (JCI)

accreditation and numerous facilities are accredited by HCAC—serves as an important signal of quality assurance and patient safety for international medical tourists (Tamimi et al., 2024).

Purchase Intention of International Tourists

In studies of international medical tourism, purchase intention is frequently used as a proxy for actual purchase decisions because it is a more feasible and measurable indicator of potential consumer behavior. Purchase intention reflects an individual's willingness or likelihood to obtain a specific service in the future and is widely recognized as a strong predictor of actual behavior in both consumer behavior and healthcare service research (Meng et al., 2023). This concept serves as an important link between individuals' perceptions and evaluations, on the one hand, and their actual behavioral decisions, on the other (Demir et al., 2025). Behavioral frameworks such as the Theory of Planned Behavior (TPB) emphasize that behavioral intention constitutes the most immediate determinant of actual behavior, as it reflects individuals' readiness to perform a particular action based on their attitudes, perceived social norms, and perceived behavioral control (Putra et al., 2024). Consequently, purchase intention has become a widely adopted construct for predicting future healthcare consumption and medical travel decisions (Yilmaz et al., 2021).

Within the context of medical tourism, the concept of purchase intention assumes greater complexity compared with traditional tourism or other consumer services. The decision is not limited to purchasing a single product or service; rather, it involves selecting an integrated healthcare system that includes the treatment destination, hospital, physician, and supporting healthcare services, often within a different cultural and linguistic environment (Zhong et al., 2021). As a result, international patients typically undergo a complex decision-making process that involves extensive information search, evaluation of healthcare quality, assessment of perceived risks, comparison of treatment costs, and consideration of alternative medical destinations before making a final treatment decision. Because these processes occur before the actual treatment stage, measuring the real purchase decision during data collection is often difficult. Therefore, purchase intention provides a more appropriate construct for capturing patients' behavioral tendencies during the evaluation and planning stages of medical travel (Gao et al., 2024). In medical tourism literature, purchase intention is generally conceptualized as a multidimensional behavioral construct comprising several interconnected outcomes, such as the intention to select a particular medical destination, the intention to revisit the destination for future treatment, and the intention to recommend the destination to others (Esfandiar & Hadinejad, 2026). These behavioral outcomes collectively reflect the degree of confidence and trust that patients place in healthcare providers and treatment facilities (McCartney & Wang, 2024)

Empirical studies indicate that international patients' intentions to seek treatment abroad are strongly influenced by perceived healthcare service quality, trust in medical professionals, destination reputation, and expected treatment outcomes (Fetscherin & Stephano, 2016; Khan et al., 2023). Medical tourism decisions are typically characterized as high-involvement and high-risk, as they entail potential health, psychological, and financial consequences (Rauf et al., 2024). The high perceived risk encourages international patients to conduct intensive information searches, compare alternative treatment options, and rely heavily on external sources such as prior patient experiences, reputation signals, and institutional credibility (Al-Nsour et al., 2021). Consequently, purchase intention becomes highly sensitive to the perceived quality of the overall treatment experience rather than merely the final medical outcomes (Rauf et al., 2024; Seow et al., 2024).

Furthermore, existing research suggests that the relationship between perceived service quality and purchase intention is not necessarily direct or linear. Instead, it is often influenced by several mediating and contextual factors, such as patient satisfaction, trust in healthcare providers, and perceptions of medical staff competence (Lee et al., 2021). When international patients perceive high service quality, combined with a strong sense of security and trust in healthcare institutions, they are more likely to exhibit positive behavioral responses, including intentions to revisit medical destinations and recommend them to others (Wong et al., 2024). This finding reinforces the notion that purchase intention emerges from a complex interpretive process involving multiple psychological and experiential factors (Al-Nsour & Al-Sahli, 2024). In the Jordanian context, medical tourists' purchase intention appears to be shaped by several overlapping factors, including the country's medical reputation, the perceived quality of healthcare services, the ease of administrative procedures, and the professional competence of medical staff (Al-Nsour & Al-Sahli, 2024).

Some studies have also highlighted revisit intention as a key indicator of the long-term success and sustainability of medical tourism destinations (Al-Nsour et al., 2025). Despite these contributions, the literature still lacks sufficient empirical models that comprehensively explain how perceived healthcare quality translates into purchase intention, particularly through the influence of human-related factors such as medical staff competence. Accordingly, further research is required to develop integrated explanatory models that clarify the mechanisms through which service quality perceptions are transformed into positive behavioral intentions among international medical tourists (Aladwan et al., 2024).

Medical Staff Efficiency

The conceptual overlap between human resource efficiency and medical service quality has been widely discussed in healthcare management literature. Addressing this overlap requires a clear distinction between the two constructs from both theoretical and methodological perspectives (Aiken et al., 2018). Human resource efficiency refers to the level of competencies, professional skills, clinical expertise, training, and performance capabilities possessed by healthcare personnel that enable them to perform their roles effectively within healthcare organizations (Al-Nsour, 2019). In contrast, medical service quality reflects the overall standard of healthcare delivered to patients and the extent to which healthcare services meet recognized quality dimensions such as patient safety, effectiveness of treatment, accessibility, and continuity of care (Lake et al., 2019). Accordingly, human resource efficiency should be conceptualized as a determinant or

influencing factor of healthcare service quality rather than a component of it. From a methodological perspective, empirical research typically maintains this distinction by treating human resource efficiency as an independent variable that influences healthcare service outcomes, while therapeutic healthcare service quality is treated as a dependent variable.

Separate measurement indicators are applied to each construct to reduce conceptual overlap and improve analytical clarity (Aiken et al., 2018). Human resource efficiency may be assessed through indicators such as staff competence, professional training, productivity, and continuous professional development, whereas healthcare service quality is commonly evaluated through indicators including patient safety outcomes, treatment effectiveness, and patient satisfaction (Ramar et al., 2025). This conceptual separation allows researchers to better analyze how workforce capabilities influence healthcare service outcomes and organizational performance within healthcare systems (Lake et al., 2019).

Within this framework, medical staff competence represents a key dimension of human resource efficiency in healthcare institutions. Medical competence refers to an integrated combination of scientific knowledge, clinical expertise, professional skills, behavioral abilities, and cumulative experience possessed by physicians, nurses, and healthcare technicians that enables them to provide safe and effective treatment services consistent with professional and ethical standards (World Health Organization, 2024). Importantly, medical competence extends beyond the technical aspects of diagnosis and treatment to include interpersonal communication skills, empathy toward patients, responsiveness to patient needs, and the ability to work effectively within multidisciplinary healthcare teams (Khaleel et al., 2022). These competencies play a crucial role in strengthening patients' trust and shaping their perceptions of healthcare service quality. Recent research confirms that higher levels of medical staff competence contribute significantly to improving treatment outcomes, reducing medical errors, and enhancing patient safety within healthcare institutions (Al-Nsour, 2019).

These improvements are reflected in increased patient satisfaction and stronger behavioral intentions toward healthcare providers, including willingness to revisit and recommend healthcare institutions to others (Mikulić et al., 2021). In the context of medical tourism, the competence of medical personnel becomes even more critical, as international patients often rely heavily on the professional reputation of physicians and hospitals when deciding to travel abroad for treatment (Zhong et al., 2021). This reliance is particularly important in situations characterized by cultural, linguistic, and institutional differences that may increase perceived uncertainty among international patients (Yilmaz et al., 2021). Empirical studies indicate that competent medical staff not only enhance the perceived quality of treatment services but also play an important role in translating perceptions of service quality into positive behavioral outcomes among international patients, including purchase intention and destination loyalty (Naqrash et al., 2025). Consequently, the efficiency and competence of medical personnel represent strategic variables within healthcare performance evaluation models, particularly in competitive healthcare environments seeking to position themselves as leading destinations for medical tourism, such as Jordan (Alawneh et al., 2025).

The importance of human resource efficiency is clearly reflected in the healthcare workforce structure in Jordan. According to national statistics, the density of physicians in Jordan reaches approximately 31.7 physicians per 10,000 people, while the density of nurses is approximately 37.5 per 10,000 people (Ministry of Health, 2022). These levels support the healthcare sector's capacity to deliver treatment services based on high levels of clinical expertise and professional competence. They also help explain the strong regional reputation of Jordanian medical personnel, particularly in managing complex medical cases and addressing the needs of patients from diverse cultural backgrounds (World Health Organization, 2024). From a broader economic and tourism perspective, the growing role of healthcare services is also reflected in Jordan's tourism performance. Reports from the Ministry of Tourism and Antiquities indicate that total tourism revenues reached approximately JD 5.132 billion in 2024, with medical treatment activities contributing to the expansion of tourism-related economic activities in recent years (Ministry of Tourism and Antiquities, 2025). These trends suggest that medical tourism represents a relatively resilient component of the tourism value chain, particularly during periods of economic uncertainty in international tourism markets. In this context, medical service quality in Jordan should not be viewed solely as a technical outcome of clinical performance but rather as the result of an integrated healthcare system in which institutional accreditation, healthcare capacity, workforce competence, and patient experience interact to create a sustainable competitive advantage in the regional medical tourism market (Naqrash et al., 2025).

Developing Research Hypotheses

The Impact of the Medical Services Quality on the Purchase Intention of International Tourists

Numerous empirical studies have demonstrated a positive relationship between the perceived quality of medical services and patients' purchase intentions in medical tourism contexts. High levels of perceived service quality enhance patients' confidence in healthcare providers and reduce perceived risks associated with seeking treatment abroad, thereby increasing the likelihood of making a medical travel decision (Yilmaz et al., 2021). In particular, research conducted in regional medical tourism destinations, including Jordan, indicates that factors such as the accuracy of diagnosis, the efficiency of medical procedures, and the level of human care and attention provided by healthcare professionals represent key determinants influencing purchase intentions among patients from Arab countries (Farid et al., 2025; Raoofi et al., 2024). However, the relationship between healthcare service quality and purchase intention is not always direct.

Several studies suggest that service quality may influence purchase intention indirectly through mediating variables such as patient satisfaction, destination image, and trust in healthcare institutions (Abubakar & Ilkan, 2016; Chahal & Kumari, 2012). From this perspective, international patients' decisions to seek treatment abroad are shaped by a broader evaluation process that includes not only clinical quality but also additional contextual factors such as treatment cost, the physical healthcare environment, ease of travel, and the availability of logistical support services. Moreover, some empirical evidence indicates that the direct impact of medical service quality on purchase intention may become

insignificant in certain contexts where healthcare providers offer relatively similar levels of service quality. In such situations, international patients may rely on alternative signals when selecting medical destinations, including physician reputation, institutional credibility, and destination attractiveness (Ye et al., 2011; Malkawi et al., 2025). These findings highlight the importance of complementary factors—particularly those related to the professional reputation and competence of physicians—in motivating purchasing behavior and shaping international patients' medical travel decisions.

H1: Medical service quality positively influences purchase intention in medical tourism.

The Impact of the Jordanian Medical Service Quality on the Medical Staff Competence

Several empirical studies have reported a positive relationship between medical service quality and the competence of medical staff. In particular, local studies suggest that the implementation of comprehensive healthcare quality standards—such as clinical risk management systems and patient-centered care practices—can contribute to improving the professional performance and competence of medical personnel (Naqrash et al., 2025). For example, research conducted in internationally accredited private hospitals found that the adoption of integrated quality management systems positively influences medical staff competence by encouraging adherence to standardized medical procedures, reducing clinical errors, and strengthening multidisciplinary collaboration among healthcare teams (Raoofi et al., 2024).

However, the relationship between medical service quality and medical staff competence remains conceptually complex and has produced mixed empirical findings. Some scholars argue that the relationship may operate in the opposite direction, as medical staff competence constitutes a fundamental input in achieving high-quality healthcare services rather than being an outcome of service quality itself (Chahal & Kumari, 2012). From this perspective, attributing improvements in staff competence solely to healthcare quality initiatives may lead to misleading interpretations, particularly in healthcare systems characterized by limited resources or high patient volumes. In such contexts, the implementation of strict quality standards may increase administrative workload and procedural requirements for healthcare professionals, potentially restricting their professional flexibility and negatively affecting perceptions of their competence (Ye et al., 2011). Furthermore, several studies have reported inconclusive or insignificant relationships between treatment service quality and the competence of medical staff, especially in healthcare institutions where professional performance relies heavily on the accumulated experience and expertise of physicians and nurses (Mikulić et al., 2021). In these cases, the professional competence of healthcare workers is largely shaped by factors such as continuous medical education, long-term clinical experience, and established professional cultures, which may operate independently of formal institutional quality policies. Therefore, the relationship between healthcare service quality and medical staff competence should be viewed as a dynamic and potentially reciprocal interaction rather than a simple linear relationship. This perspective highlights the importance of examining contextual and organizational factors that may influence how healthcare quality systems interact with workforce capabilities within healthcare institutions.

H2: Medical service quality positively influences medical staff competence.

The Impact of Medical Staff Competence on Purchase Intention of International Tourists

Some studies suggest that the competence of medical staff does not necessarily represent a decisive factor in shaping purchase intention among international medical tourists. In many cases, medical competence is perceived as a basic requirement rather than a distinguishing attribute, particularly in countries that already enjoy a strong reputation for highly qualified healthcare professionals and advanced educational systems. Under such circumstances, international patients tend to focus more on the overall treatment experience, including aspects such as the hospital's physical environment, the efficiency of administrative procedures, the availability of support services, and the comparative cost of treatment relative to competing destinations. Consequently, the competence of medical staff may be viewed as an implicit or expected attribute that does not significantly differentiate between healthcare providers during the decision-making process (Connell, 2013; Al-Hadid & Al-Salaymeh, 2019). Similarly, several studies have reported that the influence of medical staff competence on purchase intention may occur indirectly rather than through a direct relationship. In these cases, the competence of healthcare professionals contributes to strengthening mediating variables such as patient trust, satisfaction, and the perceived image of the medical destination, which in turn influence patients' behavioral intentions toward seeking treatment abroad (Yilmaz et al., 2021). In contrast, other studies—particularly recent research conducted in the Jordanian context - emphasize the critical role of medical staff competence in shaping international patients' purchase intentions. Given the high level of perceived risk associated with traveling abroad for medical treatment, international patients often rely on signals related to physicians' professional expertise, clinical experience, and the competence of nursing staff when evaluating healthcare institutions.

For example, the study conducted by Khaleel et al. (2022) found that international patients' awareness of physicians' expertise and the professional competence of nursing staff significantly enhances trust in healthcare providers and reduces uncertainty, thereby positively influencing purchase intention. Similarly, Karsana & Murhadi (2021) reported a direct positive effect of medical staff competence on purchase intention in Jordanian private hospitals. Additional evidence provided by Abu Alhaija et al. (2024) indicates that the professional reputation and sub-specialization of Jordanian physicians represent key competitive advantages for the country in the regional medical tourism market.

Furthermore, a recent study by Al-Nsour (2022) demonstrates that the competence of medical staff contributes to strengthening the international image of Jordanian hospitals, which in turn positively affects medical tourists' purchase intentions and loyalty toward healthcare institutions. Based on the above discussion, the following hypothesis is proposed:

H3: Medical staff competence has a positive effect on purchase intention among international medical tourists.

The Mediator Role of Medical Staff Competence in the Relationship between the Jordanian Medical Service Quality and the Purchase Intention of International Tourists

Several studies have highlighted the mediating role of medical staff competence in the relationship between medical service quality and purchase intention. These studies are based on the premise that the perceived quality of medical services does not automatically translate into positive behavioral intentions among international patients.

Rather, the effect of service quality is often realized through patients' direct interaction with competent medical professionals, where clinical expertise, human interaction, and the establishment of trust become critical elements in shaping patients' perceptions and behavioral responses (Yilmaz et al., 2021). In this perspective, healthcare service quality represents a structural input within the healthcare system, while medical staff competence functions as an explanatory mechanism that transfers the influence of perceived service quality into positive behavioral outcomes such as revisit intentions and recommendations. Empirical evidence further suggests that the competence of medical personnel enhances international patients' understanding of the value of healthcare services and reduces the perceived risks associated with seeking treatment abroad. By strengthening clinical trust and confidence in healthcare providers, competent medical staff can significantly increase patients' willingness to travel for treatment and their future purchase intentions (Mikulić et al., 2021). In the Jordanian context, previous studies indicate that several core dimensions of medical service quality—such as reliability, empathy, and assurance—are closely linked to the performance of physicians and nursing staff. This observation supports the assumption that medical staff competence may function as an intermediary mechanism through which service quality influences patients' behavioral intentions (Shriedeh & Ghani, 2017).

However, other scholars have raised conceptual concerns regarding the mediating role of medical staff competence. Some studies argue that the competence of medical personnel should be treated as an integral component of healthcare service quality rather than as an independent mediating variable (Chahal & Kumari, 2012). From this perspective, introducing medical staff competence as a mediator may lead to construct overlap, thereby weakening the explanatory power of causal models examining service quality and behavioral outcomes (Al-Qahtani & Al-Nsour, 2025).

Empirical evaluations of private hospitals in Jordan also suggest that elements such as physicians' professional skills, nurses' behavior, and response speed are often included within service quality measurements themselves, which means that their influence on purchase intention may occur directly through perceived service quality rather than through a separate mediating pathway (Alkhatib & Aloqaily, 2024). Furthermore, some studies have reported weak or insignificant mediating effects of medical staff competence, even when healthcare service quality demonstrates a direct influence on purchase intention. This may occur because other explanatory mediators—such as destination image, institutional trust, or perceived reputation—play a stronger role in shaping medical tourists' behavioral intentions (Demir, 2025). These findings suggest that international patients' decisions are influenced not only by clinical interactions with healthcare professionals but also by broader contextual factors, including the international reputation of medical institutions, treatment costs, ease of travel, and the availability of supporting services.

Despite these differing perspectives, examining the mediating role of medical staff competence remains important for understanding the mechanisms through which healthcare service quality influences international patients' behavioral intentions. Accordingly, the following hypothesis is proposed:

H4: Medical staff competence mediates the relationship between medical service quality and purchase intention among international medical tourists.

METHODOLOGY

1. Research Design: Research design refers to the structured framework that guides the process of data collection, measurement, and analysis to address the research problem effectively and enable the generalization of findings from the sample to the target population (Pandey & Pandey, 2015). In this study, a descriptive–causal research design was adopted to examine the relationships between the study variables. This design allows the researcher to describe the characteristics of the phenomenon under investigation and to analyze the causal relationships between variables. Specifically, the study aims to investigate the effect of medical service quality in Jordanian private hospitals on international medical tourists' purchase intention, while examining the mediating role of medical staff competence in this relationship.

2. Research Approach: According to Malhotra (2021), research approaches can generally be classified into qualitative and quantitative methods. Qualitative research focuses on gaining an in-depth understanding of phenomena through methods such as interviews, focus groups, and open-ended questions. In contrast, quantitative research aims to analyze relationships among variables using numerical data and statistical techniques. Since the primary objective of this study is to collect measurable data from a large group of respondents and test the relationships between variables, a quantitative research approach was employed. This approach involves collecting data through structured questionnaires, converting responses into numerical values, and applying statistical analyses to test the study hypotheses and draw conclusions (Malhotra, 2021).

3. Research Population: The population of the study consists of all international medical tourists receiving treatment in private hospitals in Jordan. According to the Jordanian Ministry of Health, the number of medical tourists reached approximately 92,500 visitors as of May 2025 (Ministry of Health, 2025). Based on standard sample size calculation formulas with a 95% confidence level, a 5% margin of error, and a population proportion of 50%, the recommended minimum sample size for this population is 383 respondents (calculator.net).

4. Sampling Method: To ensure representativeness, the study employed a simple random sampling technique, which is one of the most widely used probability sampling methods. In this method, each member of the population has an equal

chance of being selected, thereby reducing sampling bias and improving the reliability and validity of the results (Malhotra, 2021). A total of 383 medical tourists were randomly selected from patients receiving treatment in Jordanian private hospitals. Data regarding international patients were obtained through the Foreign Patients Offices located in the hospitals, which are supervised by the Jordanian Ministry of Health. These offices facilitated the identification and counting of medical tourists during the data collection period. All distributed questionnaires were successfully returned, resulting in a 100% response rate (383 questionnaires) used for final analysis. The data collection period took place in June 2025, which coincided with a period of increased demand for medical services in Jordan. Several factors contributed to this increase, including seasonal growth in international tourism during the summer months, school and university holidays in many source markets, and the return of Jordanian expatriates to the country during the summer season.

5. Unit of Analysis: The unit of analysis in this study consists of individual international medical tourists receiving treatment in Jordanian private hospitals. Through coordination with the Foreign Patients Offices in hospitals, questionnaires were distributed to medical tourists whose health conditions allowed them to participate in the survey and respond to the questionnaire items.

6. Data Collection Sources: The study relied on two main sources of data. Secondary data were obtained through a comprehensive review of the relevant literature, including academic books, peer-reviewed journal articles, university theses, official reports, and statistical data published by local and international institutions related to medical tourism and healthcare services. Primary data were collected through a structured questionnaire specifically developed to measure the study variables and to obtain responses directly from international medical tourists receiving treatment in Jordanian private hospitals.

7. Measurement Scale: The study variables were measured using a five-point Likert scale, which is widely used in social science research to measure attitudes and perceptions. The scale ranged from 1 (very low) to 5 (very high) to indicate the level of agreement with each statement. The Likert scale was used to measure the independent variable (medical service quality), the dependent variable (purchase intention), and the mediating variable (medical staff competence).

8. Research Instrument: The primary data collection instrument used in this study was a structured questionnaire. The questionnaire consisted of a series of statements designed to measure respondents' perceptions regarding the study variables. The survey was administered to medical tourists receiving treatment in the selected private hospitals. In some cases, respondents requested to complete the questionnaire at a later time; therefore, the researcher also provided electronic versions of the questionnaire through WhatsApp, Messenger, and email. The questionnaire was developed using Google Forms, allowing for easier distribution and data collection. To ensure the validity and clarity of the measurement instrument, the initial questionnaire was reviewed by a panel of academic and professional experts in healthcare management and tourism studies. Their feedback was used to refine the questionnaire items and ensure that the instrument accurately reflects the study constructs and research objectives.

After reviewing and discussing the existing literature, the main hypothesis of the study can be formulated as follows:

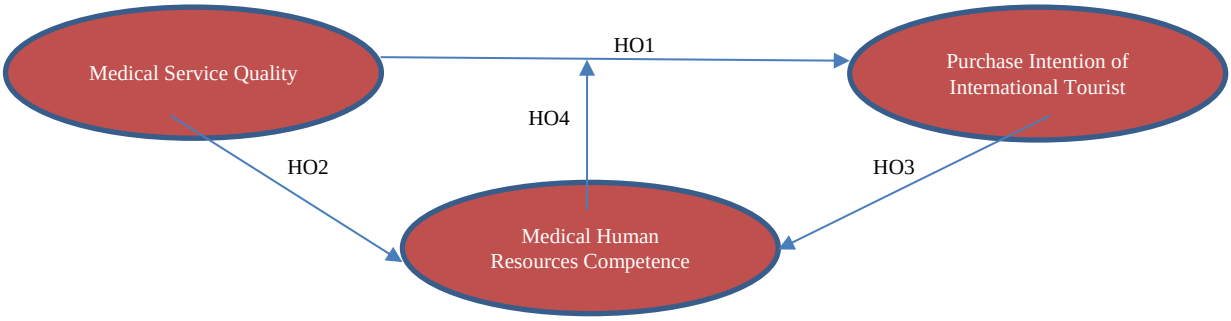

Figure 1. The Conceptual Model

Figure 1 illustrates the proposed research model, which conceptualizes medical service quality as the independent variable, purchase intention as the dependent variable, and human resource competencies as the mediating variable. This model is theoretically grounded in the service marketing and healthcare management literature, which consistently emphasizes that perceived service quality is one of the most influential determinants of consumer behavior and purchasing decisions. Previous studies in service marketing demonstrate that customers' perceptions of the quality of services provided significantly influence their behavioral intentions, including purchase intention and the intention to continue using a particular service provider (Farid et al., 2025; Parasuraman et al., 1988).

Within the healthcare context, the perceived quality of medical services plays a crucial role in strengthening patients' trust in healthcare institutions and increasing the likelihood that they will seek services from the same provider in the future. High levels of service quality contribute to improving patients' confidence in healthcare providers, which ultimately enhances their willingness to utilize healthcare services and recommend them to others (Kotler & Keller, 2016). Therefore, medical service quality can be considered a primary factor influencing international patients' behavioral intentions when selecting medical tourism destinations. At the same time, healthcare services are characterized by a high degree of human interaction, which makes human resource competencies a critical factor in translating service quality into positive patient experiences.

The competence of healthcare professionals—including their clinical expertise, communication skills, and professional behavior—plays a vital role in shaping patients' perceptions of healthcare quality and their overall treatment experience. Effective interaction between medical staff and patients enhances trust, reduces perceived risks, and strengthens patients'

confidence in the healthcare institution (Tran et al., 2025). Accordingly, human resource competencies may function as a mediating mechanism that explains how perceived medical service quality influences patients' purchase intentions. Through their professional competence and interaction with patients, healthcare personnel contribute to transforming perceived service quality into positive behavioral outcomes, such as the intention to seek treatment, revisit the healthcare institution, or recommend it to others. This mediating role is particularly important in medical tourism contexts, where international patients rely heavily on the competence and professionalism of healthcare staff when making treatment decisions in foreign destinations.

DESCRIPTIVE FREQUENCIES OF THE RESEARCH MODEL

Table 1 shows the descriptive statistics that determine respondents' perceptions regarding the study variables, including Jordanian medical service quality, purchase intention, and medical staff competence.

1. Jordanian Medical Services Quality (Independent Variable): The variable was measured using nine items. The results indicate that seven items were rated at a very high level and two items at a high level. The overall mean score was 4.309 (SD = 0.861), indicating a very high perceived level of medical service quality among international medical tourists. Approximately 82.7% of respondents expressed agreement with the statements related to this construct, suggesting that respondents generally perceive Jordanian medical services as highly reliable and effective.
2. Purchase Intention (Dependent Variable): Purchase intention was measured using four items. The findings show that three items were rated at a high level, while one item (B1) reached a very high level. The variable recorded a mean score of 4.165 (SD = 0.906), reflecting a high level of purchase intention among respondents. About 78.4% of participants expressed positive agreement with the items measuring their intention to seek treatment in Jordan.
3. Medical Staff Competence (Mediating Variable): Medical staff competence was assessed using four items, with two items rated at a high level and two items at a very high level. The variable achieved a mean score of 4.265 (SD = 0.787), indicating a very high perception of the competence of Jordanian medical personnel. Approximately 84.3% of respondents agreed with the statements measuring this construct.

Overall, the descriptive analysis indicates high to very high perceptions across all study variables, with relatively moderate standard deviations, suggesting acceptable variability in respondents' evaluations.

Table 1. Descriptive Statistics for the IV, DV, and Mediator

Item	Responses %					S. D	Mean	Application Degree
	VH	H	M	L	VL

Medical Service Quality, Purchase Intention, and Human Resources Competencies Validity and Reliability

Individual Item Validity (Outer Loadings)

Figure 2 demonstrates that the individual item validity of the measurement model was evaluated by examining the outer loadings of all items associated with the study constructs. According to Hair et al. (2024), indicator loadings of 0.70 or higher are considered acceptable, as they indicate that the item adequately represents its underlying construct.

The initial assessment included all measurement items across the study variables. However, two items related to the independent variable (Q1 = 0.636 and Q4 = 0.619) recorded loadings below the recommended threshold of 0.70. Consequently, these items were removed from the model to improve the reliability and validity of the measurement structure. After the removal of these items, the measurement model consisted of 17 indicators, while the independent variable retained seven valid items in the final model. The subsequent analysis showed that all remaining indicators achieved higher loadings on their respective constructs than on other constructs, thereby satisfying the requirements for discriminant validity. Overall, the refined measurement model demonstrated improved indicator reliability and confirmed the discriminant validity of the constructs, indicating that the retained items adequately represent their respective variables in the structural model.

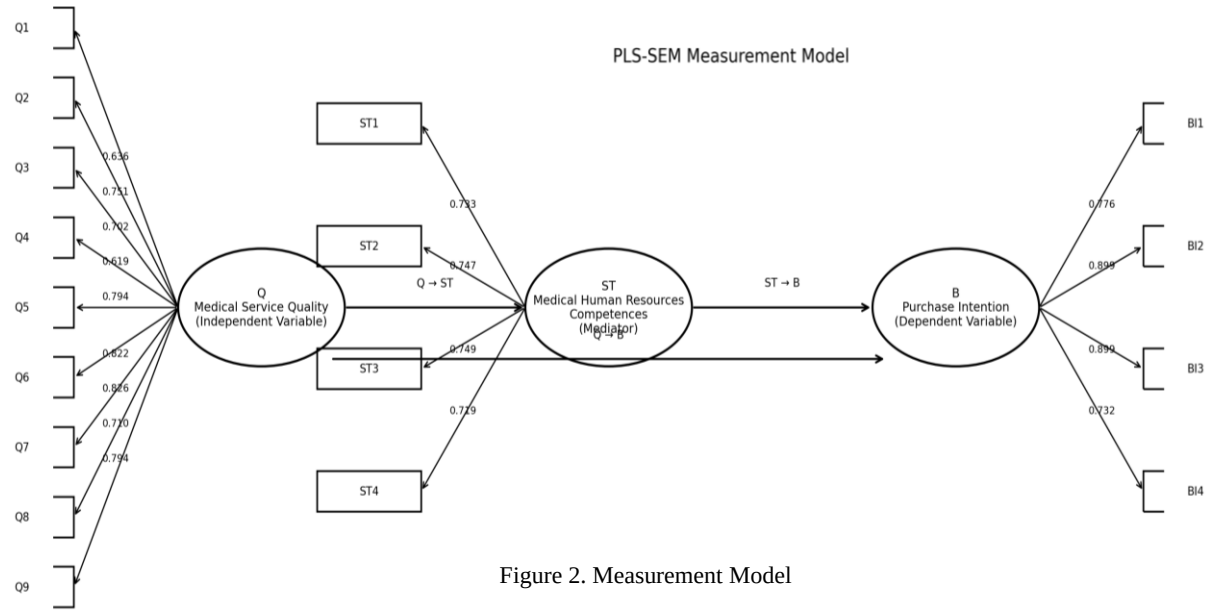

Figure 2. Measurement Model

Reliability and Convergent Validity of the Measurement Model

Figure 2 illustrates the assessment of the measurement model's internal consistency reliability using Composite Reliability (CR). According to Hair et al. (2021), CR values exceeding 0.70 indicate acceptable reliability, demonstrating that the indicators consistently measure their respective constructs. As presented in Table 2, all study constructs recorded CR values above the recommended threshold of 0.70, confirming a satisfactory level of internal consistency among the measurement items. In addition, convergent validity was evaluated using the Average Variance Extracted (AVE). According to Ringle et al. (2024), an AVE value of 0.50 or higher indicates that a construct explains at least half of the variance of its indicators. The results reported in Table 2 show that the AVE values for all study variables exceed the minimum recommended value of 0.50, indicating adequate convergent validity for the measurement model. Furthermore, rho_A reliability was calculated as an additional measure of construct reliability. Statistical guidelines suggest that rho_A values greater than 0.70 indicate acceptable reliability (Panahi et al., 2022). The results presented in Table 2 demonstrate that all constructs achieved rho_A values above this threshold. Overall, the findings indicate that the measurement model meets the recommended criteria for internal consistency reliability and convergent validity, confirming that the constructs used in the study are statistically reliable and valid for further structural model analysis.

Table 2. Cross Loading, CR, AVE, CR & VIF

Factor	Items	Cross Loading	CR	AVE	Rho_A
Medical Service Quality	Q1	0.636	0.879	0.596	0.866
	Q2	0.751			
	Q3	0.702			
	Q4	0.619			
	Q5	0.794			
	Q6	0.822			
	Q7	0.826			
	Q8	0.710			
	Q9	0.794			
Purchase Intention	BI1	0.776	0.898	0.688	0.887
	BI2	0.899			
	BI3	0.899			
	BI4	0.732			
Staff Competence	ST1	0.733	0.826	0.543	0.895
	ST2	0.747			
	ST3	0.749			
	ST4	0.719			

Discriminant Validity (Fornell–Larcker Criterion)

Finally, discriminant validity was assessed using the Fornell–Larcker (1981) criterion, which is widely applied in structural equation modeling to evaluate the distinctiveness of latent constructs. This method involves comparing the square root of the Average Variance Extracted (AVE) for each construct with the correlations between that construct and other constructs in the model. According to Fornell & Larcker (1981), the square root of the AVE for each latent variable should be greater than its correlations with other latent variables. This condition indicates that the construct explains more variance in its own indicators than it shares with other constructs in the model. As presented in Table 3, the square root of the AVE

for each study variable exceeds the corresponding inter-construct correlation coefficients. These results confirm that each construct demonstrates stronger relationships with its own measurement items than with other constructs, thereby satisfying the requirements for discriminant validity. Overall, the findings indicate that the study constructs—medical service quality, medical staff competence, and purchase intention—are empirically distinct from one another. This confirms the adequacy of the measurement model and supports its suitability for subsequent structural model analysis.

Table 3. Fornell-Larcker Criterion

Construct	Medical Service Quality	Purchase Intention	Staff Competence
Medical Service Quality	0.772	0.756	0.731
Purchase Intention	0.725	0.830	0.642
Staff Competence	0.731	0.642	0.737

RESULTS

Direct Impact Analysis

Table 4 presents the results of the structural model used to test the direct hypotheses while considering the mediating variable (medical staff competence). The relationships between the study variables were evaluated using the path coefficient (β), standard deviation (STDEV), t-value, and p-value, which determine the strength and statistical significance of each hypothesized relationship. H1: The first hypothesis examined the relationship between Jordanian medical service quality and purchase intention among international tourists. The results show strong support for this hypothesis. The path coefficient (β = 0.899) indicates a strong positive relationship between the two variables. In addition, the t-value (5.082) exceeds the critical value of 1.96, and the p-value is less than 0.001, confirming that the relationship is statistically significant at $\alpha \leq 0.05$. These findings suggest that the perceived quality of medical services is a key determinant influencing international tourists' intention to seek treatment in Jordan. H2: The second hypothesis tested the relationship between Jordanian medical service quality and medical staff competence.

The results provide strong support for this hypothesis as well. The path coefficient (β = 0.899) indicates a strong positive relationship between the two variables. The t-value (4.196) exceeds the critical value of 1.96, while the p-value (0.001) confirms the statistical significance of the relationship. This finding indicates that higher levels of perceived medical service quality are associated with greater perceived competence of medical staff in the studied hospitals. H3: The third hypothesis examined the relationship between medical staff competence and purchase intention among international medical tourists. The results show that this relationship is not statistically significant. The path coefficient (β = 0.115) indicates a weak relationship, while the t-value (0.779) is below the critical threshold of 1.96. Furthermore, the p-value (0.838) exceeds the significance level of 0.05. Accordingly, H3 is not supported, suggesting that the perceived competence of medical staff does not directly influence the purchase intention of international medical tourists. To further assess the strength of the relationships in the model, effect size (f^2) was calculated based on Cohen's (1988) criteria (0.02 = small, 0.15 = medium, 0.35 = large). The results indicate that Jordanian medical service quality has a substantial effect on both medical staff competence and purchase intention, while the effect of medical staff competence on purchase intention is very weak, which is consistent with the insignificant path identified in H3.

In addition, the coefficient of determination (R^2) was used to evaluate the explanatory power of the model. The results show that medical service quality explains 68.4% of the variance in medical staff competence ($R^2 = 0.684$), indicating a strong explanatory capacity for this relationship. Similarly, the combined effect of medical service quality and medical staff competence explains 54.8% of the variance in international tourists' purchase intention ($R^2 = 0.548$).

This value is considered acceptable and indicates a moderate level of explanatory power within marketing and tourism research contexts. Overall, the structural model results confirm the strong influence of medical service quality on both medical staff competence and purchase intention, while the direct effect of medical staff competence on purchase intention appears to be statistically insignificant in this study context.

Table 4. Direct Path Analysis

H	Relationship	Std. Beta	T-Value	P-Value	f^2	**Effect Size**	Decision	R^2	Q^2
H1	Quality → Purchase Intention	0.899	5.082	0.000	0.84	High	Supported	0.548	0.490
H2	Quality → Staff Competence	0.899	4.196	0.001	2.17	Very High	Supported	0.684	---
H3	Staff Competence → Purchase Intention	0.115	0.779	0.838	0.007	Very Weak	Not Supported		0.491

Significant at $P_0* < 0.01$; Significant at $P_0** < 0.05$

Mediation Analysis

This study examined the mediating role of medical staff competence in the relationship between Jordanian medical service quality and international tourists' purchase intention. The mediation analysis was conducted using path analysis within the Structural Equation Modeling framework (PLS-SEM). The bootstrapping technique was applied to test the indirect effects, as it provides a robust method for mediation testing without requiring the assumption of normal data distribution (Hair et al., 2021). Testing indirect effects is essential in studies involving mediating variables, as it allows researchers to determine whether the influence of an independent variable on a dependent variable occurs directly,

indirectly through the mediator, or through a combination of both. The results presented in Table 5 show that the indirect effect of Jordanian medical service quality on international tourists' purchase intention through medical staff competence was ($\beta = 0.114$). However, this effect was not statistically significant, as indicated by the Z-value (0.778) and p-value (0.437), which exceeds the acceptable significance level of $\alpha \leq 0.05$.

These results indicate that the mediating role of medical staff competence cannot be statistically confirmed. In evaluating the mediation decision, the total effect of medical service quality on purchase intention is primarily explained by the direct relationship between the two variables, rather than by the indirect path through the mediating variable. Furthermore, the direct effect of medical staff competence on purchase intention was also found to be statistically insignificant, while the direct effect of medical service quality on purchase intention remained significant.

Accordingly, the results suggest that medical staff competence does not function as a statistically significant mediator in the relationship between medical service quality and purchase intention in the present model. Although the indirect path represents approximately 11.3% of the total effect, its contribution is relatively weak. From an interpretive perspective, these findings imply that international medical tourists base their purchase decisions primarily on their perceptions of overall medical service quality, rather than on direct evaluations of medical staff competence. Elements such as efficient administrative procedures, effective coordination, rapid service response, and professional service delivery appear to play a more prominent role in shaping purchase intentions. Nevertheless, medical staff competence may still act as a supporting mechanism that enhances the overall perception of service quality, even though it does not independently influence purchasing decisions. This finding is consistent with the nature of medical tourism as a high-involvement service, where patients prioritize the overall quality of healthcare services when selecting treatment destinations, while the competence of medical staff contributes indirectly by reinforcing trust and confidence in the healthcare system.

Table 5. Direct Path Analysis

H	Relationship	Std. Beta	T-Value	P-Value	Decision	R^2	Q^2	Indirect B	Direct B	Total
H4	Quality → Purchase Intention → Medical Staff Competence	0.114	0.778	0.437	Not Supported	0.374	0.271	0.114	0.899	1.013

Predictive Relevance and Model Fit Assessment

Finally, the predictive relevance of the research model was evaluated using the Stone–Geisser Q^2 value. According to Chin (2010), a model demonstrates predictive relevance when the Q^2 value is greater than 0.00. As presented in Table 6, the Q^2 value for purchase intention of international tourists reached 0.584, indicating a strong predictive capability of the model in explaining variations in the dependent variable. In addition, the overall model fit was assessed using several goodness-of-fit indices based on the PLS-SEM methodology. These indices help determine the extent to which the proposed model adequately represents the observed data. The Standardized Root Mean Square Residual (SRMR) is considered the primary indicator of model fit, where values below 0.08 indicate a satisfactory fit between the model and the data. Furthermore, the d_ULS and d_G indices were used to evaluate the discrepancy between the empirical correlation matrix and the model-implied correlation matrix. The results show that the values of these indicators are lower than their respective critical values (HI95), suggesting an acceptable level of model fit. Additionally, the Chi-Square statistic was reported primarily for model comparison purposes. Meanwhile, the Normed Fit Index (NFI) reflects the degree of improvement of the proposed model compared with a null model. According to established guidelines, NFI values above 0.90 indicate a good model fit. Overall, the results of the predictive relevance test and model fit indices confirm that the proposed structural model demonstrates adequate predictive power and a satisfactory level of fit with the observed data, supporting its suitability for interpreting the relationships between the study variables.

Table 6. GOF Value

Variable	**Estimated Model**	**Decision**	**Q^2 (=1-SSE/SSO)**
SRMR	≤0.08	Acceptable / Unacceptable	0.584
d_ULS	≤H195	acceptable	
d_G	H195	acceptable	
Chi Square	Comparison between models		
NFI	≥0.090	Good / Weak	

DISCUSSION

The results of the current study reveal a statistically significant positive effect of the quality of medical services provided in Jordanian hospitals on the purchase intention of international medical tourists. This finding highlights the critical role of healthcare service quality in shaping purchasing behavior within the medical tourism sector. It aligns with the broader health marketing literature, which consistently identifies service quality as a primary determinant influencing international patients' decisions to travel abroad for medical treatment, particularly given the high level of perceived risk associated with healthcare services (Yilmaz et al., 2021; Connell, 2013). In the context of medical tourism, patients' perceptions of service quality extend beyond clinical outcomes alone. International medical tourists evaluate healthcare services through a comprehensive assessment of the treatment experience, including the efficiency of administrative procedures, clarity of communication with healthcare providers, responsiveness of medical staff, and

the overall quality of care throughout the treatment journey. These elements have been shown to significantly enhance patients' confidence and strengthen their purchase intentions when selecting a hospital or medical destination (Abu-Alhaija & Gillespie, 2024). The findings of the present study are also consistent with recent research conducted in the Jordanian healthcare context. Previous studies have emphasized that the quality of medical services represents a major competitive advantage that strengthens the position of Jordanian hospitals in the regional and international medical tourism market. Higher perceived service quality contributes to increased trust in the Jordanian healthcare system and improves the institutional image of hospitals, which in turn positively influences international tourists' purchase intentions. This effect becomes particularly evident when Jordanian healthcare services are compared with alternative medical destinations that may offer higher treatment costs or lower perceived service quality (Al-Nsour, 2024).

The second major finding of the study indicates a significant positive relationship between medical service quality and the competence of medical staff in Jordanian hospitals. This result is consistent with the principles of Total Quality Management (TQM) in healthcare, which suggest that the implementation of quality standards and accreditation systems contributes to improving the professional performance of healthcare personnel. The adoption of structured quality systems helps standardize clinical procedures, enhance adherence to treatment protocols, and foster a culture of continuous improvement and organizational learning within healthcare institutions (Donabedian, 1988; Al-Dmour et al., 2025).

From this perspective, healthcare quality should not be viewed merely as an outcome but rather as an organizational and operational framework that directly influences the competence and professional capabilities of healthcare providers. Evidence from Jordanian hospitals indicates that the adoption of international accreditation systems, such as Joint Commission International (JCI) standards, is strongly associated with improvements in medical staff performance, enhanced coordination among multidisciplinary medical teams, and a reduction in medical errors.

These improvements ultimately contribute to strengthening the perceived competence of healthcare professionals from both patients' and institutional perspectives (Abu Alhaija et al., 2024). Based on these findings, the results suggest that medical service quality functions as an antecedent variable influencing the competence of medical staff.

A healthcare environment that emphasizes quality management practices creates conditions that empower healthcare professionals, enhance their professional skills, and improve the effectiveness of service delivery (Aboalganam, 2024). Overall, the current study provides empirical support for the theoretical relationships between medical service quality, medical staff competence, and purchase intention within the context of medical tourism. The findings confirm that medical service quality represents a fundamental pillar in shaping the medical experience of international patients. It influences purchase intentions both directly, by enhancing perceptions of healthcare value, and indirectly, by improving the competence and performance of medical staff. Consequently, strengthening service quality remains essential for enhancing the competitive position of Jordanian hospitals in the rapidly expanding global medical tourism market.

On the other hand, the results of the current study indicate no statistically significant direct effect of medical staff competence on the purchase intention of international tourists seeking treatment in Jordanian hospitals. This finding contributes to the ongoing debate in the medical tourism literature regarding the actual role of medical competence in shaping international patients' purchasing decisions. This result is consistent with several previous studies suggesting that in medical destinations with a well-established professional reputation, the competence of medical staff is often perceived as a basic and expected requirement rather than a differentiating factor influencing patients' decisions (Connell, 2013; Al-Sharif et al., 2024). In such contexts, international patients tend to assume that healthcare professionals possess the necessary expertise and qualifications, which reduces the explanatory power of staff competence in predicting variations in purchasing behavior. Furthermore, research in medical tourism indicates that patients' decisions are rarely based on a single factor. Instead, international patients typically evaluate the overall healthcare experience, which includes service quality, administrative efficiency, hospital facilities, ease of procedures, and treatment costs.

Han et al. (2021) argue that broader aspects of the service experience often play a more influential role in shaping behavioral intentions than perceived competence among individual healthcare professionals.

When the medical destination already enjoys a strong reputation and high professional standards, patients may rely more heavily on these broader service attributes when making treatment decisions. Evidence from studies conducted in the Jordanian healthcare context supports this interpretation. Previous research suggests that the strong reputation of Jordanian healthcare professionals reduces international patients' sensitivity to differences in medical staff competence across hospitals, as competence is generally assumed to be consistently high throughout the healthcare system (Karsana & Murhadi, 2021). From a theoretical perspective, the current findings also align with models suggesting that medical staff competence influences purchase intention indirectly rather than directly. In such models, staff competence contributes to strengthening mediating factors such as patient trust, satisfaction, and the perceived image of the hospital or medical destination, which subsequently influence behavioral intentions. Studies have shown that international patients' perceptions of healthcare professionals' competence help build trust and reduce perceived risk associated with medical travel. However, these perceptions may not translate into purchase intention unless they are supported by a comprehensive and satisfactory service experience that meets patients' expectations (Karsana & Murhadi, 2021).

Nevertheless, the results of the current study differ from some previous research that identified a direct influence of medical staff competence on purchase intention, particularly in emerging medical tourism markets or relatively unknown healthcare destinations. In such environments, professional competence often serves as a crucial signal of credibility that helps reduce uncertainty and perceived risks associated with seeking treatment abroad (Yilmaz et al., 2021). The differences between these findings may be explained by variations in the maturity level of medical tourism markets, healthcare system reputation, and contextual characteristics of the study setting.

In more established medical tourism destinations such as Jordan, where healthcare professionals already enjoy strong regional credibility, patients may place greater emphasis on the overall quality of healthcare services and institutional reputation rather than on individual assessments of medical staff competence. Consequently, the Jordanian context provides an important explanatory framework for interpreting the current results.

Finally, the results of the current study indicate no statistically significant mediating effect of medical staff competence on the relationship between Jordanian medical service quality and international tourists' purchase intention. This finding reflects the complex and multidimensional nature of decision-making among international medical tourists when selecting a treatment destination. Specifically, the results suggest that medical service quality directly influences purchase intention, without the need for the effect to pass through medical staff competence as a mediating variable. This outcome is consistent with previous studies indicating that in well-established medical tourism destinations, medical staff competence is often perceived as a fundamental and expected characteristic rather than a distinct channel through which service quality influences purchasing behavior (Al-Nsour, 2020).

In such contexts, international patients assume a high level of professional competence among healthcare providers, which reduces their explanatory role in mediating the relationship between perceived service quality and behavioral intentions. From a theoretical perspective, this finding aligns with models suggesting that international patients evaluate medical destinations through a comprehensive assessment of the overall treatment experience. In this evaluation process, healthcare service quality represents a broader construct encompassing organizational efficiency, service delivery, administrative procedures, responsiveness, and the overall treatment environment. These elements collectively shape patients' perceptions and directly influence purchase intentions, independent of the perceived technical competence of healthcare professionals (Yilmaz et al., 2021). Accordingly, medical service quality can be viewed as a holistic construct that directly affects purchasing behavior without necessarily requiring mediating mechanisms.

In this context, medical staff competence may still play an indirect and supportive role in shaping the healthcare experience by contributing to factors such as trust, satisfaction, and institutional image, rather than acting as a direct mediator between service quality and purchase intention. Recent studies suggest that the influence of medical staff competence becomes more evident when it is examined within more complex models that incorporate additional mediating or moderating variables, such as institutional trust, hospital reputation, or destination image (Karsana & Murhadi, 2021).

These factors may serve as more powerful explanatory mechanisms linking service quality perceptions to behavioral intentions in medical tourism contexts. At the same time, the findings of the present study differ from some research that has identified a significant mediating role of medical staff competence, particularly in emerging medical tourism markets or relatively less established healthcare destinations. In such contexts, professional competence functions as a critical signal that helps reduce uncertainty and perceived risk among international patients (Karsana & Murhadi, 2021). The differences between these findings may be attributed to contextual variations and the maturity of the medical tourism market in Jordan. Jordan has developed a strong regional reputation for high-quality healthcare services and well-qualified medical professionals. As a result, professional competence may be perceived as a standard expectation rather than a differentiating factor capable of mediating the effect of service quality on purchase intention.

Overall, the results of the current study contribute to the medical tourism literature by providing empirical evidence from the Jordanian context, indicating that medical staff competence does not function as a mediating variable in the relationship between medical service quality and purchase intention. Instead, it operates as part of a broader system of factors shaping the overall healthcare experience of international patients. These findings also highlight the need to reconsider traditional explanatory models and encourage future research to explore more comprehensive frameworks that incorporate multiple mediating or moderating variables. Such approaches may better capture the dynamic and multidimensional nature of international medical tourists' decision-making processes and provide deeper insights into the mechanisms through which healthcare service quality influences behavioral intentions.

Based on the findings of the current study, several managerial implications can be proposed to enhance the competitiveness of Jordanian hospitals in the international medical tourism market:

1. Improving medical service quality: Hospitals should prioritize enhancing clinical and administrative service processes, including treatment efficiency, simplified procedures, and effective multilingual communication, as service quality strongly influences international patients' purchasing behavior.
2. Adopting international quality standards: Implementing internationally recognized healthcare accreditation systems, along with investing in modern healthcare infrastructure and hospital environments, can strengthen service quality and enhance the global reputation of Jordanian hospitals.
3. Integrating medical staff competence into patient experience: Medical competence should be incorporated within a comprehensive patient experience strategy that emphasizes coordination among medical teams, effective communication, and personalized care throughout the treatment journey.
4. Strengthening institutional trust and destination image: Building institutional trust, enhancing the international image of Jordanian hospitals, and increasing the perceived value of healthcare services are essential for encouraging international patients to choose Jordan as a medical tourism destination.

Finally, the findings of this study provide important theoretical insights, alongside critical policy and managerial implications, for strengthening Jordan's position in the regional and global medical tourism market. The results confirm that medical service quality is the most influential determinant of international patients' purchase intentions, highlighting the need for policymakers and healthcare administrators to prioritize quality-driven strategies within the national medical

tourism agenda. In this context, service quality should be treated not merely as an operational issue at the hospital level but as a strategic policy instrument capable of enhancing Jordan's competitiveness in the international healthcare market.

From a practical and policy perspective, the results suggest that Jordan's comparative advantage in medical tourism lies primarily in its reputation for reliable healthcare services and cost-effective treatment, rather than solely in the professional competence of individual physicians. While Jordanian doctors are widely recognized for their expertise in specialties such as oncology, cardiology, and orthopedic surgery, the study indicates that international patients perceive this competence as a baseline expectation rather than a decisive competitive differentiator. Consequently, public and private stakeholders should shift their strategic focus from promoting individual medical expertise to strengthening the institutional quality of the healthcare system, including administrative efficiency, patient coordination mechanisms, and service integration across healthcare facilities. Furthermore, the findings imply that medical tourism policy in Jordan should increasingly emphasize system-level service quality rather than isolated clinical excellence. This includes developing standardized international patient pathways, improving hospital accreditation systems, and enhancing coordination between healthcare providers and tourism institutions. Such measures can help position Jordan not only as a destination for high-quality medical treatment but also as a comprehensive healthcare experience destination.

The results also highlight the importance of leveraging Jordan's unique therapeutic and wellness assets as part of a broader medical tourism value proposition. Destinations such as the Dead Sea, internationally recognized for its therapeutic properties, and specialized institutions such as the King Hussein Cancer Center represent strategic assets that can strengthen Jordan's international positioning in the medical tourism market. Integrating these assets into a coordinated national medical tourism strategy would enable Jordan to move from a hospital-centered model of medical tourism toward an integrated healthcare and wellness ecosystem. At the strategic level, sustaining Jordan's competitiveness requires a policy framework that integrates healthcare quality, tourism infrastructure, and international marketing efforts. This involves strengthening collaboration between the Ministry of Health, the Ministry of Tourism and Antiquities, private hospitals, and international medical facilitators. Such coordination can improve Jordan's global visibility as a trusted destination for medical treatment while ensuring that service quality standards remain consistent across the healthcare system. Overall, the study demonstrates that Jordan's future success in medical tourism will depend less on promoting isolated elements of healthcare competence and more on developing an integrated, high-quality healthcare system capable of delivering a reliable and seamless patient experience for international medical tourists.

CONCLUSION

This study examined the factors influencing international tourists' purchase intention to obtain medical services from Jordanian hospitals, focusing on medical service quality and medical staff competence within an integrated analytical framework. The results indicate that medical service quality is the most influential factor shaping international tourists' purchase intention. This finding highlights the importance of perceived service quality in high-risk service environments such as medical tourism, where patients evaluate the overall treatment experience, including clinical outcomes, administrative efficiency, communication, and service organization. The study also found a significant positive relationship between medical service quality and medical staff competence, suggesting that healthcare quality standards and accreditation systems contribute to improving professional performance within healthcare institutions. However, the results showed no direct or mediating effect of medical staff competence on purchase intention, indicating that in well-established medical destinations such as Jordan, medical competence is perceived as a basic prerequisite rather than a differentiating factor influencing patient decisions. Overall, the findings emphasize that medical service quality directly drives purchase intention, while medical staff competence contributes indirectly by supporting the quality environment. From a practical perspective, strengthening Jordan's competitiveness in medical tourism requires continued investment in healthcare service quality, institutional reputation, and the overall international patient experience.

Research Limitations and Future Research Directions

Despite its contributions, this study has several limitations that provide directions for future research. The findings showed no statistically significant mediating role for medical staff competence in the relationship between medical service quality and purchase intention, suggesting the need to explore alternative mediating variables such as institutional trust, patient satisfaction, destination image, and perceived value to better explain international medical tourists' purchasing behavior. Future studies may also incorporate moderating variables related to patient characteristics, including nationality, type of treatment, length of stay, and perceived health risk, as these factors may influence how international patients evaluate healthcare services and form their purchase intentions. In addition, since the study focused primarily on private hospitals in Jordan, comparative research between public and private hospitals or between Jordan and competing medical tourism destinations could enhance the generalizability of the findings. Future research may also benefit from adopting mixed-method or longitudinal approaches to provide deeper insights into international medical tourists' experiences and to examine how purchase intentions evolve into actual treatment decisions over time.

Abstract: Tourism serves as a vital engine for the Thai economy, contributing significantly to national wealth; however, persistent disparities exist in income distribution between primary and secondary provinces. This study aims to analyze the current tourism situation in Thailand and identify appropriate strategic adjustments to enhance the industry's resilience and sustainability. By evaluating the concentration of visitors and revenue, the research seeks to provide a roadmap for more equitable economic growth through tourism. This research utilizes secondary time-series data from 2012 to 2023 obtained from the Tourism Authority of Thailand (TAT). Descriptive statistics and box plot analyses were performed using SPSS to observe data distribution across 77 provinces. Furthermore, the study employs Mapping Strategy Groups and heat maps to classify provincial tourism characteristics into distinct tiers. Finally, a SWOT and TOWS Matrix analysis was conducted to evaluate the internal strengths and external competitive environment, formulating strategic recommendations for policymakers. The findings reveal that tourism revenue and arrivals are heavily concentrated in a few major provinces, specifically Bangkok, Phuket, and Chonburi, which consistently act as "Maxi-Outliers." While domestic tourism shows a slightly more balanced distribution, it generates significantly lower income compared to international tourism. The COVID-19 pandemic disproportionately affected primary provinces, whereas secondary provinces remained stagnant due to a pre-existing lack of infrastructure and clear destination identity. Interpretation suggests that Thailand must shift toward a decentralized strategy. This involves expanding transportation infrastructure to secondary cities and leveraging unique local cultural landmarks to create distinct value. Implementing a more diverse tourism model will not only attract repeat international visitors but also encourage high-spending Thai tourists, who usually travel abroad, to explore domestic destinations. Ultimately, addressing these structural imbalances is essential for reducing economic inequality and ensuring long-term tourism growth.

Keywords: Thai tourism, strategic management, major provinces tourism, first-tier provinces tourism, second-tier provinces tourism, inequality

INTRODUCTION

Thailand has an overall population of approximately 71.7 million and received around 315.5 million tourists in 2023. This includes 249.08 million Thai visitors (people traveling for tourism and other purposes, such as visiting friends or relatives, both overnight and non-overnight) and 66.46 million foreign visitors (foreigners who traveled to Thailand before the immigration checkpoint was closed and resided in various provinces). This tourism generated income for the country of approximately 2.17 trillion baht, divided into income from Thai tourists of 0.858 trillion baht and foreign tourists of 1.31 trillion baht (TAT, 2023). Moreover, tourism has been proven to contribute to the economic growth of Thailand in the long term and helps promote economic activity both regionally and macro-economically, especially in developing countries (Sungkaew, 2020). For example, food tourism that impacts the regional economy of Thailand, particularly in areas with a strong food identity such as the Central, Southern, Eastern, and Northern regions, will be positively affected by the expansion of tourism (Thongkaw et al., 2024). In addition, stimulating tourism in second-tier provinces had a significant impact on economic growth in those provinces (Chanthawong & Choibamroong, 2020).

On the other hand, although many studies confirm that tourism contributes to economic growth and increases income for local people, and that tourism promotion policies have a positive effect on the country's economy, there are still some limitations that prevent tourism from having a positive effect on the country's economy in all dimensions such as income distribution. From the study by (Wattanakuljarus & Coxhead, 2008); it was found that tourism growth increases overall household income but worsens income distribution. This is because the tourism sector is not labor-intensive in the Thai context, and tourism expansion creates general equilibrium effects that reduce the profitability of the trade sectors on which the poor depend for their income. In addition, promoting tourism in 55 second-tier provinces in Thailand is a policy aimed at reducing poverty and income inequality. The 22 first-tier provinces can reduce the poverty rate, but overall income inequality increases. However, increasing domestic tourism can slightly decrease income inequality (Sudsawasd et al., 2022). As with a study of tourism in 13 countries, it was found that tourism growth did not reduce

poverty or income inequality, but it did narrow the poverty gap (Mahadevan & Suardi, 2019). As for the tourism situation in Thailand, it was found that the tourism industry is an important engine that drives the country's economy and increases the wealth of its people. However, tourism is unable to influence better income distribution, especially in second-tier provinces that benefit less from the tourism sector than first-tier provinces.

Past tourism statistics from the Tourism Authority of Thailand (TAT) have found that tourism is concentrated only in first-tier provinces such as Bangkok and Chonburi, while second-tier provinces receive significantly fewer tourists compared to these major provinces. Although, second-tier provinces have planned tourism strategies to attract tourists such as: Sakon Nakhon Province promotes cultural tourism by leveraging its unique identity to attract visitors (Panich et al., 2014). The strategic linkage between rural villages in Tom Lod, Mae Hong Son Province, and high-potential tourism in Chiang Mai Province can significantly enhance the economic impact of rural tourism (Lacher & Nepal, 2010).

Nong Khai Province employs a religious tourism strategy, capitalizing on its numerous famous religious ritual sites to draw tourists (Maneenetr & Tran, 2014). Additionally, Chanthaburi Province uses marketing strategies focused on creating the right image and awareness to attract tourists (Srisangkaew, 2017). Recent studies also highlight the importance of faith-based and cultural attractions in promoting tourism distribution to secondary provinces, such as Nakhon Si Thammarat, which can generate significant local economic impact (Waiyasusri, 2025).

However, it has not succeeded in elevating the level of tourism in these provinces as expected. Therefore, it is necessary to reassess the tourism situation in Thailand to develop strategies that are appropriate for each tourism area.

Previous literature emphasizes the significant effect of tourism on economic development in rural areas and second-tier cities. A comprehensive study of tourism in China found that tourism impacts 341 cities and suggested that cities should leverage the tourism influence of neighboring cities. By establishing inter-city tourism organizations or agencies, cities can enhance the efficiency of tourism development (Yang & Wong, 2012).

Moreover, the development direction of rural tourism in China is guided by government policies that focus on investing in infrastructure, upgrading tourist attractions, and increasing local income to attract tourists. Additionally, future planning is influenced by the rural tourism development blueprints of developed countries. This includes promoting the culture and identity of rural communities to create unique experiences for visitors and attract more tourists. It also involves implementing tax reduction measures to encourage tourism (Wang et al., 2013). A study in Japan found that the development of high-speed rail (Shinkansen) played an important role in attracting tourists to non-major city prefectures and influenced regional economic activities (Kurihara & Wu, 2016). As with rural tourism in France, tourism in general has not significantly improved the local economy because tourists tend to spend less on tourism activities. Visitors' stays in three rural regions during the summer season often involve visits to friends or relatives. However, more expensive stays are the most common, involving activities aimed at experiencing the outdoors or enjoying local sights, based on natural and cultural amenities mainly located in regional natural parks. The main forms of accommodation are campsites and rural cottages. Gastronomic tourism has also emerged as an activity that attracts higher-spending visitors (Bel et al., 2015).

On the other hand, the tourism situation in Indonesia demonstrates that tourism can significantly stimulate the economy and generate impressive income for primary tourism provinces. However, the results in second-tier provinces are disappointing. It is the duty of the government to continue promoting tourism policies in these provinces (Rahmayani et al., 2022). Similar to South Africa, where tourism is concentrated in major cities while secondary cities rely heavily on domestic tourism, this leads to uneven development, making these areas prone to high poverty and low development (Rogerson, 2015).

From the review of foreign tourism literature, it was found that promoting tourism in secondary cities requires the development of transportation infrastructure, accommodation, and various facilities before issuing policies to promote tourism in these areas. Moreover, in developing countries, tourism in secondary cities primarily comes from domestic tourists and has not yet generated sufficient income to develop the local economy as expected. In addition, uncertainties such as the COVID-19 pandemic and geopolitical issues have significantly affected the tourism sector. Thailand should analyze the data to determine appropriate tourism strategies for each area, addressing the problems and promoting tourism effectively. Furthermore, recent literature highlights the significance of transportation infrastructure (Srikhwan & Choibamroong, 2025) and tourist behavior in ecotourism (Praprom & Laipaporn, 2025) as crucial factors for developing sustainable tourism destinations in Thailand.

MATERIALS AND METHODS

This study uses time-series secondary data between 2012 to 2023 from the Tourism Authority of Thailand (TAT). And considered from observation of the distribution of data by descriptive statistic explore method form SPSS program. Tourism data such as number of total visitors, number of foreign visitors, number of domestic visitors, total tourism revenue, foreign revenue, and domestic revenue of 77 provinces are arranged in a graph (Box plot) to show the distribution of data as shown in Figure 1. The concentration of tourists will cause the data for first-tier provinces to fall into the Maxi Outlier range, indicating that these provinces benefit significantly from tourism.

In contrast, second-tier provinces do not benefit as much from tourism promotion. Moreover, all data will be plotted on a graph to illustrate the differences in tourism activity across each province. This will help visualize the dynamics of tourism data and assess the impact of tourism promotion policies and uncertain events. The data obtained will then be analyzed to create a Mapping Strategy Group. The Mapping Strategy Groups, shown in Figure 2, illustrate the number of tourists and tourism income for each province. These groups classify the character of tourism in each province by considering overall tourism, international tourism, and domestic tourism. This classification helps identify gaps and problems in the country's tourism sector and serves as a tool for policy making and strategy determination. Finally, the study results will be subjected to a SWOT analysis to evaluate the competitive situation of tourism in Thailand.

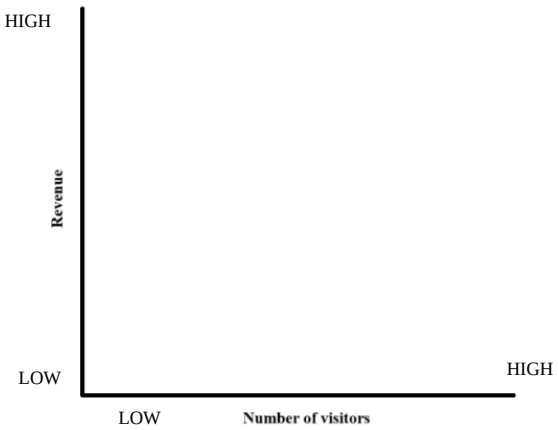

Figure 2. Strategic Positioning Map based on Number of Visitors (Low–High) and Revenue (Low–High)

RESULTS AND DISCUSSION

The results of this study will be classified into overall tourism, international tourism, and domestic tourism, considering the number of tourists and tourism revenue, as well as the uncertainty caused by the COVID-19 outbreak. The overall data on tourists by province revealed that many of Thailand's 77 provinces fell into the Maxi-outlier range. Bangkok (BKK) was the most significant Maxi-outlier, standing out the most from other provinces. Following Bangkok were Chon Buri (Chon), Kanchanaburi (KAN), Phuket, Prachuap Khiri Khan (PACHOB), Phetchaburi (PECHBURI), Chiang Mai, Nakhon Ratchasima (Nakornrajsrima), and Phra Nakhon Si Ayutthaya (Ayuthaya), all of which were clustered in the Maxi-outlier range. While there remains a significant difference in the number of tourists between first tier and second-tier provinces, this disparity is evident across the data range, including the maximum, upper bound, lower bound, and minimum levels, as shown in Figure 3. Figure 3 illustrates the impact of tourist adjustments on nine specific provinces, with Bangkok being the most affected. In contrast, the overall number of tourists in provinces outside these nine have remained relatively nearly stable from 2012 to 2023. In addition, the COVID-19 outbreak during 2020-2021 significantly impacted the overall number of tourists in the country. Bangkok experienced the most substantial decline, while the other eight provinces were less affected. The outbreak led to a decrease in tourist numbers across 68 other provinces, resulting in no significant difference between the upper-bound and lower-bound ranges of tourist numbers, which exhibited similar values as shown in Figure 4.

(Source: Compiled by the author based on TAT data)

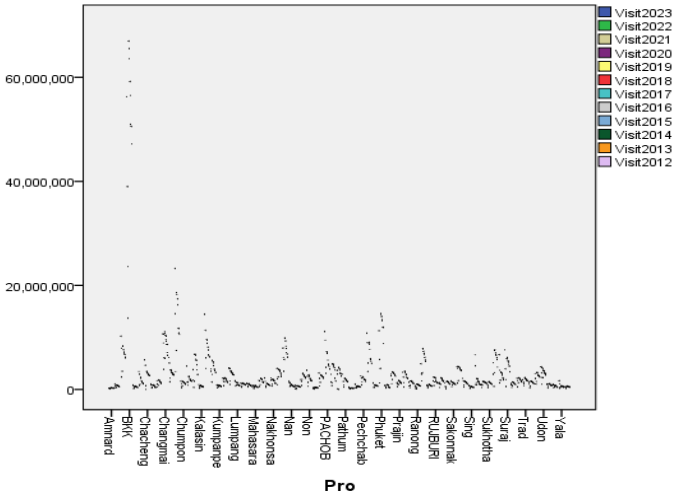

Figure 4. The data plot shows the number of tourists in each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

Figure 5 presents data on the number of foreign tourists across various provinces. Bangkok, Chonburi, and Phuket are identified as Maxi-outliers, exhibiting significantly higher numbers of foreign tourists compared to other provinces. Bangkok remains the province with the highest influx of foreign tourists. Other provinces within the Maxi-outlier range, such as Surat Thani, Chiang Mai, Songkhla, Krabi, Rayong, Chiang Rai, and Ayutthaya, display clustering patterns distinct from the top three provinces. In contrast, the distribution of foreign tourist data in the other provinces (especially in second-tier provinces) is stable and does not show significant variation. Figure 6 confirms that the distribution of tourists is concentrated in first-tier provinces, whereas several second-tier provinces have not experienced a significant increase in tourist numbers. The spread of COVID-19 has significantly impacted the number of foreign tourists.

The outbreak has directly affected first-tier major provinces, whereas second-tier provinces have remained largely unaffected due to the already low number of foreign tourists under normal circumstances as shown in Figure 5 and 6.

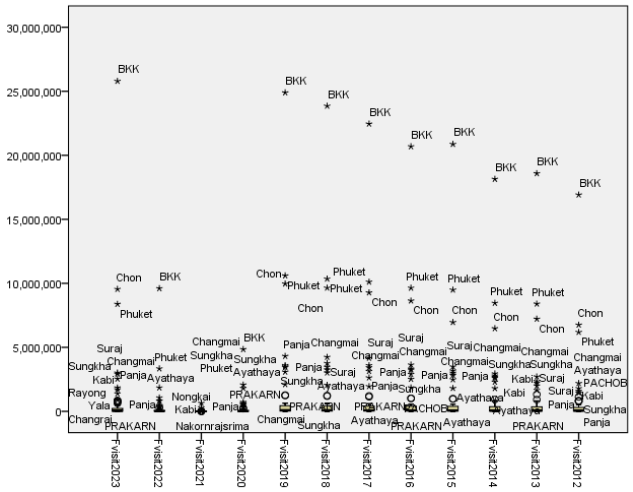

Figure 5. The box plot shows the distribution of foreign tourism visitor data for each province from 2012 to 202
(Source: Compiled by the author based on TAT data)

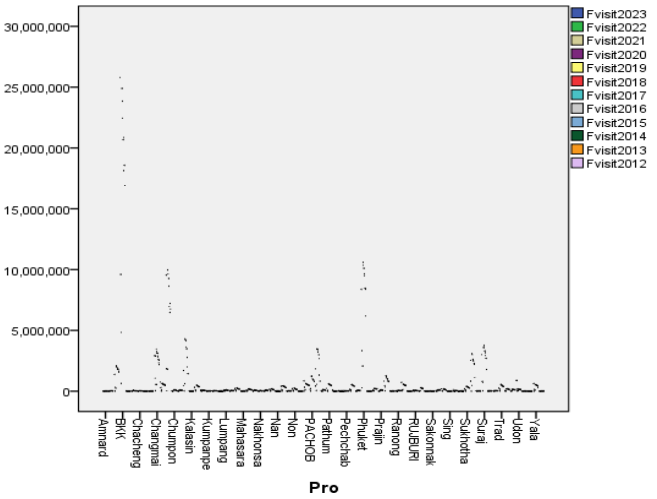

Figure 6. The data plot shows the number of foreign tourists in each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

The data on the number of domestic tourists reveals that Bangkok remains the province with the highest number of tourists, significantly outpacing other provinces. It is followed by Kanchanaburi, Chonburi, Prachuap Khiri Khan, Ayutthaya, Chiang Mai, Nakhon Ratchasima, Rayong, and Phetchaburi, among others. These provinces are categorized as Maxi-Outliers. Furthermore, an analysis of the data range, including the maximum, upper bound, lower bound, and minimum, indicates a significant difference in the number of domestic tourists between primary and secondary provinces, as shown in Figure 7. Figure 8 illustrates the distribution of foreign tourists across various provinces. The data reveals that most tourists concentrate in major first-tier provinces such as Bangkok. While secondary provinces also experience fluctuations in tourist numbers, these changes are not as pronounced as those in the main provinces. Nonetheless, the number of tourists in secondary provinces still shows significant variation. The COVID-19 pandemic has significantly impacted tourist numbers across various provinces, particularly in major first-tier countries. In other provinces, a noticeable decline in tourist numbers has resulted in a lower than normal for 2020 and 2021. This is evident from the maximum and upper bound values shrinking to approach the lower bound and minimum values, compared to other years.

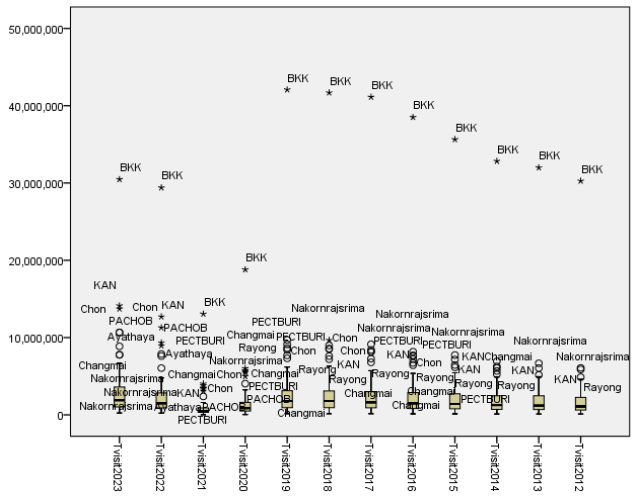

Figure 7. The box plot shows the distribution of domestic tourism visitor data for each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

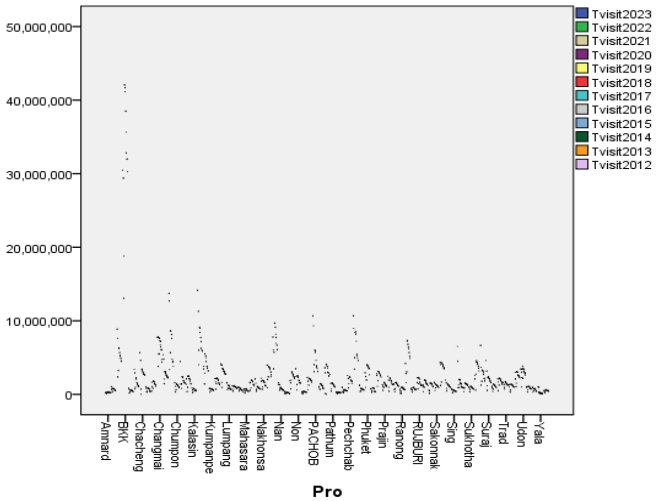

Figure 8. The data plot shows the number of domestic tourists in each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

The analysis of tourism income across 77 provinces revealed that Bangkok generated the highest revenue from tourism, significantly surpassing other provinces. Following Bangkok, the provinces of Phuket, Chon Buri, Surat Thani, Krabi, Chiang Mai, Chiang Rai, Songkhla, Phang Nga, Kanchanaburi, Prachuap Khiri Khan, and Phetchaburi also exhibited high income levels, classified as Maxi-outliers. In contrast, the remaining 65 provinces displayed relatively uniform tourism income levels, as illustrated in Figure 9. This pattern aligns with the distribution of tourism income, which is heavily concentrated in the primary provinces, leading to notable disparities in the data. Consequently, the other 65 provinces did

not experience significant annual variations in total tourism income as shown in Figure 10. While the COVID-19 outbreak has disproportionately impacted the income of the 12 major provinces, data presented in Figures 10 and 11 indicate that its effect on tourism in the remaining 65 provinces has been comparatively less severe. Furthermore, the situation in these 65 provinces does not significantly deviate from what would be expected under normal circumstances without an outbreak.

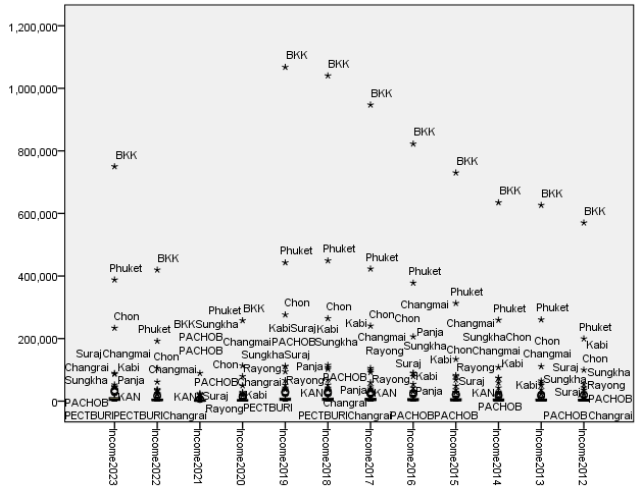

Figure 9. The box plot shows the distribution of income from tourism for each province from 2012 to 2023
(Source: Compiled by the author based on TAT data (2025)

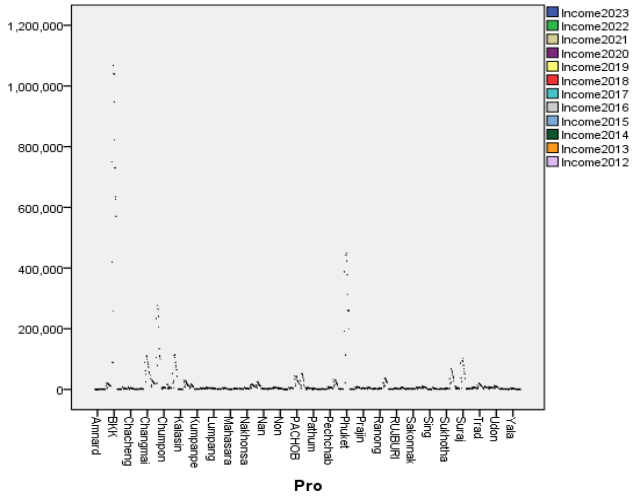

Figure 10. The data plot shows income from tourism in each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

In terms of income from domestic tourism, major provinces such as Bangkok continue to generate the highest revenue, significantly surpassing other provinces. Conversely, provinces like Chonburi, Chiang Mai, Prachuap Khiri Khan, Chiang Rai, Phuket, Surat Thani, and Krabi are notable for receiving higher income from foreign tourists, as indicated by their classification within the Maxi-outlier range. Additionally, the remaining 69 provinces exhibit minimal variation in tourism income, as illustrated by the data distribution in Figure 11 and the characteristics of the data in Figure 12.

The Covid-19 outbreak has significantly impacted income from domestic tourists, as well as overall tourism revenue. However, the recovery of income from domestic tourists has been more adversely affected than the total tourism income, particularly in the Bangkok area, as illustrated in Figure 11.

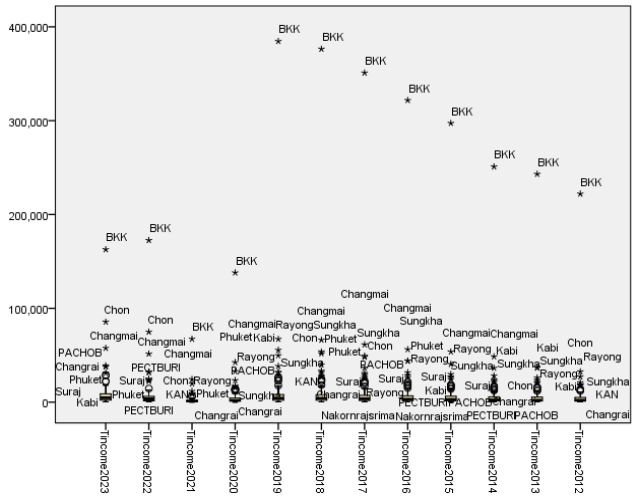

Figure 11. The box plot shows the distribution of income from domestic tourists data for each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

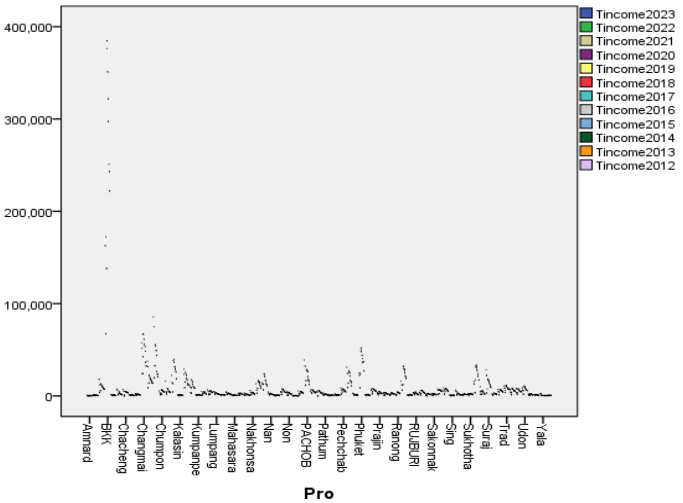

Figure 12. The data plot shows income from domestic tourists in each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

Income from foreign tourists shows that Bangkok remains the province with the highest income, followed by Chonburi. Additionally, Surat Thani, Songkhla, Chiang Rai, Rayong, Krabi, Phang Nga, Prachuap Khiri Khan, Chiang Mai, and Trat are provinces that receive significant income from tourists. In contrast, the remaining 65 provinces do not exhibit substantial changes in income from foreign tourists, as illustrated in Figures 13 and 14.

The spread of COVID-19 has directly impacted income from foreign tourists in major provinces more than in secondary provinces, particularly in Bangkok and Phuket. However, the recovery of income from foreign tourists has been rapid, with many major provinces nearing pre-outbreak income levels.

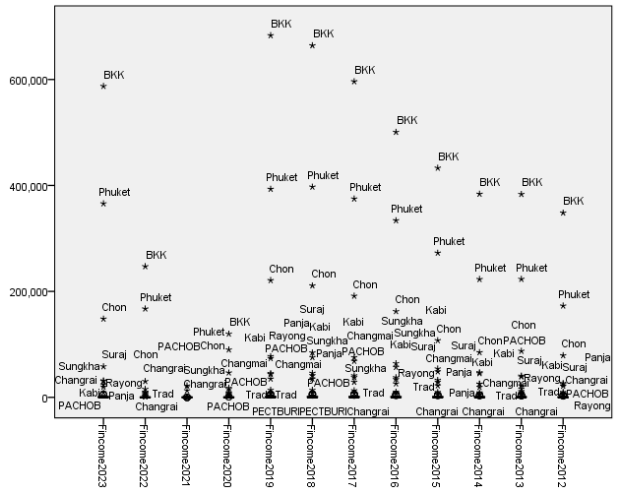

Figure 13. The box plot shows the distribution of income from foreign tourists' data for each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

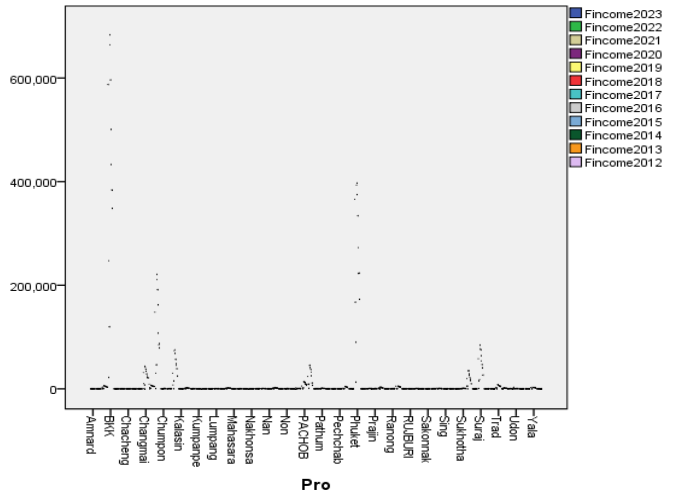

Figure 14. The data plot shows the income from foreign tourists in each province from 2012 to 2023
(Source: Compiled by the author based on TAT data)

Based on the above information, a heat map of Thailand can be created to display the number of tourists. This map will classify tourists into domestic and international categories, as well as show overall tourism, as illustrated in Figure 15 to 20.

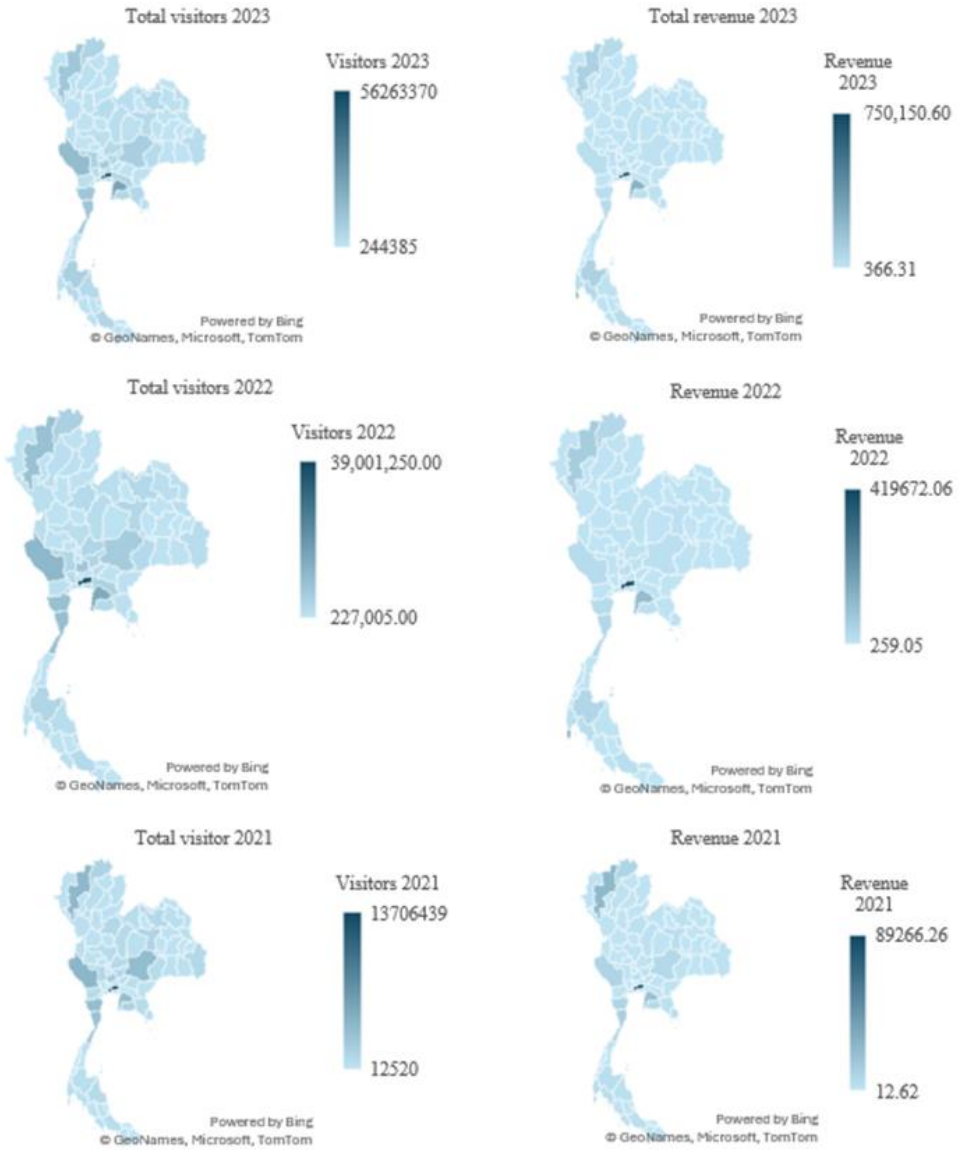

Figure 15. Heat map shows the total tourism visitors and total tourism revenue from 2023, 2022, 2021
(Source: Compiled by the author based on TAT data)

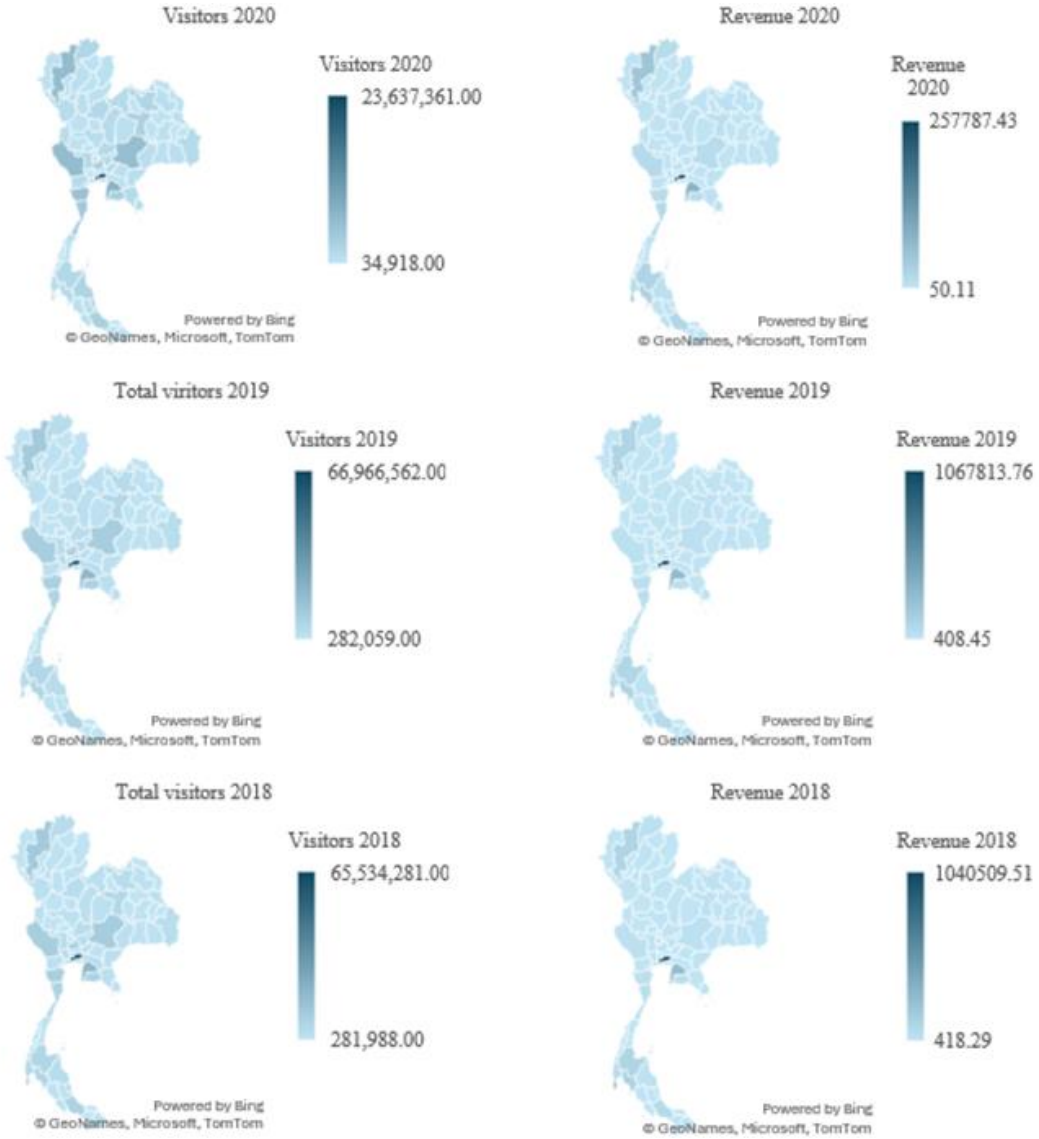

Figure 15. Heat map shows the total tourism visitors and total tourism revenue from 2020, 2019, 2018
(Source: Compiled by the author based on TAT data)

The findings indicate that: For overall tourism in the country, it was found that both income and the number of tourists are concentrated in a few main provinces, particularly Bangkok. Bangkok has the highest number of tourists and tourism income, significantly surpassing other provinces. In contrast, secondary provinces have a much lower number of tourists and tourism income compared to the main provinces, as illustrated in Figure 15. When analyzing the data using the Mapping Strategy Groups tool, as shown in Figure 16, it was found that Bangkok ranks among the top provinces in terms of the number of tourists and tourism income. Several factors contribute to this dominance. As the only metropolis in the country, Bangkok boasts the most extensive infrastructure and facilities, as well as the greatest cultural diversity. It serves as the central hub for job opportunities, business ventures, and various other prospects, making it difficult for other provinces to replicate its success.

Phuket, on the other hand, generates the second-highest tourism income after Bangkok and attracts a comparable number of tourists to other leading provinces. Its unique geographical features and infrastructure, such as a large port capable of accommodating tourists and supporting the construction of hotels, resorts, and luxury residences amidst beautiful natural scenery, draw a significant number of high-income tourists. This is another factor that is challenging for other provinces to imitate. Chonburi is also a notable tourism province, ranking just behind Bangkok in terms of tourist attractions.

Although it does not generate as much tourism income as Phuket, Chonburi benefits from its coastal location and proximity to Bangkok. Its infrastructure is similar to that of Bangkok, which has helped it become a frequent destination for tourists. This advantage sets it apart from other major tourism provinces that struggle to compete with Bangkok, Phuket, and Chonburi. In contrast, many secondary provinces are often overlooked by tourists due to their significantly fewer supporting factors compared to the leading provinces. In terms of domestic tourism, it was found that the number of tourists and income from domestic tourists were better distributed compared to overall tourism. The heat map indicates that the number of tourists and income from tourism were more evenly spread across various provinces. However, when all the data were analyzed using Mapping Strategy Groups, Bangkok remained the province with the highest number of tourists and income from domestic tourism, due to a lock-in factor that prevented other provinces from replicating its success.

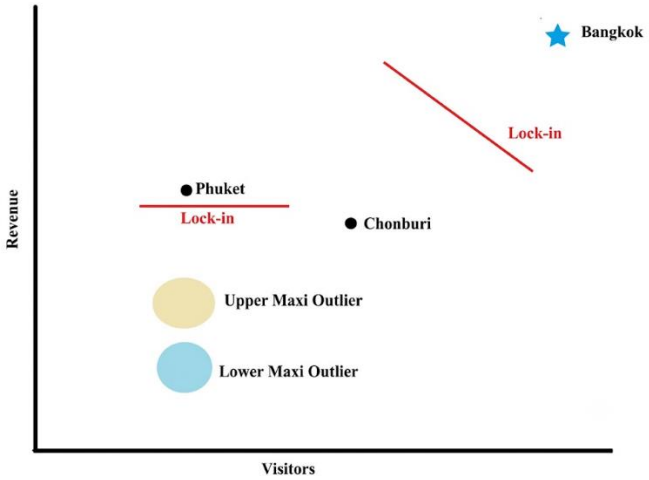

Figure 16. Mapping Strategy Groups for tourism in Thailand (Source: Compiled by the author based on TAT data)

Meanwhile, provinces such as Chonburi, Chiang Mai, Prachuap Khiri Khan, Phetchaburi, Kanchanaburi, Ayutthaya, and Nakhon Ratchasima had competitive advantages stemming from infrastructure and natural resources that attracted tourists. Despite these advantages, they did not possess a unique factor that prevented other provinces from imitating them. Therefore, tourism promotion policies could still play a significant role in enhancing tourism in secondary and neighboring provinces as shown in Figure 17 and 18.

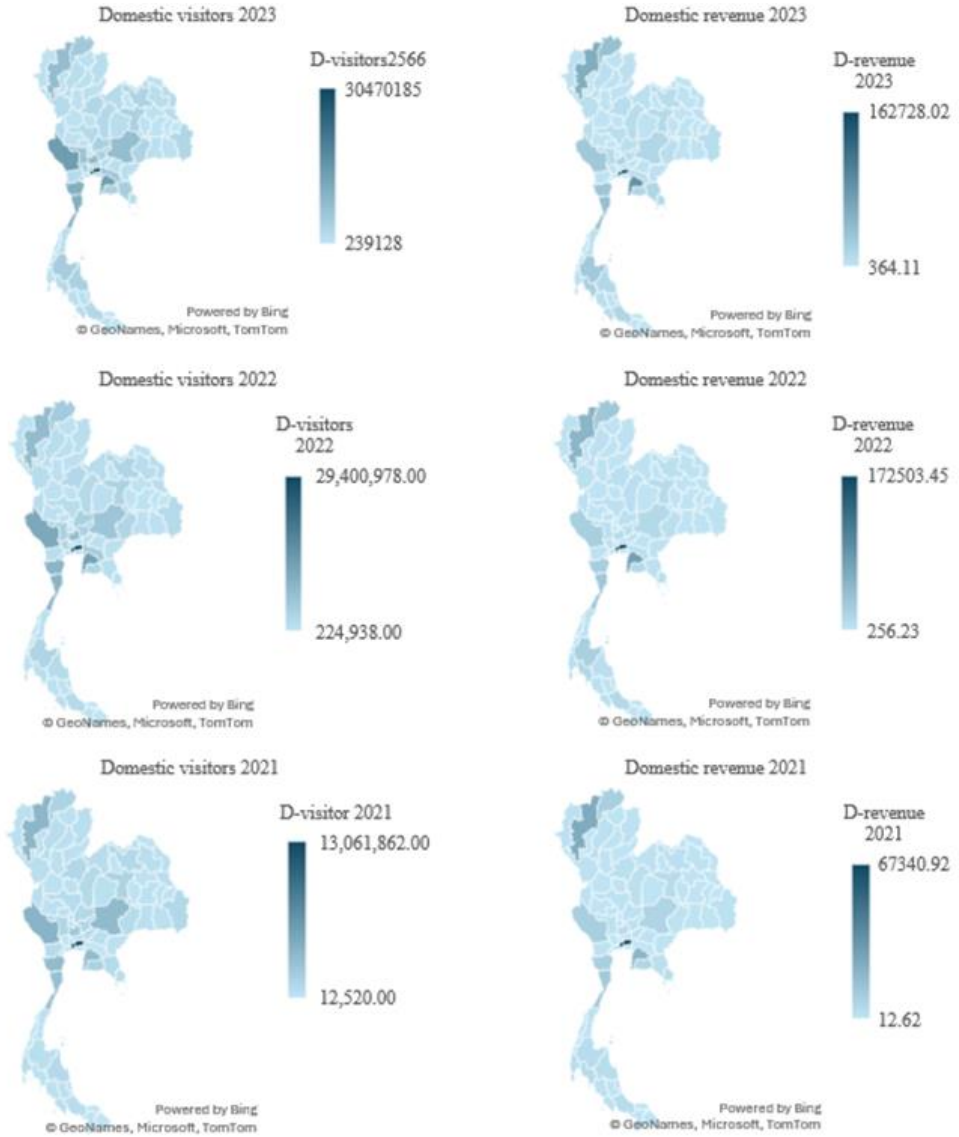

Figure 17. Heat map shows the domestic tourism visitors and domestic tourism revenue from 2023, 2022, 2021 (Source: Compiled by the author based on TAT data)

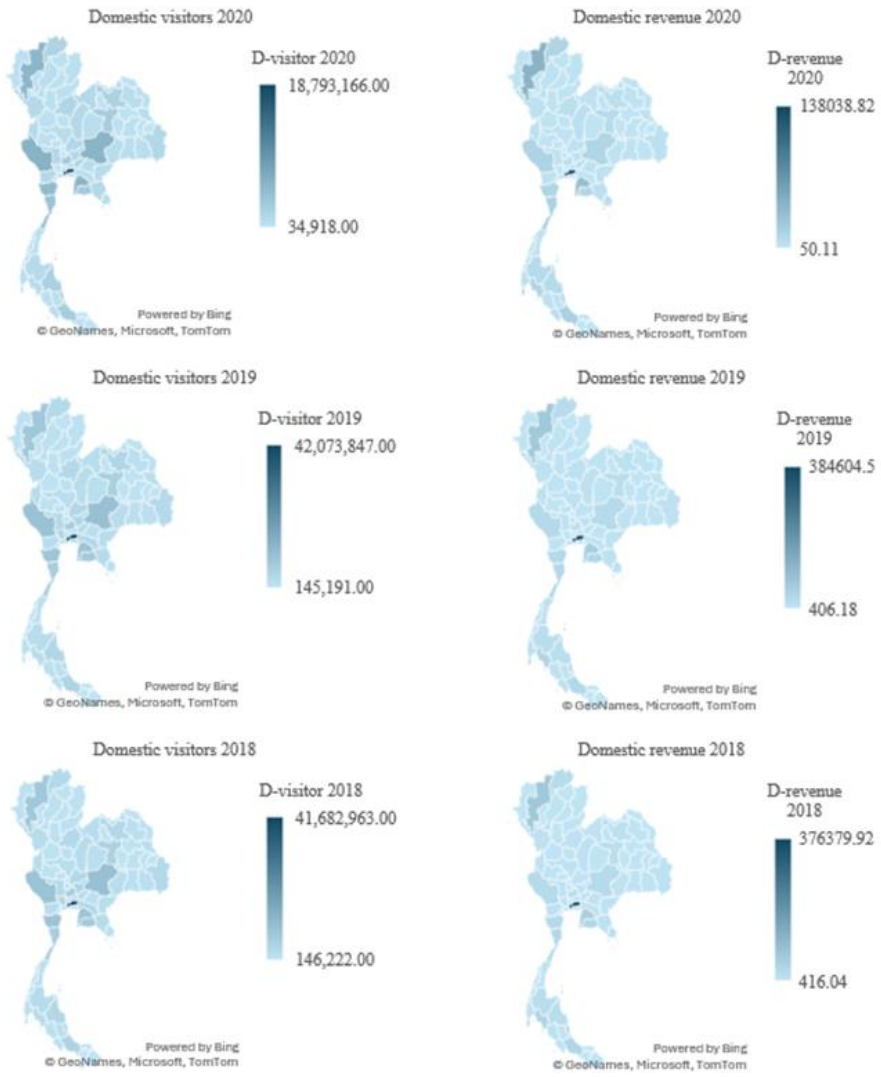

Figure 17. Heat map shows the domestic tourism visitors and domestic tourism revenue from 2020, 2019, 2018 (Source: Compiled by the author based on TAT data)

Figure 18. Mapping Strategy Groups for tourism form domestic tourist in Thailand (Source: Compiled by the author based on TAT data)

In the tourism sector, it was found that the provinces with the highest number of foreign tourists and tourism income were Bangkok, Phuket, and Chonburi, respectively. In contrast, other provinces failed to attract any tourists, as indicated by the data presented in the heat map in Figure 19. Further analysis using Mapping Strategy Groups revealed that Bangkok, Phuket, and Chonburi possess advantages in infrastructure and resources that facilitate and attract foreign tourists. Conversely, other provinces have fewer advantages in these factors, resulting in a clear competitive disadvantage (lock-in). Additionally, provinces such as Krabi, Surat Thani, Songkhla, and Chiang Mai have some infrastructure and natural resources that could attract tourists. However, there remains a significant disparity compared to the three main provinces shown in Figure 20.

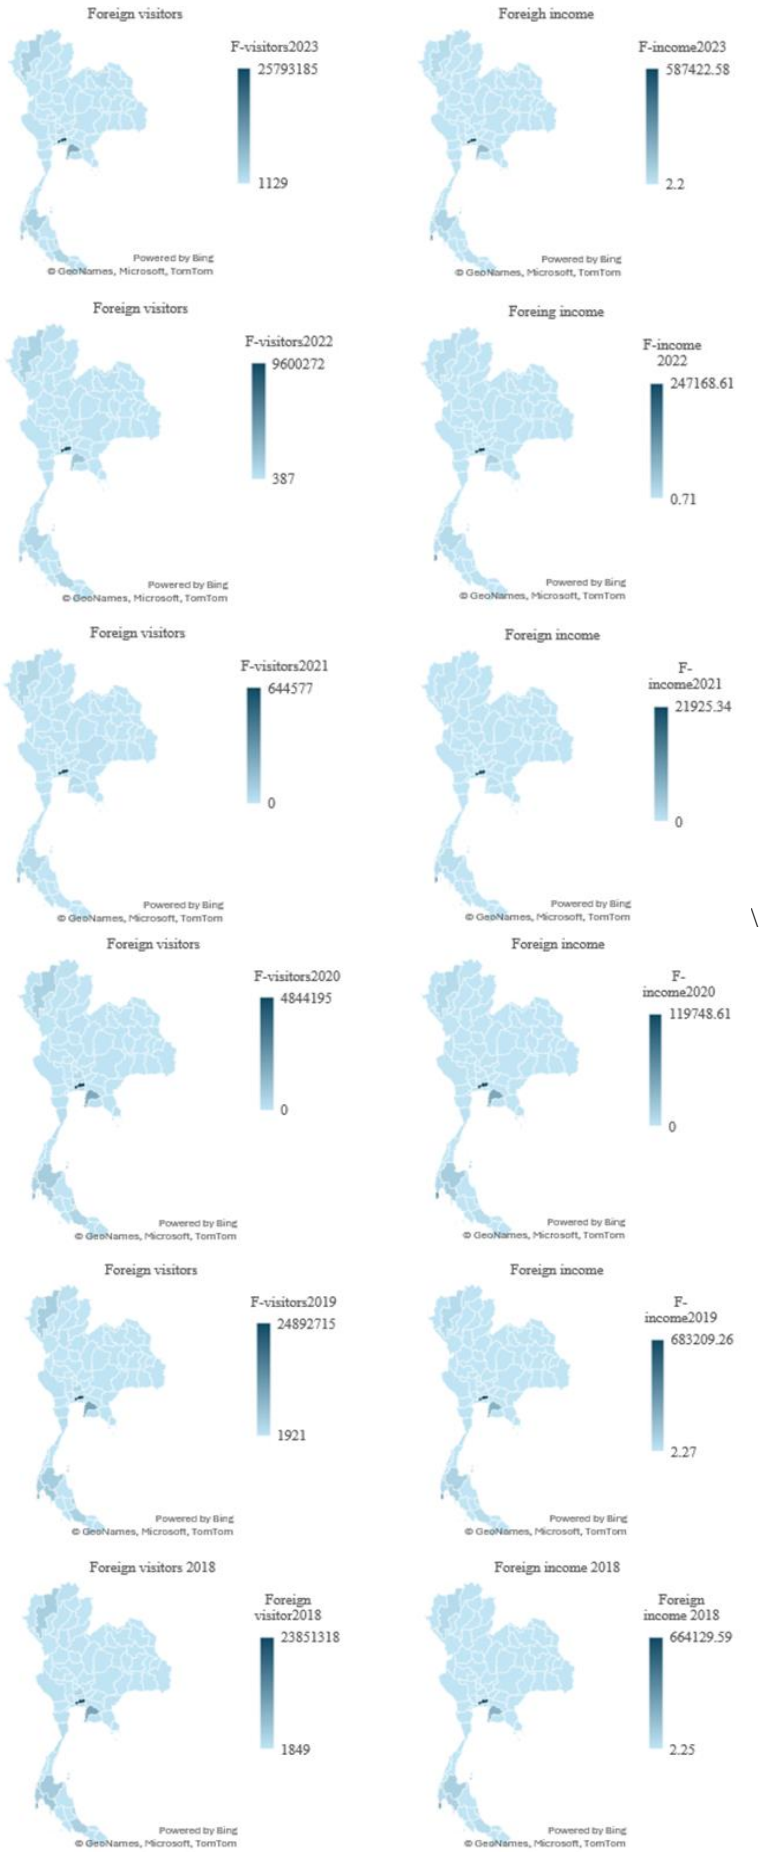

Figure 19. Heat map shows the foreign tourism visitors and revenue from foreign tourist 2018 to 2022 (Source: Compiled by the author based on TAT data)

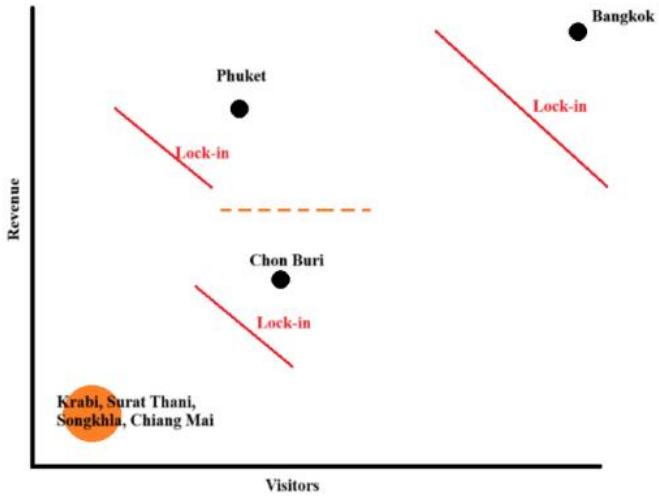

Figure 20. Mapping Strategy Groups for tourism form foreign tourist in Thailand (Source: Compiled by the author based on TAT data)

According to tourism data in Thailand from 2012-2023, tourism in Thailand remains concentrated in a few key provinces. When separating domestic tourism from foreign tourism, it is evident that foreign tourism continues to focus on major provinces such as Bangkok, Chonburi, and Phuket. However, domestic tourism has expanded to a wider variety of provinces, including Krabi, Surat Thani, Songkhla, and Chiang Mai.

Other secondary provinces attract some Thai tourists, but the overall picture of Thai tourism shows that Bangkok, Chonburi, and Phuket are the three main provinces. Chiang Mai, Prachuap Khiri Khan, Phetchaburi, Kanchanaburi, Ayutthaya, and Nakhon Ratchasima have a fair number of tourists but cannot compete in terms of income with the three main provinces. Based on the above data, we can analyze the SWOT and define the TOWS Matrix strategy as follows. The analysis of the external environment enables us to identify and categorize the opportunities and threats facing Thai tourism as follows:

Opportunities: Increased travel and flights, the rise in the number of foreign tourists (including new groups from China and India), government tourism promotion policies, and public and private sector promotions have all contributed to the growth of the tourism industry.

Treat: Countries with significant potential for tourism in ASEAN include Vietnam, Malaysia, Indonesia, the Philippines, and Singapore. These nations face various challenges such as geopolitical issues, trade wars, fluctuations in the global economy, and uncertain events. Additionally, alongside global uncertainties, local environmental challenges such as air pollution continue to negatively affect the overall number of tourists and the pace of recovery in Thailand (Nonthapot et al., 2024). For the analysis of the internal environment, the strengths and weaknesses of the country's tourism can be classified as follows:

Strength: The cost of tourism is low, and the infrastructure is quite comprehensive, particularly in large cities. Accommodation and food are abundant and diverse, with excellent service and beautiful natural resources.

Weakness: Convenient and comprehensive infrastructure is predominantly available in the Bangkok area, while other provinces have limited public transportation options. Accommodation, shops, and service businesses are concentrated mainly in the primary tourist areas of these provinces. Natural resources that attract tourists are concentrated in only a few provinces. The lack of a unique identity in secondary provinces makes tourists perceive them as less worthwhile destinations. Additionally, tourism relies heavily on income from foreign tourists.

From the SWOT analysis, we can derive strategies using the TOWS Matrix as follows:

Maxi-Maxi Strategy (SO): Develop packages and campaigns to attract tourists by enhancing the potential of transportation systems. Improve connections to airports and various tourist attractions to make them more convenient, thereby drawing more visitors to key landmarks. Enhance the quality-of-service systems to create a memorable experience and engage with tourists. Additionally, maintain and improve the aesthetics of tourist attractions and natural resources, ensuring they remain clean and beautiful at all times.

Maxi Mini Strategy (ST): Monitor competitors and adjust response strategies to build confidence, improve service quality, and optimize tourism costs, thereby creating competitive advantages. Ensure equal acceptance of tourists, regardless of race, religion, or language. Establish joint ventures and strategic alliances in various countries to promote tourism and mitigate geopolitical issues. Advocate for government implementation of neutral policies to maintain Thailand's political neutrality.

Mini Maxi Strategy (WO): To promote tourism in secondary cities for foreign tourists, several strategies can be implemented:

1. Organize Tours: Develop and offer organized tours that highlight the unique attractions of secondary cities.
2. Improve Transportation: Enhance both inter-provincial and intra-provincial travel and transportation channels to make these destinations more accessible.
3. Promote Local Businesses: Support and promote potential shops and accommodations in secondary provinces to boost local economies.

4. Highlight Unique Identities: Emphasize the distinct identities and charms of each province to attract tourists. Furthermore, integrating smart tourism technologies like augmented reality with local art routes can significantly enhance tourist engagement in secondary destinations like Songkhla (Trakulmaykee et al., 2025).

5. Create Attractive Packages: Develop tourism packages that include secondary provinces alongside main provinces, offering them at attractive prices to increase awareness.

6. Utilize Media: Publicize secondary provinces through various media channels to ensure foreign tourists are aware of these destinations

Mini Mini Strategy (WT): Promote tourism among high-income and high-spending domestic tourists to encourage more travel within Thailand. Enhance confidence, improve the environment, and develop infrastructure and facilities to attract potential foreign tourists to settle down.

CONCLUSION

From the literature review, data analysis, and SWOT analysis, it was found that the tourism sector is a key driver of the economy, generating economic circulation and effectively distributing income across various sectors. This is particularly true in developed countries, which benefit from robust infrastructure, facilities, and a variety of attractive tourist attractions and landmarks. In contrast, the situation in developing countries differs, particularly in terms of income distribution.

In these countries, tourism income is often concentrated in major urban areas and large business groups, rather than being distributed to communities. This is due to a lack of comprehensive basic facilities and the absence of attractive tourist attractions and significant landmarks in secondary provinces. As a result, these countries struggle to attract repeat visitors or regular tourists, as there is a lack of variety and uniqueness in each area. This makes tourism experiences in these regions monotonous, often leading to a one-time visit being sufficient for travelers.

Similar to the tourism situation in Thailand, income and tourists are concentrated in only a few important provinces, particularly Bangkok, Phuket, and Chonburi. Other provinces receive significantly less income from tourism due to insufficient infrastructure and facilities, as well as a lack of identity and charm to attract tourists. These factors prevent other provinces from competing equally with Bangkok, Phuket, and Chonburi (Pattaya).

When considering SWOT analysis along with basic information, it is evident that Thailand lacks distributed facilities and infrastructure beyond Bangkok and its vicinity. This results in tourists and tourism income being concentrated in Bangkok, with some distribution to Chonburi due to its beaches, tourist facilities, and numerous leading hotels. Chonburi's proximity to Bangkok (only an hour and a half by car) also contributes to this concentration. Meanwhile, Phuket attracts tourists with its beautiful natural resources, including beaches and mountains, as well as important ports and yacht piers that serve as gateways to islands and tourist beaches along the Andaman coast.

Additionally, Phuket's many luxury hotels and resorts appeal to high-income tourists. Data indicates that Thailand's tourism industry relies heavily on these three provinces. Other provinces are secondary destinations for tourists who have already visited Bangkok, Phuket, or Chonburi. Consequently, tourists, especially foreigners, are less likely to return to Thailand multiple times due to the lack of sufficient attractions.

Domestic tourism generates relatively little income compared to foreign tourism.

To address this, Thailand must adjust its tourism strategies by focusing on distributing infrastructure and facilities to other important and secondary tourism provinces. Strategies should also include promoting and encouraging tourists to explore other provinces. Additionally, promoting the uniqueness and landmarks of each area can create awareness and value among tourists. A more distributed and diverse tourism approach will attract repeat visits from foreign tourists and high-income Thai tourists who typically travel abroad. Thailand's beautiful natural resources, excellent service, diverse hotels, accommodations, and food (especially street food), along with low travel costs, are attractive to tourists. However, this advantage is not sustainable and can be easily challenged by competitors from neighboring ASEAN countries such as Vietnam or Malaysia, as well as countries with high tourism potential like Japan. Therefore, Thailand needs to adjust its tourism strategy to create a competitive advantage and generate more economic benefits.

Abstract: Transport infrastructure represents a fundamental spatial component shaping tourist mobility patterns and the sustainability of destinations. Despite extensive research on tourism development, limited attention has been given to the relationship between transport accessibility and tourist experience in emerging destinations. This study analyzes how transport infrastructure influences visitor satisfaction and sustainable tourism development, with a case study focusing on Kosovo. The research applies a quantitative approach based on a structured questionnaire administered to 97 tourists visiting different destinations. Descriptive and comparative statistical analyses were used to evaluate perceptions of road infrastructure, public transport accessibility, alternative mobility options and information availability. The methodological approach follows similar quantitative designs applied in recent tourism studies in Kosovo. The findings indicate that transport quality significantly affects tourist satisfaction, particularly road conditions and travel comfort, accessibility, safety, and overall travel convenience. While limited public transport accessibility and insufficient information reduce destination attractiveness. The results also show moderate interest in sustainable mobility, suggesting that improving alternative transport infrastructure can enhance both visitor experience and environmental sustainability. The study highlights that accessibility is not only a logistical factor but also a strategic component of destination competitiveness. Furthermore, the findings emphasize that better integration of transport planning with tourism policies, improved multimodal connectivity, and greater investment in sustainable mobility solutions can strengthen destination accessibility, enhance visitor satisfaction, increase tourism competitiveness, and contribute to the long-term sustainable development of tourism in Kosovo and other emerging destinations. Integrating transport planning with tourism policies is essential for balancing tourism growth and environmental protection in emerging destinations.

Keywords: transport accessibility, tourist experience, sustainable tourism, mobility, destination competitiveness, Kosovo

INTRODUCTION

Tourism development is strongly dependent on spatial accessibility, which determines the ability of visitors to reach, explore and experience destinations. Among the different components of destination competitiveness, transport infrastructure represents a critical factor influencing tourist mobility patterns, travel comfort and overall satisfaction. Accessibility conditions not only shape the attractiveness of destinations but also influence the distribution of tourist flows and the intensity of tourism activities. Recent tourism research increasingly links mobility systems with sustainable development, emphasizing that transport affects environmental pressure, spatial concentration of visitors and the socio-economic benefits generated for local communities. Efficient and integrated transport networks facilitate movement between attractions, reduce travel uncertainty and improve the perceived quality of the tourism product, while inadequate infrastructure may limit visitation and negatively affect destination image. Although the relationship between transport and tourism has been widely discussed, limited empirical research has examined how accessibility conditions influence tourist experience in emerging destinations, particularly in Southeast European transition economies.

In these contexts, rapid tourism growth is often not accompanied by coordinated transport planning, creating imbalances between development and environmental sustainability. To address this gap, this study investigates the influence of transport infrastructure on tourist experience and sustainable destination development using a quantitative approach based on visitor perceptions. The research evaluates road infrastructure quality, public transport accessibility, alternative mobility

options and information availability as determinants of satisfaction and destination competitiveness. The findings aim to support integrated planning strategies linking transport policy and tourism development in order to achieve sustainable territorial growth. Based on the identified research gap, this study aims to evaluate the relationship between transport accessibility and tourist satisfaction, identify the main accessibility barriers affecting tourist mobility within destinations, and assess the contribution of sustainable mobility options to destination competitiveness and sustainability.

Accordingly, the study addresses the following research questions: **(RQ1)** How does transport accessibility influence tourist satisfaction and the overall travel experience? **(RQ2)** What accessibility barriers limit tourist mobility within destinations? **(RQ3)** Do sustainable mobility options contribute to perceived destination sustainability? Based on these research questions, three hypotheses were formulated: **H1:** Higher perceived quality of transport infrastructure is positively associated with tourist satisfaction. **H2:** Limited transport accessibility negatively affects tourists' perceived ease of movement within the destination. **H3:** The availability of sustainable mobility options, including public transport and alternative transport modes, positively influences perceived destination sustainability.

Transport constitutes a fundamental component of the tourism system because it determines the physical accessibility of destinations and the possibility of experiencing tourism products. Accessibility connects tourist-generating regions with destination areas and enables participation in tourism activities (Page, 2009). Consequently, the quality of transport infrastructure influences not only visitation levels but also visitors' perceptions of destination attractiveness and their intention to revisit. Transport functions as an interface between tourists and destinations, shaping first impressions through travel time, comfort, safety, and cost (Prideaux, 2000). Therefore, the travel phase should be considered an integral part of the tourism experience rather than merely a logistical stage preceding the visit. Recent studies emphasize that the tourist experience begins before arrival at the destination, during the planning and travel stages. Difficult, unsafe, or uncomfortable transport conditions may generate negative perceptions even when the destination itself offers high-quality attractions (Dileep & Kurien, 2021). As a result, mobility conditions influence tourist satisfaction and post-visit behavioural intentions (Thompson & Schofield, 2007).Empirical evidence from emerging tourism destinations indicates that visitor perceptions and destination competitiveness are strongly shaped by infrastructure quality and supporting development strategies (Tahiri et al., 2025). These findings highlight the importance of accessibility conditions in forming the overall tourism experience. Furthermore, digitalisation has expanded the role of mobility systems in tourism.

Access to online booking systems, real-time transport information, and navigation applications reduces travel uncertainty and improves destination usability. Mobility convenience has therefore become an increasingly important competitive factor in destination choice, particularly for younger generations of tourists (UNWTO, 2022). Overall, the literature demonstrates that perceived transport quality directly affects tourist satisfaction and behavioural intentions, supporting the assumption that accessibility constitutes a key determinant of the tourist experience.

Transport infrastructure and sustainable tourism development

Sustainable tourism development requires balancing economic growth with environmental protection and social well-being. Within this framework, transport infrastructure plays a strategic role because it simultaneously enables tourism activity and generates environmental pressures. Accessibility improvements increase visitation and economic benefits, while intensive motorised mobility contributes to emissions, congestion and spatial pressure on destinations (Dickinson & Robbins, 2008). Consequently, transport planning has become a central component of sustainability-oriented destination management. Public transport is widely recognised as a mechanism for improving both sustainability and social equity in tourism. Reliable and affordable services therefore contribute not only to mobility efficiency but also to the attractiveness and quality of the tourist experience (Parahoo et al., 2014). Unlike private car dependency, collective transport systems facilitate broader access to attractions, support spatial distribution of visitors and reduce environmental impact. Regular, reliable and affordable services therefore contribute not only to mobility efficiency but also to the equitable distribution of tourism benefits among different social groups (Beirão & Cabral, 2007).

Recent tourism strategies increasingly incorporate alternative and low-carbon mobility solutions, including walking infrastructure, cycling routes and shared mobility services. These approaches reduce environmental externalities while simultaneously enhancing the experiential quality of destinations by supporting slower and place-based forms of tourism. Technological innovations such as smart mobility systems, real-time information platforms and renewable energy transport solutions further reinforce the transition toward sustainable travel behaviour (UNEP, 2022).

In emerging destinations, the effectiveness of sustainable mobility depends on coordinated governance and policy implementation. Empirical research in Kosovo highlights the importance of integrated development strategies and institutional engagement in supporting sustainable tourism outcomes (Tahiri et al., 2025).

Overall, the literature indicates that sustainable destination development depends not only on transport infrastructure quality but also on the availability of alternative mobility options and policy coordination, supporting the assumption that sustainable transport contributes to perceived destination sustainability.

Public policies and investments in transport for sustainable tourism

The development of transport infrastructure in tourism destinations depends largely on public policy frameworks and long-term strategic investments. Governments play a central role in coordinating land-use planning, transport networks and environmental protection measures in order to support sustainable destination development (Hall, 2008). Integrated policies align mobility systems with tourism growth, preventing uncontrolled spatial expansion and environmental degradation. Effective transport planning also requires continuous monitoring and evaluation. Infrastructure should not be considered a

completed intervention after construction but a dynamic process requiring performance assessment over time (Li et al., 2021). Indicators such as emission reduction, accessibility improvement, visitor satisfaction and local economic impact are essential for evaluating the sustainability of transport investments (Kovaçi et al., 2023). Contemporary policy approaches increasingly incorporate digitalisation and smart mobility solutions (Myrovali et al., 2025). Real-time transport information, shared mobility services and integrated payment systems improve operational efficiency while reducing congestion and environmental pressure (UNEP, 2022). These measures demonstrate that governance quality and institutional coordination are critical determinants of sustainable tourism outcomes, particularly in developing destinations.

Overall, the literature indicates that transport sustainability depends not only on infrastructure provision but also on policy effectiveness and institutional capacity to manage mobility systems. The development of transport infrastructure in tourism destinations depends largely on public policy frameworks and long-term strategic investments (Khadaroo & Seetanah, 2007). Sustainable tourism development requires balancing economic growth with environmental protection and social well-being. Within this framework, transport infrastructure plays a strategic role because it simultaneously enables tourism activity and generates environmental pressures. Improvements in accessibility increase visitation and economic benefits, while intensive motorised mobility contributes to emissions, congestion, and spatial pressure on destinations (Dickinson & Robbins, 2008). Consequently, transport planning has become a central component of sustainability-oriented destination management. Public transport is widely recognised as a mechanism for improving both sustainability and social equity in tourism. Reliable and affordable services contribute not only to mobility efficiency but also to the attractiveness and quality of the tourist experience (Parahoo et al., 2014). Unlike private car dependency, collective transport systems facilitate broader access to attractions, support the spatial distribution of visitors, and reduce environmental impacts.

Recent tourism strategies increasingly incorporate alternative and low-carbon mobility solutions, including walking infrastructure, cycling routes, and shared mobility services. These approaches reduce environmental externalities while simultaneously enhancing the experiential quality of destinations by supporting slower and place-based forms of tourism. Technological innovations, such as smart mobility systems, real-time information platforms, and renewable-energy transport solutions, further reinforce the transition toward sustainable travel behaviour (UNEP, 2022).

In emerging destinations, the effectiveness of sustainable mobility depends on coordinated governance and policy implementation. Empirical research in Kosovo highlights the importance of integrated development strategies and institutional engagement in supporting sustainable tourism outcomes (Tahiri et al., 2025).

Overall, the literature indicates that sustainable destination development depends not only on transport infrastructure quality but also on the availability of alternative mobility options and effective policy coordination, supporting the assumption that sustainable transport contributes to perceived destination sustainability. The development of transport infrastructure in tourism destinations depends largely on public policy frameworks and long-term strategic investments. Governments play a central role in coordinating land-use planning, transport networks, and environmental protection measures to support sustainable destination development (Hall, 2008). Integrated policies align mobility systems with tourism growth, preventing uncontrolled spatial expansion and environmental degradation. Effective transport planning also requires continuous monitoring and evaluation. Infrastructure should not be considered a completed intervention after construction but rather a dynamic process requiring regular performance assessment over time (Li et al., 2021).

Indicators such as emission reduction, accessibility improvement, visitor satisfaction, and local economic impact are essential for evaluating the sustainability of transport investments (Kovaçi et al., 2023). Contemporary policy approaches increasingly incorporate digitalisation and smart mobility solutions (Myrovali et al., 2025). Real-time transport information, shared mobility services, and integrated payment systems improve operational efficiency while reducing congestion and environmental pressure (UNEP, 2022). These measures demonstrate that governance quality and institutional coordination are critical determinants of sustainable tourism outcomes, particularly in developing destinations. Overall, transport sustainability depends not only on infrastructure provision but also on policy effectiveness and institutional capacity to manage mobility systems (Khadaroo & Seetanah, 2007).

Transport infrastructure also represents a structural component of the tourism product because it shapes the visitor experience throughout all travel stages, from trip planning to on-site mobility (Page, 2009). Accessibility conditions influence perceived convenience, travel effort, and the ability to participate in tourism activities within the destination (Chen et al., 2025). Visitor satisfaction is strongly associated with transport attributes such as travel time, comfort, safety, reliability, and service frequency (Swarbrooke & Horner, 2006). When these conditions are favourable, tourists tend to engage in more activities and develop positive perceptions of the destination.

Recent studies show that tourists increasingly value environmentally friendly mobility systems (Kim et al., 2024). The availability of sustainable transport options, including cycling infrastructure, shared mobility, and clean vehicles, enhances destination image and aligns with visitors' environmental attitudes (ETC, 2018). Consequently, transport quality contributes both to experiential value and to perceived destination responsibility. Moreover, the rapid digital transformation of the tourism sector has created new opportunities to enrich tourist experiences through technologies such as Virtual Reality (VR) and Artificial Intelligence (AI). For example, research from Vietnam demonstrates that digital innovations, including virtual destination previews and AI-powered travel assistants, are transforming the way tourists plan, experience, and evaluate their journeys (Dang & Duong, 2025). These developments indicate that modern transport systems are increasingly integrated with digital technologies to improve accessibility, convenience, and visitor satisfaction. Building upon this body of literature, the present study examines the role of transport infrastructure and mobility conditions in shaping tourists' experiences, satisfaction, and perceptions of destination accessibility and sustainability in Kosovo.

METHODOLOGY

Research design and data collection

This study applies a quantitative research design to examine the relationship between transport infrastructure and tourist experience. Primary data were collected through a structured questionnaire administered to tourists visiting several destinations in Kosovo. The survey approach was selected because visitor perception represents a key indicator for evaluating accessibility conditions and experiential quality in tourism research. The questionnaire included items measuring perceived transport infrastructure quality, accessibility, travel comfort, travel time and the use of sustainable mobility options. Responses were recorded using a five-point Likert scale, allowing the measurement of attitudes and satisfaction levels related to mobility conditions within destinations. Collected data were analysed using descriptive and inferential statistical methods. Descriptive statistics were used to evaluate general perception patterns, while association analysis was applied to examine relationships between transport accessibility and tourist satisfaction.

This methodological approach enables empirical testing of the proposed hypotheses regarding the influence of transport infrastructure on visitor experience and perceived sustainability.

Sample and measurement variables

The study is based on a field survey conducted among tourists visiting multiple destinations in Kosovo. A total of 97 valid questionnaires were collected and used for analysis. Respondents were selected using a random intercept approach in tourism areas in order to capture diverse visitor profiles and travel behaviours.

The questionnaire consisted of closed-ended questions measured on a five-point Likert scale (1 = very low to 5 = very high). The instrument included three groups of variables:

- Transport infrastructure quality (road conditions, safety, travel time, comfort)
- Accessibility and mobility (ease of movement, public transport availability, information availability)
- Sustainable mobility perception (use of alternative transport modes and environmental awareness)

Data were processed using SPSS statistical software. Descriptive statistics were used to examine overall perception patterns, while association analysis was applied to evaluate the relationship between transport accessibility and tourist satisfaction and to test the proposed hypotheses.

Ethical considerations

Participation in the survey was voluntary and anonymous. Respondents were informed about the purpose of the study and their right to withdraw at any time. No personally identifiable information was collected, ensuring confidentiality and compliance with standard research ethics guidelines.

RESULTS

Sample characteristics

The study included 97 respondents. In order to improve the visibility of the demographic data, the sample characteristics are presented separately according to gender, age group, origin and education level. As shown in Figure 1, the gender distribution of the sample was relatively balanced. Female respondents represented 53.6% of the sample, while male respondents represented 46.4%. This balance provides a more inclusive overview of tourist perceptions across both gender groups. Figure 2 shows that the largest age group was 26–35 years, representing 36.1% of respondents. This was followed by the 18–25 age group, which accounted for 28.9%.

Respondents aged 36–50 represented 21.6%, while those over 50 formed the smallest share, with 13.4%. Overall, the sample is mainly composed of young and middle-aged tourists.

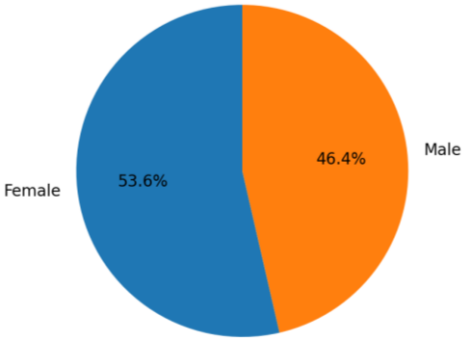

Figure 1. Gender distribution of respondents (n= 97) (Source: Author's own survey data)

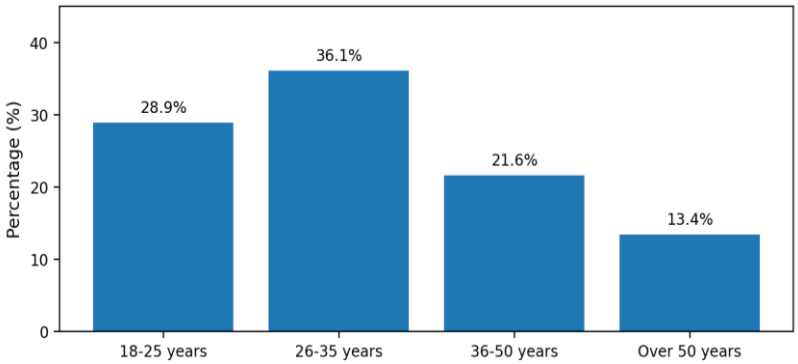

Figure 2. Age distribution of respondents (n= 97) (Source: Author's own survey data)

As presented in Figure 3, international visitors made up 56.7% of the sample, while domestic tourists represented 43.3%. This indicates that the study includes perspectives from both foreign and local tourists, which is important for understanding how transport infrastructure and accessibility are perceived by different types of visitors. Figure 4 shows that most respondents had a higher education background. Nearly half of the sample held a Bachelor's degree, while 32.0% had

a Master's degree or higher. The remaining 18.5% belonged to other education levels. This suggests that the sample is relatively well educated and likely able to provide informed evaluations of transport quality, accessibility and sustainable mobility conditions. Overall, the sample reflects a diverse group of respondents in terms of gender, age, origin and education. These characteristics are relevant for the study because tourists' demographic profiles may influence how they perceive transport infrastructure, mobility conditions and destination accessibility in Kosovo.

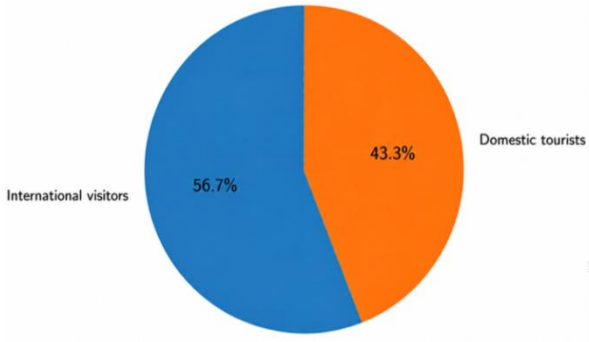

Figure 3. Origin of respondents (n= 97)
(Source: Author's own survey data)

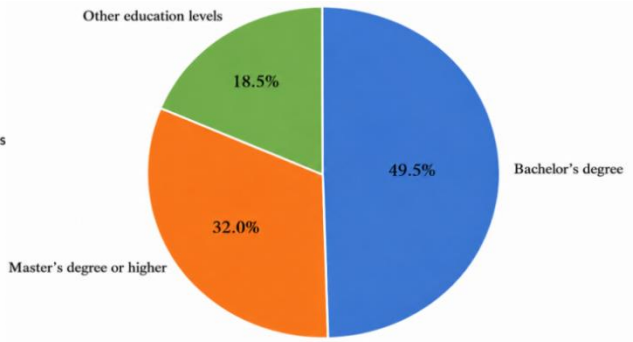

Figure 4. Education level of respondents (n= 97)
(Source: Author's own survey data)

Transport infrastructure perception

Tourists reported a moderately positive perception of road infrastructure, with a mean value of 3.7/5 and 62% of respondents expressing satisfaction. These findings indicate an acceptable basic level of accessibility, although infrastructure quality still leaves room for improvement in terms of destination competitiveness.

Public transport accessibility received lower evaluations, with a mean value of 3.4/5 and only 57% of respondents considering it easily accessible. The results suggest the existence of mobility barriers within destinations, particularly related to information availability, service frequency and connectivity between tourist attractions.

Overall, the results indicate that while primary access to destinations is relatively satisfactory, internal mobility remains a limiting factor for the tourist experience and may reduce the potential for sustainable travel behaviour.

Transport quality and sustainable mobility perception

Respondents strongly confirmed the importance of transport quality for the tourism experience. In order to improve the visibility of the results, the main findings related to transport quality and sustainable mobility are presented in Figure 5.

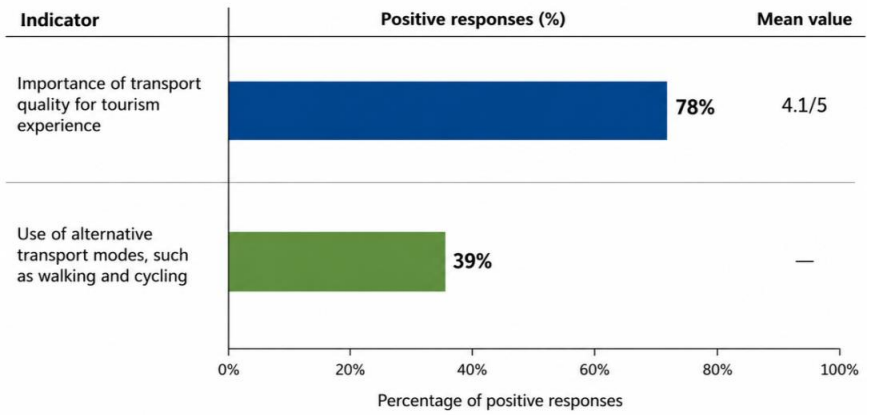

Figure 5. Perceptions of transport quality and sustainable mobility (Source: Author's own survey data)

As shown in Figure 5, transport quality was evaluated as an important factor in shaping the tourism experience, with a mean value of 4.1/5 and 78% positive responses. This indicates that mobility conditions represent one of the main determinants of visitor satisfaction and directly influence the perceived attractiveness of destinations.

Regarding sustainable mobility, 39% of tourists reported using alternative transport modes such as walking and cycling. Although this shows a noticeable interest in low-impact travel behaviour, the relatively moderate share suggests that limitations in infrastructure may still restrict the wider use of sustainable mobility options.

Overall, the findings suggest that improving transport service quality may increase visitor satisfaction, while expanding alternative mobility infrastructure could enhance both tourist experience and environmental sustainability.

Policy awareness and information accessibility

Tourists demonstrated relatively low awareness of sustainable tourism policies. To make the results clearer for readers, the main findings related to policy awareness and information accessibility are presented in Figure 6.

As shown in Figure 6, awareness of sustainable tourism policies received a mean evaluation of 3.0/5, with only 45% of respondents perceiving the existence of such measures. This suggests that sustainability initiatives may either be limited or insufficiently communicated to visitors, reducing their potential influence on tourist behaviour and destination image.

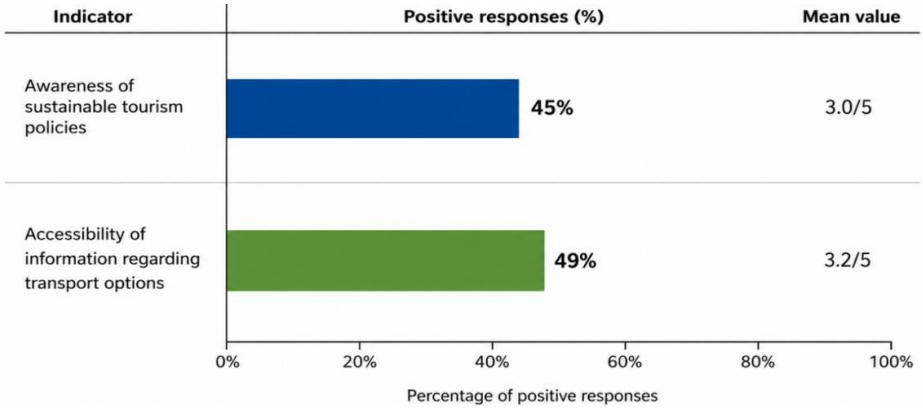

Figure 6. Policy awareness and information accessibility (Source: Author's own survey data)

Similarly, information accessibility regarding transport options received modest evaluations, with a mean value of 3.2/5 and 49% positive responses. These results indicate that visitors may face difficulties in obtaining clear mobility information, including routes, schedules and available transport modes.

Overall, the findings reveal that beyond physical infrastructure, informational and institutional aspects of mobility also affect tourist experience and the perceived sustainability of destinations.

DISCUSSION

The findings confirm that transport accessibility constitutes a central component of the tourist experience. The positive relationship between perceived transport quality and visitor satisfaction supports previous research emphasizing accessibility as a determinant of destination attractiveness (Page, 2009; Prideaux, 2000). The strong influence of mobility conditions on overall experience indicates that tourists evaluate destinations not only through attractions but through the entire travel process. This reinforces the argument that transport infrastructure should be considered part of the tourism product rather than a supporting service.

At the same time, the results reveal the presence of internal mobility constraints. Limited accessibility between attractions and insufficient transport information reduce tourists' ability to explore destinations effectively. These findings align with accessibility-based destination development theories, which emphasize that poor connectivity restricts tourism participation and spatial distribution of visitors (Hall, 2008). Therefore, even when primary access to destinations is acceptable, weak internal mobility may limit tourism competitiveness.

The study also highlights the role of sustainable mobility and policy visibility. Moderate use of alternative transport modes combined with low awareness of sustainability policies suggests that environmental strategies are not fully integrated into visitor experience. Similar observations have been reported in emerging destinations where institutional implementation lags behind infrastructure development (Tahiri et al., 2025). This indicates that sustainability depends not only on physical infrastructure but also on communication and governance mechanisms.

Overall, the results demonstrate that transport influences tourism through three interconnected dimensions: accessibility, experience quality and perceived sustainability. The contribution of this study lies in showing that improving infrastructure alone is insufficient without integrated mobility management and policy communication. This means that transport development should be understood as part of a wider tourism governance system, where physical infrastructure, public transport services, visitor information and sustainability policies work together. The findings suggest that tourists' experiences are shaped not only by the possibility of reaching a destination, but also by the quality, clarity and convenience of mobility within the destination. In the case of Kosovo, this highlights the need to combine infrastructure investment with improved public transport accessibility, better information about routes and schedules, and stronger visibility of sustainable mobility options. Therefore, a more coordinated approach to transport and tourism policy could contribute to higher visitor satisfaction, a stronger destination image and more sustainable tourism development.

CONCLUSIONS

This study examined the relationship between transport infrastructure, tourist experience and sustainable destination development using visitor perception data. The results confirm that accessibility conditions significantly influence tourist satisfaction and perceived destination attractiveness. Transport quality affects not only mobility convenience but also behavioural outcomes such as destination evaluation and revisit intention.

The findings further indicate that internal mobility represents a critical limitation. While primary access to destinations is relatively acceptable, insufficient public transport accessibility and limited information availability restrict visitor movement within destinations. This demonstrates that tourism competitiveness depends on the efficiency of local mobility systems rather than solely on external accessibility. The research also shows that sustainable mobility remains

underutilised. Moderate use of alternative transport modes and low awareness of sustainability policies suggest that environmental strategies are not fully integrated into the tourism experience. Therefore, sustainable destination development requires coordinated infrastructure, policy implementation and communication measures.

From a practical perspective, improving destination competitiveness requires integrated mobility planning focused on internal connectivity, reliable public transport services and accessible visitor information systems. Supporting low-impact mobility solutions may simultaneously enhance tourist experience and environmental sustainability.

Limitations of the study

This study has some limitations. First, it is based on a sample of 97 respondents, which limits the possibility of generalising the findings to all tourists visiting Kosovo. Second, the research relies on self-reported survey data, meaning that the results reflect tourists' perceptions rather than direct measurements of transport infrastructure or service quality. Third, the study focuses on selected destinations and does not establish direct causality between transport conditions and tourist satisfaction. Future research could include a larger sample, cover more destinations and combine survey data with interviews or official transport data. Despite these limitations, the study provides useful evidence that transport infrastructure, mobility management and policy communication are important for improving tourist satisfaction and supporting sustainable tourism development in Kosovo.

Architectural heritage of as-salt, Jordan: Comprehensive analysis, tourism development potential and structural assessment framework. *Geojournal of Tourism and Geosites*, 67(3), 2509–2525. https://doi.org/10.30892/gtg.67359-1871

Abstract: This study examines As-Salt, Jordan's architectural legacy, which is crucial to cultural heritage tourism since it was added to the UNESCO World Heritage List in 2021. This study explores the unique architectural features of As-Salt through thorough documentation and analysis of the city's historical building stock. These features include the city's famous yellow limestone construction, the fusion of Ottoman and European classical influences, and the patterns of spatial organization that developed during the Golden Age (1860–1920). In order to assess the built heritage of As-Salt's current relevance and preservation potential, this study combines architectural documentation, morphological analysis, and tourism development perspectives. The results show that the city's architecture, which combines Ottoman spatial traditions, European neoclassical elements, and native stone-building techniques that developed from nineteenth-century commercial vernacular through early twentieth-century modernization, is a singular example of architectural synthesis and cultural coexistence. The study problems key conservativeness by questioning the trade-off development between tourism and heritage. Discussions may be on the emergent management of heritage that would see the integration of sustainable tourism with respect to the cultural significance of a sacred site, which also provides for quality visitor experience. These conclusions are of much value for those professionals managing urban historic districts in the ME and point to the fact that architectural heritage is highly crucial in respect to sustainable urban development. In this research, a framework is proposed for structural assessment and restoration, which consists of non-destructive diagnostics integrated with a compatible intervention strategy. Literature evidence suggests that utilizing ultra-fine lime-based grouts (D_{90} under 100 μm) in conjunction with Textile-Reinforced Mortar (TRM) systems can offer a high-performance solution for enhancing ductility and seismic resistance. This framework aims to ensure safe adaptive reuse of heritage assets for the tourism sector while maintaining structural integrity in a seismically active region.

Keywords: As-Salt, Architectural Heritage, UNESCO World Heritage, Cultural Heritage Tourism, Heritage Conservation, Ottoman Architecture, Jordan, NDE, TRM, Lime grouts

INTRODUCTION

Jordan's As-Salt City is a prime example of late 19th- and early 20th-century traditional Levantine architecture. The city saw substantial architectural development during its heyday (1881–1918), propelled by regional trade and the blending of Ottoman, European, and indigenous building traditions. A unique architectural vocabulary with distinctive façade compositions, material choices, and spatial arrangements resulted from this synthesis (Assi, 2020; Zalloom & Tarrad, 2020). In 2021, As-Salt's historic core was inducted into the World Heritage List by UNESCO, which acknowledged the city's Outstanding Universal Value as a demonstration of architectural excellence, urban hospitality, and cultural tolerance (UNESCO, 2021). Built primarily of native yellow limestone using traditional masonry techniques, the city's significant heritage building stock is both a cultural asset and a conservation challenge that calls for thorough documentation and strategic management (Cotella et al., 2025; Aburamadan et al., 2022).

As-Salt's UNESCO designation has put it in a favorable position for the growth of heritage tourism, but it has also made preservation more difficult. Sustainable heritage management necessitates striking a balance between community

involvement, economic viability, accessibility for tourists, and conservation imperatives (Garrod & Fyall, 2000). Maintaining the site's Outstanding Universal Value while creating tourism infrastructure and programming that doesn't jeopardize architectural integrity or disturb residential communities is the main source of conflict (Jamhawi & Hajahjah, 2017). To support heritage management strategies that promote sustainable tourism development while maintaining the city's cultural authenticity and spatial character, this study looks at important architectural typologies found in As-Salt's historic center. The unique masonry typology of As-Salt's architectural legacy consists of load-bearing walls made of yellow limestone that can reach a thickness of one meter and support intricate cross-vaulted systems.

Because the city is close to the Dead Sea Transform, which is an active seismic zone, structural conservation requires a thorough understanding of the mechanisms underlying lime mortar carbonation and long-term durability performance (Balzani et al., 2024; Chen et al., 2024). In order to maintain the UNESCO-listed fabric and guarantee seismic safety, this study suggests combining sophisticated non-destructive testing fusion protocols (combining sonic velocity profiling with electromagnetic mapping) (Roumeliotis et al., 2024; Barrile et al., 2024).

Understanding this architectural legacy requires situating it within its historical context. The highest possible level of economic development came during the final days of Ottoman rule, therefore during this period, As-Salt became the economic axis of East Jordan. The city's geographical location was the main impetus behind its economic development as a passage along trade routes connecting Palestine and Syria with their Transjordanian backwoods. The kind of wealth managed by the mercantile elite trickled down in a manner creating changes in the landscape, redeploying storeys of privately-built mansions by wealthy families which purported to mark some discriminator of wealth and status in terms of Levantine architectural style (Rogan, 1999; Assi, 2020). During the golden season, some merchant families from the cities of the Levant brought architectural know-how, building techniques, and a very particular set of decorative traditions to As-Salt (UNESCO, 2021). This changing of cultural mores produced a peculiar architectural trend combining Ottoman interval structures, elements of European styles, and local building techniques (Assi, 2020).

It was this migration of skilled craftsmen to As-Salt that made this development possible, aided sharply by the master builder of Nablus, ʿAbd al-Rahman al-ʿAqruq, who shared his accomplishments, among others, in advanced Levantine architectural techniques transforming many a local bizarre design into yellow lime parts, fancy building fronts, and more than functional room designs (Jordan News, 2021; UNESCO World Heritage Site Guide, 2014).

These historical dynamics are best interpreted through established analytical frameworks. Ottoman architectural theory (Necipoğlu, 2005) and Islamic urban morphology studies (Bianca, 2000) establish analytical frameworks for understanding As-Salt's spatial organization. These theoretical foundations provide essential context for interpreting the synthesis of architectural traditions evident in As-Salt's built heritage. Regional architectural research examines economic-architectural relationships in Levantine cities (Assi, 2020), Ottoman administrative contexts (Rogan, 2020), and digital heritage documentation methodologies (Cotella et al., 2025).Building on these frameworks, heritage tourism scholarship (Timothy & Boyd, 2003; McKercher & du Cros, 2002) provides conceptual tools for evaluating sustainable tourism development potential. These frameworks emphasize the relationship between architectural authenticity and visitor experience quality, balanced with conservation imperatives and community engagement (Garrod & Fyall, 2000).

Alongside these cultural and touristic considerations, the structural dimension of heritage conservation demands equal attention. Contemporary approaches to heritage masonry conservation emphasize minimum intervention principles (ICOMOS) while addressing seismic vulnerability through compatible materials. Research demonstrates that ultra-fine lime-based grouts ($D_{90} < 100$ μm) combined with Textile-Reinforced Mortar (TRM) systems offer effective solutions for enhancing ductility and seismic resistance while maintaining material compatibility with historic fabric (Petrovčič & Kilar, 2022; Dinç-Şengönül et al., 2023). Non-destructive testing fusion protocols enable comprehensive structural assessment without compromising heritage values (Roumeliotis et al., 2024; Barrile et al., 2024).

PROBLEM STATEMENT, RESEARCH QUESTIONS, AND OBJECTIVES

Problem Statement

There is a significant lack of thorough architectural documentation of As-Salt's stock of historic buildings, even with the city's 2021 UNESCO World Heritage designation. Although recent literature has recognized the site's cultural and architectural significance (Assi, 2020; Zalloom & Tarrad, 2020; Cotella et al., 2025), there is still a dearth of systematic architectural analysis. The way Ottoman, European, and vernacular architectural traditions coexist in As-Salt's urban fabric has not been thoroughly examined in previous research. The Abu Jaber House is one of the few exceptions to the general lack of comprehensive architectural documentation and technical evaluation of heritage buildings. This lack of documentation makes it difficult to integrate architectural heritage into frameworks for sustainable tourism development and limits evidence-based conservation planning (Alnsour et al., 2023; Zalloom & Tarrad, 2020). In the heritage context of As-Salt, a thorough scholarly analysis is necessary to determine the relationship between architectural authenticity, spatial quality, and visitor experience.

For As-Salt and the surrounding area to benefit economically and socially from the city's cultural assets, a thorough research framework that connects formal architectural analysis, heritage documentation, and sustainable tourism principles is necessary. Beyond documentation, As-Salt's heritage faces two structural challenges: the inherent seismic vulnerability of multi-leaf limestone masonry walls, which often have internal voids and insufficient shear transfer capacity, and increased live loads from tourism adaptation (Dinç-Şengönül et al., 2023; Van Gemert et al., 2015). In similar contexts, historical interventions with incompatible materials, especially Portland cement, have accelerated the deterioration of limestone through As-Salt crystallization (Loke et al., 2025). In order to overcome these obstacles, knowledge-based structural evaluation that complies with ICOMOS minimum intervention guidelines must replace aesthetic restoration (Petrovčič & Kilar, 2022).

Research Questions

Main Research Question: How do the city's architectural heritage buildings aid in their promotion of tourism potential and sustainable heritage development, in As-Salt City and its surroundings? Sub-Questions:

First, what are the architectural elements and construction methods characteristic of traditional buildings in As-Salt City reflecting Ottoman, European, and local architectural characteristics? Second, how does the Abu Jaber House exemplify the evolution of architecture and craftsmanship during As-Salt City's golden age, and what are the architectural lessons to be learned from the analysis of the Abu Jaber House? Third, what recurring architectural patterns and typologies define the cityscape of historic downtown As-Salt, and how do these contribute to the urban fabric and visual integrity of the surroundings in the historic fabric? Fourth, in terms of tourism allure, how do the architectural qualities of As-Salt's heritage buildings, such as authenticity, aesthetics, and spatial experience, suitably cater to an urban situation? Fifth, what strategies could be suggested in order to work towards sustainability in tourism through use and maintenance of As-Salt City from the perspective of architectural heritage and its preservation through architectural authenticity and integrity? Sixth, what structural assessment framework and intervention strategies can be recommended, based on current research, to support the safe adaptive reuse of As-Salt's Ottoman-era heritage buildings for tourism?

Research Objectives

General Objective: The main aim of this research is to analyze the architectural characters in As-Salt city being combined in heritage buildings and their significance on sustainable heritage tourism development.

Specific Objectives: This study aims to document and analyze architectural variations of style and construction methods of traditional architecture of As-Salt city, which shows the blend of Ottoman, European, and indigenous architectural traditions; to undertake a comprehensive architectural analysis of the House of Abu Jaber as a grand case study of the city's past architectural magnificent achievement; to analyse architectural elements and urban design implications of Hammam Street and illustrate the examples of its spatial organization and business heritage; to examine how architectural authenticity, aesthetic value, and spatial qualities of historic buildings influence the experience of tourists as well as define the tourism appeal of As-Salt; to design sustainable tourism strategies balancing heritage conservation with community linkages; to contribute to the increased academic knowledge on heritage conservation by offering exhaustive documentation of a UNESCO World Heritage Site; and to establish a comprehensive structural assessment framework specifically for historic buildings in As-Salt based on literature evidence.

RESEARCH METHODOLOGY

Research Design and Approach

This research employs a qualitative methodological framework to examine As-Salt's architectural heritage through integrated architectural documentation, historical analysis, and heritage assessment protocols. The overall structure of the research methodology is illustrated in Figure 1. The study is structured around six representative case studies selected through purposive sampling to exemplify the dominant architectural typologies of As-Salt's Ottoman-European synthesis period (1881–1918). The methodology synthesizes three complementary analytical approaches, as outlined in Figure 1:

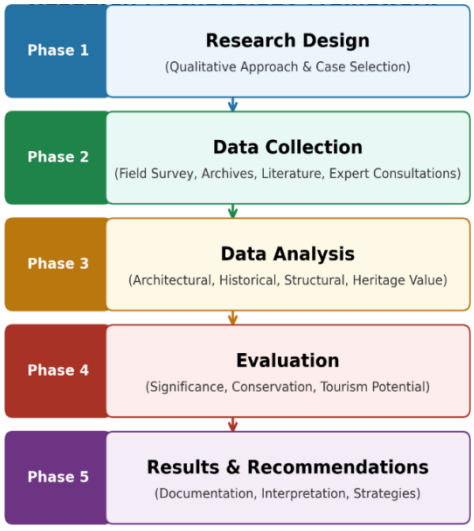

Figure 1. Conceptual framework of the research methodology, from research design to results and recommendations (Source: Authors)

A. Documentation and Architectural Analysis: Systematic documentation of heritage buildings within As-Salt's historic center employs multiple data collection methods, including direct field observation, detailed measured architectural surveys, comprehensive photographic documentation, and material characterization. These records capture architectural features, structural systems, construction materials, spatial organization, and decorative elements. Abu Jaber House serves as the principal case study, with comparative analysis extending to five additional significant heritage structures to identify recurring architectural patterns and typological characteristics.

B. Historical-Contextual Analysis: The late Ottoman period (1881–1918) witnessed significant architectural transformation in As-Salt, driven by urban expansion and evolving socio-economic conditions. This research utilizes archival sources, historical documentation, and published scholarship to contextualize architectural developments within broader patterns of regional trade, cultural exchange, and urban modernization.

C. Evaluating Heritage Tourism: This component evaluates the relationship between architectural authenticity, spatial quality, and visitor experience within sustainable tourism development frameworks. The analysis examines how As-Salt's architectural heritage can be effectively integrated into tourism programming while maintaining conservation standards and community engagement. Field investigations and analysis were conducted over 18 months (2024-2025).

Study Area and Scope

A. Geographic Scope: The research focuses on the historic center of As-Salt (32°02′N, 35°44′E), the administrative capital of Al-Balqa Governorate, situated approximately 28 km northwest of Amman, Jordan. Positioned along the

eastern edge of the Jordan Rift Valley escarpment, the city occupies a rugged mountainous terrain at elevations ranging from approximately 700 to 1,100 m above sea level (Figure 2).

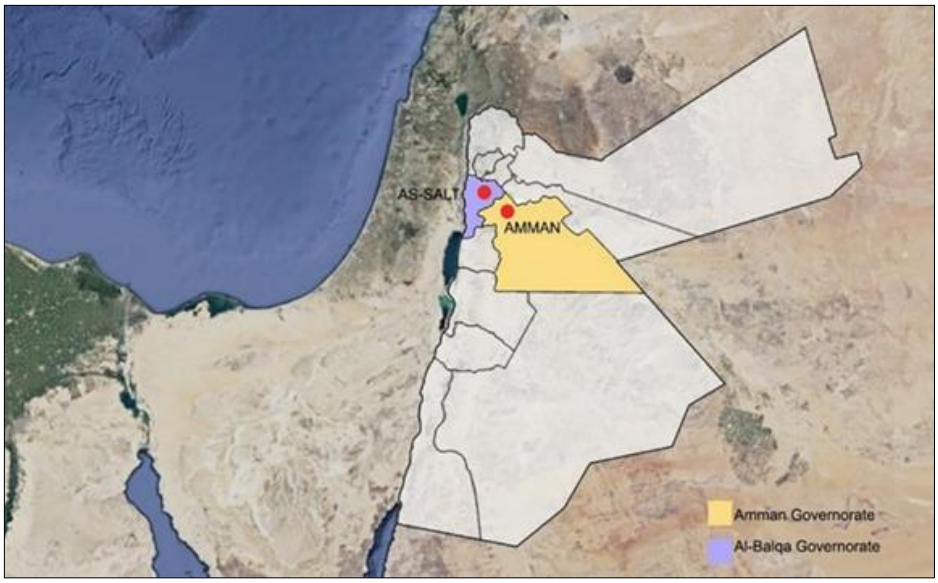

Figure 2. Location of the study area: As-Salt (32°02′N, 35°44′E) within Jordan, approximately 28 km northwest of Amman (Source: Aburamadan et al, 2022)

In 2021, As-Salt's historic core was inscribed on the UNESCO World Heritage List under the title "As-Salt – The Place of Tolerance and Urban Hospitality." The designated heritage area, covering approximately 70 hectares, is characterized by a distinctive urban morphology shaped by three prominent hills: Al-Qal'a, Al-Jad'a, and Al-Salalem. The organic street network and dense residential fabric of the old town have developed in direct response to this challenging topography, yielding a compact, vertically layered urban form (Figure 3).

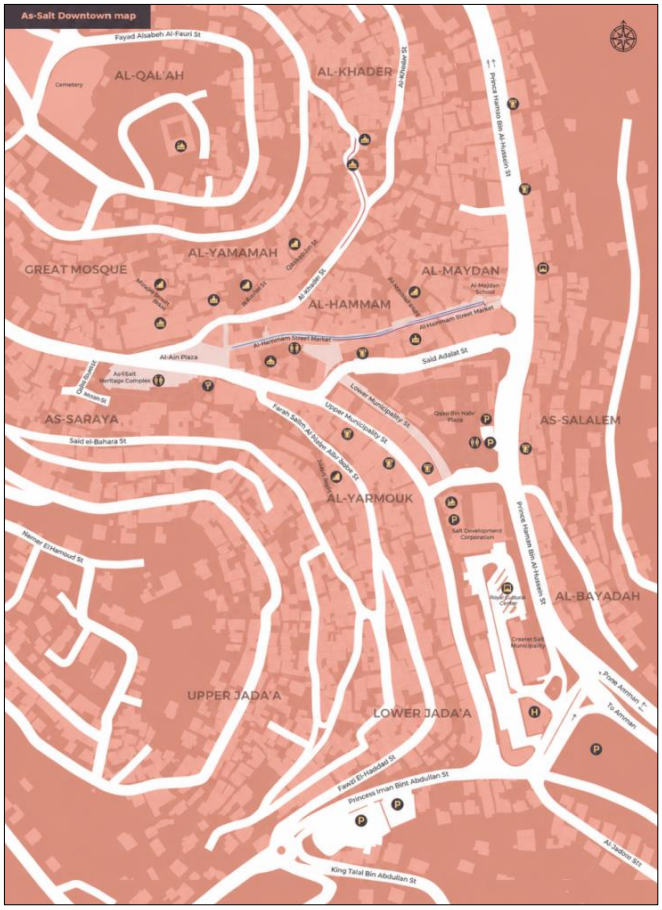

Figure 3. Location of the study area: the three principal hills — Al-Qal'a, Al-Jad'a, Al-Salalem — and Hammam Street (Source: Salt Development Corporation, n.d.)

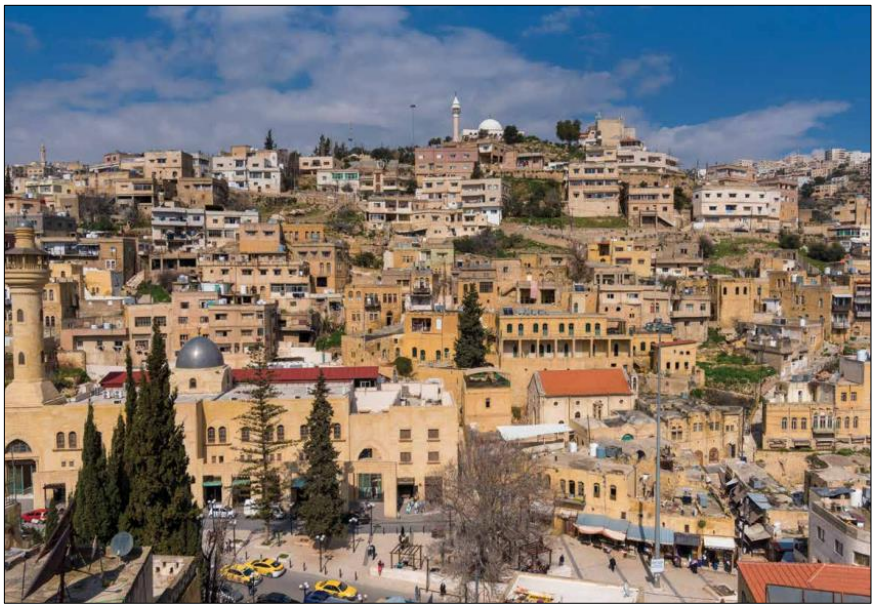

Figure 4. Panoramic view of Al-Qal'a Hill from Al-Jad'a Hill, showing the yellow limestone urban fabric and the Great Mosque dome (Source: Salt Development Corporation, n.d.)

Particular attention in this study is directed toward Hammam Street, the principal commercial artery that traverses the valley floor between the three hills, serving as the primary connector among the surrounding historic neighborhoods. The street and its immediate architectural context constitute the primary spatial unit of analysis.

The historic core of As-Salt is built across three closely-spaced hills — Al-Qal'a (Figure 4), Al-Jad'a (Figure 5), and Al-Salalem — creating a distinctive steep urban landscape where residential neighborhoods on the slopes are connected to the public spaces below through a network of stairs, alleyways, and nodes.

B. Temporal Scope: The study examines architectural developments during As-Salt's Golden Age (1881-1918), documenting their conservation status as of 2026. This temporal frame captures the city's most significant period of architectural production and subsequent conservation interventions.

C. Case Study Selection: While As-Salt's historic core contains an extensive inventory of heritage buildings, this study employs purposive sampling to select six representative case studies that exemplify the dominant architectural typologies of the Ottoman-European synthesis period. Selection Criteria:

- Architectural integrity: Buildings retaining original spatial organization and material fabric
- Typological diversity: Representation of distinct building categories (palatial residences, merchant houses, commercial structures)
- Structural condition: Varied states of preservation enabling comparative conservation analysis
- Documentation accessibility: Permission for detailed survey and non-destructive investigation
- Historical significance: Buildings documented in archival sources and heritage inventories

Selected Case Studies:

1. Primary case study: Abu Jaber House (comprehensive architectural and structural analysis)
2. Secondary case studies: Touqan House, Muhyar House, Al-Dawood House, Qaqish House, Falah Al-Hamad House.
3. Urban context: Hammam Street commercial corridor and surrounding heritage fabric.

This sampling strategy enables in-depth architectural analysis while maintaining research feasibility and ensuring representation of As-Salt's diverse architectural heritage.

D. Structural Assessment Framework: The methodology establishes a structural evaluation protocol for representative buildings characterized by thick load-bearing limestone masonry walls and cross-vaulted systems. This framework integrates:

- Non-destructive testing (NDT) fusion protocols: Combining sonic velocity profiling with electromagnetic mapping to assess masonry integrity without fabric damage.
- Material characterization: Laboratory analysis of historical lime mortars, limestone properties, and decay mechanisms.
- Seismic vulnerability assessment: Evaluation of lateral load capacity and shear transfer mechanisms in multi-leaf masonry construction.
- Compatible intervention strategies: Development of repair material specifications (ultra-fine lime-based grouts, Textile-Reinforced Mortar systems) informed by published studies on heritage masonry conservation.

This approach adheres to ICOMOS minimum intervention principles while addressing the dual challenges of seismic vulnerability and increased live loads from tourism adaptation.

Data Collection Methods

This research integrates multiple data collection methods to ensure comprehensive documentation and analysis of As-Salt's architectural heritage.

1. Field Surveys and Architectural Documentation: Systematic field investigations were conducted throughout As-Salt's historic center during 2024-2025, encompassing exterior surveys of heritage buildings, interior documentation of publicly accessible structures (museums, cultural centers, commercial establishments), and detailed observation of construction techniques, materials, and conservation conditions. Architectural measurements recorded essential dimensional data including building footprints, wall thicknesses, opening dimensions, vault spans, and urban spacing patterns. Comprehensive photographic documentation captured building exteriors, architectural details, construction materials, interior spaces, and urban fabric characteristics, providing visual records for comparative architectural analysis across the six case studies.

2. Archival and Documentary Research: Historical documentation was gathered from multiple institutional sources. Primary materials included UNESCO's 2021 World Heritage nomination file and ICOMOS advisory evaluation for As-Salt, JICA's 2010 cultural resources survey, and Jordan's Ministry of Tourism and Antiquities heritage management documentation. The research also consulted technical conservation reports, architectural surveys, restoration assessments, and interpretive materials from As-Salt Historical Museum (Abu Jaber House). These archival sources provided historical context for architectural development patterns and informed comparative analysis of building typologies.

3. Literature Review: The literature review synthesized scholarship across four thematic domains. Ottoman architectural theory (Necipoğlu, 2005) and Islamic urban morphology studies (Bianca, 2000) established analytical frameworks for understanding As-Salt's spatial organization. Regional architectural research examined economic-architectural relationships in Levantine cities (Assi, 2020), Ottoman administrative contexts (Rogan, 2020), and digital heritage documentation methodologies (Cotella et al., 2025). Heritage tourism scholarship (Timothy & Boyd, 2003; McKercher & du Cros, 2002) provided conceptual tools for evaluating sustainable tourism development potential. This synthesis revealed gaps in empirical architectural analysis and visitor experience research specific to As-Salt, justifying this study's integrated approach linking architectural heritage documentation with tourism development frameworks.

4. Expert Consultations: Informal consultations with local heritage specialists, conservation practitioners, museum staff, municipal heritage officers, and community historians provided contextual knowledge regarding As-Salt's architectural evolution, current conservation challenges, and community perspectives on heritage management priorities.

Analytical Framework

1. Architectural Analysis Methods: The architectural analysis employs a multi-layered methodological approach integrating typological, stylistic, material, and spatial investigation strategies. Typological analysis classifies buildings according to functional categories (residential, commercial, mixed-use) and identifies recurring spatial organization patterns, including courtyard houses and triple-arcade plans characteristic of As-Salt's Ottoman-European synthesis period. Structural systems are categorized by construction technique (cross-vaulted, flat-roofed, hybrid timber-masonry configurations). Stylistic analysis documents architectural influences—Ottoman, European neoclassical, and indigenous Levantine traditions—through examination of decorative programs, artistic elements, and façade composition strategies. Material and technical analysis investigates construction materials (local yellow limestone varieties, imported elements), structural techniques (load-bearing masonry walls, arches, vaults, early steel beam applications), and material supply chain patterns. Spatial analysis examines interior organization, circulation sequences, courtyard environmental strategies, and building-street relationships within the historic urban fabric.

2. Heritage Value Assessment: Heritage significance is evaluated through criteria adapted from UNESCO World Heritage and ICOMOS frameworks, assessing architectural significance (design uniqueness, craftsmanship quality, technical innovation), historical significance (association with As-Salt's Golden Age development), cultural significance (community identity, social values), authenticity (material integrity, design continuity), and integrity (structural completeness, contextual preservation). This multi-criteria assessment establishes the conservation priorities and informs intervention strategies for each case study building.

3. Tourism Development Potential: Tourism evaluation examines the relationship between architectural authenticity and visitor experience quality, considering spatial characteristics that enhance sensory engagement, interpretive programming opportunities, accessibility for diverse visitor demographics, adaptive reuse potential for sustainable economic functions, and integration capacity within As-Salt's broader heritage tourism infrastructure. This assessment framework links architectural qualities directly to tourism development strategies while maintaining conservation standards.

Ethical Considerations

This research adhered to established ethical protocols throughout all phases of heritage documentation and analysis. Field investigations maintained strict respect for private property rights and resident privacy, limiting architectural documentation to publicly accessible spaces, building exteriors, and cultural institutions open to visitors. All historical photographs and archival materials sourced from institutional repositories are appropriately attributed to their originating collections. The research approach demonstrates sensitivity to local cultural values and community perspectives on heritage preservation, acknowledging the invaluable contributions of indigenous architectural knowledge and local expertise in interpreting As-Salt's built heritage. These ethical considerations ensured that the documentation process respected both the physical heritage assets and the living communities that maintain cultural continuity within the historic center.

RESULTS

Architectural Synthesis: Ottoman, European, and Indigenous Influences

As-Salt's architectural heritage exemplifies a sophisticated synthesis of Ottoman, European, and indigenous building traditions that emerged during the Late Ottoman period. This architectural hybridity reflects the city's cosmopolitan

character and strategic position within regional trade networks, where foreign influences were selectively integrated while maintaining strong roots in local construction practices.

A. Ottoman Architectural Traditions: As-Salt's residential architecture demonstrates substantial Ottoman influence through characteristic structural and spatial configurations. Key Ottoman elements include vaulted construction systems (domes, barrel vaults, cross vaults), which define primary load-bearing techniques. These structural systems reflect the geometric harmony inherent in Ottoman architecture, where builders employed transitional elements such as squinches and pendentives to achieve spatial continuity between the cubic base and the vaulted ceiling (Al-Mughrabi et al., 2026; Necipoğlu, 2005). Centrally-located or strategically-positioned enclosed courtyards structure domestic spatial organization. These courtyard systems provided environmental comfort, privacy hierarchies, and social differentiation while expressing Islamic cultural values regarding family privacy, hospitality, and gender relations—features consistent with widespread Ottoman domestic architecture throughout the Levant (Bianca, 2000; Necipoğlu, 2005).

B. European Neoclassical Influences: Alongside Ottoman traditions, late 19th-century architectural production incorporated European neoclassical elements reflecting the city's economic and cultural openness. European influences manifest through sloping tiled roofs, imported steel beams, projecting balconies, and tall vertical windows inspired by contemporary European residential design. Material imports—Italian marble, German ceramics, Belgian stained glass—signify the cosmopolitan aspirations of As-Salt's merchant elite and their engagement with modernizing architectural aesthetics (Assi, 2020; Zalloom & Tarrad, 2020).

C. Indigenous Construction Practices: Despite global architectural currents, indigenous building practices remained fundamental to As-Salt's built environment. The predominant use of locally-quarried yellow limestone established the city's visual identity while ensuring material compatibility with regional climate and traditional construction methods (UNESCO, 2021). Architectural responses to As-Salt's mountainous topography—terraced construction, climate-responsive fenestration patterns, natural ventilation strategies—demonstrate site-specific design adaptations that integrate buildings with the natural environment and local climatic conditions (Daoudi et al., 2019; Salameh & Touqan, 2022). This synthesis of imported influences with indigenous practices reinforces local cultural identity within a cosmopolitan architectural vocabulary.

Comprehensive Analysis: Abu Jaber House

1. Historical Background and Basic Information

Located in As-Salt, the Historical Museum is housed in the Abu Jaber House, one of the finest examples of late Ottoman residential architecture in the city's historic center. The building was commissioned by the Abu Jaber family and constructed between 1896 and 1906. Situated at the base of Al-Jad'a Hill, the house reflects the characteristic yellow limestone construction and arched facades that define the surrounding historic neighborhood, as shown in Figure 5.

Figure 5. As-Salt historic urban fabric and architectural character of the study area, showing Al-Jad'a Hill with its dense layered arrangement of yellow limestone heritage buildings

Figure 6. Abu Jaber House / As-Salt Historic Museum, Hammam Street, combining white and local yellow limestone (Source: Authors)

The ground floor of the building which opened in 1896 used local yellow limestone for its construction and served as both storage areas and guest reception space (Trillo et al., 2020). The designer of the building ʿAbd al-Rahman al-ʿAqruq al-Nabulsi used advanced Eastern Mediterranean building methods which included cross-vaulted ceilings and intricately designed arched windows (Aburamadan et al., 2022). The second floor which finished construction in 1905 used decorative elements that combined local materials with international products to create spaces which included residential areas for the family (Cotella et al., 2025; UNESCO, 2021). The house demonstrates architectural styles which became common among As-Salt merchant families during the late Ottoman era as it combines traditional building methods with European decorative art (Assi, 2020). This master of Nabulsi craftsmen, Abd al-Rahman al-Aqruq, actually supervised the building, further transferring Nabulsi architectural traditions to As-Salt through superior craftsmanship and superior building technologies (Assi, 2020; Trillo et al., 2020). He was one of the notable builders who moved from Nablus in the last decades of the Ottoman period and brought with him specialized knowledge about stone building, decor, and spatial organization (Aburamadan et al., 2022). A comprehensive restoration was done on the building which had been inaugurated as the As-Salt history museum, ensuring the preservation of its architectural integrity and adapting the interior spaces to house museum

functions (Figure 6) (UNESCO, 2021; Cotella et al., 2025). It has now become a focal point in As-Salt heritage conservation operations, interpreting the city's social, architectural, and cultural history for visitors (Alnsour et al., 2023).

2. Structural Analysis and Architectural Elements

Ground Floor: The bottom floor is supported by a traditional structural system consisting of thick-bearing walls of stone and semi-circular arches used by late-ottoman domestic architecture in As-Salt. As far as the roofing of main interior spaces is concerned, a cross-vault system has been used to cover its wide area without the aid of internal walls. Not only does this system contribute to increased structural stability, but it also offers some flexibility in the use of space within the defined structural parameters, thereby integrating technical construction knowledge with locally rooted social and spatial practices (Municipal Heritage Platform Balqa Governorate, 2025; Bianca, 2000; Necipoğlu, 2005). The building demonstrates the characteristic use of local yellow limestone, the primary construction material sourced from nearby quarries during As-Salt's Golden Age (UNESCO, 2021). The distinctive yellow limestone which became a historical construction material for As-Salt architectural development originated from local quarries that included the Al-Salalem area (UNESCO, 2021). The high-quality construction of Abu Jaber House demonstrates the building standards from its time period because builders used local yellow limestone to create the structure which expert craftsmen from Nablus built under the guidance of master builder Abdel Rahman al-Aqrouq (Assi, 2020 UNESCO, 2021). Rounded cobblestones were used for floors. The coloring made them in black and light white. In the guest hall, decorative colored tiles with geometric and floral patterns measuring 30×30 cm were used, in colors including black, yellow, pink, and the natural stone color, indicating a high level of craftsmanship.

Second Floor: The second floor denotes a distinct shift higher up in the construction technology of As-Salt in the late Ottoman period. Imported European steel beams were used to support the ceilings of the upper floor, thus allowing the walls to be kept at a thickness of almost 30 cm, as opposed to the significantly thicker walls of the ground floor. That technological advancement has allowed for big, roomy, and not dogmatically organized interior spaces with an increased natural light and breathing ability, testifying to the success of Western structural innovation within a traditional Levantine architectural context (Assi, 2020; Necipoğlu, 2005). Italian Carrara marble was used to tile the second floor of Abu Jaber House. The marble was specially imported from Italy to Haifa port by sea, then transported by train from Haifa to Daraa, followed by the Hejaz Railway from Daraa to Amman, and finally carried on camels' backs from Amman to As-Salt.

Figure 7. Interior of the Madafa (guest reception hall), Abu Jaber House, showing Italian marble flooring and yellow limestone walls (Source: Authors)

Figure 8. Interior hall, Abu Jaber House / As-Salt Historic Museum, now a cultural event space, with arched windows and marble floor tiling (Source: Authors)

This complex logistics chain demonstrates the exceptional wealth and determination of the Abu Jaber family to create one of the finest houses in As-Salt (Jordan News, 2021). German tiling on pitched roofs ridge balconies evokes durability and the essence of European architecture. Belgian glass functions for the window openings, whether clear or tinted color glass, ensuring the daylighting and place embellishments (Zalloom & Tarrad, 2020). On the second floor, three separate apartments were designed, each incorporating a small interior courtyard that served as a secluded open-air retreat and a decorated guest reception hall (madafa) (Figure 7). Adapted from the Ottoman residential tradition to the specific urban context of As-Salt, the spatial arrangements reflect the social rituals of wealthy merchant households, including the formal reception of visitors, private family living, and leisure (Bianca, 2000; Assi, 2020). The structural components of the second floor demonstrate a high degree of material finish and construction precision. Pitched ceilings clad with red clay tiles were supported on sloped timber rafters, while cantilevered stairs (volée) projected from the façade to maximize interior space. These elements exemplify the late Ottoman architectural practice of integrating European construction techniques to enhance functional adaptability, while the applied ornamentation complements the architectural character of the historic fabric (Necipoğlu, 2005; Assi, 2020; Municipal Heritage Platform, Balqa Governorate, 2025).

3. Decorative and Artistic Elements

The house of Abu Jaber presents beautiful scenes from tiles of Eastern and Western design culture are woven together to form an interesting fusion of decorative elements (Figure 8). Geometric patterns embody Islamic design practices in never-ending and tightening repetitive actions that impart continuity and rhythm in the visual; floral decoration shows the influence of European design, with naturalistic patterns deriving from the sources of organic forms, truly exemplifying the

patterns of the botanical world, inspired also being with water-based ornamentation, and counterbalancing the whole sky with compositions of geometric forms.The wall paintings in Abu Jaber House are a unique artistic phenomenon in As-Salt City, not found in any other building. These include European rural house paintings discovered during restoration work, kitchen paintings mimicking oak bark (a decorative technique common in Europe), and ceiling paintings depicting the four seasons executed using oil paints. The German artist 'Menlik' from Haifa is believed to have executed these works.

Recurring Architectural Patterns in As-Salt

1. Yellow Limestone as Unifying Element: Local yellow limestone constitutes the unifying architectural element that connects As-Salt's heritage buildings and gives them their distinctive architectural identity (Figure 9). This distinctive yellow limestone was traditionally extracted from local quarries, particularly from the Al-Salalem area, though these historical quarries are now closed (ICOMOS, 2021). Current conservation work sources similar stone from quarries in Dair Allah and the Mafraq region (UNESCO World Heritage Centre, 2021). The limestone exhibits warm yellow coloring ranging from light yellow to golden, relatively smooth texture easy to carve and shape, durability resistant to weather conditions, and creates visual unity when used in adjacent buildings.

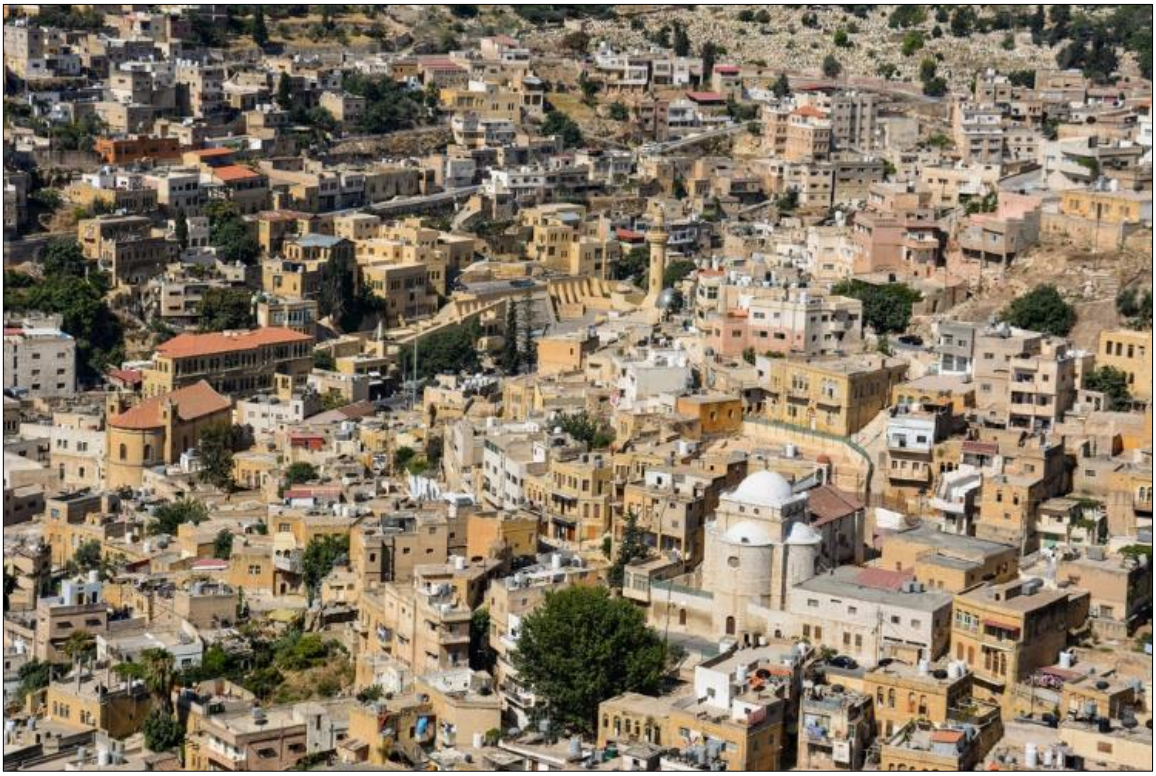

Figure 9. Panoramic view of As-Salt's historic center, showing the yellow limestone urban fabric cascading along Al-Qal'a and Al-Jad'a hills (Source: Authors)

2. Arches and Arcades: Arches and arcades are among the most eye-catching architectural features in As-Salt buildings, serving both structural and aesthetic purposes. Structurally, they support ceilings and distribute loads on side walls, reduce pressure from load-bearing walls, and allow coverage of wide spaces without internal columns. Aesthetically, they create harmonious visual rhythm in facades and express craftsmanship skill and artistic mastery. Types include pointed arches, semi-circular arches, cross vaults, and segmental arches.

3. Windows and Openings: As-Salt buildings are characterized by abundant arched windows, predominantly in the upper stories, reflecting European architectural influences adapted to local climatic needs (Assi, 2020; Trillo et al., 2020). These carefully proportioned openings ensure ample natural lighting and ventilation, demonstrating the synthesis of imported design aesthetics with climate-responsive building practices (Aburamadan et al., 2022; UNESCO, 2021). A representative example is found on the upper floor of the Abu Jaber House, where triple-arched windows combine pointed arches with polychrome stained glass in green, red, and yellow, set within ornamental wrought-iron grilles that exemplify the European influences integrated into the traditional Levantine residential design of As-Salt's Golden Age (1881–1918) (Figure 6, 8, 10).

4. Roofing Systems: Roofing systems (Figure 2, 5, 6, 9) in As-Salt buildings varied according to time period and economic level. Traditional roofs included stone vaults and small domes in some rooms. Advanced roofs featured sloped wooden roofs covered with red tiles and modern flat roofs using steel beams.

5. Urban Fabric and Topographic Integration: As-Salt extends over three main hills — Al-Qal'a, Al-Jad'a, and Al-Salalem — giving the city a unique architectural character (UNESCO, 2021). Yellow limestone buildings are arranged on the slopes of these hills, forming a cohesive architectural mass consistent with the natural contours of the terrain (Figure 9). Urban fabric characteristics include vertical gradation with buildings terraced on the hillsides, compact density with narrow

spaces between buildings, and winding streets following the natural topography. The city's distinctive monumental stairways connect the hillside neighborhoods and serve as primary pedestrian routes (Figure 11 a), while the coexistence of mosques and churches within the historic skyline reflects the cultural tolerance that defines As-Salt's urban identity (Figure 11 b).

Figure 10. Triple-arched stained-glass windows, upper floor, Abu Jaber House (Source: Authors)

Comparative Case Studies

1. Touqan House: Located on Prince Hamza Street near Hammam Street in As-Salt, Touqan House is a prominent heritage building constructed between 1900 and 1905 by master builder ʿAbd al-Rahman al-ʿAqruq for the Touqan family, who migrated from Nablus (Trillo et al., 2020; UNESCO, 2021). The house currently serves as the As-Salt Archaeological Museum, showcasing artifacts from the Roman, Byzantine, and Islamic periods. The building's entrance exhibits cross-vaulted and barrel-vaulted ceilings which serve as structural roofing systems for the building while the upper floor uses iron girders which match the construction materials that builders used for the Hijaz Railway infrastructure (UNESCO, 2021). Architecturally, the frontage portrays unique decorative elements. The façade integrates Art Nouveau and Neoclassical elements, including decorated columns, floral-petal pilasters, and a symmetrically composed stone staircase with ornate balustrades (Cotella et al., 2025). These architectural features exemplify the blending of European aesthetic traditions with the local Levantine building vocabulary that characterized late Ottoman-era merchant residences in As-Salt (Assi, 2020; Aburamadan et al., 2022) (Figure 12).

2. Muhyar House: The Muhyar complex on Hammam Street exemplifies the integrated commercial-residential typology that defines As-Salt's historic commercial district. The complex consists of two buildings: the Muhyar Building, with its main entrance and two-storey design, and the Muhyar House, which lies to the east of the main building; both structures were constructed using local yellow limestone (UNESCO, 2021). The main exterior of the Muhyar House features two distinct window styles combined with three arched windows extending across the principal entrance area. The design employs Ottoman architectural elements to create street frontages that support commercial activities (Cotella et al., 2025). The main entrance provides access to a curved stairway linking the ground-level commercial spaces to the upper residential quarters. Documentary sources confirm that street-level vaulted rooms functioned as commercial premises, while the upper floors served as family living quarters (Trillo et al., 2020; Alnsour et al., 2023). This architectural arrangement was widely adopted

in Ottoman-Levantine trading towns, as it enabled merchant families to operate their businesses from home while maintaining the privacy of their domestic life (Assi, 2020) (Figure 13 a, b). The yellow limestone construction and seamless integration into Hammam Street's commercial fabric contributed to As-Salt's inscription on the UNESCO World Heritage List in 2021, which recognized the city's integrated urban development and diverse architectural styles (UNESCO, 2021).

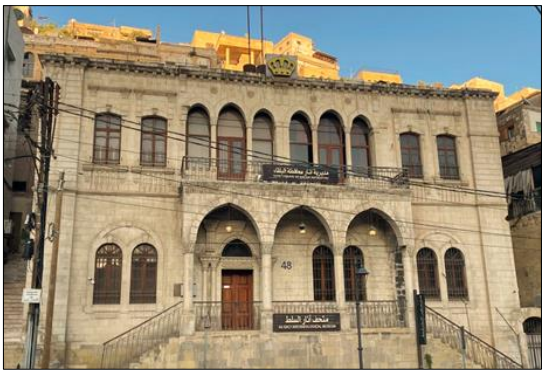

Figure 12. Touqan House, now the As-Salt Archaeological Museum: façade showing ground-floor arcade, decorative columns, and yellow limestone masonry (1900–1905) (Source: Authors)

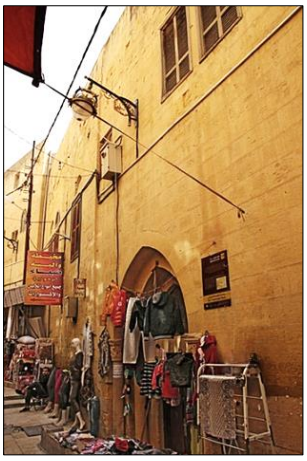

(a)   (b)

Figure 13. (a) Muhyar House, Entrance (b) Hammam Street by day, showing ground-floor commercial spaces (*souq*) with mixed-use commercial-residential buildings typical of Ottoman-Levantine trading towns (Source: Authors)

3. Al-Dawood House (Dawood Triangle): Al-Dawood House, commonly known as the Dawood Triangle, stands at the junction of Al-Khader Street and Hammam Street, opposite Al-Ain Plaza. The building demonstrates a distinctive architectural response to non-standard urban land configurations. Constructed by the Daoud family in the late 19th century, this two-storey mixed-use building features a triangular plan that was purposefully designed to conform to the acute corner site at one of the key intersections of As-Salt's historic commercial district (Jamhawi & Hajahjah, 2017; Trillo et al., 2020) (Figure 14 a, b).

4. Qaqish House: The Qaqish House, constructed between 1895 and 1900, is located in the Al-Qal'a district on Al-Khader Street (Figure 15). The building exhibits a traditional courtyard plan that ensures visual privacy while facilitating natural ventilation throughout the interior spaces (Trillo et al., 2020; UNESCO, 2021).

(a)   (b)

Figure 14. Al-Dawood House (Dawood Triangle) at Al-Khader/Hammam junction: (a) triangular-plan mixed-use building in yellow limestone; (b) view from Al-Ain Plaza within its urban setting (Source: Authors)

The design of both interior and exterior spaces establishes a harmonious relationship with the surrounding mountainous landscape and the local temperate climate (Aburamadan et al., 2022). Architecturally, the Qaqish House represents the evolution from simple peasant dwellings to the more refined stone residences built by prosperous merchants during the late Ottoman period, incorporating characteristic elements such as cross-vaulted ceilings, yellow limestone walls, and arched window openings (Trillo et al., 2020). The building is recognized as one of As-Salt's earliest significant heritage residences and currently serves as the headquarters of As-Salt's City Development Project (Aburamadan et al., 2022).

5. Falah Al-Hamad House: Falah Al-Hamad House is located on Prince Hassan bin Talal Street, approximately 400 metres uphill from the Historic Old As-Salt Museum (Figure 16). Constructed between 1890 and 1918 for Falah al-Hamad, a municipal council member and tribal court specialist, the building represents the quintessential architectural character of As-Salt's merchant residences (UNESCO, 2021). The façade features an elaborately decorated entrance portal with twisted columns exhibiting Art Nouveau and Neoclassical stylistic elements, reflecting the multicultural influences that shaped As-Salt's architecture during the late Ottoman period (Cotella et al., 2025). The building served multiple functions across four generations: the first floor operated as "Al-Khreisat Madafa," a traditional guest reception hall in accordance with Levantine hospitality customs, while the ground floor housed a flour mill that remained operational until the 1970s (Trillo et al., 2020; UNESCO, 2021). During the 1948 Arab-Israeli War, the house served as a refuge for Palestinian refugees, demonstrating its significant social and humanitarian role within the local community (UNESCO, 2021). The building is currently planned for restoration and adaptive reuse as a public library, incorporating spaces that will preserve its historical function of hospitality and community service (Alnsour et al., 2023).

Urban Commercial Corridor: Al-Hammam Street

1. Historical Development: Al-Hammam Street (Figure 17) was established during the 1880s by merchants coming from Nablus, and named after an old Turkish bath whose remains are still visible. The street creates a unique commercial pathway which stretches 300 meters from Al-Ain Plaza to its pedestrian-only area (Khirfan, 2013). The urban plan demonstrates how a street connects with the historical city area while commercial buildings create a street front that harmonizes with the area's natural landscape (Khirfan, 2017).

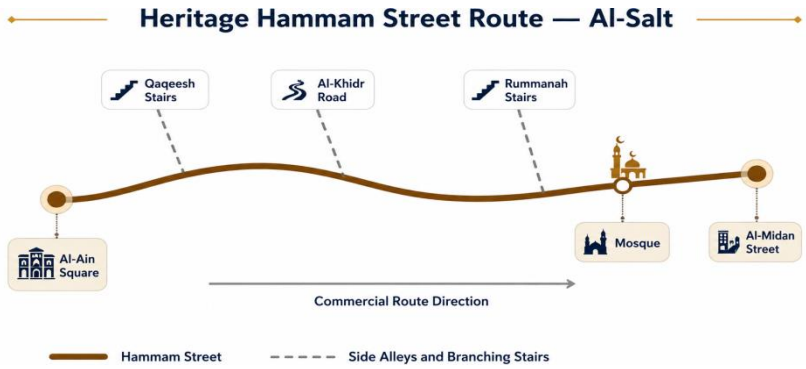

Figure 17. Urban plan of Al-Hammam Street, connecting Al-Ain Square to Al-Maidan Street (Source: Authors)

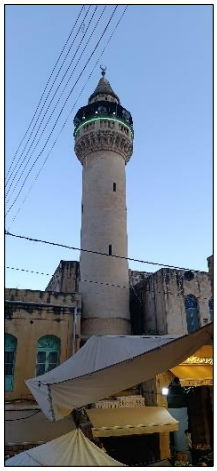
2. Architectural Characteristics: Al-Hammam Street demonstrates the mixed-use development pattern that defines As-Salt's commercial building design. The Abu Alouf Building (constructed 1881–1884) by master builder Abdel Rahman al-Aqrouq for Daoud Abdul Rahman Touqan from Nablus exemplifies this pattern, with five commercial shops and a main gateway at street level opening onto Al-Hammam Street, and two residential apartments of varying sizes on the upper floor accessed through a stairway from the main entrance. The architectural design establishes a continuous commercial frontage that merges with residential spaces, showcasing urban planning practices from the late Ottoman era. The building's construction used local yellow

quarried limestone, while the ground floor contains wide openings directly facing the street and the upper floor features arched windows typical of the period (Khirfan, 2013; Universes in Universe, n.d.), as shown in Figure 18.

Figure 18. The Abu Alouf Building, Al-Hammam Street: mixed-use building in local yellow limestone construction (Source: Authors)

3. Religious and Commercial Integration: The Small Mosque (Figure 18 a, b) was constructed in 1906-1907 by Sulaiman Abu Al-Hussein, a local builder from As-Salt, using traditional yellow limestone quarried from the surrounding area (UNESCO, 2021). The mosque demonstrates Islamic architectural design principles which have been modified to fit the architectural practices of the As-Salt area. The building design creates a wide prayer space that connects to a wooden narrow mezzanine which contains a minbar and a mihrab that displays elaborate Islamic geometric and floral patterns of late Ottoman religious design (Trillo et al., 2020; UNESCO, 2021). The decorative features showcase the expert skills of local craftsmen who operated according to traditional Islamic design standards. The mosque's most distinctive architectural feature is its minaret, which designers built to replicate the minaret of the Hanbali Mosque in Nablus, Palestine (Cotella et al., 2025). The architects created this design to show the deep cultural and trade ties between As-Salt and Nablus which existed during the late Ottoman period when Nabulsi merchants and craftsmen, including builders like ʿAbd al-Rahman al-ʿAqruq, contributed significantly to As-Salt's architectural development (Assi, 2020). The minaret thus serves as a physical manifestation of the architectural lineage and cultural exchange between these two important Levantine trading centers.



(a)   (b)

Figure 19. (a) The minaret (b) As-Salt Small Mosque on Al-Hammam Street: arched entrance integrated with commercial market stalls, demonstrating religious-commercial coexistence (Source: Authors)

Figure 20. A nighttime view of Al-Hammam Street, showing limestone-paved sidewalks, wooden shopfronts, and the commercial corridor's overhead canopies (Source: Authors)

4. Street Infrastructure and Pedestrian Networks: Since the Ottoman period, As-Salt's historic center has retained its original street plan with stone-paved roads and sidewalks typical of late-Ottoman urban design principles. Hammam Street shows the older form of street design with proper stone-paved sidewalks and progressive walking and vehicular pathways (UNESCO, 2021). Street surfaces use limestone blocks from local quarries arranged in geometric patterns. The street network system enables the city to overcome topographic challenges spanning three hills through advanced design using stone staircases and stepped pathways (Zalloom & Tarrad, 2020). The Harmony Trail, serving as a heritage walking path, starts at Abu Jaber House and takes visitors through historical streets showing As-Salt's traditional urban fabric (UNESCO, 2021). Figure 20 illustrates the northern section of Al-Hammam Street, highlighting the preserved stone-paved pathways and traditional wooden shopfronts that characterize this historic commercial corridor.

DISCUSSION

Architectural Heritage as Tourism Asset

1. Tourism Value of Architectural Elements: As-Salt architectural heritage represents a unique tourism resource due to its authenticity and uniqueness, creating a visual and cultural experience not repeated elsewhere. The density and concentration of heritage buildings within a compact area (approximately 2,000 meters diameter) enriches the visiting experience. The uniform yellow stone creates visual integration across the urban fabric, while functional diversity of heritage buildings as museums, cafes, commercial shops, and residences provides immediate material experience of living heritage rather than static display.

2. Visitor Spatial Experience: Visitors to downtown As-Salt city experience a multidimensional spatial journey. The visual experience features As-Salt's hillside setting creating continuous streetscapes of yellow limestone facades achieving unity through repeated arched openings, decorative stonework, and human-scale proportions. The movement experience includes staircases and narrow lanes connecting hillside neighborhoods, with courtyards and small plazas punctuating the urban fabric. The sensory experience engages multiple senses: yellow limestone unifies building facades and paving creating tactile warmth; street sounds from markets and cafés animate the district; aromas of traditional coffee and sweets from historic shops evoke cultural memories tied to place.

3. Future Tourism Development Potential: As-Salt's architectural heritage possesses significant tourism potential through heritage hotels via adaptive reuse of heritage buildings into boutique hotels, heritage restaurants and cafes occupying heritage buildings allowing visitors to experience traditional architecture while dining, specialized museums dedicated to traditional crafts and local architecture, workshops teaching traditional crafts such as stone carving and traditional carpentry providing interactive visitor experience, and specialized architectural tours led by architecture and history specialists targeting tourists interested in architectural heritage.

Structural Assessment and Conservation Framework

1. Non-Destructive Evaluation Methods: Accurate diagnostic protocols are essential for structural intervention. Non-destructive testing (NDE) is recommended for mapping internal deficiencies without compromising the building's integrity. Sonic and ultrasonic testing techniques (measuring wave velocities between 1000 and 4000 m/s) should be used to identify density variations and delamination within cross-sections. Furthermore, ground-penetrating radar (GPR) should be used to plan internal geometry and determine moisture distribution, achieving a void detection resolution of 1–5 cm (Hussain & Akhtar, 2017). Further, integrate these datasets through NDE fusion enhance diagnostic accuracy. Specifically, combining sonic velocity profiles with GPR radargrams provides a comprehensive assessment of injection efficiency and void continuity (Roumeliotis et al., 2024). In addition, infrared thermography (IRT) should be used to detect thermal anomalies indicative of subsurface discontinuities or moisture pockets (Tejedor et al., 2022). The flat-jack test remains the reference for determining the modulus of elasticity and stress states in situ (Hussain & Akhtar, 2017). In the context of As-Salt, these techniques are recommended for confirming wall configuration and identifying moisture-induced limestone erosion and thus guiding intervention point locations (Hussain & Akhtar, 2017; Tejedor et al., 2022).

2. Intervention Strategies for As-Salt's Ottoman Masonry: The structural rehabilitation of heritage buildings in As-Salt requires a comprehensive integration of materials science, diagnostics, and structural analysis. The evaluation phase should initiate with visual inspection and moisture mapping, acknowledging carbonation inhibition outside the 50–70% RH range (Chen et al., 2024). This is followed by NDT fusion to locate internal voids within cross-sections (Hussain & Akhtar, 2017; Roumeliotis et al., 2024). Repair materials should be carefully selected to ensure compatibility with existing limestone properties (mechanical and chemical properties). Priority should be given to lime mortars modified with pozzolans achieving compressive strengths of 2.5–7.8 MPa (Tombulca & Çavuş, 2023). The structural rehabilitation should encompass three integrated components. First, mass consolidation through mineral grouts with $D_{90} < 100$ μm should be used to restore monolithic behavior (Padovnik et al., 2024), targeting 61% shear strength recovery (Dinç-Şengönül et al., 2023). Second, seismic strengthening by TRM (Textile-Reinforced Mortar) systems with lime-based matrices should be used to address out-of-plane vulnerability and provide breathable reinforcement without vapor impermeability (Petrovčič & Kilar, 2022; Azimi et al., 2025). Third, post-rehabilitation monitoring should compare pre- and post-injection UPV measurements (Roumeliotis et al., 2024), supplemented by permanent wireless sensor networks to track dynamic responses for early detection of settlement or seismic damage (Pallarés et al., 2021; Barrile et al., 2024). This integrated approach respects the minimum intervention principles for heritage rehabilitation while guaranteeing structural safety in a seismically active zone.

3. Assessment Framework: Vulnerability Modeling and Monitoring: For seismic vulnerability assessment of heritage buildings, pushover analysis should be employed to derive capacity curves and identify collapse mechanisms. Equivalent frame modeling is recommended to approximate nonlinear behavior (Petrovčič & Kilar, 2022). Assessment should focus on

susceptibility to soft-story mechanisms and out-of-plane failures, particularly at floor–wall connections (Yildizlar et al., 2019; Htet et al., 2025). As-Salt is situated near the Dead Sea, one of the most active seismic zones. Therefore, hazard analyses shall account for inertial forces from massive limestone walls. Accordingly, interventions should be designed to maximize ductility and stability (Balzani et al., 2024; Petrovčič & Kilar, 2022). Furthermore, structural digital twins within Heritage Building Information Modeling (HBIM) increasingly support risk management and maintenance protocols (González et al., 2025). Permanent Structural Health Monitoring (SHM) networks should be integrated into significant heritage structures for long-term performance verification. The monitoring framework should incorporate: (1) Operational Modal Analysis (OMA) to track shifts in modal frequencies and damping ratios as early indicators of stiffness degradation, (2) accelerometers and tiltmeters to detect minute deformation trends enabling service life prediction (Pallarés et al., 2021), and (3) laser scanning with drone photogrammetry to provide high-precision point clouds for tracking millimetric shifts (Barrile et al., 2024).

Heritage-Tourism Integration and Sustainability

The primary challenge lies in balancing tourism development with heritage conservation while maintaining As-Salt's Outstanding Universal Value. Increased visitor numbers generate economic benefits but create risks including structural stress from increased live loads, wear on historic fabric from intensive use, and potential disruption to residential communities. Sustainable tourism development requires strategic planning that integrates conservation imperatives with accessibility, economic viability, and community engagement. Key strategies include implementing visitor capacity management to prevent overuse, establishing conservation protocols for adaptive reuse ensuring structural safety while maintaining authenticity, developing community-based tourism initiatives ensuring local economic benefits, creating interpretive programming that educates visitors about heritage values and conservation needs, and establishing monitoring systems tracking both tourism impacts and conservation outcomes. Success requires collaboration among local and central government, academic institutions, private sector developers, local communities, and international heritage organizations.

CONCLUSION AND RECOMMENDATIONS

As-Salt City's architectural heritage portrays an exclusive architectural trend from the late Ottoman era to the early 20th century. The city successfully integrated Ottoman architectural symbols, European influences, and local traditions to manufacture a distinctive architectural style embodying local authenticity. Detailed analysis of Abu Jaber House and other heritage buildings demonstrates that As-Salt's traditional architecture stands out through: yellow limestone as the main element for construction giving tangible identity; evolution from traditional construction methods to contemporary materials and technology; rich decorative style integrating Eastern and Western motifs; and effective integration with mountainous terrain creating harmonious urban form. The research concludes that the preservation of As-Salt as a global tourism destination requires a shift toward "knowledge-based restoration". The proposed framework demonstrates through literature evidence that minimum interventions can meet the safety requirements of building codes. In addition, the proposed framework begins with NDT fusion and concludes with compatible repair materials. Published evidence confirms that lime mortars modified with pozzolans represent the most effective choice for balancing compressive strength (up to 7.8 MPa) with the required flexibility (Tombulca & Çavuş, 2023). Furthermore, permanent SHM networks should be integrated into the most significant structures to detect millimetric deformations early, thereby ensuring the sustainability of cultural tourism and the protection of life in historic city (Pallarés et al., 2021; Roumeliotis et al., 2024; Barrile et al., 2024). Building on these conclusions, several practical recommendations follow. For heritage conservation: implement systematic documentation of remaining undocumented heritage buildings; establish conservation protocols based on ICOMOS minimum intervention principles; prioritize compatible repair materials (ultra-fine lime grouts, TRM systems) over Portland cement-based solutions; and integrate permanent SHM systems in key heritage structures. For tourism development: develop heritage hotels through adaptive reuse maintaining architectural integrity; establish specialized architectural tours with trained guides; create interpretive centers explaining architectural heritage and conservation; implement visitor capacity management preventing overuse; and develop community-based tourism ensuring local economic benefits. For structural safety: conduct seismic vulnerability assessments using pushover analysis; implement NDT fusion protocols before intervention; establish monitoring frameworks tracking long-term performance; and develop emergency response protocols for heritage structures.

Future research should further address: quantitative assessment of tourism economic impacts and visitor satisfaction; long-term monitoring of conservation interventions measuring effectiveness; comparative studies of As-Salt with other Levantine heritage cities; development of digital heritage platforms using HBIM for management; investigation of climate change impacts on limestone deterioration; and community perception studies regarding heritage tourism development.

In closing, As-Salt's architectural heritage represents an exceptionally fine cultural and tourism asset. Should this heritage continue to be preserved and developed, it can become synonymous with cultural authenticity and economic wealth. The Abu Jaber House and similar heritage buildings are not mere yellow stones joined piece after piece, but dramatic representations of the golden age in architecture and culture; they become a link connecting past and present and a sustainable asset for the city's future. Success requires relentless energy by principal stakeholders—local and central government, academia, industry, community, and international organizations—working together to ensure As-Salt's heritage maintains its deeper meanings and implications for generations to come.

Limitations

This research acknowledges several methodological constraints. Access to privately-owned heritage buildings limited interior documentation to publicly accessible structures, while deteriorated conditions prevented safe entry to some buildings.

Original architectural drawings and detailed construction specifications are absent for most heritage structures, and historical records regarding construction dates and ownership chains remain incomplete. The scope of field surveys was constrained by single-researcher capacity, and long-term conservation monitoring extends beyond the research timeframe. Limited availability of tourism economic data and visitor statistics restricted quantitative tourism impact assessment.

Abstract: Smart tourism destinations have become increasingly important in the era of digital transformation and sustainable tourism development. Despite growing scholarly interest, previous studies have mainly examined technological factors or behavioral theories separately, leading to limited understanding of how digital perceptions and sustainability-oriented norms jointly influence tourist behavior. This study aims to extend the Theory of Planned Behavior by integrating e-attitude and resource efficiency norms to explain tourists' visit intention and actual behavior toward Smart tourism destinations. A quantitative research design was employed using survey data collected from tourists visiting smart tourism destinations. To conduct the study, the authors conducted direct interviews with 441 tourists visiting several smart tourist destinations in Can Tho City, Vietnam (Ninh Kieu Wharf, Cai Rang Floating Market, Son Island, Truc Lam Phuong Nam Zen Monastery, and Binh Thuy Ancient House) using a convenient sampling method. Convenience sampling was adopted due to accessibility and the exploratory nature of the study. The collected data were analyzed using Partial Least Squares Structural Equation Modeling. Reliability and validity of the measurement model were assessed through indicator loadings, composite reliability, average variance extracted, and discriminant validity. The structural model was evaluated using path coefficients, effect size (f^2), predictive relevance (Q^2), variance inflation factor (VIF), and standardized root mean square residual (SRMR). The results reveal that e-attitude significantly and positively influences visit intention and represents the strongest predictor in the model. Resource efficiency norms also positively affect visit intention, although with a relatively weaker effect. Furthermore, visit intention significantly influences actual visiting behavior and mediates the relationships between antecedent constructs and behavior. These findings indicate that tourists' decisions in smart tourism contexts are shaped by both digital perceptions and sustainability-oriented norms. The study contributes to the literature by extending TPB with digital and sustainability dimensions, thereby providing a more comprehensive explanation of tourist behavior in smart tourism environments. The findings also provide practical implications for destination managers and policymakers seeking to improve digital experiences and promote sustainable tourism practices.

Keywords: e-Attitude, e-Consumption behavior, resource efficiency norms, smart tourism destinations, visitor behavior

INTRODUCTION

The rapid advancement of digital technologies, including artificial intelligence (AI), big data analytics, the Internet of Things (IoT), and mobile platforms, is fundamentally transforming the tourism industry. In this evolving landscape, smart tourism destinations (STD) have emerged as an integrated development model that leverages digital infrastructure to enhance tourist experiences, optimize resource utilization, and support sustainable destination management (Gretzel et al., 2015; Mandić & Kennell, 2021). Unlike traditional destinations, STD operate as interconnected ecosystems where tourists, service providers, and governing bodies interact through real-time data and intelligent systems (Buhalis & Amaranggana, 2015).Existing research on smart tourism has primarily focused on technological infrastructure, destination attributes, and sustainability outcomes. Prior studies have emphasized the role of smart technologies in improving service quality, enhancing tourist satisfaction, and fostering sustainable development (Cavalheiro et al., 2020; Dabeedooal et al., 2019). Furthermore, studies grounded in behavioral theories-particularly the Theory of Planned Behavior (TPB)-have demonstrated that attitudes, subjective norms, and perceived behavioral control significantly influence tourists' behavioral intentions toward smart tourism destinations (Ajzen, 1991; Sun et al., 2020; Torabi et al., 2022).

However, despite these contributions, important gaps remain in the literature. First, from a theoretical perspective, existing studies largely rely on traditional behavioral frameworks such as TPB, which were developed in pre-digital contexts. These models primarily capture rational and cognitive evaluations but may not fully explain tourists' behaviors in technology-mediated environments, where digital interactions, online perceptions, and electronic experiences play a central role in decision-making (Hasan, 2022b; Jeong & Shin, 2019). Second, from a construct perspective, there is limited integration of digital-era psychological factors-such as e-attitude-into tourism behavior models. E-attitude reflects

individuals' evaluations of digital technologies and platforms, which are increasingly critical in shaping tourist decision processes (Hasan, 2022a; Berhe et al., 2020). In addition, sustainability-related norms, particularly resource efficiency norms, have been underexplored in the context of smart tourism behavior, despite their growing relevance in environmentally conscious travel (Farrow et al., 2017; Wang et al., 2018).

Third, from a contextual perspective, empirical evidence from emerging smart tourism destinations remains scarce. Most prior studies have been conducted in developed tourism markets, limiting the generalizability of findings to developing regions where digital transformation is still evolving (Novianti et al., 2022). In particular, cities such as Can Tho - an emerging tourism hub in the Mekong Delta of Vietnam-represent an important yet underexplored context for examining the interaction between digital transformation, sustainability, and tourist behavior.

To address these gaps, this study adopts an extended behavioral framework by incorporating e-attitude and resource efficiency norms into the analysis of tourists' visiting behavior toward smart tourism destinations. Specifically, this study aims to: (1) examine the effects of e-attitude and resource efficiency norms on tourists' intentions to visit STD, and (2) investigate the influence of visit intentions on actual visiting behavior.

By doing so, this study makes several contributions. Theoretically, it extends behavioral research by integrating digital and sustainability-related constructs into a unified framework, thereby providing a more comprehensive explanation of tourist behavior in smart tourism contexts. Empirically, it offers evidence from an emerging destination, contributing to the diversification of research settings in the smart tourism literature. Practically, the findings provide implications for policymakers and destination managers in designing strategies that enhance digital engagement and promote sustainable tourism development. Overall, this study responds to the growing need for a more nuanced understanding of tourist behavior in the digital era and contributes to advancing research on smart tourism destinations.

LITERATURE REVIEW

Research on STD has evolved significantly in recent years, particularly with the rapid advancement of digital technologies and the increasing emphasis on sustainability. The existing literature can be critically synthesized into three major research streams: (1) technology-enabled smart tourism systems, (2) behavioral models of tourist decision-making, and (3) digital consumption and sustainability-oriented behavior.

The first stream focuses on the role of smart tourism technologies (STTs) in shaping tourism ecosystems. Early studies conceptualize STD as technology-driven systems that integrate ICT, big data, and IoT to enhance tourist experiences and destination management. More recent studies have extended this perspective by emphasizing the complexity and multi-level nature of smart tourism systems. For instance, a recent systematic review (Yap et al., 2025) highlights that STTs function as interconnected systems in which technological attributes, mediating mechanisms, and contextual conditions jointly shape tourism outcomes under conditions of uncertainty and complexity. Similarly, emerging research has examined how smart tourism service ecosystems and digital platforms influence user experience and engagement, particularly in emerging markets (Qiao et al., 2026). Despite these advancements, this stream remains largely supply-oriented, focusing on technological capabilities while underexploring the psychological and behavioral mechanisms of tourists.

The second stream builds on established behavioral theories, particularly the TPB, to explain tourist intentions and actions. Prior studies consistently confirm that attitude, subjective norms, and perceived behavioral control significantly influence behavioral intention, which in turn predicts actual behavior. However, recent studies have begun to question the adequacy of traditional models in digitally mediated environments. For example, Inmor et al. (2025) propose a context-sensitive model demonstrating that tourist engagement with smart tourism services is shaped by multiple interacting conditions, including technological, social, and experiential factors. Likewise, Singh et al. (2025) highlight the role of technology engagement in strengthening place attachment through smart travel applications, suggesting that emotional and experiential dimensions extend beyond traditional cognitive evaluations. These findings indicate that while TPB remains a useful foundation, it may not fully capture the complexity of behavior in digital tourism contexts.

The third stream focuses on digital consumption behavior and sustainability-related constructs. With the increasing integration of digital platforms, artificial intelligence, and data-driven services, tourists' decision-making processes are increasingly shaped by digital interactions. Recent research shows that features of digital tourism platforms significantly influence tourist experience and revisit intention (Qiao et al., 2026). At the same time, sustainability considerations-particularly resource efficiency and environmental norms-have gained increasing attention as key drivers of responsible tourist behavior. However, these two perspectives (digital behavior and sustainability) are often examined separately, leading to a fragmented understanding of tourist decision-making. A critical synthesis of these research streams reveals several important gaps. First, there is a lack of theoretical integration between technology-driven perspectives and behavioral theories, resulting in limited explanatory power for digitally mediated tourist behavior. Second, digital-era constructs such as e-attitude and technology engagement have not been systematically incorporated into mainstream behavioral models. Third, sustainability-related norms, particularly resource efficiency norms, remain underexplored in the context of smart tourism behavior. Finally, although recent studies (e.g., Yap et al., 2025) have begun to explore emerging markets, empirical evidence from developing smart tourism destinations remains limited.

To address these gaps, this study integrates insights from the three research streams by incorporating e-attitude and resource efficiency norms into an extended behavioral framework. E-attitude captures tourists' evaluations of digital technologies and platforms, while resource efficiency norms reflect socially embedded expectations regarding sustainable behavior. By combining these constructs with behavioral intention, this study aims to provide a more comprehensive explanation of tourists' visiting behavior toward smart tourism destinations, particularly in emerging contexts. Through this

integrative approach, the study contributes to bridging the gap between technology-driven, behavioral, and sustainability-oriented perspectives, thereby advancing the theoretical and empirical understanding of tourist behavior in the digital era.

Smart tourism destination visiting behaviors

Behavior is understood as specific actions of an individual that can be observed and measured based on widely accepted standards (Godey et al., 2016). Within the framework of behavioral theories, many studies affirm that behavior is a direct result of intention, and this intention is influenced by underlying psychological factors. Specifically, Sun et al. (2020) and Hasan & Aziz (2024) show that behavior is a function of intention, where intention is formed based on attitudes, subjective norms, and the individual's perceived behavioral control – consistent with Ajzen (1991) argument in the TPB. This implies that when individuals have a positive assessment of their behavior, receive support from their social environment, and believe in their ability to perform the behavior, they tend to translate their intention into actual action.

In the context of tourism, Ghosh & Mukherjee (2023) argue that tourist behavior reflects the entire decision-making process, including destination selection, trip execution, and evaluation of the experience at that destination. At the same time, Torabi et al. (2022) suggest that the behavior of visiting STD is significantly influenced by the subjective attitudes and norms of tourists. Based on these arguments, it can be argued that the behavior of visiting STD is a result of the visit intention, where the intention is formed not only from traditional elements of TPB but also from elements specific to the digital environment. Specifically, STD visit intention can be determined by online attitudes (e-attitude) and norms of resource utilization efficiency. These factors reflect how tourists value digital experiences, the degree of resource optimization when using technology, and their concern for sustainable tourism development.

This study adopts an extended behavioral framework grounded in the TPB (Ajzen, 1991), integrating digital-era and sustainability-oriented constructs to better explain tourist behavior in smart tourism destinations (STD). TPB has been widely applied in tourism research to predict behavioral intention and actual behavior (Han et al., 2010; Lam & Hsu, 2006). It posits that behavioral intention is the most immediate predictor of behavior, shaped by individuals' attitudes, subjective norms, and perceived behavioral control (Ajzen, 1991). However, TPB was developed in a pre-digital context and primarily emphasizes rational cognitive evaluations. Recent studies suggest that such traditional models may not fully capture decision-making processes in digitally mediated environments, where interactions are increasingly shaped by online platforms, real-time information, and user-generated content (Jeong & Shin, 2019; Hasan, 2022b; Ghosh & Mukherjee, 2023). In addition, sustainability considerations have become increasingly important in shaping tourist behavior, particularly in smart tourism contexts (Mandić & Kennell, 2021; Wang et al., 2018). To address these limitations, this study extends TPB by incorporating two key constructs: e-attitude and resource efficiency norms.

E-attitude and Visit Intention

E-attitude refers to an individual's evaluative disposition toward digital technologies and online platforms used in tourism contexts (Hasan, 2022a; Berhe et al., 2020). In smart tourism environments, tourists rely heavily on digital interfaces such as mobile applications, online reviews, and real-time information systems, which shape perceptions and influence decision-making (Buhalis & Amaranggana, 2015; Gretzel et al., 2015).

Prior research indicates that positive attitudes toward digital technologies significantly enhance users' intention to adopt smart services and engage with digital platforms (Venkatesh et al., 2012). From a theoretical perspective, e-attitude can be considered an extension of the traditional "attitude" construct in TPB, capturing technology-mediated evaluations in digital environments. Accordingly, the following hypothesis is proposed:

H1: E-attitude positively influences tourists' visit intention to smart tourism destinations.

Resource Efficiency Norms and Visit Intention

Resource efficiency norms refer to socially shared expectations regarding responsible and sustainable use of resources (Farrow et al., 2017; Wang et al., 2018). In smart tourism contexts, sustainability is increasingly embedded in destination strategies, often facilitated by digital technologies that promote efficient resource use and environmentally responsible behavior (Mandić & Kennell, 2021). Norm-based theories suggest that individuals' behavioral intentions are influenced by perceived social expectations and moral obligations (Ajzen, 1991; Schwartz, 1977). In tourism, studies have shown that pro-environmental norms significantly affect tourists' decision-making and behavioral intentions (Han et al., 2010; Juvan & Dolnicar, 2014). Thus, resource efficiency norms can be conceptualized as an extension of subjective norms in TPB, emphasizing sustainability-oriented social expectations. Therefore, the following hypothesis is proposed:

H2: Resource efficiency norms positively influence tourists' visit intention to smart tourism destinations.

Visit Intention and Actual Behavior

Consistent with TPB, behavioral intention is the most direct predictor of actual behavior (Ajzen, 1991). In tourism research, visit intention has been widely validated as a strong predictor of actual travel behavior (Lam & Hsu, 2006; Sun et al., 2020). In the context of smart tourism, tourists who develop strong intentions based on digital perceptions and sustainability norms are more likely to translate these intentions into actual visiting behavior.

Thus, the following hypothesis is proposed:

H3: Visit intention positively influences actual visiting behavior toward smart tourism destinations.

Mediating Role of Visit Intention

TPB also suggests that intention serves as a central mediating mechanism linking psychological factors and actual

behavior (Ajzen, 1991). Empirical studies have confirmed that intention mediates the relationship between attitudes, norms, and behavior in tourism contexts (Han et al., 2010; Sun et al., 2020). In this study, visit intention is expected to mediate the effects of both e-attitude and resource efficiency norms on actual behavior.

Therefore, the following hypotheses are proposed:

H4: Visit intention mediates the relationship between e-attitude and actual visiting behavior.

H5: Visit intention mediates the relationship between resource efficiency norms and actual visiting behavior.

Based on a literature review and the formulation of hypotheses regarding the relationships between latent variables, the author proposes a research model -"Factors Affecting Smart Tourist Destination Visiting Behavior: A Case Study in Can Tho City, Vietnam"- as illustrated in Figure 1 below.

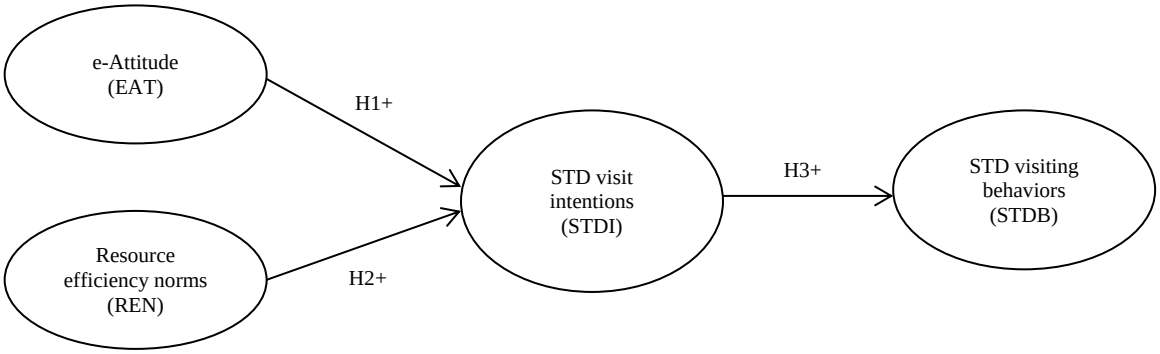

Figure 1. Proposed research model

RESEARCH METHODOLOGY

Measurement scale

All measurement items were adapted from previous studies to ensure the validity of the scale. The content of the scale was slightly modified to align with the research context. Each measurement item was evaluated using a 5-point Likert scale. Refer to Table 1 for a detailed overview of all scales used in this study.

Table 1. Interpretation of observed variables in the research model

Construct	Code	Observed variables	Source
e-Attitude	EAT1	I have a positive view on the application of information and communication technology (ICT) in smart tourism destinations	Hasan et al. (2026)
	EAT2	In my opinion, deploying ICT in smart tourism destinations is a reasonable and effective choice	
	EAT3	I believe that using ICT in smart tourism destinations brings many practical values and benefits to tourists	
	EAT4	The application of IT helps improve the quality of services at smart tourism destinations	Additional information from expert interviews (2025)
	EAT5	I support continued investment and development of IT at smart tourism destinations.	
Resource Efficiency Norms	REN1	I believe that smart tourism destinations adopt water-saving technologies, such as low-flow showerheads, to minimize water usage	Hasan et al. (2026)
	REN2	I believe that smart tourism destinations implement energy-efficient lighting solutions, including LED or CFL bulbs	
	REN3	I believe that smart tourism destinations apply effective insulation materials to buildings to reduce energy consumption for cooling	
STD Visit Intentions	STDI1	I intend to visit smart travel destinations in the near future	Hasan et al. (2026)
	STDI2	I am ready to choose smart travel destinations for my trip	
	STDI3	I will make an effort to arrange my plans so that I can visit smart travel destinations	
STD Visiting Behaviors	STDB1	I frequently visit smart tourism destinations	Hasan et al. (2026)
	STDB2	When traveling, I tend to choose and visit smart tourism destinations	
	STDB3	I often prioritize visiting tourist destinations that incorporate the features of smart tourism	

Data collection

The survey was conducted between August and October 2025 in Can Tho using a convenience sampling approach due to the difficulty of accessing the entire tourist population. According to Hair et al. (2022), convenience sampling is considered acceptable in exploratory and prediction-oriented studies employing Partial Least Squares Structural Equation Modeling (PLS-SEM), particularly when the target population cannot be comprehensively identified. Data were collected through face-to-face interviews to ensure respondents clearly understood the questionnaire items and to improve response validity. The survey participants consisted of tourists visiting representative smart tourism destinations in Can Tho, including Ninh Kieu Wharf, Cai Rang Floating Market, Son Islet, Truc Lam Phuong Nam Zen Monastery, and Binh Thuy Ancient House, which were selected because they represent prominent tourism attractions increasingly integrating digital technologies and smart tourism

practices. A total of 500 questionnaires were distributed, yielding 472 returned responses, corresponding to a response rate of 94.4%. After removing incomplete and unreliable questionnaires, 441 valid observations were retained for analysis, satisfying the recommended sample size requirements for PLS-SEM analysis (Hair et al., 2022). The demographic characteristics of respondents were measured using categorical variables and reported as percentages (%) representing the proportion of respondents within each category relative to the total valid sample (n=441). Regarding gender, male respondents accounted for 46.94% and female respondents accounted for 53.06%. Age was measured in years and classified into ordinal age groups, including under 20 years old (20.86%), from 20 to under 30 years old (40.82%), from 30 to under 40 years old (19.27%), and from 40 to under 50 years old (2.72%). Monthly income was measured in million Vietnamese Dong per month (million VND/month), with 16.33% earning less than 3 million VND, 28.34% earning from 3 to under 6 million VND, 42.86% earning from 6 to under 9 million VND, and 12.47% earning more than 9 million VND per month.

Information on the characteristics of the eligible study sample is presented briefly in Table 2. Overall, the sample structure indicates that young and middle-income tourists constitute the majority of respondents. This demographic profile is consistent with previous tourism technology studies suggesting that younger tourists are generally more familiar with digital technologies and more likely to engage with smart tourism services and technology-enabled travel experiences.

Table 2. The demographic survey data

Demographic profile		**Frequency (n = 441)**	**Percent (%)**
Gender	Male	207	46.94
	Female	234	53.06
Age	Under 20	92	20.86
	From 20 to under 30	180	40.82
	From 30 to under 40	85	19.27
	From 40 to under 50	72	16.33
	Above 50	12	2.72
Income	Under 3 mil VND/month	72	16.33
	From 3 to under 6 mil VND/month	125	28.34
	From 6 to under 9 mil VND/month	189	42.86
	Above 9 mil VND/month	55	12.47

RESULTS

In the initial stage, the measurement model was assessed and analyzed to confirm its quality before advancing to the second stage, which involved evaluating the structural model.

Measuring model

Table 3 demonstrates that all measurement items achieved convergent validity. The table includes Cronbach's Alpha values, average variance extracted (AVE) statistics for each dimension, and factor loadings for each item. With only rare exceptions, the results indicate that the outer loadings of the items were approximately 0.708 or higher, supporting the proposed factor structure (Hair et al., 2022). The AVE values range from 0.639 to 0.748, surpassing the recommended threshold of 0.50 (Hair et al., 2022). Additionally, the composite reliability (CR) and Cronbach's Alpha values, which ranged from 0.719 to 0.907, confirm construct reliability, exceeding the significance threshold of 0.7.

In this study, the heterotrait–monotrait (HTMT) criterion was applied to assess discriminant validity (Henseler et al., 2015). Discriminant validity is established when the square root of the AVE for each construct exceeds its correlations with other constructs. The results presented in Table 4 indicate that the square root of the AVE is higher than the correlations between all pairs of dimensions, confirming discriminant validity.

Table 3. Construct reliability and validity (Notes: CA: Cronbach's Alpha; CR: Composite Reliability, AVE: Average Variance Extracted; OL: Outer Loadings; EAT: e-Attitude; REN: Resource Efficiency Norms; STDI: STD Visit Intentions; STDB: STD Visiting Behaviors)

Construct	**Code**	**CA**	**CR**	**AVE**	**OL**

Construct	Resource Efficiency Noms	STD Visit Intentions	STD Visiting Behaviors	e-Attitude
Resource Efficiency Noms	**0.800**			
STD Visit Intentions	0.342	**0.846**		
STD Visiting Behaviors	0.223	0.587	**0.865**	
e-Attitude	0.257	0.635	0.630	**0.814**

Structural model

The structural relationships among the constructs were examined using standardized path coefficients (β) and their associated p-values. As reported in Table 5 and Figure 2, both e-Attitude and Resource Efficiency Norms exhibited positive and statistically significant direct effects on STD Visit Intentions ($\beta = 0.586$, $p < 0.05$; $\beta = 0.191$, $p < 0.05$). The significance of these relationships is supported by t-values greater than 1.96 at the 5% significance level, in line with the criteria suggested by Henseler et al. (2009). Notably, e-Attitude emerged as the most influential predictor of STD Visit Intentions, indicating that favorable perceptions of smart technologies strongly enhance tourists' visit intention such destinations. Together, e-Attitude and Resource Efficiency Norms explained 43.8% of the variance in STD Visit Intentions ($R^2 = 0.438$), reflecting a moderate level of explanatory power for the proposed model.

Table 5. Hypothesis analysis results

Relationship	Path coefficients	P- values	Hypotheses	Decision
Direct effects				
EAT → STDI	0.586	0.000	H_1	**Accepted**
REN → STDI	0.191	0.000	H_2	**Accepted**
STDI → STDB	0.587	0.000	H_3	**Accepted**
Indirect effects				
EAT → STDI → STDB	0.344	0.000	H_4	**Accepted**
REN → STDI → STDB	0.112	0.000	H_5	**Accepted**

Notes: EAT: e-Attitude; REN: Resource Efficiency Norms; STDI: STD Visit Intentions; STDB: STD Visiting Behaviors

Hypothesis H_2 posited that resource efficiency norms have a significant effect on tourists' visit intention smart tourism destinations. The results support this hypothesis ($\beta = 0.191$, $p = 0.000$), indicating that stronger resource efficiency norms are positively associated with higher visit intentions. In other words, tourists who are more conscious of efficient resource use are more inclined to visit smart tourism destinations. This finding is in line with previous research by Wang et al. (2018), which also identified a significant relationship between personal norms and visit intention in the smart tourism context.

Similarly, Hypothesis H_3 suggested that the visit intention smart tourism destinations significantly influences actual visiting behavior. The empirical evidence confirms this relationship ($\beta = 0.587$, $p = 0.000$), thereby supporting H_3. This result implies that stronger and more positive intentions increase the likelihood that tourists will engage in actual visiting behavior. The finding is consistent with the study conducted by Hasan and Aziz (2024), which likewise demonstrated that visit intention is a significant predictor of visiting behavior in smart tourism settings.

Collinearity Assessment (VIF): To assess potential multicollinearity issues among the predictor constructs, variance inflation factor (VIF) values were examined. The results indicate that all VIF values ranged from 1.357 to 2.462, which are well below the recommended threshold of 5.0 (Hair et al., 2022). This finding confirms that multicollinearity is not a concern in the structural model and that the predictor constructs are sufficiently distinct from one another. Furthermore, the full collinearity assessment revealed that all VIF values were below the more conservative threshold of 3.3, suggesting that common method bias (CMB) is unlikely to threaten the validity of the results (Kock, 2015). These findings support the robustness and reliability of the proposed model.

Effect Size (f^2): Effect size (f^2) was calculated to evaluate the relative impact of each exogenous construct on endogenous variables. Following Cohen (1988), f^2 values of 0.02, 0.15, and 0.35 indicate small, medium, and large effects, respectively. The results indicate that e-attitude has a large effect on visit intention ($f^2 = 0.571$), suggesting that digital perceptions represent the most influential determinant of tourists' intention to visit smart tourism destinations. In contrast, resource efficiency norms demonstrate a small effect on visit intention ($f^2 = 0.061$), indicating a relatively weaker but still meaningful contribution. Furthermore, visit intention exerts a large effect on actual visiting behavior ($f^2 = 0.526$), confirming the strong predictive role of intention in shaping tourists' actual behavior toward smart tourism destinations. These findings indicate that e-attitude is the dominant predictor of visit intention.

Predictive Relevance (Q^2): Predictive Relevance (Q^2): The predictive relevance of the model was assessed using the blindfolding procedure. According to Hair et al. (2022), Q^2 values greater than zero indicate that the model has predictive relevance for endogenous constructs. The results show that the Q^2 values for visit intention $Q^2 = 0.305$ and actual behavior $Q^2 = 0.254$ are above zero, confirming that the proposed model possesses satisfactory predictive capability.

Model Fit (SRMR): The overall model fit was assessed using the standardized root mean square residual (SRMR). The results show that the SRMR value is 0.070, which is below the recommended threshold of 0.08 suggested by Henseler et al. (2015). This indicates that the proposed model demonstrates an acceptable level of fit and that the discrepancy between the

observed and predicted correlations is relatively small. Therefore, the structural model can be considered well-fitted to the empirical data, supporting the adequacy and robustness of the proposed framework.

Mediating effects

Beyond their direct effects on STD Visit Intentions, the results reported in Table 5 and Figure 2 also indicate the presence of significant indirect relationships. Specifically, e-Attitude has a positive and statistically significant indirect effect on STD Visiting Behaviors through STD Visit Intentions ($\beta = 0.344$, $p < 0.001$). Similarly, Resource Efficiency Norms indirectly influence STD Visiting Behaviors via STD Visit Intentions ($\beta = 0.112$, $p < 0.001$).

These findings suggest that STD Visit Intentions serve as a mediating variable, transmitting the effects of both e-Attitude and Resource Efficiency Norms onto actual visiting behavior. Thus, tourists' favorable attitudes toward smart tourism technologies and their resource efficiency norms contribute to visiting behavior primarily by strengthening their visit intention smart tourism destinations.

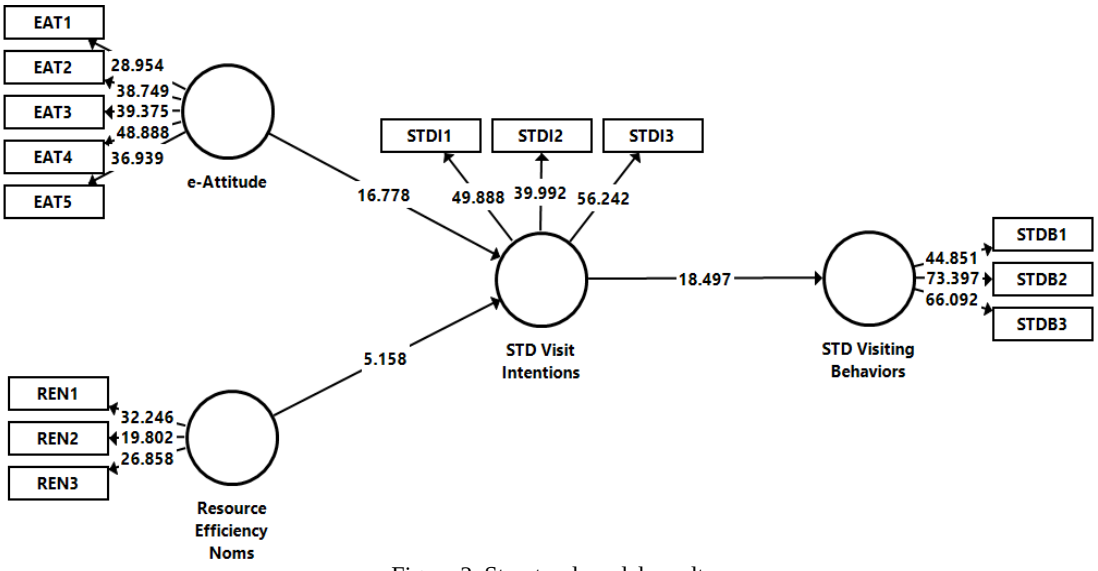

Figure 2. Structural model result

DISCUSSION

This study aims to explain tourists' visiting behavior toward smart tourism destinations (STD) by extending the Theory of Planned Behavior (TPB) with digital and sustainability-related constructs. The findings provide several important theoretical and practical insights.

First, the results demonstrate that e-attitude has a significant and positive effect on visit intention, with the strongest explanatory power among the antecedents. This finding suggests that tourists' evaluations of digital technologies play a central role in shaping behavioral intentions in smart tourism contexts. Unlike traditional tourism settings, where attitudes are formed primarily through offline experiences, smart tourism environments rely heavily on digital interfaces such as mobile applications, online platforms, and real-time information systems. As a result, e-attitude becomes a critical determinant of decision-making. This finding extends TPB by showing that attitude formation in the digital era is increasingly mediated by technology-based interactions rather than purely cognitive evaluations. It is consistent with prior studies highlighting the importance of digital engagement in influencing tourism behavior, but it further emphasizes that such influence operates as a core psychological mechanism rather than a peripheral factor.

Second, the results indicate that resource efficiency norms significantly influence visit intention, highlighting the role of sustainability-oriented social expectations in shaping tourist behavior. This finding supports the extension of subjective norms in TPB by incorporating environmental and resource-related considerations. In the context of smart tourism, where digital systems often promote efficient resource use and sustainable practices, tourists appear to internalize these norms and incorporate them into their decision-making processes. Compared to earlier studies that focus primarily on pro-environmental attitudes, this result suggests that socially embedded expectations regarding sustainability may exert a more structured influence on intention formation. This contributes to the literature by integrating sustainability norms into behavioral models of smart tourism.

Third, the study confirms that visit intention significantly predicts actual visiting behavior, consistent with the core assumption of TPB. This finding reinforces the robustness of intention as a key determinant of behavior, even in digitally mediated environments. Importantly, it suggests that despite the increasing complexity of tourism decision-making, the intention–behavior link remains valid when extended with context-specific constructs. This supports the continued relevance of TPB as a foundational framework while highlighting the need for contextual adaptation.

Fourth, the mediating analysis reveals that visit intention plays a crucial mediating role in linking both e-attitude and resource efficiency norms to actual behavior. This finding provides empirical support for the mechanism proposed in the extended framework, demonstrating that psychological factors influence behavior indirectly through intention.

More importantly, it highlights that both digital perceptions and sustainability norms are not directly translated into behavior but are filtered through a deliberate decision-making process. This insight contributes to a more nuanced understanding of how different types of antecedents operate within the behavioral process in smart tourism contexts.

From a theoretical perspective, this study makes several contributions. First, it extends TPB by integrating digital-era constructs (e-attitude) and sustainability-oriented norms (resource efficiency norms), thereby enhancing its explanatory power in the context of smart tourism. Second, it bridges previously fragmented research streams by combining technology-driven perspectives with behavioral and sustainability-oriented approaches. Third, it provides empirical evidence from an emerging tourism destination, contributing to the diversification of research contexts in the smart tourism literature.

From a practical perspective, the findings suggest that destination managers should prioritize digital experience design to enhance tourists' e-attitude. Investments in user-friendly mobile applications, real-time information systems, and interactive platforms can significantly influence tourists' visit intention.

In addition, policymakers should promote sustainability-oriented communication strategies that reinforce resource efficiency norms, thereby encouraging responsible tourism behavior. Integrating digital innovation with sustainability messaging may create synergistic effects in attracting tourists to smart destinations.

Overall, the study highlights that tourist behavior in smart tourism contexts is jointly shaped by digital perceptions and sustainability considerations, mediated through behavioral intention. This underscores the importance of adopting an integrated approach that combines technological advancement with environmental responsibility in both research and practice.

The findings of this study are broadly consistent with, yet extend, existing research on smart tourism behavior. First, the significant effect of e-attitude on visit intention aligns with prior studies that emphasize the role of digital engagement and technology acceptance in shaping tourist decisions (Jeong & Shin, 2019; Ghosh & Mukherjee, 2023). While earlier research often treats technology-related factors as external drivers of behavior, this study advances the literature by conceptualizing e-attitude as a core psychological construct within an extended behavioral framework. This suggests that digital perceptions are not merely contextual influences but are internalized as part of tourists' evaluative processes.

Second, the positive impact of resource efficiency norms on visit intention is consistent with studies on pro-environmental behavior in tourism (Han et al., 2010; Juvan & Dolnicar, 2014), which highlight the importance of social and moral norms in influencing decision-making. However, this study extends prior work by focusing specifically on resource efficiency within smart tourism contexts, where sustainability is often embedded in digital systems and destination management strategies. This indicates that sustainability-related norms may operate more explicitly and systematically in smart tourism environments compared to traditional tourism settings.

Third, the strong relationship between visit intention and actual behavior confirms the foundational assumptions of the Theory of Planned Behavior (Ajzen, 1991) and is consistent with empirical findings in tourism research (Lam & Hsu, 2006; Sun et al., 2020). Importantly, the present study demonstrates that this relationship remains robust even when the model is extended to include digital and sustainability constructs, thereby supporting the adaptability of TPB in contemporary tourism contexts.Finally, the mediating role of visit intention is in line with prior studies that identify intention as a key mechanism linking psychological factors and behavior (Han et al., 2010; Sun et al., 2020). However, this study contributes further by showing that both digital perceptions (e-attitude) and sustainability norms (resource efficiency norms) operate through this mediating pathway. This provides a more integrated understanding of how diverse antecedents jointly influence tourist behavior in smart tourism destinations.

Overall, while the findings are generally consistent with existing literature, they extend prior research by integrating digital and sustainability perspectives into a unified behavioral framework, thereby offering new insights into tourist decision-making in the era of smart tourism.

CONCLUSION AND LIMITATIONS

This study investigates tourists' visiting behavior toward STD by extending the TPB with digital and sustainability-related constructs. Specifically, the study examines the roles of e-attitude and resource efficiency norms in shaping visit intention and subsequent actual behavior within an emerging smart tourism context.

The findings reveal that both e-attitude and resource efficiency norms significantly influence tourists' visit intention STD, with e-attitude emerging as the strongest predictor. In turn, visit intention plays a central role in translating these psychological factors into actual visiting behavior. The mediating analysis further confirms that intention serves as a key mechanism linking digital perceptions and sustainability norms to behavior. These results highlight the importance of integrating both technological and environmental considerations in understanding tourist decision-making.

From a theoretical perspective, this study contributes to the literature in several ways. First, it extends TPB by incorporating e-attitude and resource efficiency norms, thereby enhancing its explanatory power in digitally mediated and sustainability-oriented contexts. Second, it bridges previously fragmented research streams by integrating technology - driven and sustainability perspectives into a unified behavioral framework. Third, by providing empirical evidence from an emerging smart tourism destination, the study broadens the geographical and contextual scope of existing research.

From a practical perspective, the findings suggest that destination managers should focus on enhancing tourists' digital experiences to foster positive e-attitudes. Investments in user-friendly digital platforms, real-time information systems, and interactive services can significantly increase tourists' visit intention.

In addition, policymakers should promote sustainability-oriented initiatives and communication strategies that reinforce resource efficiency norms, thereby encouraging responsible tourism behavior. The integration of digital innovation and sustainability practices can create a competitive advantage for smart tourism destinations.

Despite these contributions, the study has several limitations. The use of convenience sampling may limit the generalizability of the findings, and the focus on a single destination context may restrict external validity. Furthermore, the study considers a limited set of constructs, and future research is encouraged to incorporate additional variables, such as perceived behavioral control, trust in technology, and perceived risk. Longitudinal and comparative studies across different destinations would also provide deeper insights into the dynamics of tourist behavior in smart tourism environments.

In conclusion, this study demonstrates that tourist behavior in smart tourism destinations is shaped by the combined influence of digital perceptions and sustainability-oriented norms, mediated through behavioral intention. By adopting an integrated theoretical approach, the study provides a more comprehensive understanding of tourist decision-making in the digital era and offers valuable implications for both research and practice.

Citation: Bunruang, J., & Nonthapot, S. (2026). The factors influencing the satisfaction of thai passengers on the international railway route between Bangkok (Thailand) and Vientiane (Laos). *Geojournal of Tourism and Geosites*, 67(3), 2536–2547. https://doi.org/10.30892/gtg.67361-1873

Abstract: Laos is a destination with beautiful culture, traditions and nature that attracts many tourists, especially Thai tourists, so there is a strong tourism link between the two countries. The Thailand-Laos railway, the Krung Thep Aphiwat Central Terminal - Vientiane (Khamsavath) route, which is an important new railway tourism route to connect the capitals of the two countries. This research aims to study the experiential international economic factors, the market mix and satisfaction factors for Thai service users on the Thai-Laos railway service. The samples are Thai passengers who used the train service on the route between Krung Thep Aphiwat Central Terminal (Bangkok) of Thailand and Vientiane Railway Station (Khamsavath) in Laos in both directions with 394 respondents. Questionnaires collected from Google Forms were employed to collect data from a randomly selected convenience sample. Data were analysed using confirmatory factor analysis (CFA) and structural equation model analysis (SEM) to verify the accuracy of the latent variable structure and the consistency of the model with empirical data by using the JASP 0.19.3 software. Analysis results from CB-SEM revealed that the marketing mix factor had the greatest positive influence on satisfaction and the dimension of service delivery was found to be the main factor. In addition, experiential and international economic factors were found to have a significant indirect influence. This emphasizes the importance of security management and clear information communication. Relevant agencies should adopt guidelines, seamless service and joint testing to reduce the travel time and anxiety of passengers. In addition, there are suggestions to integrate cross-border travel insurance into the ticketing system to reduce risk perception and to meet international safety standards for tourism on the Thailand-Laos railway route.

INTRODUCTION

Rail transport is crucial in connecting various aspects, including society, culture, economy, tourism, and investment, both domestically and internationally. This leads to development in connected areas, generating income and employment, attracting investment, and facilitating cultural exchange. An example is the Laos-China railway line, which connects the economy, investment, and tourism in the Greater Mekong-subregion. In regard to the intermediary country in the Mekong sub-region, the Lao People's Democratic Republic (Laos), there are unique tourist attractions and beautiful nature that attract both domestic and international tourists to popular destinations in Lao, such as Luang Prabang and Vang Vieng.

According to a report by The Laotian Times (2025), Laos was expected to welcome more than four million tourists, an increase of nearly one million compared to 2023. This was a result of the "2024 Visit Laos Year" policy where Laos granted special visa waivers to visitors from more than 30 countries. In addition, Luang Prabang was descibed as "a hidden paradise" by Time magazine in 2023 and one of the 50 best places to visit (Vientiane Times, 2025). This implies that Laos is a popular tourist attraction in the GMS. In 2024, The Laotian Times (2025) reported that the number of Thai tourists traveling to Laos ranked first at 1,215,553. This was followed by Vietnam and China. Hence, Thai tourists are significant in the regional market of Laos. There is, therefore, a strong connection between the tourism businesses of Thailand and Laos.

The Lao government has invested in infrastructure development, such as roads, transportation such as trains and facilities to support tourism (Lao News Agency, 2024). In addition, a new railway route has been created while the train route from Krung Thep Aphiwat Central Terminal (Bangkok) to Vientiane Railway Station (Khamsavath) also began to provide services. The first train operation between Krung Thep Aphiwat Central Terminal and Vientiane Railway Station (Khamsavath) was inaugurated on 19 July 2024 (Figure 1.). There was a lot of interest from tourists and the public and, as a result, all of the seats were booked in a short time (State Railway of Thailand (SRT), 2024).

This railway is part of the international economic and development cooperation in Southeast Asia between Thailand and Laos (Nonthapot et al., 2025). The railway supports cost reduction and increases the potential for cargo transportation.

Figure 1. International rail link Thailand and Laos: Krung Thep Aphiwat Central Terminal – Vientiane Station (Khamsavath) route (Google Maps, 2025; datasource for the photos: authors, 2025)

It is continuous investment and creates opportunities for the Thai private sector to do business in Laos (Neighboring Countries Economic Development Cooperation Agency (NEDA), 2023).

Laos is a destination with beautiful culture, traditions and nature that attracts many tourists, especially Thai tourists, so there is a strong tourism link between the two countries. The Thailand-Laos railway, the Krung Thep Aphiwat Central Terminal - Vientiane (Khamsavath) route, which is an important new railway tourism route to connect the capitals of the two countries. As a result, tourism, investment, opportunity creation, and international development have been enhanced. Studying tourist behavior in regard to marketing strategies is considered important to plan and develop services to be effective and responsive to needs. and to determine the level of satisfaction with the use of the service (Qin, 2012)

However, there are still limited academic studies on satisfaction in regard to the use of the Thailand-Laos railway (Krung Thep Aphiwat Central Terminal (Bangkok) - Vientiane Railway Station (Khamsavath). The study based on marketing education in this area in regard to rail transportation lacks academic attention. In order to better understand the factors affecting the satisfaction of using the railway service between Thailand and Laos need to be studied to fill the gaps. The results can be used as guidelines to support the government and the private sector, who will be able to use the information obtained from the research to develop and improve services to meet the demand for the Thailand-Laos railway.

MATERIALS AND METHODS

Related concepts and theories

Ideas and research related to the marketing mix and satisfaction. Tourism industry marketing research is the analysis of tourism resources and services that can be sold to tourists. This research is a study of Thai passengers using the Thailand-Laos railway service, and in the rail transportation business, there are three important elements: 1) trains, 2) routes, and 3) railway stations. Once the resources and services are known, attention is given to the tourism marketing mix, which is a strategic marketing tool that entrepreneurs can employ to generate results and drive demand to meet their goals by encouraging tourists to travel and buy tourism services. This allows tourism business operators to make profits and to develop services to satisfy tourists (Jittangwattana, 2012; Kotler et al., 2014). Furthermore, the future research directions proposed by Wahpiyudin et al. (2025) emphasize the importance of developing marketing models tailored to local context, which aligns with the present study's focus on analyzing marketing factors along the Thai-Laos railway route.

This marketing model consists of several components. Kotler et al. (2014) described the marketing framework in terms of the basic marketing mix, or 4Ps, which consist of Product, Price, Place, and Promotion. These are the main elements used in general marketing strategy. However, in the context of service marketing, Booms & Bitner (1981) expanded this concept, suggesting that in addition to the basic 4Ps, three more elements should be emphasized to reflect the specific characteristics of the service: People (including employees and stakeholders), Process (related to the procedures and methods of service delivery), and Physical Evidence (which helps build awareness and trust among service recipients).

Thus, these seven Ps are used as a key conceptual framework in service marketing. In addition, Jittangwattana (2012) proposed a tourism marketing concept with basic elements like Booms & Bitner's (1981) but adapted it to the specific

context of the tourism industry. The key difference is that the role of the people component in the tourism industry (people in tourism) was expanded to encompass a wider range of dimensions.

Furthermore, elements such as the integration of tourism services (packaging in tourism) to create value and convenience for tourists, the organization of activities or events to attract tourists (tourism programming), and the creation of business partnerships (partnership in Tourism) have been added to strengthen the networks and to enhance the overall competitiveness of the tourism industry (Jittangwattana, 2012). Kotler et al. (2014) described the 4Ps as follows:

1) Product means the goods and services offered by the entrepreneur to the target market.

2) Price refers to the amount of money that customers have to pay to acquire the product or service.

3) Distribution channel (Place) refers to the activities of the entrepreneur that enables the product or service to reach customers.

4) Promotion refers to activities used to communicate the value of products and services to attract customer interest.

The desired outcome of tourism operators is satisfaction. Satisfaction helps researchers to understand the needs of consumers and confirms the consumer's ability to make decisions about goods and services (Oliver, 1997). Consumer satisfaction is an emotional response, and the focus of the response is based on a comparison of performance with certain standards, which vary from context to context. It may be a comparison of general or specific standards, and the period in which consumers evaluate satisfaction can occur at a variety of moments (Giese & Cote, 2000). It is divided into three levels. Dissatisfaction occurs when a customer receives a product or service that is worse than expected; satisfaction occurs when a customer receives a product or service that meets their expectations, and a high level of satisfaction occurs when a customer receives a product or service that exceeds their expectations.

A review of relevant research in the tourism and hospitality industries revealed that the marketing mix affects satisfaction regarding the decision to buy products or services in the tourism industry. Rattanasomchok (2015), Pannarong (2017), Sirimongkol (2023), Thet (2023), Baidun et al. (2022), Tielung & Untu (2021), Do & Vu (2020), Magatef (2015) all pointed out that the 7Ps marketing mix affects consumer satisfaction in different contexts.

In addition, studies conducted in the context of bus travel in Thailand and Asia by Kieanwatana et al. (2022), Chanchai & Suwan (2021), and Phornthepkasemsant et al. (2021) also discussed the factors influencing decision-making and satisfaction in regard to train travel in normal and COVID-19 situations. It was found that passengers paid attention to safety, time, and the care of the staff, the convenience of service and connecting to the train station, access to information and a fast process for buying tickets and making payments. In addition, Sangpikul (2018); Vuong et al. (2024); Setiawan et al. (2024) discussed service quality factors related to customer experience, such as service providers, reliability, customer experience, Internet of Things (IoT), services and facilities, safety and cleanliness, which all affect satisfaction and loyalty to the service or destination.

The components of satisfaction measured by the passenger's experience after using the service on a train journey are consistent with the concept of Yuda Bakti & Sumaedi's (2015) P-TRANSQUAL which was developed from Parasuraman's SERVQUAL concept, Zeithaml & Berry (1988) and Cronin & Taylor (1992) as described by Yuda Bakti & Sumaedi (2015). They described the elements, which included 1) Comfort, 2) Tangible components, 3) Personnel, and 4) Reliability in measuring the quality of land transportation services in Indonesia. Nonthapot & Nasoontorn (2020), also studied the impact of service quality on the satisfaction of passengers traveling on routes between Thailand and Laos.

Concepts and research related to the field of travel experience

Social factors influence consumer behavior, including some informal groups, such as friends, family members, colleagues and neighbors. Family members can have a great influence on purchasing decisions, including abstract travel product purchases. Before deciding to purchase goods or services, tourists cannot usually experience the good or services to see if they will be satisfied or not. Therefore, it is important to rely on the recommendations of others (Kotler, 2000; Jittangwattana, 2012). This is in line with Pan et al. (2021) who studied tourist destination choice as affected by the destination images of social network members. This study revealed that the decision of tourists to visit destinations is influenced by family members, friends, colleagues, and social media members, who contribute by increasing their knowledge about the destination. It is also consistent in terms of reviews on social networks (Kim & Park, 2017), and it can also predict the performance of the services.

In other words, the review score on social media affects the user's decision to use the service. In addition, Nonthapot (2019b) also found that the people who influence travel decisions, the length of stay and the method of booking also affect the decision to travel. In the context of the China-Laos railway corridor, Liu et al. (2026) demonstrate that the railway infrastructure plays a significant role in reducing time-related frictions, which is a critical factor shaping the travel experience of time-sensitive passengers who prioritized speed and reliability. Nonthapot & Thomya (2020) also found that knowledge of Thai and foreign tourists traveling in Nong Khai and Bueng Kan provinces, which are linked to Laos, consists of life experience, learning lifestyle and travel experiences. From the above review, according to Nonthapot (2019b), the travel experience factor is influenced by the people around you, including family and friends, as well as social media, the length of stay, and how a reservation is made. Therefore, this research employs seven variables 1) the people around them, 2) social media, 3) booking method, 4) length of stay, 5) duration of travel, 6) life experience, and 7) lifestyle.

Concepts and research related to the field of international economics

Marketing analysis of the tourism industry involves analyzing the needs and behaviors of tourists, which change over time and depend on economic and social environments. These factors affect consumption and spending in various ways. It was found that tourists desire destinations with a low cost of living but standard services, as well as convenience and safety

(Jittangwattana, 2012; Kotler et al., 2014). These are consistent with Yai-in et al. (2023), a study of the economic corridors of the Greater Mekong Subregion countries along the Ayutthaya-Nong Khai-Vientiane-Luang Prabang-Bangkok route revealed that relatively low costs influence tourists' decisions to travel along the Mekong Subregion Silk Road. Foreign tourists perceive the cost of living in these countries as not excessively high when comparing the exchange rates of Western currencies against the currencies of China, Thailand, and Laos. It is also in line with the findings of Nonthapot & Lean (2015), cited in Nonthapot (2019b), which revealed that exchange rates are an important variable that affects travel. The lodging business, which is part of the tourism industry, may be also be related. Train travel is also one of the elements of the tourism industry. In addition, Ruengmaneekit & Chaiboonsri (2014), studied the international tourism demand model by studying Malaysia, Thailand and Singapore by analyzing the relationships between the following economic variables: tourist income, exchange rate, and travel expenses that affect the travel of foreign tourists. The change is in the same direction as the number of tourists visiting Thailand. In other words, if these economic factors change, it may result in an increase in the number of tourists visiting Thailand. However, the cost of travel has changed in the opposite direction to the number of tourists entering Thailand. If the cost of travel increases, the number of tourists visiting Thailand will decrease.

In addition, the studies by Rifai & Kurniawan (2023) and Nonthapot (2019b) both revealed that the number of foreign tourists visiting Indonesia is significantly influenced by economic growth and exchange rate fluctuations, reflecting the role of macroeconomic factors in foreign tourists' travel decisions. Beyond exchange rates affecting travel, Nonthapot (2019b) further noted that the opening of the country and participation in the ASEAN Economic Community (AEC) significantly facilitate international tourist movement and clearly stimulate regional tourism. These findings are consistent with the work of Pimsakul & Nimsai (2015), who predicted the impact of AEC policies on trade and tourism in border towns of Chiang Rai province. They found that border trade and transportation and economic connectivity with neighboring countries in the Mekong sub-region acted as important attractions, positively impacting the expansion of trade and tourism in the area. This aligned with the regional cooperation context highlighted by Yang et al. (2026), who found that regional collaboration and infrastructure development particularly the Thai-Laos railway serves as key factors in reducing cross-border trave barriers, thereby facilitating passenger's decisions to travel by rail.

In conclusion, the international economic factors in the decision to use the Thailand-Laos railway service of Thai passengers are observed in regard to five variables: 1) exchange rate, 2) immigration formalities, 3) travel expenses, 4) participation in the ASEAN Economic Community (AEC), 5) connection with neighboring countries.

Moreover, in regard to the 7Ps marketing concept, the correlation coefficients between the variables showed the relationship between the 'People' and 'Process' variables. In order to prevent problems of multicollinearity, the researcher considered the concept of Hair et al. (2019) to combine the two variables, which is based on the theoretical concept of Grönroos & Ravald (2011), which described the service as business logic that involves the connection between the service provider and the functional system of these two variables. This is also consistent with the Service Delivery System in the work of Lodorfos et al. (2015) in terms of employee performance elements and process control with the goal of bridging the gap between customer expectations and the experience gained.

In addition, Brady & Cronin (2001) stated that interaction quality is a dimension that measures the functional quality of a service, which reflects the elements of 'People' (measured by the attitudes, behaviors, and expertise of employees) and 'Process' (delivery methods). Therefore, the researcher defined the Service Delivery (SERV) variable and renamed the observable variable in the next step of the confirmatory component analysis. The proposed conceptual framework and the hypotesized relations among the study variables are graphically illustrated in Figure 2.

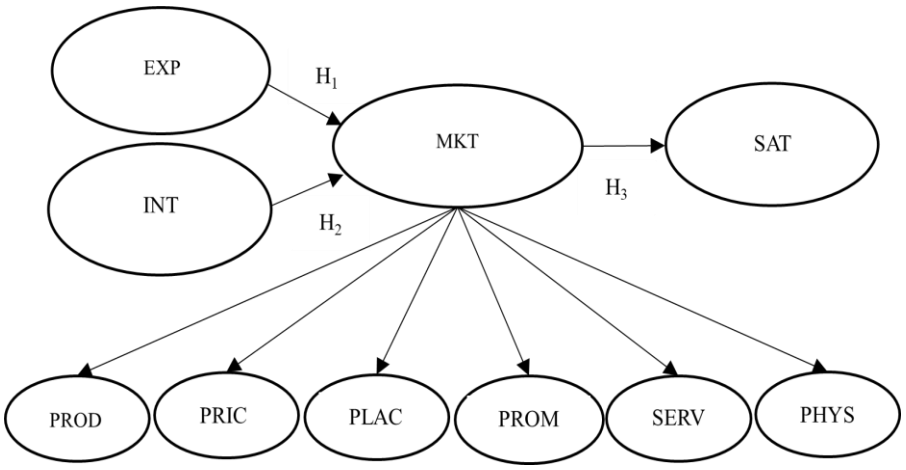

Figure 2. The proposed conceptual framework of the study

Hypotheses in the study

H1: Experience factors influence the decision to use the Thailand-Laos railway, depending on marketing mix factors.

H2: International economic factors affect the decision to use the Thailand-Laos railway, depending on marketing mix factors.

H3: Marketing mix factors affect satisfaction with the Thailand – Laos Railway Service.

Population and sample selection

The target population of this study consisted of Thai passengers who used the train service on the route from Krung Thep Aphiwat Central Terminal and Vientiane Railway Station (Khamsavath) in both directions. Due to the unknown total population size, a sample size of 400 was determined, following the methodological precedents of Sihabutr & Nonthapot (2021), cited in Nonthapot et al. (2024) and Nonthapot et al. (2025). This sample size ensures accuracy in data analysis. A convenience sampling technique was employed for data collection. Following the collection phase, data screening was conducted to identify multivariate outliers using Mahalanobis Distance Square. Observations with a p-value of less than 0.001 were excluded from the dataset, resulting in a final valid sample of 394 respondents for the structural equation modeling analysis.

Research Instrument and Measurement

The research instrument was a structured questionnaire comprising 54 items, organized into four main sections. The first section gathered respondents' demographics and general information. The second section assessed factors related to passenger experience and international economics, which influenced the decision to use the service. The third section examined the Marketing Mix (7Ps) and its impact on satisfaction. The fourth section measured the overall satisfaction level of passengers using the Thailand – Laos railway service. All items in the second to fourth sections were measured using a 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (Strongly agree) (Best, 1981).

Statistical Data Analysis

1) Basic statistical analyses of the studied variables, including mean, median, popularity, skewness, and skewness were conducted. In normal distribution checks, the absolute value of the skew does not exceed 1.0 and the absolute value of the skewness does not exceed 1.5 (Schumacker & Lomax, 2004; Sirimat & Nonthapot, 2025).

2) Correlation coefficient analysis between variables/indicators (Correlation Coefficient) consider the direction and relationship of the variables.

3) Verification of the consistency of the model with empirical data (Overall Testing). It is a confirmatory component analysis to prove the acquired model, which is determined by statistical values. The acceptable value of the Relative Chi-Square: χ^2/Degree of Freedom value must be less than 5.00 (Wheaton et al., 1977); for RMSEA (Root Mean Square Error of Approximation), the acceptable value must be less than 0.07 (Steiger, 2007); the CFI (Comparative Fit Index)/TLI (Tucker-Lewis Index) value must not be less than 0.90 (Hu & Bentler, 1999; Schumacker & Lomax, 2004), and for the statistical value SRMR (Standardised Root Mean Square Residual), the acceptable value must be less than 0.08 (Hu & Bentler, 1999).

4) Structural Straightness Evaluation of Latent Variable Measurement Models (Measurement Model) is based on the weight of the elements (λi), which should be greater than 0.50 or the statistically significant Cronbach's Alpha should be greater than 0.70 and the average of the extractable variability of the latent variable (AVE) should be greater than 0.50 (Henseler et al., 2015)

5) Evaluation of the classified accuracy between the latent variables (Discriminant Analysis Validity) checks that the relationship of the latent variables in the structural equation model are sufficiently correlated to analyze the structural equation model.The correlation coefficients between the latent variables in the research model are not more than the square root value of AVE (Fornell & Lacker, 1981).

6) The conformity of the model (Overall Testing) is developed with empirical data based on model consistency index values, as well as structural straightness tests. The value of each parameter and the reasonableness of the size and direction of each parameter value is according to the assumption mentioned above.

RESULTS

General information of the respondents

Based on the analysis of the sample data, the number of train users 394 was found to be as follows: 225 females, accounting for 57 percent. 167 people aged between 21-30 years old, accounting for 42 percent.The highest level of education was at the undergraduate level, with 254 students, accounting for 64.5 percent, of which 239 students or 60 percent were students, followed by employees/employees of private businesses. 54 people, 13.7 percent, with an average monthly income of not more than 10,000 baht, 182 people, or 46.2 percent, followed by 115 people with an income of 10,001 – 20,000 baht, at 29.2 percent.

Empirical Analysis

Regular Distribution Verification for Suitability of Element Analysis Assertionist and Structural Equation Model Analysis. The results of the analysis of the skewness and popularity of the variables showed that the skewed value was in the range of -1.00 to -0.51. The absolute value of skewness was not more than 1.00 and the absolute value of the skewness was in the range of -0.64 to 0.89 (Schumacker & Lomax, 2004) and represents data from that variable with a normal distribution. This set of data is suitable for estimation by the Maximum Likelihood (ML) in affirmative element analysis and structural equation model analysis.

Results of confirmatory component analysis to verify the structural straightness of latent variables

When the data has been normalized and the structural model has been adjusted, the next step is to test the confirmatory component to see whether the model is consistent with the empirical data. It is measured by the consistency value of the model (Model Fit) and evaluates the structural accuracy of the measurement model (Construct Validity) including the classification

of the latent variables. Moreover, Discriminant Validity is employed to examine the relationship of the latent variables in the structural equation model as to whether there is a sufficient correlation to analyze the structural equation model.

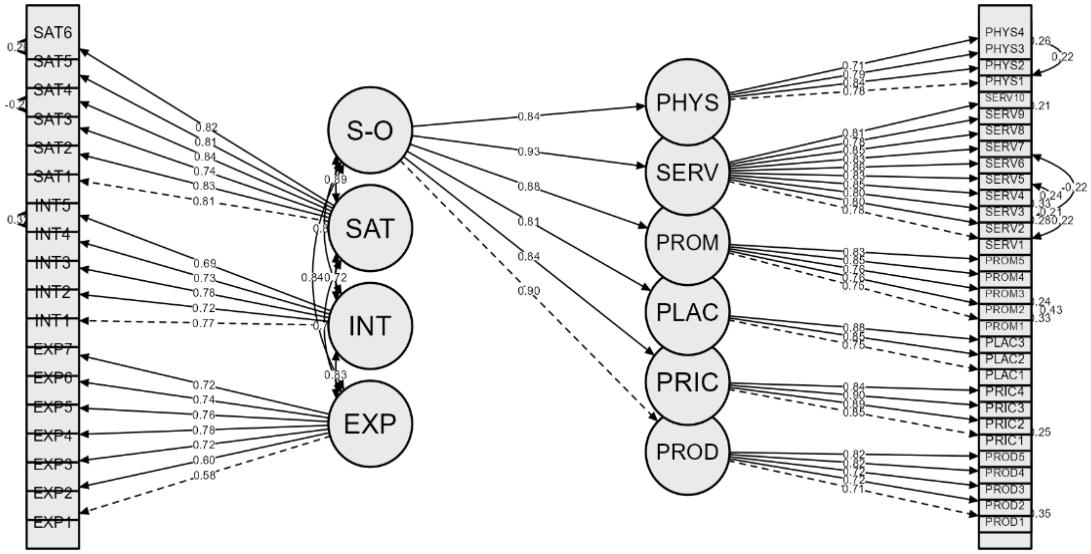

Figure 3. CFA Diagram of the measurement model Source: Output from JASP 0.19.3 (2025)

Figure 3 shows that the model is consistent with the empirical data. From the conformity measurement index of the model through a specified criterion, the statistical value of the relative kai-square (Relative Chi-Square: χ^2/Degree of Freedom) is 2.447, where the acceptable value must be less than 5.00 (Wheaton et al., 1977). The acceptable value of RMSEA must be less than 0.070 (Steiger, 2007). The CFI/TLI (Tucker-Lewis Index) values are 0.902 and 0.900 respectively. The acceptable value must not be less than 0.90 (Hu & Bentler, 1999; Schumacker & Lomax, 2004) and the statistical value SRMR value is 0.046, while the acceptable value must be less than 0.08 (Hu & Bentler, 1999).

$$\chi^2 = 2687.082, df = 1098, \chi^2/df = 2.447, CFI = 0.902, TLI = 0.900, RMSEA = 0.061, SRMR = 0.046$$

Variable: EXP = Experience Factor; EXP1 = Personal recommendations (Word-of-Mouth from family and friends); EXP2 = Social media influence and online travel reviews; EXP3 = Online booking accessibility via website and mobile applications; EXP4 = Length of stay at the destination; EXP5 = Travel duration; EXP6 = Experiential learning and life experience through rail travel; EXP7 = Lifestyle-based transportation mode preference; INT = International economics; INT1 = Currency exchange rate volatility; INT2 = Simplicity and convenience of immigration procedures; INT3 = Overall travel and tourism expenditures; INT4 = Regional integration (AEC membership and visa-free policies); INT5 = Cross-border linguistic proximity and communication ease; MKT = Marketing Mix; PROD = Product; PROD1 = Expediency and swiftness of travel; PROD2 = Frequency/Headway of train departures; PROD3 = Cleanliness of seating and interior cabin; PROD4 = Safety and security of the passenger coaches; PROD5 = Adequacy of on-board facilities and amenities; PRIC = Price; PRIC1 = Perceived value for money regarding service quality; PRIC2 = Fare proportionality relative to travel distance; PRIC3 = Fare affordability and economic reasonableness; PRIC4 = Diversity of fare classes and pricing options; PLAC = Place; PLAC1 = Convenience of ticket purchasing and refund processes; PLAC2 = Adequacy of ticket counters at railway stations; PLAC3 = Diversity and accessibility of ticket booking channel; PROM = Promotion; PROM1 = Diverse multi-channel advertising and public relations; PROM2 = Corporate Social Responsibility (CSR) activities during festivals; PROM3 = Communication via telephone hotline (Call Centre 1690); PROM4 = Tourism promotion and destination marketing; PROM5 = Modernized corporate image of the State Railway of Thailand; SERV = Service delivery; SERV1 = Appropriateness of staff appearance and grooming; SERV2 = Staff courtesy and professional conduct; SERV3 = Staff attentiveness and helpfulness; SERV4 = Effectiveness and accuracy of staff communication; SERV5 = Promptness in staff problem-solving; SERV6 = Efficiency in travel safety management; SERV7 = Travel convenience and comfort; SERV8 = Service delivery speed and responsiveness; SERV9 = Train punctuality and on-time performance; SERV10 = Adequacy of staffing levels for passenger service; PHYS = Physical; PHYS1 = Adequacy of station amenities and structure; PHYS2 = Visibility and accessibility of station information counters; PHYS3 = Adequacy, cleanliness, and safety of station waiting areas; PHYS4 = Cleanliness of restroom at station, terminal, and platforms; SAT = Satisfaction; SAT1 = Overall perceived safety and security of service; SAT2 = Physical environment of trains and stations (modernity and functional utility); SAT3 = Cleanliness of passenger coaches and station facilities; SAT4 = Service performance of on-board and station staff; SAT5 = Adequacy of train capacity and coach dimensions; SAT6 = Reasonableness of waiting and travel time duration

Table 1 shows that all variable measurement models are consistent with the empirical data, and all observable variables are observed. It can explain the variance of the measurement model statistically significant at the level of 0.001 and has a component confidence value where CR is 0.855 – 0.953 as well as having a straightness that is measured by the average of the extractable variability of all variables according to the specified criteria.

The AVE value is 0.497 – 0.758 and from the AVE value of the EXP variable (AVE = 0.497), the value is less than 0.50, but with the criteria of Fornell & Larcker (1981) is acceptable since the CR value is greater than 0.700 (CR = 0.873), so it can be concluded that all variables are structurally straight.

Discriminant Validity Assessment Results

Based on the estimation of the variable classified straightness measurement model (Discriminant Validity) from the

evaluation method of Fornell & Larcker (1981), the evaluation criterion is that the correlation coefficient between the latent variables must not exceed the square root value of the value. The AVE of the latent variables defined criterion has one pair where the correlation coefficient is greater than the square root of the value (Table 2).

Table 2. Discriminant validity assessment using the Fornell & Larcker (1981) criterion (Source: Compiled from the authors' calculations)

For the result of the Heterotrait-Monotrait Ratio (HTMT) of correlations in Table 3, it was found that for the threshold of the HTM that can be used to evaluate the categorical accuracy, all variables meet the specified criteria, which are not more than 0.85 (Voorhees et al., 2016; Roemer, 2021). Therefore, there is a value that fits the criteria (Anderson & Gerbing, 1998; Bagazzi & Phillips,1982).

Results of Hypothesis Testing, Experience Factors, International Economic Factors, and Market Factors Affecting Satisfaction with the Thai-Laos Railway Service

Figure 4 demonstrates that the structural equation model is consistent with the empirical data at an acceptable level. The conformity measurement index of the model met the specified criteria. $X^2 = 2543.809$, df = 1049, $X^2/df = 2.424$, RMSEA = 0.060, CFI = 0.905, TLI = 0.900 and SRMR = 0.047. From all the ststistic values, it can be estimated as shown in Table 6.

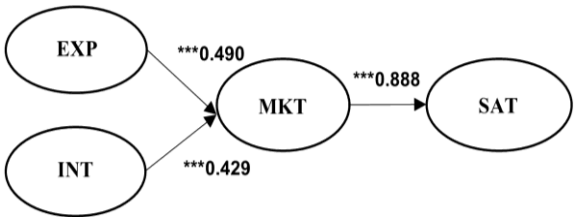

Figure 4. Results of the structural equation model (SEM) for factors influencing the satisfaction of Thai passengers in using the Thai - Lao railway (Source: Compiled by the authors based on JASP 0.19.3 output (2025)

$X^2 = 2543.809$, df = 1049, X2/ df = 2.424, CFI = 0.905, TLI = 0.900, RMSEA = 0.060, SRMR = 0.047

H2: INT → MKT	0.429***	Supported
H3: MKT → SAT	0.888***	Supported

Table 4 presents the results of the analysis which showed that the satisfaction factor in using the Thai-Laos railway service was influenced as a whole with the highest being the marketing mix factor (TE = 0.888). The marketing mix factor is a factor that has a direct and positive influence on the satisfaction factor of using the Thai-Laos railway service.

In addition, it was found that the factors of experience and international economic factors are factors that indirectly influence the satisfaction factor in using the Thai-Laos railway service.

Both the experience factor and the international economic factor have an indirect influence of 0.439 and 0.377, respectively. For the marketing mix factor, it was found that it was the result of the factors of experience and international economic factors (TE) were equal to 0.490 and 0.429 respectively as shown in Table 5.

DISCUSSION

The purpose of this research was to analyze the factors affecting the satisfaction of users of the Thailand-Laos railway service by using a structural equation model with Covariance Based (CB-SEM) to test the causal relationship between various variables from the results of statistical estimation. The important findings of studies that can be discussed in the dimensions of economics and tourism are as follows:

The results of the study show that the marketing mix factor, which consists of six main components, namely service delivery, product, marketing promotion, physical characteristics, price, and distribution channel, can explain the latent variables of the marketing mix factor. This is a factor in the consideration of using the Thai-Laos railway service and can act as a structural representation of the latent variables (MKT).

The satisfaction with the Thai-Laos Railway service factor consists of six main components. All components can explain the latent variables of satisfaction, with the component weight values being high in all respects. This indicates that these six indicators are important factors in creating the satisfaction factor for the use of the Thai-Laos railway service and can act as a structural representation of latent variables (SAT).

The experience factor (EXP) consists of a total of seven main components. As this result, this point is consistent with Nonthapot & Thomya (2020), who found that the service user wants to acquire life experience. In addition, the duration of the trip and the length of stay were also found to be important factors in the decision to travel on the Thailand-Laos route (Nonthapot, 2019b). In addition, the international economic factors (INT), which consist of five main components. It confirms that these structural factors serve as important agents in explaining the desire to use the Thai-Laos railway service.

The indicators indicate that in the context of the Thai-Laos railway, which is an international railway connecting the region, users pay attention to travel expenses, in line with the concept of Chittangwattana (2012) and Kotler et al. (2014), as well as a study by Anek Aiin et al. (2023), which stated that the cost of travel is a factor in deciding to travel to an accessible destination and obtain standard service. In addition, the exchange rate factor affects the decision to travel (Nonthapot & Lean (2015) cited in Nonthapot (2019b) and Rifai & Kurniawan (2023), and Nonthapot (2019b), who also noted that membership of AEC also affects travel.

In regard to the influence of the marketing mix factor on the user satisfaction factor of the Thai-Laos railway service, the results of the analysis of the structural equation model showed that the marketing mix factor has a positive influence on the satisfaction factor with a total influence value. The factors of experience and international economic factors also indirectly influenced the satisfaction factor. The decision to use the railway is based on the consideration of the marketing mix factors. The user also considered the experience of the user and the economic factors of the two countries.

Moreover, the results determined the relationship between Marketing Mix Factors (MCT). It was found that the dimension that plays an influential role was satisfaction (SAT), the highest being the dimension of service delivery (SERVE). This indicates that users of the Thailand-Laos railway service attach the most importance to the dimension of service delivery. In other words, the user considers receiving services from the staff and the service system as a priority. In terms of the indicators of satisfaction in using the Thai-Laos railway service, the service of employees on trains and stations was considered to be important. It is evident that service users value receiving services from both service providers and systems that mediate services as well as speed of service and clear and accurate communication to bridge the gap between customer expectations and the experience received (Lodorfos et al., 2015)

CONCLUSIONS

As mentioned above, the factors of service delivery (SERV) are the most important and indicate that the marketing mix factors affect the satisfaction of using the Thai-Laos railway service. Consequently, the State Railway of Thailand should develop a seamless service system (Seamless Service). Emphasis should be placed on the speed of information communication and the clarity of the public information points, including the development of staff competencies in providing clear and precise information, especially in the border crossing procedures at Nong Khai and Vientiane stations (Khamsavath) to reduce the anxiety of service users and to increase the efficiency of travel time management.

Moreover, both governments should consider extending cooperation to offer "Juxtaposed Border Facilities" or joint testing at one point (a one-stop border post). This will reduce redundancy in checking baggage and border crossing

documents, which will reduce the total travel time (McLinden et al., 2010; Kieck, 2010). Cross-border travel insurance integrated into the ticket price is an option for users that reduces the perception of risk when making travel decisions. In addition, to enhance standards of safety, confidence and protection of service users (Quintal et al., 2010; OECD, 2020) accident insurance is available for all parties including passengers and operators of the MRT who are on duty on the passenger train. This includes getting on or off a train and accidents caused by the operation of the train from the departure station to the destination station (SRT, 2023) and may consider providing additional insurance options by extending coverage to accidents that occur during a trip.

In term of the experience dimension, the State Railway of Thailand, in collaboration with the tourism authorities of both Thailand and Laos, should consider developing integrated travel packages that emphasize 'life learning experience.' These packages must take into account travel duration and length of stay to effectively attract the younger traveler segment who prioritizes these factors. Furthermore, service delivery should be enhanced by ensuring accurate and clear communication from frontline personnel, particularly regarding cross-border and immigration procedures, to mitigate passenger anxiety and to bolster confidence. Additionally, providing a diverse fare structure and seating classes is essential to offer value for money and to cater to varying people with different purchasing powers, allowing passengers to manage their budgets effectively and encouraging repeat usage in the future.

Abstract: This study investigates the role of strategic public relations communication in shaping tourists' behavioral intentions by examining the mediating role of destination image in a tourism context. The study employs a quantitative, cross-sectional research design to examine the relationships among strategic public relations communication, destination image, and tourists' behavioral intentions. Data were collected from 526 respondents who had either previously visited Jordan or were actively considering visiting the destination and had experience with official or institutional communication related to Jordan. The data were analyzed using partial least squares structural equation modeling (PLS-SEM). The findings indicate that strategic public relations communication positively influences destination image, while destination image positively influences tourists' behavioral intentions. However, strategic public relations communication does not have a statistically significant direct effect on tourists' behavioral intentions. The analysis further demonstrates a significant indirect relationship between strategic public relations communication and tourists' behavioral intentions through destination image, supporting its mediating role. These findings suggest that strategic public relations communication contributes to tourists' behavioral intentions primarily by shaping their perceptions of the destination rather than by directly influencing behavioral intentions. The study highlights destination image as an important explanatory mechanism linking institutional communication with tourists' behavioral responses and provides empirical evidence from the tourism context of Jordan.

Keywords: strategic public relations, destination image, tourists' behavioral intentions, tourism decision-making processes, Jordan

INTRODUCTION

Strategic planning of tourism has progressively moved from direct acquaintance to destination characteristics toward mediated communication practices that frame tourists' assessments prior to travelling. Tourists, in existing tourism markets, trust largely on digital and institutional communication so that they may evaluate destination credibility, understand representative meanings, and minimize apparent ambiguity before making minds to travel. This conversion has been made quicker due to effective advertisement of information abundance, digitalized platforms and intensified risk-related sensitivity, especially in the destinations where institutional trust and reputational narratives robustly effect tourist awareness (Ahmad et al., 2025; Gretzel et al., 2020; Buhalis & Sinarta, 2020). In recent times, the evidence-based research endorse that institutionally and officially created communication plays a pivotal role in making tourists' observations and behavioral intents under information overload and uncertainty conditions (Marine-Roig & Huertas, 2020).

In tourism research work, tourists' behavioral intents, generally measured as purposes to visit, revisit and suggest destinations, are broadly documented as critical predictors of destination competitiveness and long-term sustainability.

Afshardoost & Eshaghi (2020); Sabiote-Ortiz et al. (2024) argue that a quantitative evidence's substantial body establishes that these intentions are determined mainly by tourists' reasoning and perceptual assessments instead of objective features of destination. Destination image, among these perceptual determining factors, has reliably appeared as a significant descriptive concept. According to Stylidis et al. (2020); Marine-Roig & Huertas (2020), destination image is usually considered as a cognitive–touching demonstration that depicts tourists' emotions, beliefs and inclusive destination impressions: additionally, observation-based research frequently endorses its powerful impact on behavioral intentions of tourists across different tourism backgrounds.

Although there exists the significance of destination image in research related to tourism behavior, current critical reviews highlight that the literature remains inordinately result-focused. Whereas many studies articulate the destination image effects

on behavioral intentions, relatively inadequate consideration has been given to conceptualizing the way destination images are tactically created through the processes of institutional communication (Alrahman, 2025; Alsharairi et al., 2026; Tasci et al., 2022). In this sense, communication is often observed as a functional effort, such as message frequency, information provision or promotional manifestation. It is not treated as a relational and strategic process entrenched within institution-based practices. Such theoretical decline constrains the descriptive tourism behavior models' depth by complicating the mechanisms with which communication frames interpretive frameworks of tourism before the formation of intention.

Within tourism studies, this mentioned restraint is specifically obviously observable in the strategic communication treatment. Huerta-Álvarez et al. (2020); Gorji et al. (2023); Alsharairi & Jamal (2021) argued, though the current research progressively recognizes the significance of engagement, credibility and transparency in communication of destination, these components are frequently investigated in isolated ways or included under wider branding and marketing frameworks. Subsequently, communication is mostly abridged to content quality or message efficacy, restraining tourism models the ability to constitute relational constructs such as institutional credibility, trust and perceived validity or legitimacy. Such exclusions are theoretically substantial, specifically in the destinations categorized by high-alleged menaces. In this risk, institutional signs instead of promotional claims powerfully form decisions made by tourists. Contrastingly, in view of Valentini (2021); Ki et al. (2021), scholarship of public relations theorizes strategy-based communication as an institutional procedure aiming to build long-standing relationships, trust and credibility through dialogic, planned and clear interaction held between organizations and their people. Fundamentally, strategic public relations communication is different from marketing-centered communication by giving priority to legitimacy, relationship management, and reputational solidity over persuasion of short-time nature. Strategic public relations communication, especially when applied to tourism contexts, can thus be theorized as the synchronized institutional usage of communication to frame how destinations are brought into interpretation, trust, and legalized by forthcoming tourists, specifically under uncertainty conditions.

While discussing from a theoretical point of view, the exclusion of strategic public relations communication from prevailing tourism behavior models becomes challenging (Alyaqoub & Alsharairi, 2020). Modern-day environments of tourism are categorized by information asymmetry, digital mediation, and elevated observations of risk; these are the situations in which tourists are improbable to interpret institution-based communications directly into behavioral dispositions. Actually, there should be affectively and communication processing, building image of destination as an explanatory mechanism where in tourists may assess destinations and then prepare their intentions (Alsharairi et al., 2025; Li et al., 2025; Sabiote-Ortiz et al., 2024). While handling communication as a direct forbearer of intention, takes tourist decision-making to oversimplification and confines the existing models' theoretical accuracy. However, the current study aims to address the theoretical limitation mentioned above by creating a theoretically based mediation model through which is conceptualized as an institution-based antecedent building destination image formation prior to the development of behavioral intention. Along with it, strategic public relations communication works in such a way that its effect functions fundamentally with the help of destination image as a cognitive and influential mechanism interpreting institutional communication into behavioral results. While acting so, this study moves off from prevailing marketing-centered enlightenments repositioning communication as a strategy-focused institutional forebear within theory of tourism behavior. It is an important point that the current study, instead of expanding the Planned Behavior Theory, functions outside its attitudinal structure by conceptualizing strategic public relations communication as a pre-attitudinal, exogenous construct shaping image formation prior to intention development (Laskin & Freberg, 2024).

The utilized theoretical gap is specifically prominent in destinations where credibility of institutions, arbitrated reputation and safety discernments play a pivotal role in evaluations of tourism. According to the observation of Hassan & Soliman (2021), research related to tourism continues to be controlled by East Asian and Western backgrounds, highlighting apprehensions about the context-specific generalizability and robustness of dominating communication-focused models. Existing destinations in the Middle East, like Jordan, exemplify systematically expressive backgrounds in which institution-centered communication and external risk descriptions strongly form the destination images of tourists. Strategic public relations communication in such kind of settings ranges beyond the promotion, working as a critical mechanism to legitimize destinations and handle reputational improbability.

In order to ground the suggested relationships theoretically, the current study derives understandings from destination image research and public relations scholarship. This study theoretically has been grounded in the relational angle of public relations. These relations theorize strategic communication as an institutional process aiming at constructing trust, credibility and long-standing associations between the organizations and their masses instead of attaining short-duration persuasive results (Laskin & Freberg, 2024). Valentini (2021); Ki et al. (2021) are of the view that communication, especially from this point of view, does not prompt behavioral responses directly; rather, it directs the way stakeholders affectively and cognitively interpret organizational legitimacy and institutional messages. When it is applied to the backgrounds of tourism, the relational approach comes ahead proposing that official destination communication shows influence on tourists' assessments by constituting understandings of safety, credibility and institutional reliability instead of directly persuading travel plans. In order to elaborate how these communication-centered evaluations are interpreted into behavioral results, the destination image theory further assists the present study, and is theorized as a cognitive–affect based explanatory mechanism; through this mechanism, tourists incorporate institutional communication clues into general destination assessments that direct formation of intention (Alsharairi et al., 2025; Stylidis et al., 2020; Tasci et al., 2022). The current study, by incorporating the relational aspect of public relations with the destination image theory, adopts a process-based theoretical framework that elaborates behavioral intentions of the tourists as the result of arbitrated insight formation instead of direct communication impacts.

In this regard, the present study provides three theoretically based contributions to tourism related communication, and destination-based image research work. The current study, against this contextual background, makes tourism communication research advanced by clearly incorporating strategic public relations communication as an outsider descriptive variable within a destination image analytical framework. The study produces three theoretical contributions by establishing and experimentally verifiable testing a mediation-centered organizational model while utilizing quantitative data taken from the tourism context of Jordan. Firstly, in tourism research, conceptually it differentiates public relations communication from marketing-centered communication. Secondly, it strengthens destination image theory by placing image as a dominant explanatory mechanism instead of a simple behavior antecedent. Third, it makes the context-based reliability of tourism communication models strengthen by investigating a reputationally and geographically sensitive-centered destination background. The subsequent section advances the theoretical framework and hypotheses supporting the given model.

LITERATURE REVIEW

The present study theoretically grounds in the relational perception of public relations conceptualizing strategy-focused communication as a long-standing institutional process having an aim to build credibility, trust and shared discernment between the organizations and their masses (Ledingham & Bruning, 2000). This aspect, especially within tourism background, indicates that institutional communication does not predominantly functions as a direct convincing mechanism; rather it develops stakeholders' affective and cognitive evaluations, which facilitate behavioral results.

The placement of this theoretical perspective is incorporated with the destination image theory, which theorizes destination image as a cognitive–influencing explanatory structure with which the tourists develop mediated information and institutional indicators while framing behavioral intents and evaluative results (Stylidis et al., 2020). With the incorporation of these two perceptions, the current study assumes a process-centered framework, which elaborates behavioral intentions of the tourists as the result of interceded viewpoint development instead of direct communication impacts.

Strategic Public Relations Communication in Tourism

In recent times, the tourism scholarship progressively recognizes the dominant role of communication in building tourists' perceptions and judgement processes, specifically in digital-oriented mediated situations. According to Huerta-Álvarez et al., (2020), much of this literature, however, goes on approaching communication with the help of a mainly marketing-centric lens, showing emphasis on content quality, message exposure, or promotional usefulness. Although, such perspectives have provided contribution in perceiving outcomes of destination promotion, they provide inadequate theoretical understanding into how institutional or organizational communication develops relational sense, trust, and legitimacy known as dimensions, which are critical in circumstances featured by perceived risk and improbability. Additionally, strategic public relations communication offers a distinctive theoretical perception which ranges beyond persuasive and marketing objectives. Strategic communication, when discussed in perspective of contemporary public relations theory, is brought to conceptualization as an institutional and relationship-intended process aiming at developing trust, credibility and long-standing legitimacy with the help of strategic, transparent and dialogic communication with shareholders (Alsharairi et al., 2026; Valentini, 2021). Contrary to the marketing communication that mainly pursues short-lived attitudinal responses, public relations communication stresses over management of relationship as well as repute-based durability as strategic results. These distinctions, when discussed in tourism contexts, are especially prominent since tourists mostly assess destinations not merely grounded on attractiveness but on institutional trustworthiness and considered safety as well. Ki et al. (2021) argued that though studies on tourism progressively recognize concepts related to public relations like credibility, transparency and institutional repute, such constructs are often investigated in segmented ways or included under wider marketing and branding frameworks. Consequently, communication grounded on strategic public relations is hardly put forward or tried as a distinctive illustrative construct in quantitative-based models of tourism. Such kind of conceptual uncertainty compels the tourism research ability to capture the institutional communication's unique role in building tourists' insights prior to intent development.

Destination Image as a Cognitive–Affective Interpretive Framework

In tourism research, destination image vestiges one of the most comprehensively investigated constructs; it is also broadly acknowledged as one of the main factors of behavioral or attitudinal intentions of tourists. Its definitions in recent times, as argued by Valentini et al. (2020), theorize destination image as a multifaceted construct incorporating both affective responses that consist of feelings and emotional touches toward the destination, and cognitive evaluations including knowledge and beliefs regarding characteristics of destination. A wide-ranging frame of experiential proof endorses that destination image expressively effects tourists' intentions of visiting, revisiting, and suggest destinations all over different tourism backgrounds (Afshardoost & Eshaghi, 2020). Although it has empirical strength, critical reviews in recent times indicate continuous theoretical restrictions in the destination image research. Moreover, lot of the literature exists as outcome-centric concentrating initially on the behavioral destination image outcomes, however giving relatively inadequate focus to its formation processes and antecedents (Tasci et al., 2022). As the antecedents become under examination, they are mostly applied as experiential factors or fragmented information sources instead of as incorporated institution-based processes of communication. This isolated conduct restricts theoretical perception of the way destination images are built strategically prior to travelling. Similarly, studies conducted in recent times recommend that destination image should be considered not as a fixed insight; it should be understood as an energetic cognitive–affective explanatory structure in which tourists proceed interceded information and institutional indicators (Marine-Roig & Huertas, 2020).

Destination image, from this viewpoint, works as an underlying process that interprets communication inputs into evaluative decisions, framing how destinations are evaluated and understood before the formation of behavioral intentions.

This kind of reconceptualization highlights the significance of investigating communication-guided image building process instead of concentrating completely on post-image behavioral or attitudinal results.

Tourists' Behavioral Intentions in Mediated Decision-Making Contexts

In tourism research, behavioral intentions of tourists are fundamental outcome variables, as they possess robust projecting validity for destination performance and real travel behavior. According to the findings of Sabiote-Ortiz et al., (2024), behavioral intentions are generally brought under operation as visit or revisit intentions, and suggest destinations; hence they are extensively utilized as signs of destination durability and competitiveness. In this regard, empirical research persistently reveals that objective destination characteristics do not influence but the perceptual and affective evaluations vigorously effect these intentions (Alsharairi et al., 2023; Afshardoost & Eshaghi, 2020).

Whereas dominant behavioral models, like the Planned Behavioral Theory, accentuate on subjective norms, attitudes and interpreted behavioral control as direct intention determinants, the contemporary tourism-based research raises questions on the adequacy of these frameworks in high-uncertainty and digitally mediated circumstances. Tourists, in such environments, mostly develop intentions before having direct experiences, trusting deeply on organizational communication as well as mediated prompts. Subsequently, attitude-forming constructs like destination image has to play an important role in building formation of intention by constructing how one interprets information affectively and cognitively.

However, the current empirical research progressively back mediation-grounded elucidations of a tourist's behavior. Gorji et al. (2023); Li et al. (2025) claimed that these studies also represent the destination image that show impacts of constructs namely trust, reputation and observed menace on behavioral intentions. The findings recommend claiming that models having direct-effect tend to fabricate decision-making processes of the tourists by ignoring the explanatory systems in which communication effects behavior. Nonetheless, mounting empirical assistance for mediation-grounded methods, the research with limitations has investigated destination image considering it as a mediator involving strategic public relations-based communication behavioral tendencies of tourists.

Integrating Strategic Public Relations Communication and Destination Image

Public relations communication has its importance especially when it is linked with the institutions. In this regard, incorporation of strategic public relations-based communication with destination image research comes ahead to address a vital theoretical breach in the studies of tourism. In a unique way, position is given to public relations communication as it involves relationship management, credibility and transparency (Alyaqoub et al., 2023; Valentini, 2021).

Contrary to promotion-linked messaging, which may mainly influence impressive responses or awareness, strategic public relations communication frames how prospective tourists interpret, legitimize and trust the destinations. Destination image is considered a key element in tourism industry. Research on tourism conducted in recent times indicates the significance of institutional repute and reliability in determining destination image, especially in the circumstances categorized by intensified observed risk or negative storylines of the media (Hassan & Soliman, 2021; Tahat, 2025).

The derived outcomes correspond with public relations theory, which suggests that legitimacy and trust building are key processes; through these mechanisms, institutional communication affects the perceptions of the stakeholders. Nonetheless, the research on tourism has still to systematically incorporate these kinds of mechanisms into models quantitative in nature that explicate behavioral intentions of tourists. The current study, while theorizing strategy-based public relations communication as an external institutional forbearer/antecedent and destination image as a mediating cognitive–emotional explanatory mechanism, reacts to calls for more interpretative and theory-guided tourist decision-making models. The current study, grounded on this incorporation, advances a mediation-rooted model connecting strategic public relations communication, behavioral intents of tourists and destination image. In view of that, the hypotheses given below are suggested.

Hypotheses Development

Development of hypothesis may lead to a direction connected to expected outcomes. Whereas strategic public relations communication concerns are well defined as the strategic institutional usage of communication performs aiming at constructing transparency, credibility, and long-standing relational trust with the shareholders (Valentini, 2021). Similarly, destination image is considered as a multi-faceted cognitive–touching demonstration depicting tourists' emotions, beliefs, and general views regarding a destination (Stylidis et al., 2020). Behavioral intentions of tourists speak of individuals' detailed possibility of captivating in upcoming travel-linked behaviors, together with visiting and suggesting destinations for tourism (Afshardoost & Eshaghi, 2020).

Strategic Public Relations Communication and Destination Image

Strategic public relations communication in the present study leads to practices of institutional communication featured by transparency, integrity along with relationship-centered involvement aiming to frame destinations interpretations of the tourists. However, within present-day tourism contexts, tourists more and more depend on this institutional communication in order to assess destinations before going to travel, specifically under information asymmetry conditions as well as repute-based perception. In view of this aspect, public relations scholarship put emphasis that communication, having base on institutional legitimacy and trust developing, plays an influential role in building understandings of the stakeholders (Valentini, 2021). Such kind of communication practices, especially in tourism situations, are as a result estimated to leave an impact on destination image by constituting how tourists affectively and cognitively perceive destination-specific information (Marine-Roig & Huertas, 2020). Additionally, destination image works as a cognitive emotion-based depiction illustrating tourists' destination-directed beliefs and emotions. In perspective of the interpretive role by destination image in

interceded decision-taking, planned public relations communication is anticipated to exercise a determinative impact on how tourists consider destinations before formation of their intention to travel. Therefore, the subsequent hypothesis is suggested:

H1: Strategic public relations communication has a prominent and positive influence on the destination image.

Destination Image and Tourists' Behavioral Intentions

Regarding different tourism situations, destination image has been regularly recognized as a key determining factor of behavioral intentions of tourists. Any supporting destination image enriches evaluation-based decision-making sense, decreases perceived vagueness, and boosts tourists' readiness of visiting, revisiting, and suggesting destinations. Empirical studies and meta-analytic facilitate strong proof that destination image leaves a prominent impact on behavioral intents by interpreting conceptual assessments into behavioral promptness (Afshardoost & Eshaghi, 2020; Stylidis et al., 2020). The current proof also exhibits that a supportable destination image prominently encourages tourists' behavioral intentions, comprises visit, revisit, as well as suggestions referring intentions, especially in experientially and culturally enriched tourism backgrounds (Chuamuangphan et al., 2025). Destination image as a cognitive–affective concept plays a significant role in connecting pre-travel assessments to intention development. Within digital-mediated contexts, where the tourists depend greatly on non-direct information means, destination image functions as a main underlying process through which insights are transformed into behavioral results. For that reason, the succeeding hypothesis is suggested

H2: In this hypothesis it is claimed that destination image reflects a prominent positive impact on behavioral intentions of tourists.

Strategic Public Relations Communication and Tourists' Behavioral Intentions

Strategic public relations communication, however, is conceptualized to initially leave an impact on tourist's behavior with the help of perception-based mechanisms, before the tourism research recommends that institutional communication may also put a direct impact on behavioral intentions of the tourists. While official communication addresses destination credibility, institutional reliability and safety, it may build tourists' preparedness to think of or be engaged with a destination even before full consolidation of destination image (Gorji et al., 2023; Hassan & Soliman, 2021).

When this direct relationship is investigated, it permits for a more accurate evaluation to know whether strategic public relations communication reflects influence on intention framing beyond its non-direct effect with the help of destination image. Within the recommended theoretical placement, the direct impact of strategic public relations communication on the behavioral intentions of tourists is dealt as investigative instead of supposed to be in dominating position.

Resultantly, the hypothesis given below is suggested:

H3: The hypothesis reflects that strategic public relations communication depict a direct impact on tourists' behavioral intentions.

The Mediating Role of Destination Image

The current advancements in tourism research progressively assist mediated descriptions of tourist judgement finalizing, stressing that perception-centered concepts perform as explanatory mechanisms connecting communication contributions to behavioral results. To intercede the institutional reputation impacts such as trust, and perceived risk on behavioral intentions of tourists, destination image has been presented making its central role prominent in interpreting communication-centered assessments into behavioral reactions (Gorji et al., 2023; Li et al., 2025). Strategic public relations communication, from this point of view, is improbably to effect tourists' behavioral intentions not with first framing their affective and cognitive destination evaluations. According to the findings of Purwanto & Suryanto (2022), the studies conducted in the past progressively favor mediation-oriented interpretations of tourist's decision-making, manifesting that destination image works as an explanatory process with which underlying (antecedent) aspects leave impacts on visit-linked intentions.

The present study, by placing destination image as a mediating process, goes beyond direct-impact elucidations, and provides a more theoretically accurate explanation of the way institutional communication shows impact on the tourist's behavior. In view of that, the current study examines whether destination image completely or to some extent mediates the association existing between strategic public relations communication and behavioral intentions of the tourists. In this sense, the following hypothesis is suggested:

H4: Destination image mediates the relationship between strategic public relations communication and tourists' behavioral intentions.

Conceptual Framework of the Study

The present study, while focusing on public relations theory and destination image research, recommends a mediation-centered conceptual framework clarifying how strategic public relations communication leaves impact on the behavioral intention of tourists. The framework places strategic public relations communication as an institution-based antecedent that builds tourists' insights through transparent, credibility-oriented and practices of relationship-related communication. Instead of presuming a genuinely persuasive task, communication is developed as a strategy-grounded mechanism; this process constitutes how affectively and cognitively destinations are understood before moving to travel. Similarly, destination image, within this theoretical framework, is dealt as a fundamental cognitive–moving structure interpreting institutional communication into evaluation-based findings regarding destination. Moreover, destination image, going on consistently with prior tourism-grounded research, depicts tourists' emotions, beliefs and general impressions, and performs as a main factor of behavioral intents. Therefore, this model supposes that strategic public relations communication has impacts on tourists' behavioral intents chiefly through its influence on destination image, instead of through direct persuasive aspect only.

Simultaneously, the framework permits for the investigation of a prospective direct relationship existing between behavioral intentions of tourists and strategy-centric public relations communication. This way is involved to judge whether institutional communication that addresses safety, credibility and legitimacy may independently affect intention development of destination image or not. When both direct and indirect processes are integrated, the suggested framework makes the empirical assessment able to judge the aspect whether destination image entirely or to some extent mediates the relationship that appears between strategic public relations communication and behavioral intentions of the tourists.

In general, the suggested conceptual framework provides a theoretically based and empirically verifiable description of tourist judgement making in digital-based mediated as well as repute concerning sensitive tourism environments. Similarly, with the integration of strategic public relations communication into a destination image-grounded model, the framework empowers tourism communication research moving beyond marketing-centered descriptions and offers a clearer elucidation of the way institutional communication builds tourist behavior. Underlying the suggested framework, these conceptual relationships have been demonstrated in Figure 1.

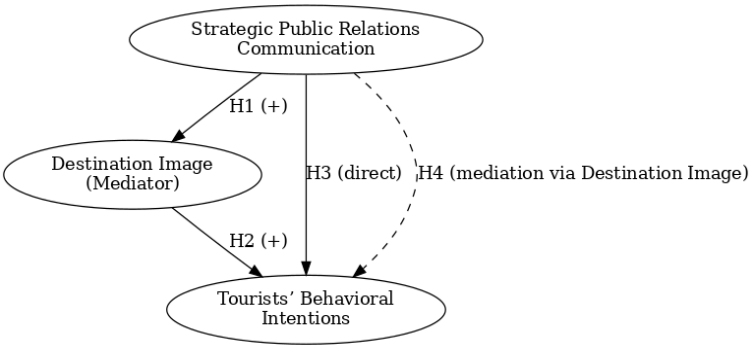

Figure 1. Conceptual framework of the study

MATERIALS AND METHODS

Research Design

The present study employs an explanatory, quantitative, cross-sectional research pattern/design to evaluate empirically the suggested conceptual framework and set hypotheses. A design explanatory in nature is considered suitable when the main objective is to investigate theoretical-based derived fundamental relationships among the underlying concepts (Hair et al., 2022). Considering that the aim of this study is to elaborate how strategic public relations communication shows influence on tourists' behavioral intentions by means of a mediating perceptual process, a quantitative approach makes systematic hypothesis able in assessing and theory authentication. The study employed cross-sectional design because the study concentrates on tourists' pre-travelling or contemporaneous assessments, instead of changes with the passage of time.

It reasons that in tourism research, cross-sectional designs are extensively utilized to investigate destination images and behavioral intents, specifically when constructs are made before being prepared to real visitation (Stylidis et al., 2020).

To collect data efficiently, this design facilitates and is considered methodologically appropriate to estimate direct and indirect associations within mediation-centered models. In this perspective, the present study bases on a positivist research pattern, which supposes that the links existing among constructs can be measured with objectively and tested statistically. Similarly, according to Kline (2023), positivist approaches govern tourism research implementing mechanized equation processing to elucidate tourist behavioral action and judging practices.

Study Context and Population

The tourism destination in Jordan is the empirical background of the present study. Jordan embodies a theoretically relevant environment because of its dependence on institutional communication regarding the management of destination image, alleged risk, as well as worldwide tourism repute. The tourism research conducted in the past establishes that destinations positioned in regionally or politically sensitivity-based situations rely greatly on institutional and official communication regarding the formation of tourists' insights and ambiguity mitigation (Hassan & Soliman, 2021; Marine-Roig & Huertas, 2020). In view of that, Jordan facilitates a suitable environment to investigate strategic public relations communication role in destination image building and behavioral intent shaping.

In this study, the selected target population involves international tourists who either have performed their visit to Jordan or have keenly considered the destination visit. The reason of the population selection was that the study concentrates on communication-guided evaluations which may be occurring both prior to and following the visitation. As argued by Afshardoost & Eshaghi (2020), tourism research, overall, persistently manifests that destination image along with behavioral intentions are widely structured with the help of mediated information source prior to travelling, molding potential visitors a theoretically suitable target population regarding the current investigation

Sampling Strategy and Sample Size

Since there has been no comprehensive sampling frame to facilitate international tourists especially exposed to destination-connected communication about Jordan, a non-probability purposive sampling technique was employed. As far as purposive sampling concerns, it is generally employed in tourism-based research specifically when the aim is to target

respondents possessing particular characteristics or informational experience pertinent to the objectives of the study (Dolnicar et al., 2018). Accordingly, in this study, the main standard was the exposure of respondents to official or institutional communication linked with the destination.

All the respondents were included in the sample based on the criteria given below:

(1) they were 18 years of age or more;

(2) had visited Jordan previously or having been actively searching to get information about Jordan to visit it;

(3) having experience in institutional or official-level communication about the destination, like official websites of tourism, promotional campaigns or social media pages

Such selected criteria make it sure that respondents have enough cognitive as well as informational base to purposefully evaluate and assess destination image, strategic public relations communication and behavioral intents (Alyaqoub et al., 2024; Peng et al., 2018). Regarding adequacy of sample size, methodological literature highlights that mediation-centered structural equation models need adequately big samples to make sure that there should be model stability, enough statistical strength and trustworthy valuation of both direct and indirect impacts (Hair et al., 2022; Kline, 2023). A minimum sample size of 200 respondents is generally commended for the models that consist of multiple experiential indicators and three underlying constructs. In the current study, data of 526 respondents were collected, considerably higher than the suggested limit. It was done purposefully aiming that such kind of sample size facilitates strong statistical power to test the suggested mediation model. Moreover, on one side it reduces the issues of estimation bias, and enhances the trustworthiness and strength of the findings on the other hand. To prove this logic, Sabiote-Ortiz et al. (2024) argue that larger sample sizes are specifically helpful in tourism research depending on communication and perceptual-based conceptualizations.

Along with handling the minimum sample size commendations, there was availed further support for the appropriateness of the sample by the "10-times rule". According to the findings of Hair et al. (2022), this rule is generally employed in PLS-SEM, in which it is recommended that the size of sample should be no less than ten times the maximum number of structural avenues focused on any underlying construct in the given model. Within the structural form of the suggested model, the gotten sample size of 526 respondents considerably goes above this requirement, making it sure that there should be model stability and enough statistical power.

Data Collection Procedure

Regarding the collection of data, there was used an online self-managed questionnaire, which was furtherly distributed through digitally oriented platforms frequently visited by international level visitors, together with social media groups related to travelling and tourism debating platforms. In modern tourism research, online surveys are accepted on a large level due to their ability and efficacy to reach the respondents, geographically disseminated (Dolnicar et al., 2018).

However, the questionnaire of this study was arranged in English, the leading language of global tourism communication. At the commencement of the survey, screening questions were included to make sure of the eligibility of the respondent was based on the pre-established sampling criteria. In order to minimize the potential influence of common method biasness, respondents were made sure of privacy; questionnaire items were made accessible in a non-evaluative and neutral way, reliable with suggested technical solutions (Podsakoff et al., 2016).

Ethical Considerations

The present study was managed according to the established ethics-based principles for social science research. Voluntary participation was administered; similarly knowledgeable consent was obtained from all the respondents before data collection process. It was ensured that not any kind of personal-based detectable information was generated and collected, and likewise confidentiality was maintained in all responses guaranteeing that data would be used entirely for academic research drives. In this way, the present study followed established ethical procedures while conducting survey-based research as suggested by Bryman (2021).

Common Method Bias Assessment

Harman's single-factor test was utilized in order to evaluate the prospective effect of common method biasness. The outcomes pointed out that there was no single factor responsible for the variance majority, signifying that common method biasness was not a serious issue in the obtained data (Podsakoff et al., 2016). Additionally, procedural solutions such as assuring secrecy to the respondent and reducing item uncertainty were executed before collection of data to further minimize latent method biasness.

MEASUREMENT SCALES AND MEASUREMENT MODEL

Measurement of Constructs

Though strategic public relations communication and destination image have been theorized as multifaceted concepts in a few strands of literature, earlier empirical research has established the suitability to specify these constructs as unidimensional underlying variables while the analytical emphasis is on overall evaluations of tourists as well as behavioral results instead of dimensional variation. In perceptual tourism kind of research, respondents incline to make incorporated decisions that integrate affective and cognitive assessments into a single overall evaluation, especially in pre-visit kind of environments in which direct experience does not exist. Regarding destination image as a single latent construct, it has regularly been functionalized to capture tourists' all-inclusive cognitive–affective assessment of a destination during the examination of intention making and behavioral eagerness (Stylidis et al., 2020; Afshardoost & Eshaghi, 2020). Likewise, public relations research theorizes strategy-centric communication as a combined institutional

insight depicting transparency, credibility and relationship-based aspects when the objective of the research is to test the theory at the structural ground (Valentini, 2021). In accordance with these recognized approaches and corresponding with the conceptual framework of the study, all concepts in the current study were particularized as one-dimensional underlying variables in order to increase conceptual clarity, closeness and model interpretation.

Moreover, the measurement of all constructs was furnished while employing earlier authenticated multi-item measuring scales adapted from the recognized tourism as well as public relations related literature. Trivial modifications in wording were furnished to confirm context-based relevance to the tourism background of Jordan not altering the genuine conceptual items' meanings. All these items were measured while utilizing a five-point Likert scale stretching from 1 (*strongly disagree*) to 5 (*strongly agree*) (Stylidis et al., 2020; Sabiote-Ortiz et al., 2024).

Strategic Public Relations Communication

The measurement of strategic public relations communication was made with the usage of five items adapted from previous strategic communication and public relations research theorizing communication as a transparency, credibility and relationship-generated institutional mechanism (Valentini, 2021; Ki et al., 2021). These items acquire tourists' all-inclusive perceptions connected to official destination-based communication as reliable, transparent and oriented towards long-standing relationships construction instead of short-time promotional prompt. All items were stipulated to map onto a unified underlying concept demonstrating strategic public relations communication.

Destination Image

To measure destination image, five items were used, taken and adapted from the scales extensively used for destination image in tourism-specified research (Stylidis et al., 2020; Marine-Roig & Huertas, 2020). The chosen items depict tourists' incorporated cognitive–affective assessment regarding the destination by encapsulating impressions, beliefs and emotional reactions and experiences. These evaluation-based constituents were conceptualized as gauges of an only underlying concept being representative of collective destination image.

Tourists' Behavioral Intentions

Accordingly, behavioral intentions of the tourists were evaluated utilizing four items taken and adapted from the tourism research conducted in the past measuring intention-based results, together with visit intentions and intentions in recommending destinations as argued by Afshardoost & Eshaghi (2020); Sabiote-Ortiz et al. (2024). These items prove capturing respondents' inclination to be engaged in upcoming travel-linked behaviors, and thus were made specific to map onto a unified underlying concept signifying behavioral intents.

Data Analysis Strategy

The study conducted data analysis employing Partial Least Squares Structural Equation Modeling (PLS-SEM). Two stages were managed while proceeding analysis. At first, the measuring model was tested to evaluate indicator trustworthiness, internal reliability, discriminant validity and convergent validity. Secondly, the testing of structural model was managed to investigate the hypothesized associations aligning with H1, H2, H3, and then mediation analysis was held to assess H4.

Similarly, the importance of both direct and indirect effects was evaluated by means of a bootstrapping process that offers healthy estimations not depending on assumptions regarding data distribution. Explanatory power of the employed model was assessed with the usage of determination coefficient (R^2) for constructs quantified as endogenous.

RESULTS

Demographic Profile of the Respondents

The following section provides the demographic characteristics of the respondents as participants in this study. For the final analysis, a total 526 valid questionnaires were engaged. Accordingly, the demographic profile offers an impression of the sample arrangement providing necessary context-based information in order to explain understandings, insights and behavioral intentions of the tourists. In data sample, both male and female respondents were included, which indicates a relatively balanced gender distribution. Regarding the age of the respondents, their majority were determined within the socially and economically active age groups consistently connected with advanced levels of worldwide destination assessment and travel participation. Such kind of age configuration is reliable with prior research on tourism investigating before travel decision taking and intention building. Most of the respondents, when discussing their educational proficiency, had not less than a university-level education.

This specific feature is specifically pertinent in perspective of the study's concentration on communication-based assessments. It reasons that individuals having such educational qualification of higher-level are expected to dynamically engage with digital tourism and institutional communication to proceed destination-centered information systematically. Regarding the experience of travelling, a significant respondents' proportion demonstrated their previous international-level travelling experience, whereas others claimed that they had actively been looking for information about latent travelling destinations. In this sense, it recommends that the data sample include the individuals who have familiarity with tourism-associated communication, and are as a result proficient in assessing the destination image, strategic public relations communication as well as behavioral intentions in a purposeful way.

Similarly, respondents' meticulous demographic features, including gender, their age, and travelling history, are reflected in Table 1**.** As a whole, the demographic profile demonstrates that the data sample facilitate a suitable empirical base for investigating communication-grounded tourist decision formation within this study's background.

Table 1. Demographic Profile of the Respondents (N = 526)

Variable	Category	Frequency	Percentage (%)
Gender	Male	268	50.9
	Female	258	49.1
Age	18–24 years	96	18.3
	25–34 years	214	40.7
	35–44 years	128	24.3
	45–54 years	62	11.8
	55 years and above	26	4.9
Education Level	High school or below	84	16.0
	Bachelor's degree	276	52.5
	Postgraduate degree	166	31.6
International Travel Experience	Yes	372	70.7
	No	154	29.3
Active Destination Information Search	Yes	401	76.2
	No	125	23.8

Measurement Model Results

Before the evaluation of the assumed structural relationships, the model of measurement was judged to investigate the validity and reliability of the theorized constructs of this study. Adhering the recognized strategies for partial least squares structural equation modeling (PLS-SEM), the assessment showed focus on internal constancy reliability, indicator consistency, and convergent validity as argued by Hair et al. (2022) and Leguina (2025). Likewise, indicator reliability was evaluated with the usage of factor loadings having standards; reliability in internal consistency was investigated through composite reliability and Cronbach's alpha, and finally the convergent validity was assessed utilizing the average variance extracted (AVE).

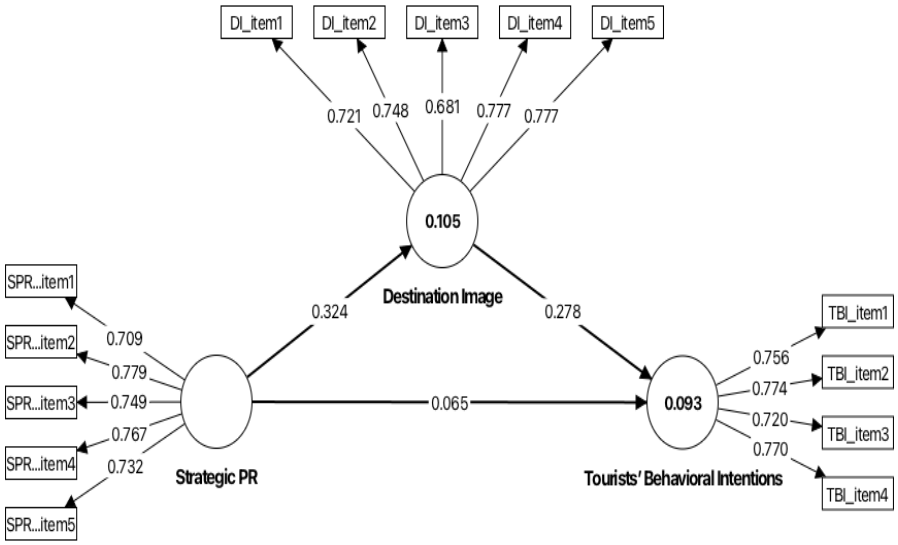

Figure 1. Measurement model with standardized factor loadings

In Figure 1, the study's measurement model has been presented, illustrating the associations found between the underlying constructs and their detected indicators together with loadings of standardized factor. All of the constructs were made specific as unidimensional and reflective, reliable with the adopted conceptualization in the current study. All the indicators, as shown in Figure 1, keep positively loading on their corresponding underlying specified constructs, with the consistent factor loadings going from 0.681 to 0.777 regarding destination image and from 0.709 to 0.779 for strategic public relations communication. Similarly, the ranging regarding tourists' behavioral intentions was from 0.722 to 0.770. These derived values demonstrate adequate indicator reliability, since the majority of loadings go above the suggested limit of 0.70 as suggested by Hair et al. (2022). One of the items related with destination image reflects a loading a little below 0.70; somehow, this derived value can be acceptable in the perspective of overall validity and reliability of the specified construct.

Table 2 the outcomes of the measurement model assessment have been stated in detail; it also includes Cronbach's alpha, factor loadings, composite reliability, as well as AVE derived values for each of the constructs. These results highlight that internal consistency reliability is positively determined. The table calculations show that Cronbach's alpha values move from 0.750 to 0.803, surpassing the generally acceptable at least edge of 0.70; it indicates adequate internal consistency existed among the measuring items (Nunnally & Bernstein, 1994).

Similarly, values of composite reliability further provide sustenance to this result along with all the constructs showing values more than 0.80. Moreover, the values ratify the consistency and stability of measuring scales. Accordingly, there exists also support for convergent validity; the AVE values for destination image are up to (0.550). Strategic public relations communication remains up to (0.559), and similarly tourists' behavioral intentions range (0.570), thus all surpass the conceptualized verge of 0.50. According to the derived results, it is judged that each construct explicates more than half of

the variance in its corresponding indicators; thus satisfactory level convergent validity is confirmed (Fornell & Larcker, 1981). There came further assessment of discriminant validity with the usage of the heterotrait–monotrait (HTMT) ratio, as it has been suggested as a vigorous standard regarding the evaluation of discriminant validity in variance-centered structural equation modeling. For all construct pairs, HTMT values were under the traditional verge of 0.85, highlighting that constructs of the study are empirically distinctive, and that the discriminant validity is established in satisfactory manner (Henseler et al., 2015). In Figure 1 and Table 2, the results indicate that the measuring model demonstrates internal consistency reliability, acceptable indicator reliability and convergent validity. The suitability of the measuring model offers a solid ground for the succeeding evaluation of the hypothesis testing as well as structural model.

Table 2. Measurement Model Results

Construct	Item	Factor Loading	Cronbach's α	CR (rho_c)	AVE
Destination Image (DI)	DI_item1	0.721	0.795	0.859	0.550
	DI_item2	0.747			
	DI_item3	0.681			
	DI_item4	0.777			
	DI_item5	0.777			
Strategic Public Relations Communication (SPRC)	SPRC_item1	0.709	0.803	0.864	0.559
	SPRC_item2	0.779			
	SPRC_item3	0.749			
	SPRC_item4	0.768			
	SPRC_item5	0.731			
Tourists' Behavioral Intentions (TBI)	TBI_item1	0.763	0.750	0.841	0.570
	TBI_item2	0.770			
	TBI_item3	0.722			
	TBI_item4	0.765			

Structural Model Results

The structural model, through the evaluation of the measuring model, was assessed to investigate the hypothesized expected associations among strategic public relations communication, behavioral intents of the tourists and destination image. According to the recognized guiding principles for partial least squares structural equation modeling (PLS-SEM), the assessment concentrated on the magnitude and importance of all standardized and normalized path parameters, together with the expounding model power as pointed out by the determination coefficient (R^2) (Hair et al., 2019; Hair et al., 2022).

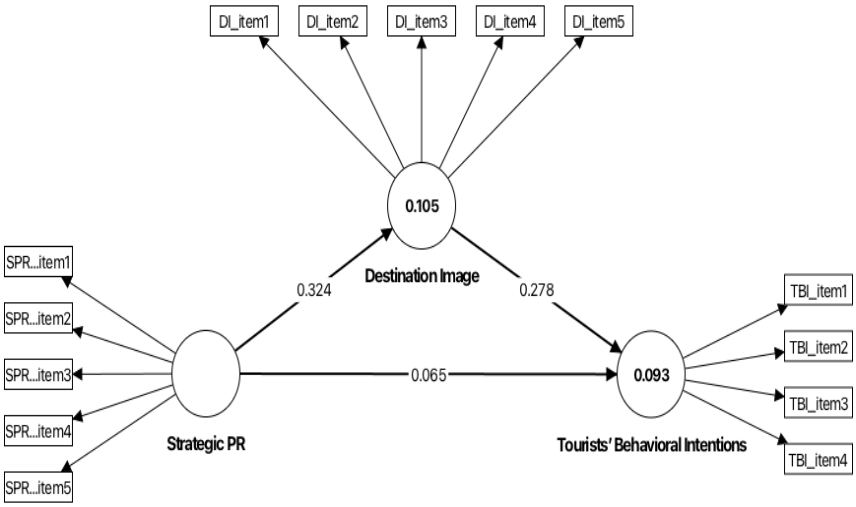

Figure 2. Structural model with path coefficients

In order to evaluate the statistical prominence of the hypothesized associations, a nonparametric bootstrapping process with 5,000 resamples was utilized, since it is suggested for the testing of hypothesis as well as mediation analysis in PLS-SEM as suggested by Hair et al. (2022); Preacher & Hayes (2008). In Figure 2 it is presented the structural model along with the standardized path coefficients and the endogenous constructs' explicated variance (R^2). Strategic public relations communication, as presented in the figure, elucidates a significant variance proportion in destination image ($R^2 = 0.105$), whereas strategic public relations communication and destination image together expound variance in behavioral intentions of the tourists ($R^2 = 0.093$). While these derived R^2 values show their appearance as being modest, such kinds of explanatory levels generally exist in perception-centered and behavioral tourism research, presenting the characteristically intricate and multi-driven feature of tourism-based decision-making process, in which intentions are formed by many contextual, psychological and situational dynamics beyond the constructs of communication field (Hair et al., 2019).

According to the results of Table 3, strategic public relations communication shows a statistically and positive important impact on the destination image ($\beta = 0.324$, $p < .001$), offering empirical sustenance to H1. The conclusion

highlights that practices at institutional communication, emphasizing transparency, credibility and relationship orientation, play an important role in forming overall perceptions of tourists regarding the destination.

Additionally, destination image leaves a statistical and positively prominent impact on behavioral intents of the tourists ($\beta = 0.278$, $p < .001$), providing support to H2. This result confirms that acceptable cognitive–affective assessments of a destination arise tourists' inclination to be engaged in upcoming travel-based behaviors like visiting or recommendations of the destination as visiting places. In comparison, the direct impact of the strategic public relations communication on tourists' behavioral intents is not statistically noteworthy ($\beta = 0.063$, $p = .182$). In accordance with it, no support is observed for H3. Such result recommends that strategic public relations communication reflect no direct interpretation into behavioral intentions as destination image of tourists is taken into consideration.

Mediation Analysis

In the perspective of this study's mediation-grounded conceptual framework, the destination image's mediating role in the connection existing between strategic public relations communication and behavioral intentions of the tourists was investigated while utilizing bootstrapping techniques. Bootstrapping can be largely considered as a strong approach to test indirect impacts in PLS-SEM, since it does not depend on suppositions of normality and thus offers more precise confidence intermissions for mediation impacts (Preacher & Hayes, 2008).

In Table 4, it has been shown that strategic public relations communication's non-direct impact on behavioral intentions of tourists through destination image remains positive and statistically prominent ($\beta = 0.090$, $p < .001$). As the concluded result is measured along with the insignificant direct impact described in Table 3, the statistical outcomes manifest that destination image completely mediates the relationship existed between strategic public relations communication and behavioral intentions of the tourists. The design of these results corresponds with existing mediation rationality, which identifies full mediation though there exists no noteworthy direct impact (Zhao et al., 2010). In this context, there remains support for H4.

Table 3. Structural Model Results

Hypothesis	Path	β	t-value	p-value	Result
H1	Strategic PR -> Destination Image	0.324	8.847	< .001	Supported
H2	Destination Image -> Tourists' Behavioral Intentions	0.278	6.635	< .001	Supported
H3	Strategic PR -> Tourists' Behavioral Intentions	0.063	1.334	0.182	Not supported

Table 4. Mediation Analysis (Indirect Effects)

Indirect Path	B	t-value	p-value	Mediation Type
Strategic PR -> Destination Image -> Tourists' Behavioral Intentions	0.090	5.309	< .001	Full mediation

Effect Size (f^2)

Along with the examination of the path importance, effect sizes (f^2) were measure for the evaluation of the relative effect of each exogenous concept on the endogenous factors (underlying variables). The derived results highlight that strategic public relations communication depicts a low-to-moderate impact on destination image, though destination image exhibits a small influence on tourists' behavioral intents. These impact-based sizes remain consistent with prospects in perception-related tourism research indicating that the perceived associations, though statistically important, exercise modest utilitarian impact (Hair et al., 2022).

Predictive Relevance (Q^2)

Model's predictive relevance was tested by using the blindfolding process. For both tourists' behavioral intentions and destination image, the Q^2 values were greater than zero. These values highlight that the prescribed model depicts satisfying predictive relevance having the capability of predicting endogenous concepts away from mere expounding power (Hair et al., 2019).

Model Fit

Ultimately, the model fit was assessed by employing the standard-based root mean square residual (SRMR). The derived value of SRMR was under the suggested verge of 0.08, recommending a satisfactory inclusive model fit for analysis of PLS-SEM and providing support to the appropriateness of the suggested structural model as prescribed by (Hair et al., 2019).

DISCUSSION

The current study's findings offer theoretically noteworthy perceptions into the institutional communication role in tourism decision-building practices. The present study began by investigating the way strategic public relations communication builds behavioral intentions of the tourists by clearly placing destination image as an interceding cognitive–affective process. With the incorporation of public relations theory into destination image-based research and empirically assessing a mediation-grounded structural model in Jordanian context, the current study contributes to long-term calls regarding more process-oriented and theoretically based clarifications of tourist decision-making action. Instead of just reinforcing accepted relationships, findings of the study provide in-depth understanding into *how* as well as *which way* institutional communication affects behavior of tourists in repute-centered and sensitive digitally mediated tourism environs.

Findings reveal that strategic public relations communication leaves a robust and statistically prominent impact on destination image, and provides strong favor to H1. Such kind of assessment corresponds intimately with in vogue public

relations academia, which theorizes strategy-centered communication as an institutional mechanism having an aim to construct trust, credibility as well as legitimacy with the help of relationship-focused and explicit interaction with the shareholders (Valentini, 2021; Ki et al., 2021). Similarly, in tourism background, where potential tourists often depend on mediation-oriented information instead of direct involvement experience, such kinds of communication come on the scene to play a determinative role in framing the way destinations are explained in a cognitive and affective way.

Notably, this finding plays a vital role in extending prior tourism-based research that has largely handled communication as a practical or promotional effort. Although, the studies in the past have shown focus on content quality, message disclosure, or labeling usefulness (Huerta-Álvarez et al., 2020), the current results recommend that tourists tend to respond healthier to communication considered as institutionally reliable and relationship-centered. Following this, this study empirically backs current concept-based argumentation that destination image is not just affected by promotion-grounded stimuli but is also dynamically formed with the help of institutional communication practices that indicate trustworthiness and legitimacy (Tasci et al., 2022). The derived finding, from a theoretical point of view, strengthens the pertinence of public relations theory for the research related to tourism; it also addresses the consistent dominating edge of marketing-oriented communication models. With the clarification that strategic public relations communication works as an important antecedent/predictor of destination image, the present study provides support to a more comprehensive insight of image formation that focuses on institutional trustworthiness not on persuasive messaging only.

Destination image, having consistency with H2, was observed in exercising a prominent constructive impact on tourists' behavioral intentions. The same result corresponds with the current outcomes highlighting that destination image functions as a strong explanatory component of tourist loyalty-based results, despite the fact that contextual and experiential factors are taken into consideration (Sobaih et al., 2024). This derived result validates a significant body of tourism research. Moreover, it specifies destination image as a core-determining factor of intention-oriented results, containing inclinations to visit and suggest travel destinations (Afshardoost & Eshaghi, 2020; Stylidis et al., 2020). The findings confirm by claiming that tourists' behavioral willingness is motivated initially by their collective cognitive–affective assessments not through objective destination qualities. In addition to validating this determined relationship, the current study shares to the destination image theory by strengthening its role as an explanatory framework instead of a static insight.

Similarly, in the digitally facilitated evaluation-judgement background, tourists repeatedly face split, and occasionally contradiction-based information. Additionally, destination image performs as a cognitive–affective framework incorporating these indications into an intelligible assessment-oriented decision making, thus making intention formation able to be formed (Marine-Roig & Huertas, 2020). Such explanatory role adopts itself especially as significant in destinations in which repute-base accounts and alleged risk build prior travel assessments.

Contrary to H1 and H2, on tourists' behavioral intents the direct impact of strategic public relations communication could not appear as statistically significant element, thus guiding to the H3 rejection. Although, communication's direct effects on intention formation have been testified in some tourism studies, especially within marketing efforts and branding the frameworks, the non-existence of a prominent direct path in the current model is hypothetically expressive instead of being problematical. Findings of the study recommend that strategic public relations communication have no proof to function as a direct convincing prompt of behavioral intents. Rather, its influence looks depending on the way tourists cognitively and affectively process the communication. This perception corresponds with direct-effect models' contemporary critiques in the research of tourism behavior, which claim that these kinds of models overgeneralize the process of decision-making by ignoring perception-based mediation processes (Li et al., 2025). The insignificant direct impact, when observed from a mediation-based logic lens, shows total consistency with contemporary perceptions of non-indirect impact. Additionally, the non-existence of a direct impact is unable to make theoretical relevance weak especially when there exists a prominent indirect source as claimed by Zhao et al. (2010). In the present study, the outcomes highlight that strategic public relations communication shows impacts on behavioral intents merely insofar as it frames destination image, highlighting the importance of perceptual explanation in tourism decision forming.

A strong empirical support is offered for H4 by managing mediation analysis. It also demonstrates that destination image serves entirely as a mediator for the relationship found between strategy-centered public relations communication and behavioral intentions of the tourists. The derivative result signifies one of the study's most significant theoretical implications. This study, by empirically authenticating a model of full mediation, goes beyond expressive relations providing a process-focus clarification of the way institutional communication interprets into behavioral results.

The current finding corresponds with contemporary tourism research, which accentuates mediation-oriented interpretations of a tourist behavior, specifically in the backgrounds categorized by perceived risk, ambiguity as well as reputation related feelings (Hassan & Soliman, 2021; Gorji et al., 2023). In order to build tourists' intents, strategic public relations communication comes ahead. It does not frame by directly inspiring action, but through affecting the emotions, meanings, and even assessments that construct destination image. While performing this, destination image serves as a cognitive–affective channel, which connects institutional indications to behavioral willingness. On theoretical level, this finding appears challenging for the consistent dependence on attitudinal frameworks like the Planned Behavior Theory in tourism backgrounds in which institutional communication leads to the formation of attitude. When strategic public relations communication is place as a pre-attitudinal construct, while destination image and exogenous construct as the key explanatory contrivance, the study provides a substitute illustrative framework, which depicts present-day, communication-guided tourism atmospheres in a better way. The current study overall provides a number of significant theoretical insights.

Firstly, it empirically and theoretically differentiates strategic public relations communication from marketing-centered when related to communication held in tourism research. Additionally, it signifies its exceptional role in the formation of destination image. Secondly, it develops the theory of destination image by replacing image as a mediating explanatory

process instead of a simple behavior antecedent. Thirdly, through empirical validation of a full mediation model, this study facilitates an expanding volume of research supporting process-centric and theory-led interpretations of a tourist judgement. Lastly, this study, while concentrating on the Jordanian background, increases the context-based strength of tourism communication theory by ranging it beyond the destinations of West and East Asia.

In the present study, there have been provided a number of significant theoretical implications regarding the research based on tourism communication and destination image. Firstly, it provides insights to the expanding volume of literature that advocates going away from marketing-focused conceptualizations of tourist-centered behavior by empirically incorporating strategic public relations communication into a destination image theoretical framework. Whereas prior studies conducted on tourism concerns have mainly theorized communication as promotion-based experience or marking activity, the present results validate that communication is grounded on transparency, credibility, and similarly, relationship orientation has to play an influential role in building tourists' perceptions instead of directly encouraging behavioral intents. Peculiarity of such nature makes theoretical clarity advanced by specifying strategic public relations communication as the antecedent of an institution instead of a normative purpose-driven approach.

Secondly, this study validates the theory of destination image by experientially substantiating its vital role as intermediary thought or emotional-affective mechanism instead of a simple behavior determinant. Similarly, finding based full mediation specifies that destination image performs as an explanatory channel by which institutional communication is interpreted into behavioral promptness. Such process-centered interpretation offers a respond directly to contemporary assessments of tourism behavior frameworks and models, which attach excessive emphasis to direct impacts however ignoring perceptual and meaning-making processes (Tasci et al., 2022; Li et al., 2025).

The third point is that the nonexistence of a remarkable direct impact found between strategy-based public relations communication and behavioral intentions of the tourists reflects significant theoretical contributions. Instead of putting communication theory into contradiction, the current finding corroborates existing mediation reasoning, which accentuates that the institutional directives or guidelines are surely cognitively and affectively managed before persuading intention building as argued by (Zhao et al., 2010). It interrogates the persistent dependence on linear, direct-impact presumptions rooted in attitudinal framework like the Planned Behavior Theory, especially in the context of tourism in which communication occurs to the attitude formation and development.

Lastly, testing the model through observation-based data in the Jordanian context, this study expands the geographical as well as context-centered space of the theory of tourism communication. Similarly, much of the contemporary literature focuses on East Asian and Western designed destinations, possibly restricting the generalizability of in vogue models. However, findings of the study recommend that in repute-based sensitive and institution-level facilitated destinations, the strategy-centric public relations communication tends to play a specifically prominent role in building destination image, thus supporting to a more context-oriented strong theoretical knowledge of tourist decision-choice.

The current study's findings provide a number of practical insights for destination management organizations (DMOs) and the policymakers of tourism industry. First, findings of the study highlight claims that strategic public relations communication in a sense must not be handled as a supplemental or peripheral activity; instead, it should be considered as an essential constituent of the destination management tactic. Communication efforts that prioritize transparency, credibility, and relationship building appear more effective in shaping favorable destination images than purely promotional messaging. Secondly, the nonexistence of a direct impact between the strategic public relations communication and behavioral intentions of the tourists recommends that DMOs should reconsider and adjust their prospects concerning communication results. Instead of trying to encourage for visit intentions with the help of advertisement-based campaigns, practitioners must concentrate on building trustworthy and coherent destination descriptions that increase collective cognitive–affective assessments of tourists. Regarding this, destination image appears as the main influential idea with which investments in communication produce behavioral outputs.

Thirdly, findings depict relevancy especially for destinations working in the environments categorized by highly observed risk, repute related sensitivity, or even geopolitical complication. Strategic public relations communication, in such kinds of environments, can perform as a legitimacy-framing process, which alleviates uncertainty while strengthening trust on the institutions. It emphasizes the significance of consistent, harmonized and institutionally trustworthy communication in all official tourism platforms, media relations, and digital channels.

Lastly, tourism related management should identify that the usefulness of communication strategies rests not merely on message content but on how communication related performances are observed on institutional level. Investing in interactional involvement, response tendency, and fairness may as a result give long-standing paybacks by reinforcing destination image, and indirectly, behavioral intentions of tourists.

CONCLUSION

To conclude, the research in future may have the capacity to extend the suggested model by integrating extra moderating or mediating variables like anticipated risk, trust, or media trustworthiness. Such kinds of extensions in research work would further increase perceptions of the multi-layered underlying processes with which institutional communication shows effects on tourist behavior in existing digital based mediated tourism contexts. The present findings further indicate that strategic public relations communication is relevant to the formation of destination image, while destination image plays an important role in explaining tourists' behavioral intentions. The absence of a significant direct relationship between strategic public relations communication and behavioral intentions, together with the significant indirect relationship through destination image, highlights the importance of considering the perceptual process through which institutional communication influences

tourism-related behavioral outcomes. In this regard, the study contributes to tourism communication research by positioning destination image as a mediating mechanism linking strategic public relations communication with tourists' behavioral intentions. Overall, the findings support a process-oriented understanding of tourism communication in which institutional communication influences behavioral intentions through the destination perceptions formed by tourists.

Limitations and Future Research

In spite of this study's support and contributions, it goes under a number of limitations that paves the avenues for research to be conducted in the future. Firstly, the study used a cross-sectional research pattern, which has the ability limitations in drawing general implications concerning the vigorous advancement of destination image as well as behavioral intentions with the passage of time. The studies in future can adopt experimental or longitudinal designs to engage changes in tourists' understandings following publicity to strategic public relations based communication.

Secondly, it may happen that due to the usage of online self-managed surveys there may emerge self-chosen bias; it reasons that individuals having higher digital engagement levels and keen interest in tourism-oriented content are more probable to show their participation. Additionally, the dependence on self-diagnosed perception-based measures may become under social desirability propensities, possibly manipulating respondents' assessments.

Such kinds of methodological restrictions should be brought under consideration while explaining the inferences and generalizing the findings to larger population of tourism. Thirdly, whereas the present study made strategic public relations communication conceptualize as a unidimensional concept to improve parsimony, the research in future may go to search its multidimensional structure with more deep-digging effort. While investigating particular communication-based practices such as two-way interaction involvement, transparency gesturing or crisis communication might offer more substantive and detailed understandings into which public relations communication perspectives perform most persuasively in building destination image. Finally, this study concentrated on a single destination context.

It may bound the generalizability of the study results. Studies, having comparative nature, throughout various political, cultural or institution-level contexts would support in evaluating the strength of the suggested model and recognizing the potential peripheral situations. Specifically, future research could be able to compare reputation-based sensitive destinations having well-known and strongly established tourism marketplaces.

Place-based wellness tourism architecture at the Dead Sea: Environmental resources, spatial systems, and operational sustainability. *Geojournal of Tourism and Geosites*, 67(3), 2563–2573. https://doi.org/10.30892/gtg.67363-1875

Abstract: Wellness and health tourism has experienced significant global growth, driven by increasing demand for integrated therapeutic experiences that combine natural resources, environmental context, architecture, and interior design. The Dead Sea is one of the world's most prominent wellness destinations due to its exceptional climatic and mineral properties. However, hotel architecture in the region often continues to follow conventional hospitality models that emphasize general leisure amenities rather than spatially integrated therapeutic systems rooted in the specificity of place. This study examines the role of architecture and interior design in supporting wellness tourism at the Dead Sea by analyzing the relationship between environmental context, natural resources, wellness-oriented spatial systems, tourist experience, and the operational sustainability of hotels. A Design-Based Mixed-Methods Approach was adopted, combining typological analysis of therapeutic spatial systems, spatial assessment of selected hotels, questionnaires distributed to guests (n = 260), and semi-structured interviews with owners and managers (n = 8), supported by descriptive data analysis. The findings reveal a clear gap between the Dead Sea's exceptional therapeutic potential and its actual spatial translation within existing hotels. Recreational functions were found to dominate over specialized and integrated therapeutic systems, resulting in fragmented wellness experiences. The results also indicate a substantial mismatch between guests' strong preference for integrated therapeutic components and their limited actual availability, negatively affecting satisfaction, revisit intention, and perceived hotel performance. In addition, owners and managers confirmed a direct relationship between the efficiency and integration of therapeutic spatial systems and the operational sustainability and competitiveness of hotels. The study concludes that adopting a place-based wellness-oriented hotel architecture model, in which therapeutic systems function as generators of spatial organization rather than secondary service features, represents a strategic pathway to enhance tourist experience and strengthen the operational sustainability of Dead Sea hotels.

INTRODUCTION

Wellness and health tourism has experienced accelerated growth over the past decades, becoming one of the most dynamic segments of the global tourism industry and exerting increasing influence on spatial planning, hotel architecture, and the design of wellness-oriented environments. Contemporary wellness tourism extends beyond the provision of isolated therapeutic services to encompass integrated spatial experiences that combine environmental resources, architecture, interior design, and therapeutic activities, thereby enhancing both physical and psychological well-being, increasing the length of stay, and strengthening tourist loyalty (Hall, 2011; Jawabreh et al., 2023; McGroarty, 2023; Smith & Puczkó, 2014).

Within this evolving paradigm, architectural space and interior design are no longer passive containers of services but active agents in shaping the therapeutic experience. This aligns with the theoretical foundations of healing architecture, which emphasize the influence of spatial configuration, natural light, air quality, and environmental integration on human health outcomes (Al Fahmawee, 2023; Gesler, 2003; Kaplan et al., 1989; Ulrich et al., 2008). In this context, the Dead Sea represents one of the most prominent global destinations for wellness tourism, due to its

exceptional environmental characteristics, including its location at the lowest point on Earth, high concentrations of salts and minerals, therapeutic mud, and a unique climatic profile beneficial for dermatological, respiratory, and psychological conditions (Al Dein, 2021; Alhmoud & Alhmoud, 2024; Canton, 2021; Hassan, 2000; Organization, 2017). These attributes have established the Dead Sea as a distinctive place-based therapeutic environment, with significant potential for advanced wellness tourism development.

However, despite this exceptional environmental and therapeutic richness, hotel architecture in the Dead Sea region remains, in many cases, aligned with generic hospitality models focused on accommodation and leisure functions. Specialized wellness-oriented spatial systems are often implemented in a fragmented or symbolic manner, typically confined within conventional spa facilities, without being integrated as generative components of spatial organization or as drivers of the overall therapeutic experience (Jawabreh et al., 2025; Katz et al., 2014; Voigt & Pforr, 2013; Zmirou-Navier, 2021). This limits the ability of hotels to systematically activate local environmental resources and weakens the spatial and functional coherence of the wellness experience.This gap becomes more evident when considering contemporary approaches to place-based wellness tourism, which emphasize the importance of translating environmental resources—such as climate, water, minerals, and landscape—into structured spatial systems that reflect the identity of the place and enhance experiential value (Jawabreh et al., 2024; Lew, 2019; Smith & Diekmann, 2017). In such approaches, the place itself becomes an active therapeutic agent, rather than a passive environmental backdrop.

To clarify the spatial logic underlying this transformation, Figure 1 illustrates the proposed wellness spatial sequence, which organizes the visitor experience into a coherent progression from arrival and orientation, to treatment, recovery, and place-based experiential engagement. This sequence reflects the fundamental principle that therapeutic effectiveness is achieved through spatial continuity rather than isolated interventions. To situate the study within its geographical and environmental context, Figure 2 presents the location of the Dead Sea within the regional framework, highlighting the concentration of hotel development along the eastern shoreline and its relationship to key geomorphological features.

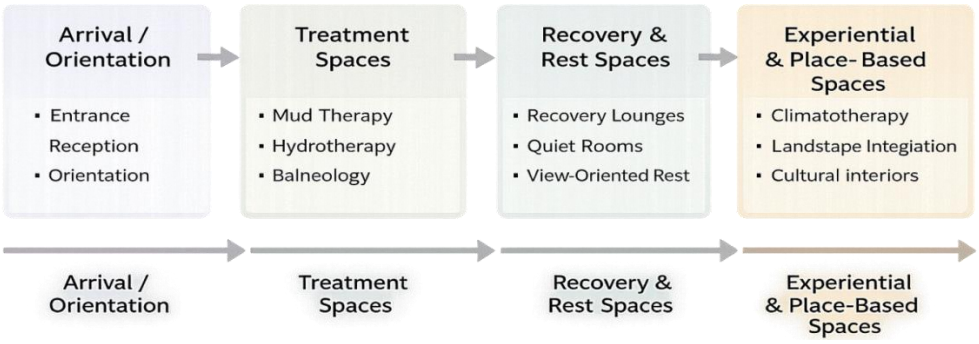

Figure 1. Wellness spatial sequence model illustrating the progression from arrival and orientation to treatment, recovery, and place-based experiential spaces within wellness-oriented hotel architecture at the Dead Sea

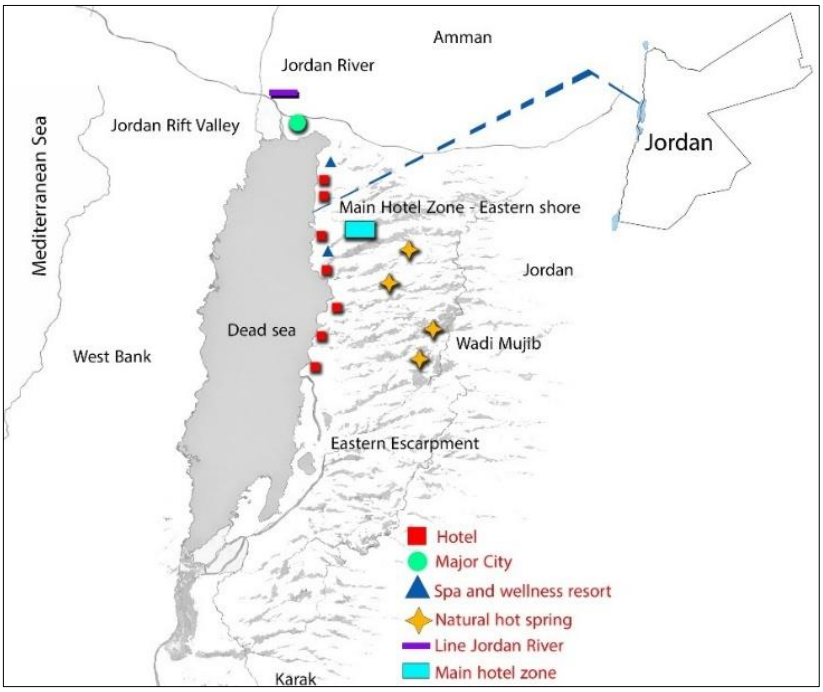

Figure 2. Location map of the Dead Sea region showing major geomorphological features and the main wellness-oriented hotel zone along the eastern shore in relation to key regional nodes

Figure 3. (Left) Freshwater cascades and natural pools within the Dead Sea hinterland landscape;
(Right) Crystalline salt formations along the mineral-rich shoreline illustrating the environmental basis of wellness tourism

In addition to its well-documented therapeutic properties, the Dead Sea region includes a diverse environmental system characterized by unique geological formations, mineral-rich shorelines, and natural landscapes that contribute to both sensory and therapeutic dimensions of the visitor experience (Al Dein, 2021; Ismail & Abd Elkader, 2023; Walls et al., 2011). These environmental features form the natural basis of wellness tourism in the region, as illustrated in Figure 3.

Despite this environmental richness, there remains a clear research gap in the absence of studies that systematically link environmental context, spatial organization, tourist experience, and operational sustainability within hotel architecture, particularly in contexts characterized by unique therapeutic resources such as the Dead Sea (Al Dein, 2022; Alhmoud, 2024; Pine & Gilmore, 2011; Pizam & Tasci, 2019).From an operational perspective, this gap is reflected in declining performance indicators in some Dead Sea hotels, including reduced occupancy rates and the closure of certain facilities in recent years, despite the strategic location of the region and its proximity to major urban and tourist centers (Aburamadan, 2022; Ministry of Tourism and Antiquities, 2024). From a broader national perspective, strengthening the competitiveness of Jordanian tourism activity remains important for supporting the sector's economic performance and sustainable growth (Saleh et al., 2023). This paradox suggests that the mere presence of environmental and therapeutic resources is insufficient to ensure sustained tourist demand or operational viability.

The core problem, therefore, lies in the absence of a systematic translation of these environmental resources into integrated wellness-oriented spatial systems within hotel architecture and interior design. This deficiency results in fragmented therapeutic experiences, reduced visitor satisfaction, limited repeat visitation, and weakened operational sustainability.

In response to this gap, this study investigates wellness tourism in the Dead Sea as both a spatial and design problem. It aims to analyze the relationship between environmental context and natural resources, the configuration of wellness-oriented spatial systems in hotel architecture and interior design, and their impact on tourist experience and operational sustainability.

To address this gap, the present study adopts a place-based architectural perspective and develops a typological framework that defines the essential wellness-oriented spatial systems required in therapeutic hotel environments. This framework, summarized in Table 1, links natural resources to therapeutic functions, spatial components, and organizational logic, providing an analytical benchmark for evaluating existing hotel conditions.To operationalize this relationship, the study develops a typological framework that identifies the core wellness-oriented spatial systems required in place-based therapeutic hotel environments. This framework is derived from the literature on wellness tourism, healing architecture, and place-based design, and serves as an analytical benchmark for evaluating existing hotel conditions.

Table 1. Typological framework of wellness-oriented spatial systems
(Source: Developed by the author based on Smith & Puczkó, 2014; Gesler, 2003; Ulrich et al., 2008)

Natural Resource	Therapeutic System	Required Core Interior Spaces	Spatial Logic
Dead Sea mud	Mud therapy system	Mud cabins, preparation rooms, wash-off areas, recovery lounges	Sequential therapeutic flow
Mineral water	Hydrotherapy system	Hydromassage pools, therapeutic baths	Controlled immersion sequence
Climate & low altitude	Climatotherapy	Solarium, aerarium, shaded decks	Exposure–recovery cycle
Saline air	Inhalation therapy	Aerosol rooms, breathing chambers	Controlled respiratory sessions
Landscape views	View-based recovery	Quiet lounges oriented to sea	Post-treatment restoration
Cultural identity	Narrative spaces	Interpretive interiors, material expression	Place-based storytelling
Physical rehabilitation	Therapeutic physical culture	Rehab gym, medical screening	Supervised recovery sequence
Family wellness	Inclusive wellness	Accessible pools, child therapy zones	Parallel therapeutic systems

Table 1 is used in this study not as a purely theoretical classification, but as an evaluative tool that supports the spatial assessment of existing Dead Sea hotels presented later in Table 2. To structure this investigation, the study adopts a conceptual framework that links Environmental Context → Natural Resources → Wellness-Oriented Spatial Systems → Tourist Experience → Operational Sustainability, as illustrated in Figure 4. Based on this framework, the research seeks to answer how environmental resources can be effectively translated into spatial systems that support integrated therapeutic experiences, and how this translation influences both visitor experience and the long-term operational performance of hotels.

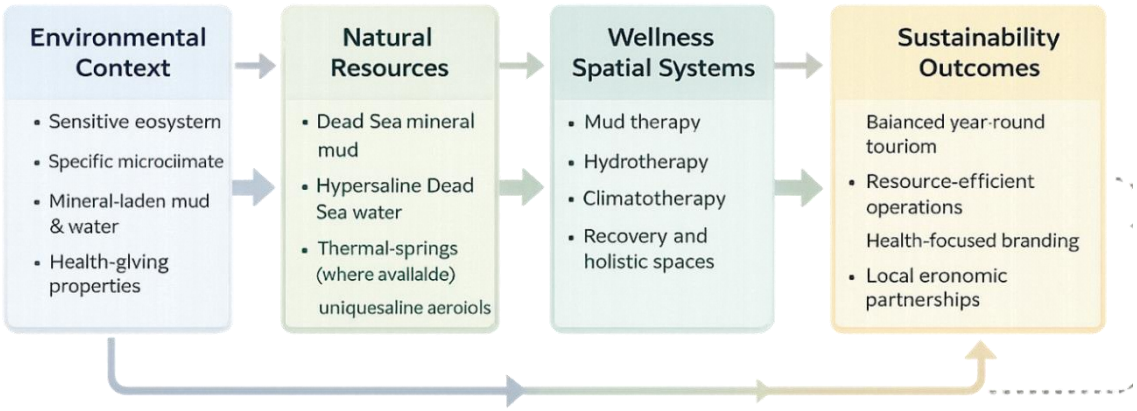

Figure 4. Conceptual framework linking environmental context, natural resources, wellness-oriented spatial systems, tourist experience, and operational sustainability in place-based hotel architecture at the Dead Sea

MATERIALS AND METHODS

This study adopts a Design-Based Mixed-Methods Approach to examine how the environmental and therapeutic resources of the Dead Sea are translated into functional wellness-oriented spatial systems within hotel architecture and interior design, and how this translation affects tourist experience and the operational sustainability of hotels. This methodological choice was deemed appropriate because the research problem is inherently interdisciplinary, situated at the intersection of architecture, interior design, tourism, and wellness studies. More specifically, the study does not treat spatial organization as a secondary design outcome, but as a central analytical variable that mediates the relationship between environmental resources and tourism performance.

The study area is defined by a distinct topographic condition that plays a critical role in shaping the spatial organization of hotel developments along the Dead Sea. The eastern escarpment forms a steep gradient descending toward the Dead Sea basin, creating a strong sectional relationship between plateau, slope, and shoreline.

This topographic configuration directly influences architectural massing strategies, circulation patterns, and visual orientation toward the sea. As illustrated in Figure 5, the descent from the escarpment to the shoreline establishes a spatial framework within which hotel architecture is often organized through stepped configurations that follow the natural terrain.

This condition is not merely a physical constraint but a generative design factor that reinforces the relationship between environmental context and spatial organization, forming a key component of place-based wellness-oriented hotel architecture.

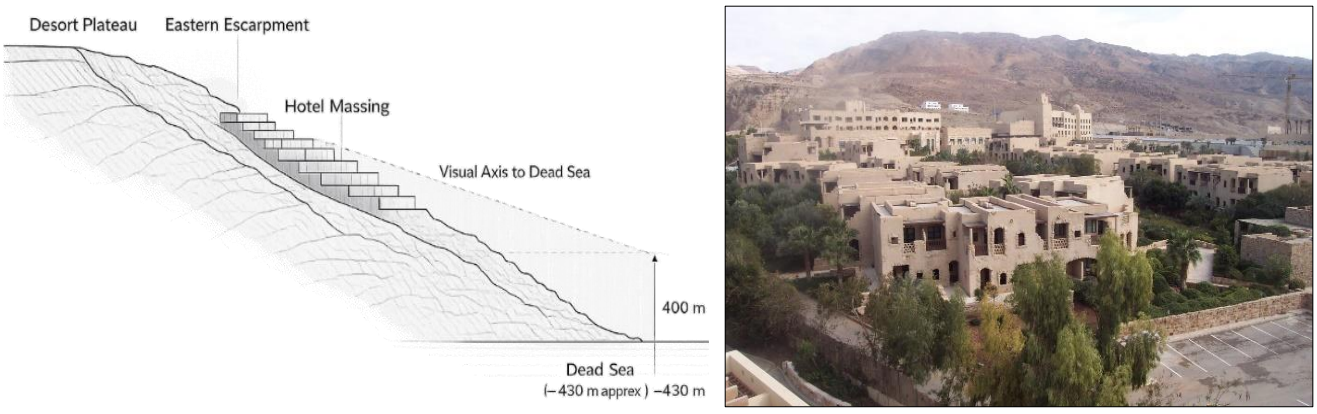

Figure 5. (Left) Topographic section showing the descent from the Eastern Escarpment to the Dead Sea basin as a key spatial and architectural condition; (Right) Stepped hotel massing along the eastern shore illustrating the role of topography as a generator of place-based, wellness-oriented hotel architecture. Source: Field photographs and analytical diagrams by the author

The methodological logic of the study is grounded in the conceptual structure introduced in the previous section, where the environmental context of the Dead Sea is understood as the starting point for the formation of therapeutic spatial systems, which in turn shape visitor experience and influence operational sustainability. In methodological terms, this logic is translated into a staged analytical process that begins with the derivation of a typological framework from the literature,

proceeds to the spatial assessment of selected hotels, and then incorporates empirical data from guests, owners, and managers in order to interpret the relationship between spatial organization and operational outcomes. Within this sequence, Table 1 functions as the analytical benchmark for therapeutic spatial systems, Table 2 as the spatial diagnostic tool for the assessed hotels, and Table 3 as the matrix through which analytical findings are translated into design implications. Likewise, the visual materials included in the manuscript support this methodological structure by linking environmental context, spatial sequence, and interpretive outcomes to the research process.

The study is based on three interrelated units of analysis. The first unit comprises the hotels themselves. The sample included six operating hotels in the Dead Sea region (n = 6), selected according to criteria that ensured analytical relevance rather than statistical representativeness. These criteria included hotel category, actual operation during the study period, the presence of spa or wellness-related facilities, and the ability of the selected cases to reflect diversity in current hospitality models within the region. Given the limited number of operational hotels with wellness-related facilities in the Dead Sea area, this sample size is methodologically appropriate for an in-depth spatial and design-oriented analysis.

The second unit of analysis consisted of hotel guests. A total of 260 questionnaires (n = 260) valid for analysis were collected from guests staying in the selected hotels. These questionnaires provided the empirical basis for assessing perceived availability of therapeutic spatial components, user expectations, elements of visitor experience, and the perceived relationship between spatial systems and hotel performance. The third unit of analysis consisted of owners and senior hotel managers, with eight semi-structured interviews (n = 8) conducted in order to represent the operational and investment perspective of the sector. This triangulated structure strengthens the reliability of the study by combining spatial diagnosis, user perception, and managerial interpretation within one coherent analytical framework.

Data collection relied on four complementary tools. First, a focused literature review was conducted to derive the analytical and typological basis of the study. The reviewed literature addressed wellness and health tourism, healing architecture, and place-based design, with the aim of identifying the main therapeutic spatial systems that should characterize hotels operating in destinations with distinctive therapeutic environmental resources. The outcome of this process was synthesized in Table 1, which links natural resources, therapeutic functions, required interior spaces, and the spatial logic of therapeutic sequencing. In this study, Table 1 is not treated as a purely theoretical classification, but as an evaluative analytical framework that supports subsequent spatial assessment.

Second, a spatial–functional assessment was carried out for the six selected hotels using the systems defined in Table 1. This process generated the comparative matrix presented in Table 2, which evaluates the extent to which core wellness-oriented spatial systems are present, absent, or only partially implemented in the case-study hotels. The assessment was based on multiple sources of evidence, including interviews with management, reviews of officially announced hotel services, and analysis of available operational and promotional materials. To reduce subjectivity in the classification, a clear operational criterion was adopted. Systems classified as Yes were those whose core spaces were available, functionally active, and organized through a recognizable therapeutic spatial sequence. Systems classified as Partial were those represented by scattered or symbolic elements without a coherent therapeutic sequence or direct relation to the specific resources of the Dead Sea. Systems classified as No were those for which no evidence of actual provision or operation could be identified. Accordingly, Table 2 should be understood as a comparative spatial diagnostic tool, not as a hotel ranking instrument.

Third, a structured questionnaire was developed and distributed to hotel guests. The questionnaire was designed to capture three main dimensions: the perceived availability of therapeutic spatial components, the experiential consequences of their presence or absence, and the operational implications as perceived by users. The survey instrument was therefore not limited to recording satisfaction in general terms, but sought to understand how guests evaluated the spatial and therapeutic completeness of the hotel environment and how this evaluation related to return intention, recommendation, and broader experiential quality. The quantitative data generated through the questionnaires provided the descriptive empirical basis for assessing the gap between actual spatial provision and user expectations.

Fourth, semi-structured interviews were conducted with owners and general managers of the selected hotels. These interviews focused on three interrelated themes: the current reality of therapeutic spatial provision within the hotels, the operational challenges associated with strengthening such systems, and the perceived relationship between wellness-oriented spatial systems and hotel occupancy performance. The interviews were analyzed through thematic analysis, allowing the extraction of recurring interpretive patterns related to spatial integration, investment logic, and operational sustainability. This qualitative component was particularly important because it enabled the study to connect spatial diagnosis and visitor expectations with the operational reasoning of decision-makers in the sector.

In order to ensure methodological rigor, the study addressed both validity and reliability. Content validity was supported through the review of research tools by specialists in architecture, interior design, and wellness tourism, ensuring that the questionnaire items and analytical categories were conceptually aligned with the objectives of the study. The internal consistency of the questionnaire was tested using Cronbach’s alpha, and the analysis showed an acceptable level of reliability for the overall scale. This supports the consistency of the empirical data used in the interpretation of guest perceptions and their relationship to spatial and operational variables. Data analysis combined quantitative descriptive analysis and qualitative interpretive analysis. Questionnaire data were analyzed using means and standard deviations in order to assess the perceived levels of therapeutic component availability, the degree of user preference for such systems, and experiential tendencies such as satisfaction and revisit intention. Interview data, by contrast, were subjected to thematic analysis in order to extract recurring patterns and managerial interpretations. The integration of these two forms of evidence was not treated as a mechanical combination of data types, but as an interpretive integration process through which spatial

observations, user perceptions, and managerial insights were brought together in the analytical matrices and figures of the study. In this way, the study moves from diagnosis to interpretation, and from interpretation to design implications.

Finally, the scope of the study is subject to several limitations that define its analytical boundaries. The research is limited to six operating hotels in the Dead Sea region and relies on descriptive and interpretive analysis, rather than advanced predictive statistical modeling. It is further limited to the spatial–functional analysis of therapeutic systems and does not extend into detailed structural engineering analysis or precise economic modeling.

Nevertheless, the study offers strong analytical transferability to other wellness destinations characterized by distinctive environmental resources, especially where the challenge lies not in the absence of therapeutic potential, but in the lack of its systematic architectural translation.

RESULTS

This section presents the empirical and spatial findings derived from the typological framework, spatial assessment of hotels, guest questionnaires, and semi-structured interviews. The results are structured in alignment with the analytical sequence of the study, ensuring consistency between the conceptual model, methodological framework, and empirical outcomes.To support the interpretation of these findings, Figure 6 illustrates the intended functional–spatial structure of wellness-oriented hotels, where therapeutic, accommodation, and recreational systems are integrated within a unified place-based spatial model derived from the environmental resources of the Dead Sea.

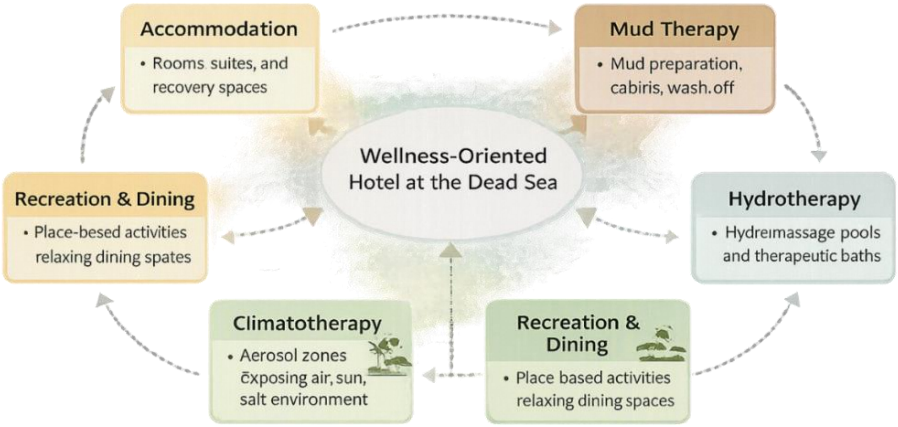

Figure 6. Functional–spatial structure of wellness-oriented hotels at the Dead Sea

Spatial Assessment of Wellness-Oriented Systems

The spatial evaluation of the selected Dead Sea hotels reveals a consistent pattern of partial or absent integration of wellness-oriented spatial systems, as summarized in Table 2. The results show that existing hotels predominantly implement wellness components in a fragmented and non-sequential manner, where therapeutic functions are embedded within conventional spa facilities rather than organized as integrated spatial systems.

Table 2. Spatial assessment of wellness-oriented systems in Dead Sea hotels

Wellness Spatial System	Core Spatial Components	Presence	Current Spatial Implementation	Key Spatial Gap
Mud therapy system	Mud cabins, preparation, wash-off, recovery	Partial	Symbolic spa-based treatments	No integrated treatment sequence
Dead Sea bathing sequence	Controlled sea access, hygiene, shaded rest	Partial	Direct sea access only	Missing safety and recovery zones
Hydrotherapy system	Therapeutic baths, hydromassage	Partial	Generic spa pools	Not resource-specific
Thermal bathing system	Thermal pools, rest zones	No	Not available	Entire system absent
Climatotherapy spaces	Aerarium, solarium, shaded decks	No / Partial	Leisure terraces only	Climate not used therapeutically
View-based recovery spaces	Recovery lounges with views	Partial	Views limited to restaurants	No post-treatment recovery logic
Inhalation / aerosol therapy	Inhalation rooms	No	Not provided	Entire function absent
Drinking cure facilities	Drinking hall, walking gallery	No	Not provided	Therapeutic ritual absent
Therapeutic physical culture (LFC)	Rehab gym, wellness screening	Partial	Fitness gym only	No wellness integration
Inclusive therapeutic pools	Accessible therapeutic pools	No	Standard pools only	Exclusion of disabled users
Narrative / identity spaces	Interpretive interior elements	No	Neutral hotel interiors	No sense of place
Cultural & evening spaces	Cultural halls, low-noise leisure	Partial	Entertainment lounges	Not wellness-integrated
Family wellness support	Children centers linked to wellness	No	Play areas only	No family-therapy logic

Guest Perception of Wellness Availability

The results of the questionnaire analysis indicate that the perceived availability of therapeutic spatial components is generally low to moderat**e**, while the desire for such components is consistently high**.** Specifically:

- Systems such as hydrotherapy, mud therapy, respiratory therapy, and psychological therapy recorded low availability levels.
- In contrast, recreational facilities (e.g., swimming pools) recorded the highest availability levels.

This divergence reflects a clear expectation–availability gap**,** where user demand for integrated therapeutic systems is not met by the current spatial configuration of hotels.

Visitor Experience Outcomes. The evaluation of visitor experience reveals that:

- Overall satisfaction levels are moderate
- Return intention is low
- Recommendation intention is limited**,** particularly for therapeutic purposes

These findings indicate that the current hotel environments do not deliver a fully integrated wellness experience, but rather a partial leisure-based experience with limited therapeutic depth**.**

Operational Insights from Interviews. The results of semi-structured interviews with hotel owners and managers show a strong recognition of the relationship between therapeutic spatial systems and hotel performance. Key insights include:

- The absence of integrated wellness systems limits the ability of hotels to attract long-term demand
- The integration of therapeutic spatial systems is perceived as essential for increasing length of stay and occupancy rates
- There is a clear need for a fully specialized wellness-oriented hotel model in the Dead Sea region

At the same time, the findings reveal a gap between strategic awareness and actual spatial implementation**,** where most hotels continue to operate under conventional hospitality models.

Synthesis of Key Findings. The results of the study can be synthesized into five core findings:

- Wellness-oriented spatial systems are largely absent or partially implemented
- Recreational functions dominate over therapeutic spatial systems
- There is a significant gap between user expectations and actual spatial provision
- The current spatial configuration negatively affects visitor experience and loyalty
- There is a strong perceived link between spatial systems and operational sustainability

These findings provide a robust empirical and spatial basis for the subsequent interpretive discussion.

DISCUSSION

This section interprets the findings of the study in relation to the conceptual framework (Figure 4) and the therapeutic spatial sequence (Figure 1), linking spatial assessment results, user perceptions, and managerial insights within a unified explanatory structure.

From Environmental Resource to Spatial System: A Design Gap

The results demonstrate that the primary challenge facing Dead Sea hotels is not the absence of environmental or therapeutic resources, but the lack of their systematic translation into integrated wellness-oriented spatial systems.

Although the Dead Sea possesses exceptional therapeutic assets, the spatial assessment results (Table 2) show that these resources are rarely organized within coherent therapeutic sequences. Instead, they are implemented as isolated or symbolic functions embedded within conventional spa environments.

This finding aligns with the literature on healing architecture and place-based wellness tourism, which emphasizes that therapeutic value emerges not from the presence of resources alone, but from their integration into structured spatial systems linking arrival, treatment, recovery, and place-based experience (Al Maani & Mubaideen, 2024; Bell, 2018; Dilani, 2008; Gesler, 2003; Smith & Puczkó, 2014; Sthapit et al., 2025; Ulrich et al., 2008). Accordingly, the identified gap in Dead Sea hotels can be defined as a design-structural gap, rather than a resource or location-based limitation.

Fragmentation of Spatial Systems and Loss of Therapeutic Depth

The dominance of recreational functions over specialized therapeutic systems represents a critical structural imbalance. The results show that facilities such as swimming pools and general spa services are widely available, while specialized therapeutic components—such as climatotherapy, respiratory therapy, and integrated recovery spaces—are either absent or weakly implemented (Table 2). This imbalance reduces the spatial depth of the wellness experience**,** transforming it into a short-term leisure-oriented stay rather than an integrated therapeutic journey.

Consistent with healing architecture theory, the absence of a clear therapeutic spatial sequence limits both the effectiveness of treatment and the experiential connection between the visitor and the place (Ritchie, 2003).Thus, fragmentation at the spatial level directly translates into fragmentation at the experiential level.

Expectation–Reality Gap and Its Impact on Tourist Loyalty

The questionnaire results reveal a clear divergence between high user demand for therapeutic components and their low level of actual availability**.** This expectation–reality gap is directly reflected in visitor experience indicators, where satisfaction remains moderate and both return intention and recommendation levels are relatively low.

These findings confirm that the current spatial configuration of Dead Sea hotels does not support a complete wellness experience, limiting the potential for developing long-term relationships between visitors and the destination. This observation is consistent with global wellness tourism trends, which indicate that spatial coherence and experiential completeness are key determinants of tourist loyalty and length of stay.

Spatial Integration as a Driver of Operational Sustainability

One of the most significant contributions of the study lies in establishing a direct relationship between spatial organization and operational performance. The results of interviews with hotel owners and managers indicate a strong awareness that improving therapeutic spatial systems contributes to increasing occupancy rates, extending length of stay, and diversifying demand. This finding shifts the role of architecture from a passive container of functions to a strategic operational driver, where spatial integration becomes a key mechanism for enhancing competitiveness and reducing seasonality. In this sense, the relationship between design and occupancy is not merely associative, but structurally embedded in how the therapeutic experience is organized. While the study adopts a design-based interpretive approach, the identified relationships are supported by converging evidence from spatial assessment, user perception, and managerial insights.

Design Implications: From Diagnosis to Spatial Strategy

Based on the spatial gaps identified in Table 2, the study translates its findings into a set of design-oriented implications, summarized in Table 3**.** The implications emphasize that improving wellness tourism performance does not necessarily require large-scale construction interventions, but rather a reorganization of spatial relationships. Key principles include:

- Reconstructing the therapeutic spatial sequence from arrival to recovery
- Integrating environmental resources (climate, views, minerals) as active spatial systems
- Prioritizing recovery spaces as essential components of the therapeutic process
- Enhancing place identity through material, narrative, and spatial strategies

These principles demonstrate that wellness-oriented spatial systems should function as generative elements of architectural organization, rather than as secondary service additions.

Table 3. Design Implications Derived from Spatial Gaps in Dead Sea Hotels

Identified Spatial Gap (from Table 2)	Design Implication	Spatial Strategy	Expected Impact on Tourist Experience	Expected Impact on Operational Sustainability
Absence of integrated treatment sequences	Reinforce therapeutic spatial sequencing	Organize spaces as Preparation → Treatment → Recovery → Experience	Enhanced therapeutic continuity and user comfort	Increased length of stay and repeat visitation
Symbolic or fragmented wellness functions	Transition toward place-based wellness systems	Integrate Dead Sea resources into the core spatial organization	Strengthened authenticity and sense of place	Improved destination differentiation and competitiveness
Underutilization of climate and views	Activate environmental resources as therapeutic assets	Develop climatotherapy zones and view-oriented recovery spaces	Improved psychological restoration and environmental immersion	Cost-efficient enhancement of wellness value and reduced seasonality
Missing post-treatment recovery spaces	Prioritize recovery as a core spatial phase	Introduce dedicated recovery lounges linked to treatment zones	Increased relaxation, satisfaction, and perceived quality	Improved treatment effectiveness and customer retention
Generic spa implementations	Replace generic spa logic with resource-specific systems	Design hydrotherapy and mud therapy around local environmental conditions	Unique and place-specific wellness experience	Stronger competitive positioning in wellness tourism markets
Absence of specialized therapeutic systems	Introduce targeted therapeutic components	Integrate inhalation therapy, respiratory treatments, or drinking-cure facilities	Expanded therapeutic scope and user relevance	Diversification of demand and improved market resilience
Lack of narrative and identity expression	Embed place-based narrative within spatial design	Integrate cultural, environmental, and material storytelling elements	Increased memorability and emotional attachment	Strengthened branding and destination identity
Exclusion of specific user groups	Promote inclusive wellness environments	Design accessible therapeutic pools and family-oriented wellness zones	Broader accessibility and inclusive user experience	Expansion of target market segments and improved occupancy stability

Toward a Place-Based Wellness Hotel Model

Figure 7 synthesizes these implications into a conceptual transformation from a generic hotel model to a place-based wellness-oriented model. This transformation is not limited to adding therapeutic facilities, but requires a fundamental reconfiguration of spatial logic, where environmental resources become structurally embedded in the organization of space and experience. Accordingly, the study contributes to the literature by proposing an integrated framework that connects:

- Environmental context
- Spatial systems
- Tourist experience
- Operational sustainability within a unified architectural perspective.

Figure 7. Conceptual transformation from a generic hospitality model to a place-based wellness-oriented hotel architecture model, illustrating the integration of environmental resources into spatial systems and experiential outcomes. (Source: Authors)

CONCLUSION

This study demonstrates that the challenges facing wellness tourism in Dead Sea hotels are not rooted in the absence of environmental or therapeutic resources, but in the lack of a coherent spatial logic capable of translating these resources into integrated wellness-oriented spatial systems. By combining a typological framework with spatial assessment and empirical analysis, the findings reveal that the fragmented or symbolic implementation of therapeutic components significantly weakens the continuity of the wellness experience and limits the operational sustainability of hotel performance.

In contrast, the results confirm that the effectiveness of wellness tourism depends on the extent to which therapeutic systems are treated as generative elements of architectural organization, rather than as secondary service functions.

The study further establishes a direct relationship between place-based design, the depth of the therapeutic experience, and key indicators of operational performance, particularly occupancy stability and visitor retention.

This relationship highlights the role of spatial integration as a mediating mechanism through which environmental resources are transformed into measurable experiential and economic value. In this sense, the research contributes to the literature by proposing an integrated analytical–design framework that links environmental context, spatial systems, tourist experience, and operational sustainability within a unified model. Beyond the specific case of the Dead Sea, the findings provide transferable design principles applicable to other therapeutic destinations characterized by distinctive environmental resources. Ultimately, the study repositions architecture and interior design from a passive supportive role to a strategic operational driver, capable of structuring therapeutic experience, enhancing destination identity, and supporting long-term sustainability in wellness-oriented tourism environments.

Limitations and Future Work

This study is subject to several limitations that define its analytical scope and should be considered when interpreting the results. First, the research is limited to a sample of six operating hotels in the Dead Sea region. While this sample is appropriate for in-depth spatial and design-oriented analysis, it does not aim to provide statistical generalization, but rather analytical insights into the relationship between spatial systems and wellness tourism performance within a specific environmental context. Second, the study relies on a Design-Based Mixed-Methods Approach combining spatial assessment, user perception, and managerial insights. Although this triangulated methodology strengthens the interpretive

validity of the findings, the quantitative component is primarily based on descriptive statistical analysis, without the use of advanced predictive or causal modeling techniques. Third, the research focuses on the spatial–functional dimension of wellness-oriented systems and does not extend to detailed economic modeling, cost–benefit analysis, or long-term financial performance indicators. As such, the operational implications discussed in the study should be understood as analytically derived relationships rather than fully quantified economic outcomes.

Despite these limitations, the study provides a robust analytical framework that can be adapted and extended in future research. Further studies may build on this work by incorporating advanced statistical modeling approaches (e.g., structural equation modeling or predictive analytics) to quantify causal relationships between spatial systems and operational performance. Additionally, expanding the geographical scope to include comparative case studies across multiple wellness destinations would enhance the generalizability of the findings.

Future research could also explore the economic dimension of place-based wellness design, including investment feasibility, return on spatial interventions, and long-term performance metrics. Moreover, deeper investigation into user-centered design variables, such as behavioral mapping and physiological response to therapeutic environments, would further strengthen the integration between architecture, health outcomes, and tourism experience.

In this regard, the present study establishes a foundation for a more integrated research agenda linking environmental context, spatial design, user experience, and operational sustainability in wellness-oriented tourism environments.

Abstract: Governance is recognised as crucial for supporting transfrontier conservation and regional cooperation; however, how governance processes translate into regional destination development outcomes across the different scales of the TFCA grounds the premise of this research. Attention is drawn to the Kavango Zambezi Transfrontier Conservation Area (KAZA TFCA) in Southern Africa, which, although formally institutionalised in 2011, has been under development since 2006, thereby providing an opportunity to examine the progress of tourism development in the region since the signing of the Memorandum of Understanding (MoU). This research aimed to explore the progress of tourism and community development as shaped by governance and stakeholder processes. This qualitative research draws on insights from interviews with tourism and governing authorities, community organisations, and community representatives located in tourism-dependent destinations in the TFCA, namely Kasane in Botswana, Livingstone in Zambia, and Hwange in Zimbabwe. The findings demonstrate that the KAZA TFCA has created an enabling environment for regional tourism development through improved cross-border mobility, regional cooperation, destination marketing, and tourism-supporting infrastructure. However, the translation of regional integration into local tourism development remains constrained by policy inconsistencies across member states, limited tourism-specific support, weak integration between regional governance structures and local tourism stakeholders, and challenges affecting tourism businesses. Overall, the findings suggest that the effectiveness of Transfrontier tourism governance depends not only on establishing regional agreements and structures, but also on their effective coordination, harmonisation, and implementation across national and local levels to ensure that regional tourism growth generates inclusive and equitable socioeconomic benefits.

Keywords: transfrontier conservation areas, meta-governance theory, regional tourism development, KAZA TFCA

INTRODUCTION

A considerable amount of research has been published on Transfrontier Conservation Areas (TFCAs), with studies focusing on their progress towards ecological outcomes (Naidoo et al., 2022; Trezza et al., 2026; Köhler & Bollig, 2025), or their contributions to poverty alleviation and community development (Mpofu et al., 2025; Bourgeois et al., 2023). This is due to the underlying goals of these transboundary protected areas; being to balance nature conservation with community livelihoods and development (Lekgau & Tichaawa, 2026; Mpofu et al., 2026).

Certainly, since their initial conception in 1920, TFCAs have become globally recognised as innovative means for broadening nature conservation, with such initiatives strengthened by the underlying collaboration and sharing of resources to tackle escalating, interrelated and intersecting concerns related to biodiversity conservation, poverty alleviation and regional development (Munthali, 2007; Usman et al., 2023). Notably, Southern Africa is a global leader in TFCA development, with TFCAs covering over 10% of the land mass of the region (Southern African Development Community [SADC], 2025). Currently, TFCAs in the region are facing a myriad of emerging challenges, including rising human and wildlife populations, human-wildlife encroachment into each other's spaces and subsequent conflict, and changing natural processes, such as changing and extreme rainfall patterns, temperatures and vegetation.

These challenges require multilevel governance and collaboration to address, while simultaneously balancing other goals, including community development, economic growth, regional cooperation and peace, and tourism (Lekgau & Tichaawa, 2021, 2026; Mpofu et al., 2026). As the latter goal is foregrounded to support the attainment of these other goals, the current study deviates from the predominant environmental focus on TFCAs in the region and shifts attention towards regional cooperation, tourism development and community development.

Communities in Southern Africa have utilised wildlife and wilderness resources for livelihood benefits, including subsistence hunting, harvesting of wild plants and other natural resources, livestock grazing, small-scale agriculture, and participation in wildlife- and tourism-related activities, with the latter considered a sustainable form of livelihood that can

generate substantial economic returns and growth. Wildlife tourism is a key lucrative market in Southern Africa, taking two primary forms: consumptive and non-consumptive (Lekgau & Tichaawa, 2026; Van der Merwe & Slabbert, 2025).

The region offers numerous wildlife experiences, with the dissimilarity of tourism products, including the diversity of wilderness and cultural landscapes, key attractions and experiences in the region, and the establishment of TFCAs, being key to stimulating cross-border tourism movement and collaboration (Blasco et al., 2014). This is especially the case in the Kavango Zambezi (KAZA) TFCA, which has been utilising well-known natural attractions such as the Okavango Delta, Victoria Falls and Hwange National Park to maximise tourist stays in the region and trigger scaffolding effects for rural development and community livelihood support. Undeniably, recent research has underlined governance as a mechanism to stimulate and support this process, with governance across borders constituting a complex task of recognising, coordinating and collaborating with several countries, communities, businesses, NGOs and various levels of government authorities (Blasco et al., 2014; Mpofu et al., 2026; Dittmann & Muller-Mahn, 2023; Tichaawa & Lekgau, 2025).

Governance and institutional perspectives on tourism at regional scales posit that the development of tourism for regional socioeconomic growth should be viewed as a process rather than an end goal (Stoffelen & Vanneste, 2017).

Accordingly, this study considers the KAZA TFCA, which, although formally institutionalised in 2011, was under development since 2006 through the signing of a Memorandum of Understanding (MoU), which laid the groundwork to formally establishment this TFCA which is the largest TFCA in the world shared by Angola, Botswana, Namibia, Zambia and Zimbabwe. There is therefore an opportunity to explore the progress of tourism development in this TFCA region since the signing of the MoU. This TFCA was primarily designed to foster cross-border conservation and tourism development, and therefore an intellectual opportunity exists to understand the effects of supranational governance processes on regional and local tourism dynamics. While existing research has increasingly recognised the role of governance in supporting Transfrontier conservation and regional cooperation, less attention has been given to understanding how these governance processes translate into regional destination development outcomes across the different scales of the TFCA. In particular, there remains limited understanding of how regional agreements and governance structures are translated into tourism development at national and local levels, and how the coordination, harmonisation and collaboration amongst different stakeholders influence the development of an integrated regional tourism destination.

This is particularly important in the context of TFCAs, where tourism development is expected to contribute to broader objectives of regional integration, community development and socioeconomic growth, but where tourism stakeholders operate within different national policy and institutional environments. This study therefore draws on a meta-governance perspective to explore the regional tourism development process within selected KAZA TFCA sites, with particular attention to how Transfrontier governance processes enable and constrain regional tourism destination development and the extent to which regional tourism objectives are translated into local tourism and community development outcomes.

LITERATURE REVIEW

From cross-border tourism to Transfrontier tourism

Cross-border tourism has increasingly been conceptualised as more than the movement of tourists across national boundaries, but, a process through which geographically proximate territories in different jurisdictions can be experienced, marketed and potentially governed as an integrated tourism destination (Studzieniecki et al., 2016; Makkonen & Williams, 2024). This perspective challenges conventional approaches to destination development that remain largely organised around administrative and national boundaries (Su & Li, 2021). Blasco et al. (2014), for example, argue that tourism destinations should increasingly be understood according to tourists' consumption patterns rather than administrative boundaries, particularly where neighbouring destinations are geographically proximate and offer complementary attractions. From this perspective, cross-border tourism emerges where the functional geography of tourism extends beyond the political geography of the state. The cross-border character of tourism can consequently create opportunities for destinations to combine attractions, infrastructure, markets and tourism resources across jurisdictions (Makkonen & Williams, 2024; Stoffelen & Ioannides, 2025). Cross-border collaboration can also provide opportunities for destinations to develop joint products, strengthen destination competitiveness, exchange knowledge and practices, and potentially increase visitor flows and tourism income (Kozak & Buhalis, 2019). In this respect, cross-border tourism can be understood as a mechanism for overcoming the fragmentation created by political boundaries and creating a broader tourism space that corresponds more closely to how visitors experience destinations (Su & Li, 2021).

However, the literature cautions against assuming that geographical proximity automatically translates into an integrated cross-border tourism destination. In their study, Stoffelen & Vanneste (2017) found that local cross-border tourism projects do not guarantee positive regional-development outcomes and may, under certain circumstances, reinforce existing socioeconomic asymmetries between neighbouring territories. Their findings as such as others suggest that the developmental contribution of cross-border tourism depends less on the number of tourism projects undertaken and more on the institutional arrangements through which these projects are embedded (Wong Villanueva et al., 2022; Stoffelen & Ioannides, 2025; Lekgau & Tichaawa, 2019). Accordingly, governance represents a central theme within the cross-border tourism literature. Cross border cooperation, and subsequently governance has become a common and fundamental strategy used to leverage on opportunities within border territories, through their integration (Wong Villanueva et al., 2022; Blasco et al., 2014; Ferrer-Roca et al., 2022). In Eastern and Southern Africa, this integration is primarily through TFCAs, which seek to leverage collective resources for broad scale conservation interventions and promoting complementary sustainable livelihoods, through wildlife tourism. Transfrontier tourism, or transboundary tourism, therefore, represents the development and organisation of a regional tourism destination within TFCAs (Mayer et al., 2019). Indeed, while many

studies have made the argument that wildlife, natural resources and their ecosystems transcend territorial and political borders and therefore require transboundary approaches to their protection and conservation, this study goes further to contend that the leveraging of these resources for tourism should also transcend national boundaries. This requires tourism development and governance processes to similarly reflect the transboundary nature of the resources upon which the tourism industry depends. Therefore, in understanding the complexities in politics and governance of multiple places and networks operating at various scales individually and collectively, with variable socio-spatial and socio-temporal articulations in the local destination, we leverage the meta-governance theory, which is unpacked in the discussion below.

Meta-governance and the TFCA perspective

Meta-governance is considered an evolutionary form of government and governance perspectives, where the latter gained much academic interest in the 1980s and typically represents a shift from hierarchical decision-making models to network-based and collaborative decision-making arrangements (Yankson, 2024). The criticisms of the governance model and its policies lie in the related market, network and state failures, which have led to attempts at redesigning governance arrangements to balance the various models of governance, thereby situating meta-governance within this discourse (Jessop, 2016; Jones, 2023). Meta-governance emerged as a response to these governance complexities by recognising the continuing strategic role of the state in coordinating diverse governance arrangements rather than directly controlling them (Bornemann et al., 2025; Ek Österberg & Qvist, 2022). Accordingly, meta-governance has been defined as "a practice by (mainly) public authorities that entails the coordination of one or more governance modes by using different instruments, methods and strategies to overcome governance failures" (Gjaltema et al., 2020:1771).

Rather than replacing governance networks, meta-governance provides the institutional architecture through which governments facilitate collaboration, manage competing interests and steer collective action towards agreed policy objectives (Ek Österberg & Qvist, 2022). Applied to tourism, this perspective suggests that the role of government in a cross-border destination is not necessarily to directly control tourism development, but to create the institutional conditions through which collaboration becomes possible (Lindström, 2024). This may include establishing enabling policies, facilitating partnerships, providing funding, connecting actors across administrative scales, developing common planning frameworks and addressing institutional asymmetries (Jessop, 2016).

The relevance of meta-governance is particularly evident within TFCAs, where conservation, tourism development and community development are negotiated across multiple sovereign states and diverse stakeholder groups. The KAZA TFCA represents a complex governance landscape comprising national governments, the KAZA Secretariat, conservation authorities, tourism organisations, community representatives, traditional leaders, non-governmental organisations and international development partners. These actors possess distinct mandates and priorities, yet are expected to collectively pursue shared objectives relating to biodiversity conservation, regional integration, tourism development and livelihood improvement. Therefore, grounding this research in the meta-governance framework enables an examination of how diverse stakeholders and coordination mechanisms operate under a consolidated governance structure within cross-border destinations, particularly those guided by several interconnected objectives. In particular, this research seeks to understand the ground-level tourism effects of meta-governance processes. The meta-governance perspective therefore provides a lens through which to examine how institutional mechanisms shape the conditions under which cross-border tourism development becomes possible.

METHODOLOGY

Study areas

The study was conducted in three tourism nodes within the KAZA TFCA, namely Kasane in Botswana, Livingstone in Zambia and Hwange in Zimbabwe. These sites were purposively selected based on their proximity to prominent tourism attractions within the KAZA landscape, namely Chobe National Park, Victoria Falls and Hwange National Park, respectively. The three locations represent important tourism destinations within the KAZA TFCA and are characterised by established wildlife and nature-based tourism activities, making them appropriate sites for examining tourism development within the Transfrontier context. The selection of these sites was also informed by their relative geographical proximity to one another, despite being located across three different national jurisdictions.

This proximity provides an appropriate context for examining the cross-border dynamics associated with tourism development, including tourist mobility, interactions between tourism stakeholders, regional tourism linkages and the influence of Transfrontier governance processes. By focusing on tourism nodes that are geographically connected through the broader KAZA landscape but administratively separated by national borders, the study was able to explore how regional tourism development processes are experienced and implemented at national and local levels.

Research approach

We followed a qualitative research approach, drawing data from semi-structured interviews with governing officials representing tourism and conservation departments, tourism businesses owners and managers as well as tourism entrepreneurs in the formal and informal economy, traditional and recognized community leaders, community-based tourism organisations' leaders and some members, and community members directly involved in the tourism industry. The interview questions were developed from a synthesis of literature on TFCA governance and community development, cross border tourism integration, and wildlife tourism and community. Accordingly, the questions were grouped under three interrelated categories; perceptions towards KAZA governance, tourism developments under the KAZA regime and

challenges hampering regional tourism growth. The semi-structured interview approach allowed for the researchers to probe further, ensuring full elaborations on each key thematic areas. The participants were selected using a purposive sampling technique, where participants were targeted based on their direct involvement, knowledge and expertise in wildlife tourism in the study sites. In terms of operationalization, key individuals representing the targeted sample groups were identified and approached and time spent in the field revealed other participants who were not on the original list, for instance, the researchers found a local tourism association in Zambia representing in informal market, of which its position in the town as well as goals of the KAZA necessitated it inclusion. We conducted a total of 59 interviews and group interviews in Kasane, Lusaka and Hwange, as shown in Table 1 below.

Table 1. Participant profiles

Participant code	Stakeholder group	Location
P1-2	Tourism and conservation authority representatives	Kasane
P3-4	Community trusts' representatives	Kasane and Kazungula
P5-9	Informal tourism entrepreneurs	Kasane
P10-11	Local traditional authorities	Kasane
P12 – 17	Formal tourism businesses	Kasane
P18 - 22	Community members involved in wildlife tourism	Kasane
P23-25	Conservation NGOs representatives	Livingstone
P26	Conservation authority representative	Livingstone
P27	Tourism association representative	Livingstone
P28 – 31	Informal tourism entrepreneurs	Livingstone
P32- 37	Formal tourism business owners/ managers	Livingstone
P38 - 41	Community members involved in wildlife tourism	Livingstone
P42 – 46	CAMFIRE representatives	Hwange
P47 – 49	Tourism and conservation authority representatives	Hwange
P50 – 55	Informal tourism entrepreneurs	Hwange
P56 – 59	Formal tourism business owners/ managers	Hwange

In most cases, interviews were conducted in English, however some participants preferred local languages which led to some interviews being conducted in Setswana in Kasane, Bemba in Lusaka and Ndebele and Shona in Hwange. The research obtained ethical clearance prior to its commencement and participants were assured of their voluntary involvement, confidentially of information and were asked for their consent in the recording of the interviews.

Data recordings were loaded onto Otter.ai for transcription, of which the output was reread and edited to ensure consistency and that contexts were captured in the transcripts. Following, the transcripts were loaded onto Atlas.ti, in which a descriptive line by line coding technique was utilized.

This process yielded 539 codes, which were subsequently reread and merged to reduce repetition. Following, similar codes were grouped together, forming the key themes which are discussed in the following section.

RESULTS

Regional integration and conservation governance

Perceptions of the KAZA TFCA revealed mixed responses on their understanding of this regional initiative, particularly as there were a significant portion not aware of the TFCA agreement amongst the five countries, through were aware of the outcomes of this transboundary collaboration. Participants that aware of the KAZA TFCA agreement described the TFCA has a means to recognise the shared ecosystems amongst the five member states. Certainly, participants alluded to the inherent collaborative nature of the partnership, underscoring the significance of its premise to conservation, tourism development and economic growth, goals which bare crucial implications for community livelihoods in the study areas.

> Because this protocol [is] between countries, a bilateral agreement between five countries because they share the waters, they share the wildlife and everything. There's also community involvement and stakeholder involvement, they [KAZA management committees] do public education. At the kgotla, here we go, they educate people and they are quite collaborative [P10 - Kasane]

Certainly, the few participants who understood this agreement, and its outcomes, had an optimistic view on its contribution towards various facets of development in the region. Largely, this optimism was directed towards harmonizing the relationships between communities and protected areas, communities and tourism as well as facilitating cooperation and social capital amongst communities in the different member states. One participant in Hwange, aptly explains:

> Because for instance, we are giving an opportunity for the TFCA, in this community, to work together and lower barriers between people in the [member] countries. And instead of us promoting conflict between the community and the Transfrontier [conservation area] [P48- Hwange]

While the understanding of KAZA TFCA as an entity was not widely understood across the study sites, the creation of wildlife corridors, being one of the key objectives of the TFCA, was widely acknowledged amongst many participants involved in this study. This may have been attributed to the information and training occurring at the local destination scale, with limited explicit linkages to the KAZA agreement, that neighbouring countries share ecosystems and subsequently wildlife, which belong to the region and not necessarily the individual states. This understanding was determined in the discussions with communities' representatives in the study sites, and captured with the quotes below:

KAZA [TFCA] is the five countries [that] have come together. They are being brought together, like their story in Germany, it was to discuss and have agreements and we have those agreements. So if animals leave Zimbabwe, they are not Zimbabwean animals, they become Zambia animals. Yes, if the leave Zambia they do to… that's how it is works. So those are just like agreements, that KAZA made. [P24 – Livingstone]

KAZA also created key wildlife corridors and free space for wildlife movement, thereby improving the gene pool for the benefit of wildlife populations and also conservancies, which will always continue to get wildlife coming from other rich protected areas like the Hwange National Park. [P47 - Hwange]

Interestingly, the study participants in Hwange underscored the centrality of inclusivity and trust in the transboundary conservation body, owing to the resources provided to support community development goals. Notably, these participants explained that CAMPFIRE was an integrated early on in the initial discussions around the KAZA, owing to the community based organisation being forefront in highlighting the concerns with the then practices of nature conservation and related community development support.

[The] relationship between the Transfrontier conservation area and the community can be served as collaborative, partnership based, trust based, empowering, respectful, inclusive and supportive in the sense that TLCA provides support and resources to help the community achieve their goals [P48 – Hwange]

That's why they came up with this Transfrontier, KAZA. It came reality through the communities exposing those irregularities [between park management and community needs]. So now KAZA is a solution to bring national parks, forestry, [those] who advise [and are] involved council together. [P33ZW

Though the KAZA TFCA is a partnership amongst five member states, a few participants reflected on the long-term aspirations of this partnership towards the future generations, *'As you know, it's like a vehicle which is being used to serve our needs, necessities to the future generations, so that our grandchildren, what overcome our generation will be now be for them'* (P42 – Hwange) as well as the broader continent and what it could someday represent. In this light, the success of the TFCA was perceived as a positive movement a more unified African continent, with some participant espousing "*If other presidents could hear the President's speech, the support, once you build yourself like that, other countries will start joining if it works out then as you can continue to have one Africa'* P26 – Livingstone.

However, despite the importance underlined above, it is important to report that a couple of participants expressed concerns over the KAZA management structure, particularly in relation to the prevalence of international donor funding organisations. One participant especially viewed this TFCA as a form of neocolonialization, stating:

I'll tell you this not because I have got a political path, but because KAZA for me is like a colonial kind of rule. And I'll explain this to you soon, KAZA is connected to like five countries. We have in the indigenous people in those countries, you know, you know, how their system works, they get in Zambia, they get, like they exchanged like leadership, and whatnot. But those are controlled by foreigners [P39 – Livingstone].

These concerns were directed towards the conservation ideologies and practices that would be utilized in the collaborative governance of nature and wildlife conservation, and relatedly tourism sector, and the implications for the role of the community in these interrelated sectors, particularly in terms of equity, representation, ownership and empowerment.

Regional tourism product development and destination competitiveness

One of the major outcomes and achievements of the KAZA TFCA agreement since its formalization, is the related to the easing of movement between the countries. On the tourism development front, the member states have introduced the concept of the KAZA UniVisa, which seeks to enable easier and seamless movement between the member states. While, this is currently being piloted between Zimbabwe and Zambia, participants attribute this as a positive step towards developing a regional tourism product. Some governing officials explained that this is still in its developmental stages:

They are also bilateral agreements between the countries. Of note also is the univisa that is currently being piloted, which is being piloted between Zimbabwe and Zambia. So if you get a visa from one of the countries you are allowed to go to all the five member states without having to reapply for another visa, it is the case. Because now, we're still piloting, like still at pilot stage, so we haven't fully rolled out. [P1 – Kasane]

Indeed, the easing of the border movements is greatly perceived as an enabling factor to leveraging on the unique resources of the individual states and forming a stronger destination product, enabling tourism growth within each state. Participants mentioned the proximity of the key destinations to one another and ability to build a travel itinerary that cross multiple countries in one day, with one tour operator highlighting the distinctiveness of such experiences in the broader Southern Africa region:

And we're also situated in an area where you can visit the three countries [in] one day, you can have breakfast in Kasane in Botswana have lunch in Zimbabwe have dinner in Zambia and be back in bed in Botswana. And nowhere else in the Southern Hemisphere can you do that. One guest just argued to me and said 'but you know in South Africa you can go to Lesotho and that's it'. That's true. I've just said Botswana, Zimbabwe, Zambia, Namibia, you can get your passport stamped four times in one day. So here's the beauty of operating in this area [P16 – Kasane]

Similarly, participants further mentioned the infrastructural improvement of the Kazangula border post, connecting Botswana and Zambia as facilitating easier border crossing and movement between the two countries. Notably, other participants underline the missed opportunity to integrate Zimbabwe in this border, '*Right now, one of our other challenges is that since Zimbabwe was not part of the Kazungula border*.' (P22- Livingstone). Generally, the efforts undertaken thus far have enabled the development of a unified destination brand, leveraging on the share wildlife resources and wilderness spaces. In this light, the cultural resources pose another resource that can be leveraged to support the existing primary

wildlife tourism product. In this regard, participant point to the cultural differences amongst the three countries as opportunities to be explored by tour operators and tourism marketers for the region, stating:

And cultures. Because it's not only wildlife tourism that caused this to tie within our communities, you know, the difference in Angola, difference in Namibia, difference in Zambia and difference in Zimbabwe. So we could target those things, you know, as the community of tour operators, or the governments, you know, to sell this product, which we think, you know, is quite unique. Yeah. But we're not there yet. [P2 – Kasane]

So many villages here, the government helps to establish like a cultural village, where all the ladies, old people can showcase their talent through weaving, basket weaving, having making skills, so tourists will come see dances, culture, dresses, showcasing their culture [P49 – Hwange].

The promotion of cultural resources, products and experiences as part of the KAZA tourism landscape was grounded to being another means to extend the potential of tourism to provide livelihood benefits to residents that are not able to enter the wildlife tourism market. Evidently, the discussions on regional tourism product development revealed some missed opportunities. Also, while participants recognise that there has been increased marketing of the region, both by individual states, businesses as well as the collective KAZA TFCA, more awareness of the region is required, particularly for natural and cultural experiences supporting the key attractions.

While this was not explicitly linked to the TFCA establishment, there was a general consensus amongst study participants, more especially in Botswana and Zambia, the tourism economy is growing and subsequently providing more income-generating opportunities for residents, largely in terms of employment and entrepreneurship developments. Similarly, some participants have alluded that the growth of tourism, the attractive natural assets and established attractions, coupled with relative stability of certain countries and focus on foreign investment policies, larger integrated tourism market due the KAZA TFCA agreement, have attracted some investors to the areas, which represent the opportunity for local communities to evolve their livelihood activities from predominantly subsistence levels. One tourism business owner cautioned that these investors need to be met openly the communities:

I think being open minded and welcoming investors. The community's understanding that people that come in here are not here to take away anything from them but to add value more than anything in what is already there. You understand? So many areas I've seen ethnic tribes be like ‘now we don't want you’ you know ‘we are just okay with our fishing’ But you can allow us to operate in your area. And we will provide a quality lifestyle both in health care and employment and you know [P16 - Kasane]

Interestingly, a number of tourism businesses owners involved in study were considering expanding their business to neighbouring countries to capitalize on the growing regional tourism market, and working with local partners in other KAZA TFCA member states:

The last year I went to Namibia because I'm trying just to on my own to try and scout for opportunities just across [the border], so that in future I know where I know where to diversify and grow my business into. [P34 - Livingstone]

However, the movement towards facilitating regional tourism development and strengthening the destination is severely hampered by the accessibility challenges in entering the region, for international tourists.

Airlines has been a major, major problem when it comes to us in the tourism industry. These is less of disadvantages. I mean, advantages. And challenges are few. But it's how the properties react towards that. Yeah, like I say, if we are working with an agent in the UK, and that person is unable to put flight together to complete their itineraries, then it means business won't materialize. We cant receive business from that particular agent. Yeah, yeah. So those are some of the challenges. [P3 - Kasane]

Similarly, a few participants recognized that the easing of border/travel barriers have already led to heightened competition amongst tourism businesses, particularly for accommodation businesses, across borders. Therefore, subsequent concerns that may arise could be related to pricing of tourism services, considering the wider destination options available for guests. In this regard, one tourism business owner already noted this issue with Zimbabwe and Zambia due to their sharing of the Victoria Falls as a key attraction, stating: “*I think the bed space, pricing, I think, we have been informed that we are a little on the higher side in comparison to our counterparts in Zimbabwe*” (P37 – Livingstone). Furthermore, other participants recognized that this regional collaborative relationship, and its benefits, are largely dependent on the vitality of the natural ecosystems, in which subsequent adverse climate changes impacts could threaten the tourism landscape, owing to its dependency on wildlife and natural resources such as extensive river systems.

I think the only thing that could destabilize is when that river dries out, Because we get that water comes all the way from Angola. Or in case where our international relations, I was with Angola, and they decided to block the water. I don't know I think government sometimes I think that is the only thing that I'm thinking of, in terms of that could that could greatly shake the tourism landscape because it's all about the wildlife and then that river sustains everything else it doesn't. So that's that river is the source of tourism its the core. (P6 – Kasane)

Governance tensions limiting tourism development

Despite the positive shift noted in the development of a regional destination product through the KAZA TFCA arrangement, however, uneven policy harmonalisation and implementation constrains tourism integration. Some of the challenges highlighted refer to the management of policies affecting local tourism businesses, border concerns, as well as political influences and nature of support for tourism businesses. The efforts to improve the accessibility amongst the countries was perceived to be hampered by the process at the borders’ posts. Some participants recall guest to have complained over the long waiting times at the border as well as some uncertainties in procedures which may cause

confusion for visitors. One participant further stated that some individuals have been exploiting this uncertainty by making false promises to guests and assisting with border paperwork. This is not permitted for agents who are not authorised to enter the border building, see quotes below:

'Okay, I think from our guests point most… the borders. Okay. They always complain about the delays of the borders. Because you know, the guys will especially the guys who drive from South Africa to here, will leave Joburg maybe about five o'clock in the morning, get to this border, maybe at six at night and spend another three hours. So we're only getting 10 at night, some 11 at night, depending on the chaos they find there.' [P33 – Livingstone]

'So I've got friends who are clearing agents. So we're just trying to see for, maybe next month, for the guys coming in from South Africa, and stuff if I could have my guy meet him there just to show them how to do the paperwork and tell them not to pay [anyone outside] because that's the process we're just supposed to do. yeah because even with that come in in the agents actually not even allowed inside the border area to clear account that needs temporary import permit and stuff. But these guys they find them outside say 'no I can do it for you' and all that so we trying to see how we can help the guests make it easier for them to come through.' [P36 – Livingstone]

Some discussions with representatives from Kasane suggest that these complaints are recognized by some government officials and under consideration by the relative authorities in the country. Another matter participants expressed concern on, and requirement of government attention was the issue of unregulated tour guiding. These concerns were largely expressed by tourism entrepreneurs in Kasane and Livingstone, where they highlight the injustice of competing with guides who have not completed the required certification and programmes and the influence this has on the guiding experience as well as income generated from the tourism industry.

'They [registered guides] are active but it's only that its hard to have those licenses, it's very hard to have those licences in tourism operations' [P12 – Kasane]

'I decided to register but then I'm paying fees, I'm legal I pay for my own licenses. It's a cost but then there are others who are doing all these things unregistered and don't have any legal consquences. Its very unfair.' [P34 – Livingstone]

'We don't have a uniform amount, legal operators will have a uniform amount. Like game drives, its $75 for internationals, so as we know it, but if you go to these that are illegal [operators], they will take $30. You know, they are putting the value down. And they make it seem like we're overcharging the client but actually that's the price.' [P37 - Livingstone]

In addition to the competition amongst legal and illegal tour guides, which extend towards how other tourism businesses, such as accommodations and activity providers are exacerbating this issue, participants underlined the importance of ensuring that national policies and their implementation are aligned with local realities and priorities. Largely, these concerned were centred on the prevalence of foreign owned businesses in the study sites, which affected local enterprises in a couple of ways. In Livingstone, some participants questioned the investor friendly policy environment created by national government, which limited the tax revenue generated from businesses that could better assist the country, while other participants noted the unfair competition amongst informal creative art traders and larger scale accommodations in selling local arts and crafts:

'So most of them [internationally owned hotels] when they come here, they come with licenses to do activities, maybe lodge, may be restaurants, but after seeing that the people that [have] visited , most of them want to buy souvenirs, they [hotels] also start selling souvenirs. So this is a good big block because they're [hotels] the people receiving guests. So it becomes a bit of contention. So those are some of the challenges, the intolerance. I think we don't have deliberate policies that can stop that.' [P29 - Livingstone]

'We need policy of some kind, you cannot go to American and start selling indigenous American art? I don't see that, it is only here in Africa where you can do that. But giving them land and they are making money out of that land. Because they are only paying their workers, the electricity and roads. So why are they encroaching in this land?' [P30 - Livingstone]

In Hwange, participants postulated that concerns with the national governing party, and the administrative challenges, had led to delays in being rewarded funds and other benefits through the KAZA TFCA, of which these support mechanisms were supposedly geared towards assisting local communities. Relatedly, participants in all study areas contended for the need to empower local entrepreneurs and local businesses, to be able to establish and grow their business and compete the tourism market. In this regard, the lack of funding opportunities from government authorities was a contentious matter, with several participants espousing the lack of financial capital experienced by a large share of the local population.

'Some of the barriers to participation is the lack of startup capital of the people, most of the people are poor, the local people don't have the capital to start companies like safari lodges, camp sites, so its the lack of funding.' [P12 - Kasane]

'I think the most top one would be funding constraints. Like the tourism department hardly gets funds. So the amount is kind of limited to bigger projects and things like that you can't really expand if you don't really have the capital' [P57 - Hwange]

'People like myself [entrepreneur] at the start, I need money to have a variety of things to do. Because let's say I want to venture into car hire, I don't have that money. Things are expensive, the dollar is high. I need like a loan or capital basically. So how it can go is if maybe they [government] are able to fund us, of course, maybe with a minimal interest?' [P37 - Livingstone]

Some governing authorities' representatives indicated the existences of several interventions and opportunities for fundings, though acknowledging the inherent limitation in such public funds. Furthermore, support structures in the sector have been under scrutiny over their internal problems that have resulted in their inefficiency in assisting locals involved in the tourism industry, with a participant in Livingstone espousing '*There are associations, Zambia tourism association, and*

Livingston tourism association but they are not doing anything' (P34 – Livingstone), while in Kasane, the misuse of funds by the community trust was frequently mentioned,

'So most of the trusts have collapsed because of that. Yes. Yeah, I guess you've seen in Maun, some of them have been fired because they used money from the trust, they'll be borrowing themselves money from the trust.' [P5 – Kasane]

One of the key strategies to action KAZA TFCA goals at the local scale is through education and training. Notably, previous studies have found this education to largely revolve around wildlife protection and harmonizing community and conservation relationships. In this regard, participants underline the significance of tourism specific skills and knowledge to enable a locally inclusive and competitive industry. For instance, some responses on this matter were communication skills development and foreign language proficiency skills, to accommodate international guests:

'For instance, you might need to have maybe, translators in case of maybe Spanish speaking people. To provide a channel for communication. And that's where communities can they can be willing to venture into what tourism activities.' [P49 – Hwange]

Participants generally agreed that even entry-level employment requires training and specific skills, and the priority on the absorption of the local labour market needs to recognise this fact:

'Because for them [communities] to be involved, there's a certain level of skills [required]. You realize that some of them are not that much educated. So that's what makes it a bit difficult. For instance, for one to be a waitress, you just have to be able to have to bring your certificate.' [P17 – Kasane]

Finally, the awareness of KAZA TFCA as a meta-governance entity was not widely known by study participants, of which those that were familiar explained that it largely operated at a supranational scale, with little integration with local stakeholders. The discussions above illustrate while that the deliverables of the collaborative arrangements were seen in the destination, the explicit linkage to the KAZA TFCA ecosystem was not apparent. This raised several questions on the localized effectiveness of the entity, particularly in Kasane and Livingstone, where participants noted the apparent disconnect between tourism and conservation outcomes of the TFCA agreement, where a few people perceive them as solely conservation governing bodies and not focused on tourism businesses, with one tourism business owner stating '*They deal with animals there, counting animal problems and all the like. I never saw myself as an operator sitting down with KAZA .I know they're operating out there'* (P5 – Kasane). Another tourism business owner had the following input:

'I think they are not driving their mandate on how as [tourism] operators we can benefit from them, and how they can also benefit from us. I don't know how to put it but if you ask me about KAZA, I won't tell you anything about KAZA, as compared to other board like BTO [Botswana Tourism Organisation] , Africa's Eden, where if you go there and meet other business operators, you know, you have a chance of getting business from them.' [P13 – Kasane]

Interestingly, in Hwange, some CAMPFIRE representatives outlined the existence of working groups fostering the integration of local stakeholders and localized imperatives to the KAZA management structure, with one such representative affirming;

'For example, if it's the KAZA, we've got working groups that have representatives of the nations, like Zimbabwe, Zambia, Namibia, Angola and Botswana. They have working groups for every sector. Can it be tourism? Can it be finance? Can it be law enforcement? They do bilateral meetings, and we have bilateral meetings at ministerial level and at the state, state aid level, and their exchange programs for the community leaders.' [P40 – Hwange].

DISCUSSION

This study sought to explore the regional tourism development process in selected KAZA TFCA sites, considering the meta-governance processes. Generally, the study found that the Transfrontier governance has fostered an enabling environment for tourism growth primarily though the easing of tourist mobility through cross border agreements and infrastructure. Cross border literature confirms the necessity of alignment amongst governing states to enable cross border tourism (see Dittmann & Müller-Mahn, 2023; Stoffelen & Vanneste, 2017; Clark et al., 2026).

In the case of Southern Africa, this alignment is grounded from the policies and agreements signed at SADC level, enabling the creation of TFCAs and and subsequently the facilitation of supporting mechanisms to grow tourism in the region. These mechanisms including facilitation of visa and cross-border formalities, improved transportation networks and transport arrangements, varied experiences and the development of tourism ecosystems, all of which Kozak & Buhalis (2019) constitute factors propelling cross border travel. From a meta-governance perspective, these developments demonstrate the role of regional governance actors in creating the institutional conditions through which tourism actors can operate across national boundaries, rather than directly controlling tourism development.

However, the study also found that while movement within the KAZA TFCA member states have become somewhat easier, regional tourism growth is hindered by the ease of travel to the region, in which case airline connectivity as well as the problems associated with national airline carriers were deemed to be key challenges. This highlights an important limitation of regional meta-governance, where progress in one component of regional integration does not necessarily result in corresponding integration across the wider tourism system.

The findings demonstrate the growth of regional tourism, supported by a previous study (see Lekgau & Tichaawa, 2025). Blasco et al. (2014) and Badimo & Matlhola (2026) recognise that political influences and relations can influence cross border regional flow. In this way, the TFCA provides several advantages in providing access to destinations that could be considered political unstable by tourists, as well as the opportunity leverage on the different pulling power of destinations in the region and then diverse this flow to other destinations. This provides a strong foundation for future plans to growth tourism beyond frequently visited areas, should such plans be supported by adequate tourism support. From a

destination marketing standpoint, research suggests that regional tourism marketing provides cost advantages to the destination through the sharing of marketing expense (Kozak & Buhalis, 2019; Clark et al., 2026), which is particularly crucial in resource constrained contexts. As such the financial assistance leveraged through the KAZA TFCA and their international donor network provides the ability for tourism to develop further and deliver on socioeconomic outcomes. These findings further illustrate the steering function of meta-governance, whereby regional actors and supporting institutions create opportunities for collective action that individual destinations may struggle to achieve independently.

However, the study highlights some implications to the structure of tourism development, particularly the extent to which guidance and support has been provided for tourism entrepreneurs. The study found heightened competition amongst tourism establishment within individual member states and across borders, often arising from the prevalence of similar tourism product development. Studies such as Park et al. (2022), Tichaawa & Lekgau (2020) and Clark et al. (2026) have underscored diversity and distinctive tourism experiences as central to promoting regional tourism growth. Local cultures are seemingly seen as an avenue to preserve distinctions amongst the states, which could assist in fostering the integration of regional wildlife tourism product but preserving the uniqueness of each destination (Park et al., 2022).

Earlier on, Tosun et al. (2005) affirmed the creation of a joint cross border tourism organisations, and increasing involvement of business stakeholders and NGOs necessary to effectively success in this endeavor. Park et al. (2022) made the same assertion, stating that this shared governance, through the introduction of robust governance mechanisms, facilitates synergistic collaboration amongst the partner states. This is clearly evident in the present study, owing to the need to facilitate the further regional tourism growth by having regional tourism development priorities being purposively integrated various scales the meta-governance structures. The findings, however, suggest that the existence of regional governance structures alone is insufficient to achieve this integration. Meta-governance requires the effective connection of regional, national and local governance levels, as well as the incorporation of actors who are directly involved in tourism development. In this regard, the limited visibility of tourism within local understandings of KAZA indicates a potential vertical governance gap between regional priorities and local tourism realities. The local perceptions of KAZA seems to predominantly focus on conservation. While this is understandably so, considering that the protection natural resources is the foregrounding motivation for the establishment of the TFCA, the tourism industry is that which can generate socioeconomic returns that support the attainment of the other goals of the agreement.

Similarly, previous studies have found that there are several education initiatives for local community members, directed to conservation matters, such as fostering positive and protective human-wildlife dynamics, or introducing wildlife tourism and conservation as potential careers (Lekgau & Tichaawa, 2025a, 2025b).

However, tourism specific education, which considers the local labour market is not as widely shared through governance structures, thereby falling onto the responsibility of businesses owners and managers. This creates a gap in the tourism environments, and the lack of cohesion amongst meta-governance structures and the local tourism industries compromises the sustainable and equitable growth of the tourism industry. Relatedly, one of the key challenges facing the KAZA TFCA, and similar transboundary agreements, is the harmonlisation of policies. Past studies have found this disconnect to be centred on conservation policies and practices (Lekgau & Tichaawa, 2025b, whereas this present research demonstrates this issue to extend to tourism and tourism affected policies and policy imperatives and adversely affect the development and growth of local tourism businesses. Policy harmonisation represents a particularly important meta-governance mechanism in this context, as the creation of a regional tourism destination requires some degree of consistency in the institutional conditions within which tourism businesses operate. Although member states may participate in a shared regional governance arrangement, differences in policy implementation, administrative procedures and institutional capacities can continue to produce fragmented tourism environments.

CONCLUSIONS

Overall, the findings demonstrate that the KAZA TFCA has contributed to creating an enabling environment for regional tourism development by facilitating cross-border mobility, strengthening regional cooperation and creating opportunities to leverage the complementary tourism resources and attractions of the five member states. The development of cross-border infrastructure, visa and border arrangements, regional marketing initiatives and donor-supported programmes demonstrates the potential of transfrontier governance to support tourism development beyond national boundaries. However, the findings also demonstrate that the existence of a transfrontier governance structure does not necessarily translate into integrated tourism development. Certainly, the effectiveness of KAZA as a meta-governance arrangement is influenced by the extent to which regional priorities are translated into coordinated actions at national and local levels. In particular, the limited visibility of tourism development within local understandings of KAZA, compared with its stronger association with conservation, raises questions about the extent to which tourism is sufficiently embedded within the broader governance processes of the TFCA.

The findings therefore suggest that strengthening tourism development within KAZA requires a shift from viewing tourism primarily as an outcome of conservation and regional integration towards recognising it as an explicit component of transfrontier governance. This requires stronger vertical coordination between regional, national and local governance structures, as well as greater horizontal collaboration between governments, conservation agencies, tourism businesses, communities and other tourism stakeholders, of which policy harmonisation is particularly important in this regard. Theoretically, this study extends the application of meta-governance to Transfrontier tourism by demonstrating that the effectiveness of transboundary governance depends not only on the establishment of regional coordination mechanisms, but also on their translation and implementation across multiple governance levels.

The study therefore conceptualises tourism development as an important outcome through which the effectiveness of meta-governance within TFCAs can be assessed, highlighting the importance of vertical coordination, policy harmonisation and local stakeholder integration in translating regional governance objectives into equitable tourism and community development outcomes.

DEVELOPMENT OPPORTUNITIES FOR SUSTAINABLE TOURISM LOGISTICS IN THE KARABAKH AND EAST ZANGEZUR ECONOMIC REGIONS OF AZERBAIJAN

Gunel ISAYEVA [1*]

Citation: Isayeva, G. (2026). Development opportunities for sustainable tourism logistics in the Karabakh and East Zangezur economic regions of Azerbaijan. *Geojournal of Tourism and Geosites*, 67(3), 2585–2595. https://doi.org/10.30892/gtg.67365-1877

Abstract: In recent decades, sustainable development, environmental protection, and decarbonization have become global priorities, making the transition toward sustainability in the tourism sector a key challenge that shapes the future development of tourism destinations. The development and implementation of tourism products, the design of tourism routes, and the integration of innovative approaches to transport and logistics issues along these routes are essential components. This study explores the potential for implementing sustainable tourism logistics in the Karabakh and East Zangezur economic regions of Azerbaijan. The main objective is to assess how green logistics solutions can support post-2020 reconstruction, reduce carbon emissions, and ensure sustainable tourism development aligned with national climate commitments. An exploratory mixed-methods approach was applied, combining literature review, field observations, and a questionnaire survey among tourists. The study evaluated ecological load, transport chains, tourism facilities, accessibility, seasonality, and tourists' awareness of green practices. Findings indicate strong prospects for sustainable tourism logistics due to newly rebuilt transport infrastructure, smart settlement initiatives, and high tourist interest. However, increased demand raises environmental management challenges. The adoption of low-carbon supply chains, green transport routes, and alternative energy solutions can minimize ecological risks, strengthen sustainable behaviours, and contribute to Azerbaijan's long-term green development agenda. Additionally, fostering collaboration between public authorities, private stakeholders, and local communities will be crucial to ensure the effective implementation and long-term success of sustainable tourism logistics in these regions.

INTRODUCTION

In recent years, the global agenda on sustainable development, environmental protection, and climate change mitigation has increased the importance of transitioning toward sustainability in all sectors of the economy, including tourism. Sustainable tourism development requires an integrated approach that considers economic, social, and environmental dimensions while ensuring long-term resilience and competitiveness of tourism destinations. Numerous researchers have emphasized the strategic relevance of sustainable tourism and tourism logistics for regional development, particularly in post-conflict territories where reconstruction and territorial rehabilitation create new planning challenges (Budeanu et al., 2016).

Following the restoration of Azerbaijan's control over the Karabakh and East Zangezur economic regions in 2020, large-scale reconstruction processes were initiated with the aim of re-establishing socio-economic activity, rebuilding critical infrastructure, and enabling the return of internally displaced persons. These efforts align with national priorities related to climate change mitigation and the Sustainable Development Goals (United Nations, 2015; United Nations in Azerbaijan, 2016). Within this broader context, tourism has been identified as a key sector for the future development of these regions, given their historical cultural value, natural landscapes, and potential to attract domestic and international visitors.

Existing scholarship on sustainable tourism highlights the importance of incorporating environmental considerations, local community interests, and resource-efficient development models into tourism planning (Lagodiienko et al., 2022). Researchers have also emphasized that environmentally responsible transport systems, energy-efficient infrastructure, and sustainable logistics solutions play a critical role in shaping modern tourism destinations.

Contemporary approaches increasingly stress the necessity of integrating sustainability principles into road network planning, tourism route design, accommodation services, and regional mobility systems.

Although these studies offer valuable insights into the conceptual and operational foundations of sustainable tourism, there remains a significant research gap concerning the application of sustainable tourism logistics in newly reconstructed or post-conflict regions**,** particularly in the context of large-scale redevelopment initiatives. In the case of Karabakh and East Zangezur, the almost complete destruction of pre-existing infrastructure, settlements, and transport systems during the

period of conflict makes the integration of sustainability principles into reconstruction especially relevant. The emerging "smart village" and "green energy zone" models currently being implemented in these territories further reinforce the importance of sustainable logistics strategies for supporting long-term tourism development (Guliyeva & Museyibov, 2022).

Given the renewed interest in the tourism potential of Karabakh and East Zangezur, a strategic approach to the green transition—encompassing sustainable mobility, eco-friendly logistics solutions, and environmentally responsible tourism products—is essential for the successful revitalization of the region. Sustainable tourism logistics can serve as a core component in facilitating visitor mobility, reducing environmental pressure, improving transport efficiency, and supporting climate-resilient destination planning. The aim of this study is to explore the potential for implementing sustainable tourism logistics in the Karabakh and East Zangezur economic regions. It also seeks to identify strategic and sustainable solutions that can support tourism development in the post-conflict reconstruction context.

LITERATURE REVIEW

Sustainable tourism logistics is increasingly recognized as a crucial factor for enhancing the competitiveness and sustainability of tourism destinations. Lanfant et al. (1995) define tourism logistics as the strategic planning and execution of transporting tourists and their goods from origin to destination, ensuring efficiency and seamless travel experiences. Tairova et al. (2019) emphasizes that tourism logistics includes planning, controlling, and coordinating resources to facilitate the flow of people, goods, services, and information within the tourism sector. Study Smarter (2025) further highlights that tourism logistics ensures the necessary infrastructure, transportation, and support mechanisms are in place to offer a smooth and enjoyable travel experience. Bowersox & Closs (1996) note that logistics in tourism should be understood in terms of physical and information flow, emphasizing cost reduction, safety, and convenience through coordination and collaboration. Butler (1980) and Theppitak (2018) also support this perspective, linking logistics to accommodations, transportation, and the overall flow of tourists. Conlin & Baum (1995) demonstrate a direct relationship between the adoption of logistics management in the tourism industry and the success of sustainable tourism development. Theppitak (2018) argues that logistics management facilitates planning for hotels, accommodations, and transport networks, enhancing eco-tourism and tourist satisfaction. Resource Orchestration Theory (ROT) has been applied in tourism contexts to understand how strategic resource bundling and coordination create competitive advantages

Peuscher (2016), Erbaş (2019) Milwood & Roehl (2018) further explain that ROT supports collaborative innovation networks, trust-building, knowledge mobility, and infrastructure development in tourism destinations. Coordination Theory, as discussed by Messori & Volo (2025), emphasizes the interdependence of tasks among tourism firms, requiring alignment of processes and stakeholder collaboration. Figini (2022) illustrates that effective coordination between destination management and tour operators improves local development outcomes, while Marques (2016) highlights the importance of balancing transport and tourism capacities to optimize infrastructure costs and efficiency. Chen (2014) emphasizes the role of coordination at a regional level, integrating supply, demand, and support subsystems to improve overall tourism logistics performance. Aksu (2025) notes that sustainable tourism logistics incorporates environmental, economic, and social dimensions. Environmentally, logistics strategies aim to reduce carbon emissions, optimize energy efficiency, and promote biodiversity conservation. Economically, they encourage long-term growth through eco-friendly business models, while socially, they engage local communities and preserve cultural heritage.

Rutaba & John (2026) argue that transportation infrastructure, when effectively optimized through logistics, enhances tourist accessibility and flow. Ivasyshyna (2024) further highlights the role of digitalization and smart transport systems in improving logistics efficiency. Akhirson et al. (2025) point out gaps in current research, including limited empirical evidence, neglect of local contexts, insufficient stakeholder perspectives, and challenges in implementing innovative technologies. Theppitak (2018) and Conlin & Baum (1995) emphasize that in special economic zones, economic, political, and technological factors significantly influence the effectiveness of tourism logistics planning.

Finally, innovations such as low-emission transport, bicycle pathways, energy and water recovery systems, composting, and food waste-to-biogas solutions are highlighted by Aksu (2025) as key strategies to enhance environmental sustainability, economic benefits, and social engagement in tourism. These approaches provide significant opportunities for the development of sustainable tourism logistics in the Karabakh and East Zangezur economic regions.

Recent research in GeoJournal of Tourism and Geosites confirms that transport accessibility is a basic condition for regional tourism development (Omirzakova & Wendt, 2025), while digital technologies can strengthen sustainable tourism marketing and planning in Azerbaijan (Hajiyeva et al., 2026).

METHODOLOGY

The study investigated the potential for implementing sustainable tourism logistics in the Karabakh and East Zangezur economic regions of Azerbaijan. Due to the exploratory nature of the research, a mixed-methods approach was deemed most appropriate, combining literature review, field observation, surveys, and analysis of transport and tourism infrastructure data. Firstly, a review of scientific sources and international best practices in sustainable tourism logistics was conducted to establish a theoretical framework. Secondly, the ecological load of existing tourism attractions, including environmental impacts of transport chains and tourism facilities, was assessed through field observations and site visits.

To gather primary data, a questionnaire survey was carried out among tourists visiting or planning to visit the Karabakh and East Zangezur regions. The survey included questions on tourists' demographic characteristics (age, gender, occupation, country of origin), travel preferences, and awareness and willingness to adopt "green" practices during their trips. Additionally, the study examined the existing composition of tourism products, including seasonality, distances from

major transport hubs and cities (Baku, Ganja), and the accessibility of tourist facilities. Opportunities and risks associated with applying sustainable logistics solutions, such as green transport routes and alternative energy sources, were also evaluated. The methodological sequence applied in this study is summarized in Figure 1.

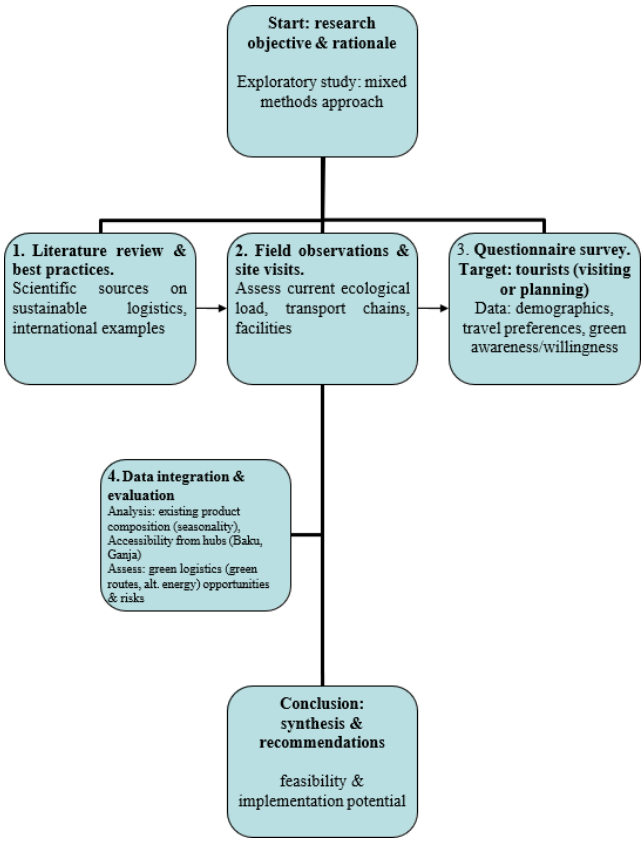

Figure 1. Research methodology flowchart (Source: Prepared by the author)

RESULTS AND DISCUSSIONS

Logistics has evolved into a strategic planning and management tool aimed at achieving synergy during the flow of goods and services from producers to end consumers within a competitive global market. Modern logistics can be analyzed through three primary lenses: managerial, economic, and financial perspectives (Imanov, 2005).

From these perspectives, key objectives include the integration of logistics processes, strategic coordination, meticulous planning, and operational control. Such approaches enhance system flexibility and enable the continuous refinement of logistics practices within the framework of a defined market strategy. At the regional level, logistics assumes a more localized, dynamic, and adaptive role (Maharramov, 2021). The primary tasks here include minimizing product storage time to facilitate faster delivery at tourism service points, reducing transportation time, optimizing vehicle allocation, responding swiftly to consumer demands, and ensuring effective processing and transmission of information. These tasks are central to the functional scope of logistics, encompassing the formation and regulation of economic relations for goods and service provision, rationalization of resource distribution, and determination of material flow volumes and directions. Importantly, regional logistics operations must also address environmental sustainability, climate change mitigation, and the transition toward a green economy (Doğan, 2020). One of the most significant contemporary applications of logistics is in the tourism sector. The role of logistics in tourism is determined by the geographic distribution of tourism resources, the characteristics of tourism products, and the accessibility of these products to consumers (Yankovenko, 2014).

Consequently, the development and growth of tourism in any region are closely tied to the attractiveness of available resources, the quality of socio-cultural and tourism infrastructure, and the strategic utilization of tourism routes. In practice, tourism logistics focuses on optimizing the interaction between tourist movement, accommodation facilities, and food service points. This involves planning, controlling, and managing operations within the tourist region, ensuring that the final tourism product reaches consumers efficiently while satisfying their preferences and requirements. Moreover, tourism logistics encompasses the transfer, storage, and processing of relevant information, as well as minimizing costs for tourists during travel from their origin to temporary destinations. It also involves optimizing the distribution of tourism products from sellers, such as tour operators or travel agents, to end consumers (Edirisinghe et al., 2021).

The relationships among the principal tourism-logistics actors are presented in Figure 2. In essence, tourism logistics functions as a service-oriented system in which multiple stakeholders—suppliers of tourism components, transport enterprises, tour operators, agents, and tourists—actively participate in decision-making processes. Effective tourism logistics ensures not only the operational efficiency of the tourism system but also enhances the overall consumer experience, thereby serving as a critical enabler for sustainable tourism development.

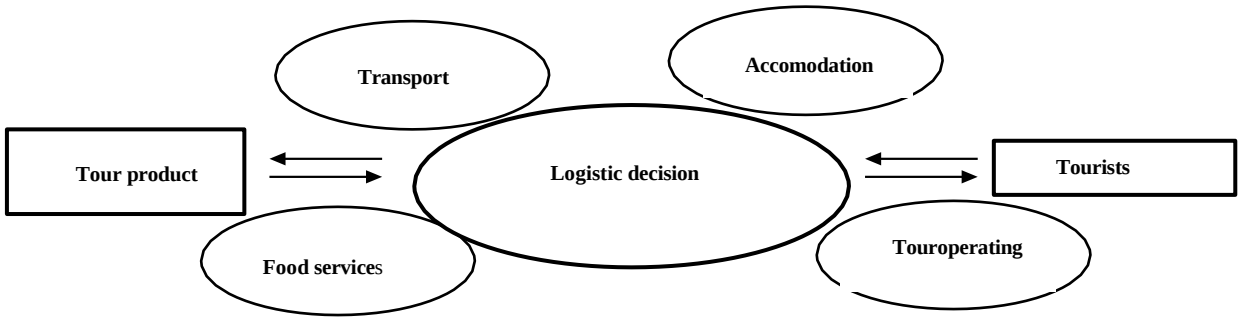

Figure 2. Tourism logistics framework (Source: Prepared by the author based on Zhang et al., 2009)

This can be described as follows: As can be seen, tourism logistics is a necessary component for the tourism industry to function as a complete system. The need to apply sustainable logistics in tourism is explained by the close connection of this area with the state policy implemented in general socio-economic and regional development, the active movement of tourists, the diversity of tourism services, and the international relations existing here.

In particular, the geographical location of the tourism region, the electric vehicles used by tourists during their travels here from various directions, as well as the use of walking and cycling opportunities, increase the importance of "sustainable logistics" in this area. On the other hand, in the context of modern industrial development, depletion of raw materials and traditional energy sources, minimizing environmental damage, and reducing waste during tourism travel are also becoming more relevant, which is explained by the fact that tourism creates an integrative relationship with many areas. All of these are issues that increase the importance of applying green logistics when organizing tourism travel.

Currently, "sustainable tourism logistics" (Akhirson et al., 2025) refers to the organization of tourism trips with sustainable use of tourism resources, less environmental impact, and low-carbon and zero-waste tours. When looking at research on sustainable tourism logistics, it is considered not only to reduce emissions during tourism trips, but also to improve the sustainable management of the destination through smart transportation, waste reduction, and energy efficiency (Budeanu, 2007). As can be seen, the highest goals set by the state in the field of tourism are taken as a basis here. Thus, the ultimate goal of planning in tourism is based on the sustainable development of the destination. According to another author (Hunter, 2002), sustainable tourism logistics is an important component of sustainable tourism development, especially in ecologically sensitive regions. Summarizing these, the activities of the elements during "sustainable tourism logistics" as a component of tourism logistics are summarized in Figure 3.

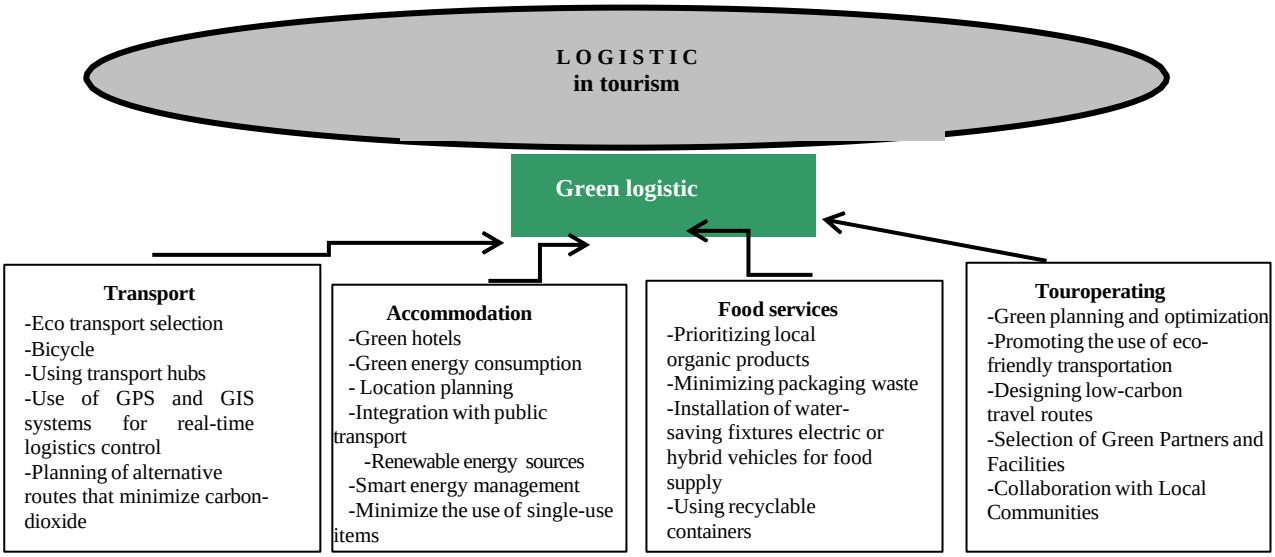

Figure 3. Sustainable tourism logistics components
(Source: Prepared by the author based on Christopher, 2016, and adapted to the sustainable tourism logistics context)

The application of tourism logistics and especially green tourism in Karabakh and East Zangezur can be explained by the current situation of these regions and the future development prospects of tourism here. Following the liberation of regions previously affected by long-term conflict, where both the economic and ecological conditions were severely impacted and tourism resources were degraded, the development of tourism has become a key priority for regional reconstruction in Azerbaijan. The return of displaced populations to these areas highlights the need for ecological restoration and sustainable development measures. As of July 2025, internally displaced persons have been successfully resettled in six cities and villages across these regions, with over 50,000 individuals now living, working, and studying locally (President of the Republic of Azerbaijan, 2025). The areas currently exhibit minimal industrial and agricultural waste; however, decades of occupation led to significant environmental degradation, including deforestation, disruption of irrigation systems, and soil erosion

(Nesirova, 2022). These conditions indicate that the implementation of sustainable tourism logistics could play a crucial role in mitigating the ecological footprint of tourism activities, promoting sustainable tourism development, and supporting the restoration of local ecosystems. Karabakh and East Zangezur economic regions: overview

The Karabakh and East Zangezur economic regions are located in the southwest of Azerbaijan, sharing borders with the Islamic Republic of Iran and the Republic of Armenia. These regions were formally established by the Decree of the President of the Republic of Azerbaijan on July 7, 2021. According to this decree, the East Zangezur economic region—encompassing the liberated Zangilan, Gubadli, Jabrayil, Lachin, and Kalbajar districts—and the Karabakh economic region—which includes Agdam, Shusha, Fuzuli, Tartar, Khojavand, Khojaly districts, the city of Khankendi, as well as Agjabedi and Barda districts—were created to ensure the restoration and sustainable development of the Karabakh economic region (President of the Republic of Azerbaijan, 2022; Figure 4).

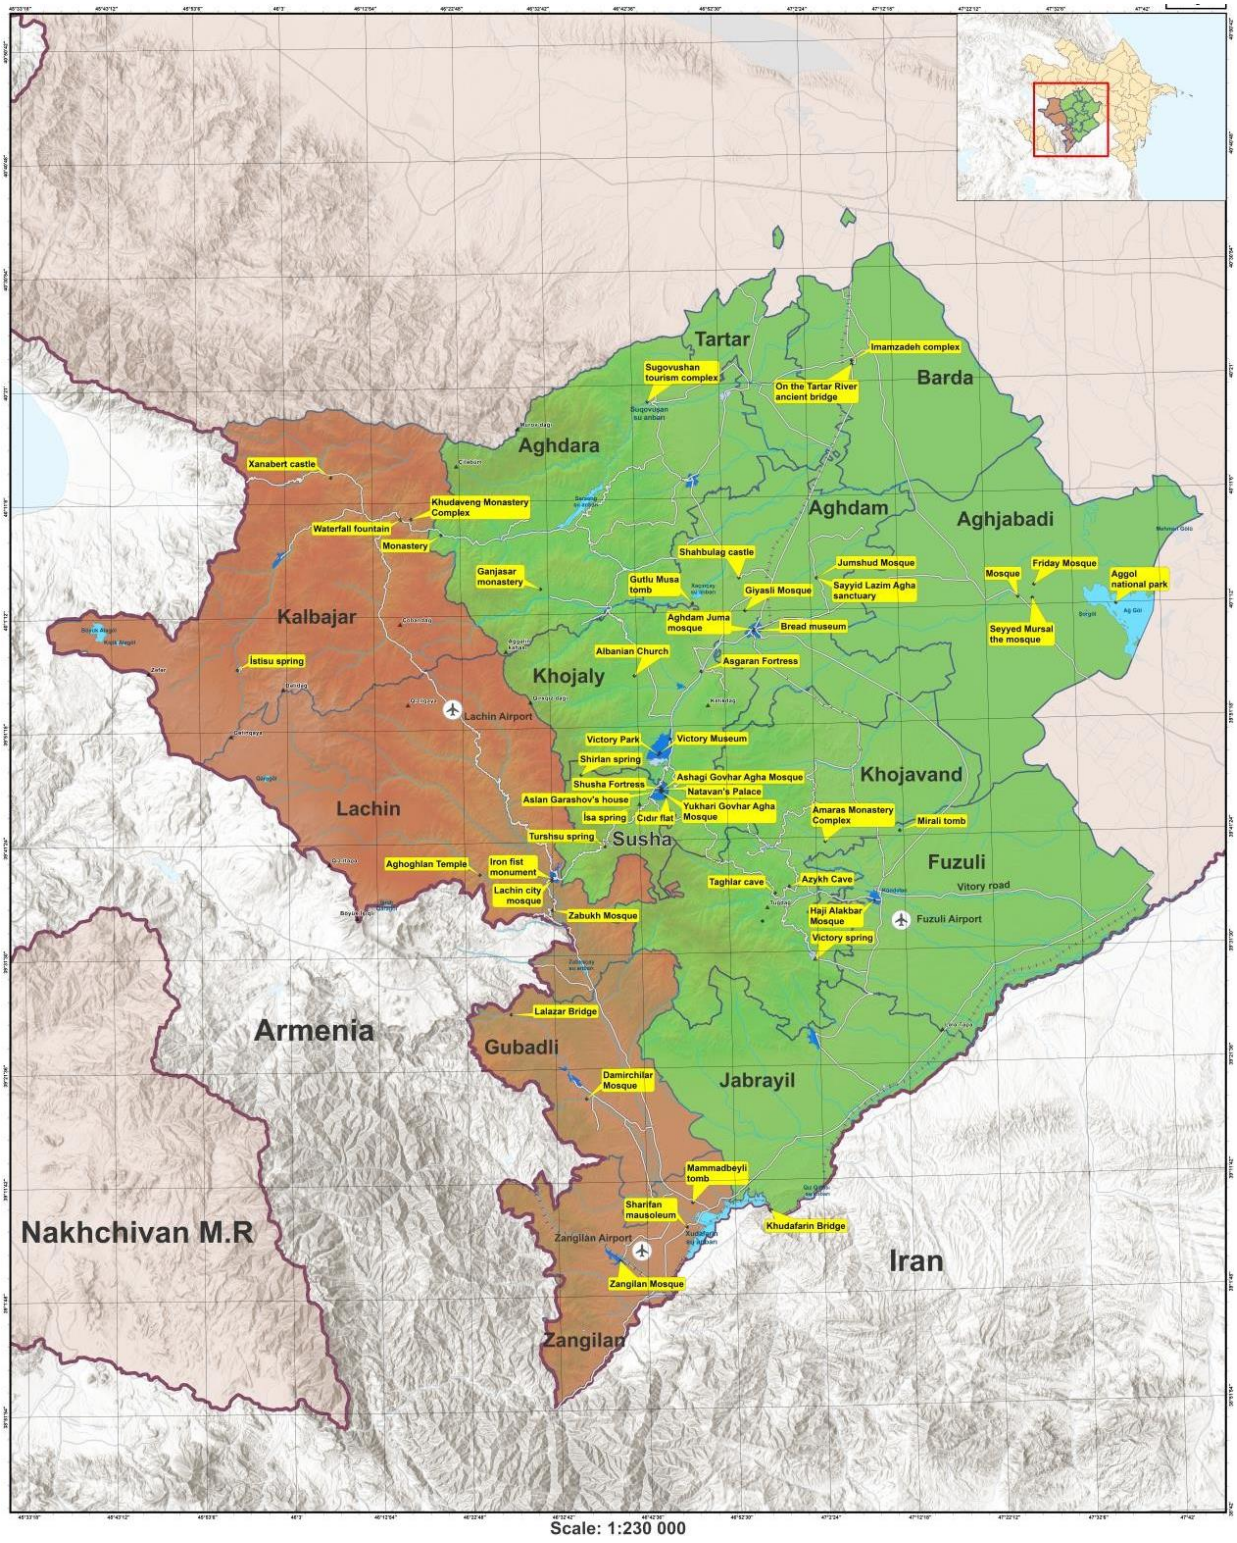

Figure 4. Map of East Zangezur and Karabakh economic regions (Source: The map was prepared by the author)

The establishment of these new economic regions aims to implement comprehensive measures for the rehabilitation of territories liberated from occupation, facilitate their long- term development, develop essential infrastructure, support the return of residents to their former homes, and promote balanced regional growth. This initiative leverages the rich economic potential, natural resources, and extensive tourism opportunities of these regions. In addition to abundant natural resources and a favorable geostrategic position, the Karabakh and East Zangezur economic regions are historically notable for their natural and cultural tourism resources, which had been prominent even prior to the occupation. During the Soviet era, a wide-ranging tourism and recreational infrastructure was established in the area. However, political conflicts since 1988 have caused substantial impacts on the tourism sector, as well as other economic activities, in both regions.

The total area of the Karabakh and East Zangezur economic regions is approximately 8.99 thousand km² and 7.47 thousand km², respectively, with a network of highways extending over 900 kilometers. Although modern railways are currently underutilized for tourism, the newly developed railway infrastructure offers opportunities for the application of sustainable tourism logistics and the transition to a sustainable economy. In particular, the Horadiz–Aghband railway line is expected to play a key role in regional integration via the Zangezur corridor and could support low-carbon tourist transportation. Another line is planned to connect Barda–Agdam–Khankendi. Existing airports in these regions, including the Fuzuli, Zangilan, and Lachin international airports and Khojaly Airport, are already accessible to tourists. The routes currently actively used by tourists in the region are presented in Table 1 (Our Road to Karabakh, 2026; Raimbekov et al., 2018).

Table 1. Road routes and their lengths in the Karabakh economic region
(Source: The table was prepared by the author based on the official data of the State Agency of Azerbaijan Automobile Roads)

№	The name of the road	Length (km)
1	Talysh – Tapgaragoyunlu – Gashalti Road	**22.0 km**
2	Gubadlı – Eyvazli Road	**28.0 km**
3	Tartar – Sugovushan – Talysh Road	**28.5 km**
4	Istisu – Kalbajar Road	**31.5 km**
5	Shukurbayli – Jabrayil – Hadrut Road	**42.0 km**
6	Fuzuli – Hadrut Road	**55.0 km**
7	Gubadlı – Lachin Road	**66.0 km**
8	Kalbajar – Lachin road	**72.8 km**
9	Toganali – Kalbajar – Istisu (general route)	**~80.7 km**
10	Toganali – Kalbajar Road	**80.7 km**
11	Fuzuli – Shusha Road	**81.6 km**
12	Zafar Road	**101.0 km**
13	Horadiz – Aghband Road	**110.4 km**
14	Barda – Agdam – Minjivan – Aghband Road	**123.6 km**
15	**Barda – Agdam – Khankendi Road**	**124.7 km**

Table 2. Cultural and green tourism potential in Karabakh economic region (Source: Prepared by the author)

№	Name of tourism resources	Location (district)	Type
1.	Khankendi Kurgans	Khankendi	Cultural tourism resources
2.	Aggol National Park	Agjabadi	Eco-tourism resources
3.	Aghdam Juma Mosque	Aghdam	Cultural tourism resources
4.	Shahbulag Castle	Aghdam	Cultural tourism resources
5.	Palace of Panahali Khan and the Imarat complex	Aghdam	Cultural tourism resources
6.	Aghdam Bread Museum	Aghdam	Cultural tourism resources
7.	Gutlu Musa Tomb	Aghdam	Cultural tourism resources
8.	Uzarliktepe settlement	Aghdam	Cultural tourism resources
9.	Barda Imamzadeh Complex	Barda	Cultural tourism resources
10.	Sheikh Babi's Tomb	Fuzuli	Cultural tourism resources
11.	Shah Abbas Caravanserai	Fuzuli	Cultural tourism resources
12.	Mirali Tomb	Fuzuli	Cultural tourism resources
13.	Asgaran Castle	Khojalı	Cultural tourism resources
14.	Azykh Cave	Khojavand	Cultural tourism resources
15.	Amaras Monastery	Khojavand	Cultural tourism resources
16.	Taghlar Cave	Khojavand	Cultural tourism resources
17.	Ancient bridge over the Tartar River	Tartar	Cultural tourism resources
18.	Sugovushan Tourism Complex	Tartar	Cultural tourism resources
19.	Khudaferin bridges	Jabrayil	Cultural tourism resources
20.	Khudaveng Monastery Complex	Kelbajar	Cultural tourism resources
21.	Lalazar Bridge	Gubadli	Cultural tourism resources
22.	Damirchilar Mosque	Gubadli	Cultural tourism resources
23.	Aghoghlan Monastry	Lachin	Cultural tourism resources

The Karabakh and East Zangezur economic regions of Azerbaijan are endowed with abundant tourism resources. During the Soviet era, these regions—second only to Baku in terms of tourist visits (excluding areas bordering the capitalist

state of Iran)—were recognized for their rich historical, cultural, and natural attractions. Notably, the city of Shusha, designated as the cultural capital of Azerbaijan, holds particular significance. As a symbol of Azerbaijan's victory in the 44-day Second Karabakh War, Shusha has experienced a marked increase in tourist numbers since 2020. Since 2020, thousands of tourists have traveled on regular bus flights organized by the Azerbaijan Land Transport Agency (ALTA) to the liberated territories. Currently, the main direction of movement of tourists in the Karabakh economic region is Fizuli-Khojavand-Shusha-Khankendi-Aghdam. In the East Zangezur economic region, the main tourism resources are located in the direction of Jabrayil-Gubadli- Lachin. The alternating location of historical-cultural and natural tourism resources in both regions and the landscape structure of these areas are also factors affecting tourism logistics here. Official restoration initiatives are also reshaping access to major heritage sites (Karabakh Revival Fund, 2026).

The tourism resources available in Karabakh and East Zangezur are presented in Tables 2 and 3.

Table 3. Tourism attractions and heritage sites in Shusha city (Source: prepared by the author)

№	Object name	Tourism resources
1.	The Upper Govhar Agha Mosque	Cultural tourism resources
2.	The Lower Govhar Agha Mosque	Cultural tourism resources
3.	Natavan's Palace	Cultural tourism resources
4.	The Karabakh Khan's Palace	Cultural tourism resources
5.	Molla Panah Vagif's Mausoleum	Cultural tourism resources
6.	Shusha Cave Camp	Cultural tourism resources
7.	Shusha Fortress	Cultural tourism resources
8.	Uzeyir Hajibeyov's House- Museum	Cultural tourism resources
9.	Bulbul's House- Museum	Cultural tourism resources
10.	Gara Boyuk Khanum Tower	Cultural tourism resources
11.	The Caravanserai of Agha Qahraman, Son of Mir Siyab	Cultural tourism resources
12.	Two-story Caravanserai	Cultural tourism resources
13.	Kazanchi Church	Cultural tourism resources
14.	İsa Spring	Natural tourism resources
15.	Cıdır Flat	Natural tourism resources
16.	Turshsu	Natural tourism resources
17.	Shirlan	Natural tourism resources
18.	Chatir Waterfall	Natural tourism resources

The implementation of sustainable tourism logistics in Karabakh and East Zangezur is based on the movement of tourists to this area and the use of tourism services through the airports, roads, bridges, tunnels created here. Also, in the form of smart settlements created here, the local population and, in general, all citizens of the Republic of Azerbaijan have the opportunity to get acquainted with new living standards in the form of new types of settlements. When looking at the services that can be provided to tourists in terms of existing tourism resources and transport logistics opportunities in these regions, the problems that arise can be shown as follows. Thus:

- Insufficient existing infrastructure at the initial stage to meet the tourist interest in Karabakh and Eastern Zangezur after its liberation;
- Uneven location of hotels, restaurants and other socio-cultural institutions to manage tourist flows along the existing road and transport network to reach tourist attractions during trips in Karabakh;
- Despite the attractive tourism resources available in the Karabakh economic region, there are restrictions on individual travel here;
- According to tourists' social media impressions, the traces of destruction (former settlements, monuments, infrastructure, landscape, etc.) that still exist around most of the attractions located on their travel routes create negative emotional feelings (Figures 5 and 6); The documented destruction of the Aghdam Bread Museum is one example (ArmenianCrimes, 2026; Ministry of Culture of the Republic of Azerbaijan, 2026).
- The threat of mine explosions remains as a result of the contamination of the territory with mines by Armenia (Mine safety).

Diversification of the routes for tourists to reach Karabakh and East Zangezur, the establishment of roadside stops, and the construction of hotels are among the prerequisites for the development of the tourism industry created in Karabakh and East Zangezur during the post-occupation recovery and return period based on the principles of sustainability. In addition, there is the issue of training personnel who will organize tour operators and excursion services for tourists in the Karabakh and East Zangezur territories. In terms of logistics, the Shusha, Agdam, Kalbajar, Lachin, Khankendi, and Zangilan routes are of primary interest for tourists traveling to Karabakh and East Zangezur. Thus, the integration of the Khojaly Airport, which previously existed in the region, and the Fizuli, Zangilan and Lachin international airports built here after the liberation of the region from occupation, as well as the newly built railway with more than 10 highways here can be considered a convincing argument in terms of green logistics research. Research in this area allows us to draw conclusions about the optimal ratio of carbon dioxide emissions reduction when using air, rail and land routes (Wang et al., 2024; Trevisan & Bordignon, 2020; EUROCONTROL, 2021; Lomachynska & Andrushchenko, 2025).

In order to conclude in this area, it is also possible to consider the socio-economic basis of the application of green logistics in tourism, and green logistics in general, according to another study (Doğan, 2020). Thus, considering that in a

period when tourism demand is increasing, up to 40 percent of the global energy market's oil demand is transported by land, and air transport accounts for up to 3 percent of global warming, it is necessary to take into account the minimization of carbon dioxide emissions caused by tourists during their travels.

Figure 5. Bread Museum destroyed in Aghdam during the occupation period (1992–2020) (Source: The author)

Figure 6. Caravanserai of the Safarov brothers destroyed in Shusha city during the occupation (1992–2020) (Source: The author)

The issues of applying green logistics during tourism activities in Karabakh and East Zangezur can be explained by the state support for this area, planning for transport hubs, hotels, food establishments, tourist camps, and the awareness of travelers about sustainable tourism logistics and their interest in walking and cycling. It should be noted that currently, the declaration of the Karabakh and East Zangezur economic regions of Azerbaijan, along with the Nakhchivan Autonomous Republic, as green energy zones, and the large-scale projects implemented here towards the transition to a green economy indicate state support for this. In these regions, as well as in the Nakhchivan Autonomous Republic, the transition to green energy, the replacement of traditional means of transport with electric vehicles, and the optimization of tourism routes indicate state support for the application of sustainable tourism logistics.

In addition, the government of the Republic of Azerbaijan expresses its support for the development of this sector through international cooperation in the field of joint fight against climate change, the transition to a digital economy in most sectors of the economy, including tourism logistics, and the adoption of an artificial intelligence strategy. The government of the Republic of Azerbaijan pays special attention to these issues in the reconstruction of Karabakh and East Zangezur, demonstrating the priority position of these regions in the transition to a green economy with the smart settlements they have built. In addition, the tunnels being built on the roads leading to Shusha, an important tourism center of Karabakh, also have an impact on green logistics. These priorities are consistent with Azerbaijan's green-economy policy agenda (COP29 Azerbaijan, 2025; Qasimli et al., 2021; Tang et al., 2017).

Planning issues for sustainable tourism logistics include increasing the share of low- carbon transport in the supply chain between tourists and tourism products and selecting optimal routes and stopping points for tourists moving from one attraction to another. According to one study, 24 percent of global carbon dioxide emissions are generated by logistics activities (Doğan, 2020). The fact that tourism ranks 3rd-4th in the global economy (UN Tourism, 2024) suggests that green logistics can make a significant contribution to reducing emissions. These issues also require resolving conflicts arising from the individual behavior of tourists, who want to see more attractions in a given travel period and at the same time spend less money by spending their time rationally.

In many developing countries, including Azerbaijan, tourists often prioritize personal leisure interests over environmental considerations, frequently traveling in hydrocarbon- fueled private vehicles and contributing to pollution and waste generation. However, organizing large group tours with lower carbon footprints—such as bus tours accommodating 18 to 45 passengers, and optimizing routes between key destinations (including hotels, restaurants, and designated rest stops) can result in more environmentally sustainable tourism practices.

Furthermore, government support for the transition to electric vehicles, along with the development of necessary infrastructure (such as electric charging stations) beyond the capital city, particularly in the Karabakh and East Zangezur economic regions, can significantly contribute to achieving these sustainability goals. In addition, prioritizing walking and cycling for individual or family travel could also be more environmentally efficient. This would allow for the regulation of carbon dioxide emissions per tourist with quotas and their alignment with international standards as environmental indicators in the logistics chain applied during tourism activities in the region.

In this context, if we refer to the analysis of the survey results (Isayeva, 2025), conducted to arrive at predictive results on sustainable tourism logistics in the Karabakh and East Zangezur economic regions, we see that the main purpose of the visits to Karabakh of respondents aged 18-25 (89.3 percent) was education (Karabakh University). At this time, it was found that 75 percent of the respondents planned their trips themselves, 46.4 percent preferred a private car, and used taxi

and private car services more often at the place of travel. 39.3 percent of the respondents reported the lack of public transport during their trip to Karabakh, 50 percent reported that logistics problems affected their stay here longer, and 46.2 percent of respondents said that this would be possible with the opening of more public transport routes in terms of how to improve tourism logistics in the region. Then, to the question about the use of environmentally friendly means of transport in Karabakh and East Zangezur, 74.1 percent of respondents answered "no".

Interestingly, 19.2 percent of those asked about the development of green means of transport in the region chose walking, and 65.4 percent of people gave a positive answer to the question about the impact of environmentally friendly transport on tourism if it were widespread in the region.

84.6 percent of respondents gave a positive answer to the question about the impact of this on tourism travel. When asked about the direction of which tourism routes green transport could be applied more in the region, 46.4 percent of respondents chose the answer "Khankendi".

Finally, respondents participating in the survey stated that 50 percent of Khankendi, 35.7 percent Shusha, 10.7 percent Lachin, and 3.6 percent Agdam were suitable for the logistics of tourism routes in the region.

Findings

To summarize all this, it can be noted that in order to achieve "green results" during tourism activities, sustainable tourism logistics to be implemented in the Karabakh and East Zangezur economic regions of Azerbaijan can be considered as an important part of the restoration and construction work carried out here after 2020. In order to achieve the target of reducing carbon emissions by 40 percent by 2050 within the framework of the commitments undertaken by the Republic of Azerbaijan in the field of combating climate change, the work to be done in this direction in the tourism sector will also be one of the main priorities. Considering the interest of Karabakh and East Zangezur in both ecotourism and cultural tourism resources, the implementation of operations with less carbon emissions in the supply chain, in terms of realizing the tourism product created here in accordance with the principles of sustainable development will create a need for the application of green logistics. The road and transport infrastructure (airports, roads and railways) created in these regions over the 5 years after 2020, relevant service facilities for overnight stays and meals for tourists, and the work carried out to create "smart settlements" in the region also reveal the prospects for the application of sustainable tourism logistics.

Although it is thought that "sustainable tourism logistics" will be applied later in the realization of the tourism potential of Karabakh and East Zangezur than traditional logistics, it is possible to predict that this will be a common context in terms of future goals for the state, private sector, local community and tourist interests.

The tourism activity created in Karabakh and East Zangezur will be an integral part of the tourism policy implemented in the Republic of Azerbaijan in general, and will lead to more positive results with the application of the completely rebuilt infrastructure and previously existing management experience.

Since the Karabakh and East Zangezur economic regions have been under occupation for 30 years and are inaccessible to citizens of the Republic of Azerbaijan, the tourist interest here is greater than in other parts of Azerbaijan, which creates corresponding problems in the management of tourism in the area, which makes the issues of environmental protection even more relevant. In this sense, "sustainable tourism logistics" on tourism routes in these two regions can be useful in minimizing environmental risks. Management models for "sustainable tourism logistics" to be applied in highly prestigious tourism regions such as the Karabakh and East Zangezur economic regions of the Republic of Azerbaijan can also strengthen the population's inclination towards hiking, cycling and group tours in the future by shaping "green behaviors" in tourists traveling there. The results achieved in the Karabakh and East Zangezur economic regions on "sustainable tourism logistics" are important in terms of prestige, in addition to their economic and social benefits, which, as a developing country, can take an important place in the "green agenda" of the Republic of Azerbaijan and allow the application of the experience gained in other parts of the country.

CONCLUSIONS

This study demonstrates that sustainable tourism logistics is a key component for the restoration, development, and future growth of the Karabakh and East Zangezur economic regions. The implementation of green logistics in these areas is closely linked to post- occupation reconstruction, socio-economic revitalization, and environmental sustainability. Investments in airports, railways, highways, tunnels, and smart settlements provide the foundation for low-carbon and efficient tourism logistics. Integration of air, rail, and road transport helps reduce CO_2 emissions while improving accessibility to cultural and natural tourism resources. Sustainable tourism logistics reduces carbon emissions, promotes eco-friendly transport, encourages responsible tourist behavior, supports resettlement of displaced populations, revitalizes local economies, and enhances tourist experiences. Survey results indicate growing interest in environmentally friendly transport and walking/cycling options, suggesting that promoting group-based, low-carbon tourism can strengthen green logistics outcomes. Government support through green energy zones, smart infrastructure planning, and integration of digital/AI tools reflects a strategic commitment to sustainable tourism logistics and provides a replicable model for other regions. Overall, applying sustainable tourism logistics in Karabakh and East Zangezur represents a unique opportunity to combine ecological, social, and economic objectives, transforming post-conflict regions into sustainable tourism hubs with minimized environmental impact.

This study has several limitations. Data primarily covers the post-liberation period (2020–2026); long- term trends in tourist behavior, infrastructure use, and environmental impact may evolve differently. The survey focused on young tourists (18–25 years) and education- related travel, which may not fully represent broader tourist demographics. While significant

progress has been made, some tourism infrastructure is still under development, and certain routes or services may not yet reflect long-term conditions. CO_2 emissions and ecological impacts are based on transport modes and routes; future empirical data will be needed to validate these estimates. Addressing these limitations in future research will enable a more comprehensive assessment of sustainable tourism logistics and its long-term environmental, social, and economic impacts in Karabakh, East Zangezur, and other post-conflict regions.

Abstract: Ecotourism governance requires coordination among public agencies, local authorities, communities, tourism businesses and conservation organisations whose mandates often overlap. This paper examines how multi-level governance shapes institutional coordination across Victoria Falls, Hwange and Binga, Zimbabwe. Using an interpretivist multiple-case design, the study draws on 39 semi-structured interviews with government and parastatal officials, conservation organisations, tourism businesses and community representatives, supported by analysis of tourism, wildlife and environmental policy documents. Four connected challenges emerged: overlapping mandates and competing priorities created uncertainty and delay; inter-agency collaboration was irregular and constrained by limited staff, budgets and follow-through; decision-making remained predominantly top-down, with weak local influence and feedback; and coordination problems differed by destination. Victoria Falls faced congestion among numerous institutions, Hwange relied strongly on protected-area networks, and Binga had fewer institutional connections and weaker access to national decision-making. These contrasts suggest that the number of institutions involved is less important than the quality, reach and consistency of their coordination. NGOs and businesses bridged some gaps but could not replace consistent public-sector coordination. The study shows that a common national framework operates differently across destinations. Governance quality therefore depends as much on working relationships and implementation capacity as on formal mandates. It recommends clearer roles, routine and resourced coordination, stronger feedback mechanisms and targeted support for destinations with weaker institutional capacity. The comparison of destinations governed through the same national framework offers evidence that coordination reforms must be adapted to differences in institutional presence, administrative access and local implementation capacity.

Keywords: ecotourism governance, multi-level governance, institutional coordination, stakeholder participation, destination governance, Zimbabwe, Southern Africa

INTRODUCTION

Ecotourism governance rarely sits within a single institution, tourism promotion and licensing, environmental assessment, protected-area management, land-use planning, local development, community participation and private-sector implementation are usually distributed across organisations with different mandates and priorities (Forje et al., 2022; Wondirad et al., 2020). Although this distribution can broaden expertise and participation, weak coordination can produce duplicated procedures, inconsistent decisions and uncertainty over responsibility (Kodir et al., 2020; Sentanu et al., 2023). The practical question is therefore not simply how many actors participate in ecotourism governance, but whether they are able to work together consistently enough to translate policy into coherent action.

Coordination is important in nature-based destinations where conservation, community livelihoods and commercial tourism are closely connected (Forje et al., 2022; Mpofu & Van Der Merwe, 2025). Previous research in sub-Saharan Africa continues to identify stakeholder participation, institutional capacity, accountability and collaboration as important conditions for effective ecotourism governance (Dangi & Petrick, 2021; Makhanyela et al., 2024; Wondirad et al., 2020). Collaborative arrangements can improve knowledge exchange and legitimacy, yet their effects are limited when responsibilities remain unclear, forums are under-resourced or participation does not influence decisions (Dangi & Petrick, 2021; Sentanu et al., 2023). Recent tourism-policy studies similarly show that power and institutional position shape which actors can influence policy networks (McLeod, 2023). These issues make coordination a central part of implementation rather than an administrative concern separate from sustainability.

Zimbabwe provides a strong setting in which to investigate this variation. Ecotourism is shaped by the Tourism Act [Chapter 14:20], Parks and Wild Life Act [Chapter 20:14], Environmental Management Act [Chapter 20:27], National Tourism Policy and local natural-resource governance arrangements, including the Communal Areas Management Programme for Indigenous Resources (CAMPFIRE) (Government of Zimbabwe, 1975, 1995, 2002, 2014). The

institutional field includes the Ministry of Tourism and Hospitality Industry, Zimbabwe Tourism Authority (ZTA), Ministry responsible for environment and wildlife, Environmental Management Agency (EMA), Zimbabwe Parks and Wildlife Management Authority (ZimParks), local authorities, community structures, NGOs and tourism enterprises (Government of Zimbabwe, 1975, 1995, 2002, 2014; Mpofu & Van Der Merwe, 2025). These bodies are functionally interdependent, but their statutory mandates do not automatically specify how competing priorities, joint approvals, information exchange or local feedback should be reconciled (Mpofu & Van Der Merwe, 2025).

The three cases examined in this paper reveal different expressions of this shared national system. Victoria Falls is an internationally visible tourism hub with a comparatively dense regulatory, commercial and civic presence; research in Zimbabwe also shows that sustainability practices vary geographically and are more widely adopted in this internationally oriented destination than in several domestic-market destinations (Shereni & Rogerson, 2023).

Hwange is organised strongly around a major protected area and the networks linking conservation agencies, operators, NGOs and surrounding communities (Mpofu & Van Der Merwe, 2025).

Binga is a more remote lakeside district where promising cultural and nature-based resources coexist with thinner institutional presence and weaker connectivity to national decision centres; research on Binga's VaTonga communities similarly identifies weak local representation, constrained access rights and limited capacity in natural-resource governance (Matsa et al., 2024). Comparing these three cases makes it possible to distinguish the existence of institutions from the territorial fit of their relationships (Guo & Li, 2025; Novalia et al., 2025).

Tourism-policy research has examined collaboration, participation, policy networks and destination management, but implementation remains under-studied, with important geographical, theoretical and practical gaps (Kifworo & Dube, 2024). Studies have examined protected-area partnerships, community-based natural resource management and local participation in particular parks or districts in Zimbabwe (Musakwa et al., 2020; Shereni & Saarinen, 2021; Forje et al., 2022; Mpofu & Van Der Merwe, 2025). What remains less developed is a comparative account of how national institutions, local authorities, non-state actors and communities coordinate across ecotourism destinations with contrasting institutional conditions. This paper addresses that gap by raising the following key questions: How do relationships among institutions and stakeholders at different levels shape coordination in ecotourism governance across Victoria Falls, Hwange and Binga, and what practical reforms could strengthen that coordination?

This study contributes a within-country comparison of how one national governance framework operates across destinations with different institutional conditions. The study shows how coordination challenges vary by place and identifies practical reforms focused on clearer roles, stronger feedback and differentiated institutional support, through combining government, business, conservation and community perspectives.

LITERATURE REVIEW

Multi-level governance in tourism refers to interaction among national institutions, subnational authorities and non-governmental stakeholders whose responsibilities intersect in policy design and implementation (Hooghe & Marks, 2003; Guo & Li, 2025). In ecotourism, such interaction is important because tourism development depends simultaneously on environmental safeguards, conservation management, local planning, infrastructure, community relationships and private investment. Tourism governance can therefore be understood as a networked process in which the effectiveness of individual organisations is partly shaped by their relationships with government, private-sector and civil society (Hartman, 2023; McLeod, 2023; Wondirad et al., 2020).

A multi-level perspective draws attention to how national decisions are translated into local action and how interactions between national and local actors affect policy implementation (Guo & Li, 2025; Novalia et al., 2025).

Institutional coordination concerns the practical arrangements through which these interdependent organisations align responsibilities, exchange information, resolve conflicting priorities and act on shared decisions (Sentanu et al., 2023; Wondirad et al., 2020). Previous studies have shown that collaboration can support sustainable destination management, but it is not effective simply because committees, partnerships or meetings exist (Dangi & Petrick, 2021; Sentanu et al., 2023; Wondirad et al., 2020). Clear institutional roles, open communication, adequate resources, continuity and commitment are important for turning collaboration into coordinated action (Harilal et al., 2025; Sentanu et al., 2023; Serruto-Perea & Zapata-Mendoza, 2026; Wondirad et al., 2020). Public–private network quality can also influence destination-management performance (Serruto-Perea & Zapata-Mendoza, 2026).

Harilal et al. (2025) demonstrate how unclear responsibilities and weak communication can reduce stakeholder coordination, while McLeod (2023) shows how the distribution of power within tourism policy networks shapes the roles that different actors perform. Coordination should therefore be assessed through actual working relationships and implementation practices rather than formal institutional structures alone (Hartman, 2023; Sentanu et al., 2023; Wondirad et al., 2020). Participation is closely connected to coordination because local knowledge is more likely to inform policy when communities have meaningful channels through which to contribute to decision-making (Dangi & Petrick, 2021; Mpofu & Van Der Merwe, 2025). Community-based tourism and conservation research shows that consultation without meaningful influence can leave local actors underrepresented and excluded from important planning and resource-management decisions (Dangi & Petrick, 2021; Mpofu & Van Der Merwe, 2025; Shereni & Saarinen, 2021).

This is particularly important in ecotourism because communities and local businesses directly experience the effects of conservation restrictions, tourism development and natural-resource management decisions (Shereni & Saarinen, 2021; Wondirad et al., 2020). Recent evidence from Hwange identifies weak legislation, fragmented institutional arrangements, limited information and inadequate local capacity as barriers to meaningful community participation in

tourism planning (Mpofu & Van Der Merwe, 2025). Effective coordination therefore requires two-way communication: institutions must communicate policies and responsibilities clearly, while communities and implementers need accessible opportunities to raise concerns, contribute knowledge and receive responses (Harilal et al., 2025; Mpofu & Van Der Merwe, 2025; Sentanu et al., 2023). Place also matters because destination governance is shaped by different combinations of institutional capacity, infrastructure, actor networks, resources and administrative relationships (Hartman, 2023; Guo & Li, 2025; Novalia et al., 2025). Research shows that common national policies can produce different local implementation pathways when institutional capacity and stakeholder relationships vary across places (Guo & Li, 2025; Khanduri, 2026; Novalia et al., 2025).

Research from Zimbabwe similarly reveals geographical differences in sustainability practices, community participation and experiences of conservation governance (Mpofu & Van Der Merwe, 2025; Shereni & Rogerson, 2023; Shereni & Saarinen, 2021). A uniform governance arrangement may therefore not be equally suitable for every destination (Guo & Li, 2025; Novalia et al., 2025; Shereni & Rogerson, 2023).

Actor-dense tourism destinations may require stronger mechanisms for coordinating numerous organisations, whereas poorly resourced or remote destinations may also require capacity building, stronger institutional access and more reliable connections with national agencies (Hartman, 2023; Novalia et al., 2025; Wondirad et al., 2020). This paper examines how institutional responsibilities are coordinated in practice, how government agencies work together, and whether local actors have meaningful opportunities to participate and provide feedback. It compares Victoria Falls, Hwange and Binga to explore how these governance processes vary across destinations with different institutional conditions.

MATERIALS AND METHODS

Institutional and geographical context

The ecotourism architecture in Zimbabwe combines national legislation with implementation by specialised agencies, local authorities and non-governmental actors. The Tourism Act [Chapter 14:20] establishes the Zimbabwe Tourism Authority (ZTA) and assigns its responsibilities relating to tourism development, promotion, research, standards, and the registration and grading of designated tourism facilities (Government of Zimbabwe, 1995).

The Parks and Wild Life Act [Chapter 20:14] establishes the Zimbabwe Parks and Wildlife Management Authority (ZimParks) and provides for the management of protected areas, wildlife and associated tourism activities (Government of Zimbabwe, 1975). The Environmental Management Act [Chapter 20:27] establishes the Environmental Management Agency (EMA) and provides for environmental impact assessment, environmental monitoring and pollution control (Government of Zimbabwe, 2002). The National Tourism Policy provides broader strategic direction for sustainable tourism development, community participation and the distribution of tourism opportunities beyond established destinations (Government of Zimbabwe, 2014).

At the local level, Rural District Councils (RDCs) and traditional institutions perform functions relating to local development, land-use planning, community representation and natural-resource governance (Government of Zimbabwe, 1988, 1998). The Parks and Wild Life Act also allows qualifying RDCs to exercise appropriate authority over wildlife in communal areas, providing the legal basis for local wildlife-management arrangements such as CAMPFIRE (Government of Zimbabwe, 1975; Shereni & Saarinen, 2021).

Tourism businesses, NGOs and community organisations contribute through tourism investment and operations, conservation partnerships, technical assistance, training and community engagement (Musakwa et al., 2020; Mpofu & Van Der Merwe, 2025). The study's document analysis found that, although these instruments assign substantial responsibilities to individual institutions, they provide limited operational detail on how overlapping mandates should be reconciled in routine ecotourism decisions. Table 1 summarises the principal institutions and their coordination needs.

Table 1. Institutional architecture of ecotourism governance in Zimbabwe (Source: Authors' analysis)

Level / domain	Principal actors	Principal roles	Main coordination need
National tourism	Tourism ministry; ZTA	Policy, promotion, facility regulation and standards	Alignment with environmental, wildlife and local-planning decisions
National environment and wildlife	Environment ministry; EMA; ZimParks	Environmental assessment, monitoring, protected areas and wildlife	Integration of conservation, tourism and local-development priorities
Subnational and local	Local authorities / RDCs; traditional and community institutions; CAMPFIRE structures	Land use, local services, community representation and local resource governance	Upward feedback, implementation resources and links to statutory agencies
Non-governmental	Tourism businesses; NGOs; associations	Investment, implementation, technical support, monitoring and training	Predictable participation, transparent decisions and public accountability

The cases were selected purposively to compare governance under a common national framework but contrasting destination conditions. Victoria Falls combines international market visibility, concentrated tourism investment and frequent interaction with regulatory institutions (Masimba, 2024; Shereni & Rogerson, 2023). Hwange is structured strongly around protected-area governance and conservation partnerships involving ZimParks, operators, NGOs and neighbouring communities (Mpofu & Van Der Merwe, 2025). Binga is more remote from major tourism and administrative

centres and relies more heavily on local government, community leadership and project-based relationships to connect with external institutions (Dahl & Tevera, 2019; Matsa et al., 2024). Figure 1 locates the three study sites.

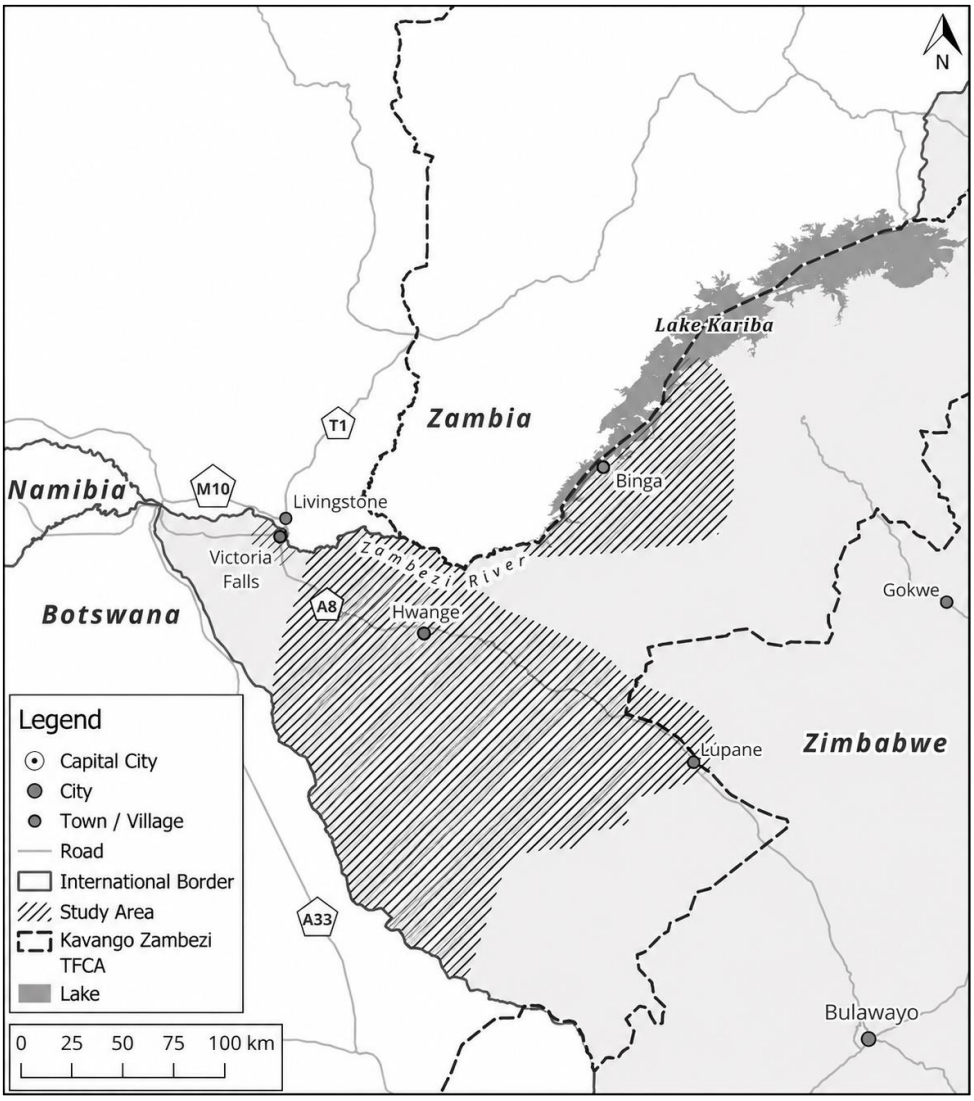

Figure 1. Location of Victoria Falls, Hwange and Binga in Zimbabwe (Source: Authors' own)

RESEARCH DESIGN

The research adopted an interpretivist qualitative multiple-case design, appropriate for examining governance processes within their institutional and geographical contexts (Ridder, 2017; Yin, 2018). The study drew on 39 semi-structured interviews across four stakeholder groups: 12 government and parastatal officials, 5 representatives of environmental and conservation organisations, 14 tourism business actors and 8 community representatives. Participants were selected purposively for their knowledge of policy design, regulation, conservation, tourism operations or community experience, consistent with the logic of purposive sampling in qualitative research (Campbell et al., 2020).

Snowball referrals complemented purposive recruitment where specialised institutional knowledge was difficult to access. Interviews were conducted in person and online during the fieldwork period, audio-recorded with consent and transcribed for analysis. Table 2 presents the distribution of the 39 interviews used in this paper.

Table 2. Distribution of the study sample by stakeholder group (Source: Authors' analysis)

Stakeholder group	Interviews
Government and parastatal officials	12
Environmental NGOs and conservation stakeholders	5
Tourism businesses	14
Community representatives	8
Total	**39**

Interview evidence was triangulated with qualitative document analysis of the principal statutory and policy instruments governing tourism, wildlife, environmental management and community-based resource use. Documents

were examined for institutional mandates, coordination requirements, participation provisions, monitoring responsibilities and areas of overlap. Documentary analysis was used to compare formal institutional design with stakeholder accounts of implementation, drawing on recent guidance for systematic policy-document analysis (Dalglish et al., 2020). Ethical clearance was granted by the University of Johannesburg School of Tourism and Hospitality Research Ethics Committee. Participation was voluntary and based on informed consent. Participant codes identify stakeholder category rather than individual identity: GOV for government and parastatal participants, NGO for environmental and conservation organisations, BUS for tourism businesses and COM for community representatives. Interview transcripts were read repeatedly and analysed thematically. Open inductive coding was first undertaken manually and then organised in ATLAS.ti to support systematic retrieval and comparison. Related codes were grouped into themes addressing institutional roles, overlapping mandates, inter-agency collaboration, participation, feedback, implementation capacity and differences among the three cases. Themes were refined by comparing evidence across stakeholder groups and sites and by examining divergent examples where coordination did work.

This process was consistent with contemporary guidance on thematic analysis and emphasised coherence between the research questions, coding decisions and interpretation (Braun & Clarke, 2021). Interview and documentary evidence were then brought together to compare formal responsibilities with reported governance practice. All direct quotations used in the paper were checked against the study records for accuracy.

RESULTS

Institutional mandates and coordination

Zimbabwe's ecotourism system contains numerous institutions with legitimate but intersecting responsibilities. Tourism agencies focus on sector development, promotion and standards; EMA regulates environmental assessment and environmental management; ZimParks oversees protected areas and wildlife; and local authorities carry planning, service and community-facing responsibilities. Participants described examples of cooperation among these bodies, including environmental assessments, inspections and conservation initiatives. The problem was therefore not a complete absence of collaboration, but uncertainty and delay when several mandates applied to the same issue. Different institutional priorities complicated coordination, a government participant explained:

“Sometimes, our priorities don't align perfectly, to mention an example, the Ministry of Tourism might be focused on increasing visitor numbers, while we at ZTA are more concerned with sustainability, but obvious we can always try to make sure that we are on the same track” (ZTA official, national level).

The comment illustrates how disagreement can occur even among institutions working within the tourism field. Participants also described situations in which tourism development, conservation and environmental requirements were considered through separate administrative processes. Although each process served a legitimate purpose, the absence of a consistently understood pathway for resolving overlaps could create duplication, slow approvals and make it difficult for operators or communities to know which institution was responsible for a final response.

Inter-agency collaboration and resource constraints

Participants from government reported working relationships among the tourism ministry, ZTA, EMA, ZimParks and local-government institutions. Joint inspections and environmental assessments showed that agencies could coordinate when a specific need arose. One official described the practical pattern as follows:

“We try to work with EMA and ZTA. We go together sometimes to check, but not all the time. Sometimes it’s hard because everyone [each organisation] is busy, you know? But we try to meet and talk about the problems.” (Tourism ministry official, national level)

The distinction between occasional cooperation and routine coordination was important. Participants described collaboration as dependent on the issue, available staff, transport and project resources. This limited continuity and made follow-through difficult. A government participant discussing proposed coordination structures captured the problem directly:

“One of our more recently proposed initiatives is the inter-ministerial committee on tourism sustainability, which aims to bring together representatives from various ministries. We can have all the committees and meetings we want, but if we don’t have the resources to follow through, we’re not going to see the results we need.” (Tourism ministry official, national level)

These accounts suggest that institutional forums alone cannot solve coordination problems. Without staff time, budgets, shared work programmes and clear responsibility for implementing decisions, meetings may improve communication temporarily but without changing routine practice.

Tourism businesses experienced this weakness through slow approvals and the need to engage several authorities sequentially, increasing the time and effort required to develop or adjust tourism activities.

Governance processes and local feedback

Participants consistently described a governance system in which rules and policy directions moved more clearly from national institutions to destinations than local experience moved back into decision-making. Businesses and communities attended consultations and interacted with local authorities, but several participants were uncertain whether their contributions influenced final decisions. A Victoria Falls business participant stated:

“We are occasionally consulted, but not as often as we should be. Sometimes it feels like decisions are made without fully understanding the practical challenges we face. Operators like us have firsthand experience with what works and what does not, so our input could definitely help shape more effective regulations.” (Tourism business representative, Victoria Falls)

The problem was not whether consultation occurred, but whether it occurred early enough to influence decisions and whether participants received feedback on the outcome. In Binga, a participant similarly described consultations that did not reliably shape higher-level decisions:

"We need to be asked what we think about tourism developments, not just told what is happening after the decisions are made." (Community representative, Binga)

This shows that stakeholders were not entirely excluded from decision-making, but opportunities to provide feedback were irregular and rarely followed by a clear response. Participants could not identify a consistent process for communicating whether locally raised concerns had been addressed, declined or referred to another institution. Access to formal meetings was also uneven, as established organisations were generally better placed to participate than small businesses and geographically dispersed communities. Thus, practical experience from the local level did not always reach the institutions responsible for policy and regulatory decisions.

Destination-level variations in institutional coordination

The cross-case comparison shows that a common national framework does not generate identical governance conditions. The same laws and national agencies interact with different levels of institutional presence, stakeholder networks and administrative access in each destination. Table 3 summarises these differences.

Table 3. Place-specific coordination conditions across the three study sites (Source: Authors' analysis)

Site	Institutional setting	Main coordination challenge	Priority response
Victoria Falls	Dense presence of regulators, established operators and environmental actors	Multiple agencies and sequential processes create congestion and delays	Coordinate approvals, monitoring and operator feedback
Hwange	Strong protected-area and conservation partnership networks	Local government and community influence is uneven within a park-centred system	Link conservation networks to a broader destination forum
Binga	Thinner institutional presence and greater administrative distance	Weak routes for local concerns, support and follow-up	Strengthen district coordination, outreach and formal feedback channels

Victoria Falls had the densest interaction among regulators, operators and environmental actors. This institutional presence improved access to agencies and made joint activity more feasible, but it also created coordination pressure because several authorities could become involved in the same proposal or issue. Businesses described administrative delay and consultation that did not always lead to visible responses. The central problem in Victoria Falls was therefore coordination among co-present institutions rather than the absence of governance actors. Hwange displayed strong conservation relationships centred on the protected area. Tourism businesses described partnerships with conservation organisations that supported monitoring, compliance, training and community initiatives. These networks provided practical capacity, yet formal governance remained strongly shaped by protected-area priorities.

Participants still reported top-down communication and limited influence over some regulatory decisions. The main challenge was to connect existing conservation networks more consistently with local government, tourism enterprises and community interests at destination level. In Binga, fewer institutions were directly involved in tourism governance, coordination therefore relied mainly on the local authority, community leaders and relationships developed through individual projects. Participants reported limited opportunity to influence policy, weaker implementation support and greater distance from national institutions. Remoteness was not the only problem, but it made coordination more difficult because there were fewer routine opportunities through which local concerns could be transmitted, interpreted or followed up. Therefore, Binga faced both a coordination problem and a capacity problem.

Bridging roles of NGOs and tourism businesses

Across the cases, NGOs and tourism businesses helped connect institutions and stakeholder groups. NGOs supported environmental assessment, training, community engagement and advocacy, while businesses translated regulatory requirements into day-to-day operations and sometimes contributed to conservation monitoring and local development projects. One NGO participant described this intermediary role directly:

"Feedback is provided to government on how these laws are being implemented on the ground, which helps to make sure that our advocacy is not only aligned with the laws and policies but also practical and reflective of community needs." (Environmental NGO representative, national level)

These bridging roles strengthened communication where formal channels were weak, but their limitations were also clear. NGO projects depend on funding, business participation varies, and neither group can guarantee that public agencies will respond to local concerns. Non-governmental actors can therefore support coordination, but they cannot replace clear public responsibility, predictable institutional processes or sustained government presence across destinations.

DISCUSSION

The findings suggest that Zimbabwe does not lack institutions or regulations for governing ecotourism. Responsibilities are already distributed among specialised government agencies, local authorities, community structures and non-state organisations. The main difficulty lies in coordinating their work when mandates intersect. Differences in

priorities, infrequent joint activities and limited resources often weaken implementation, even though formal institutions and regulations are in place. Comparable research on developing-country and forest-based ecotourism identifies fragmented governance, overlapping regulation and uneven institutional capacity as recurring implementation barriers (Forje et al., 2022; Lawasi et al., 2025; Wondirad et al., 2020). Sentanu et al. (2023) likewise found that participation and communication contribute to tourism governance only when they are supported by arrangements that enable stakeholders to coordinate decisions and carry them through. The findings help explain why establishing another committee would not, on its own, resolve coordination problems. Participants were already aware of joint initiatives, meetings and inspections, but reported that these activities were irregular and often limited by a lack of resources. Improving coordination therefore depends less on creating new structures than on making existing arrangements work consistently. Institutions need clearly defined roles, workable procedures for making and implementing joint decisions, and sufficient resources to undertake shared activities. This finding is consistent with Harilal et al. (2025), who identify communication, clarity of stakeholder roles and cohesion as important to inclusive tourism development.

The findings also indicate that decision-making within Zimbabwe's ecotourism governance system remains largely top-down. Although consultation took place, participants generally felt that they had little influence over final decisions and received limited feedback afterwards. Being invited to meetings did not necessarily amount to meaningful participation, what mattered was whether the views and practical knowledge shared by communities and implementers were considered, and whether institutions explained how this input informed their decisions.

Attendance at meetings did not necessarily amount to meaningful participation; influence, responsiveness and evidence that local knowledge shaped decisions mattered more. Similar patterns of centralised decision-making and passive community participation have been reported in South Africa and Uganda (Makhanyela et al., 2024; Nabalegwa et al., 2025). Dangi & Petrick (2021) similarly identify representation, responsiveness and collaborative participation as important elements of sustainable community-based tourism governance. Mpofu & Van Der Merwe (2025) also emphasise the need for more meaningful community participation in tourism planning in Hwange. Comparable evidence from KwaZulu-Natal shows that centralised administration, fragmented stakeholder relationships and weak coordination can limit meaningful community participation in ecotourism development (Makhanyela et al., 2024).

Improving participation may therefore depend less on creating additional consultation forums and more on ensuring that existing consultations lead to clear responses. Local authorities, community organisations and tourism businesses often encounter implementation problems first and can bring these concerns to the attention of responsible institutions. However, their contribution has little effect when issues raised during consultation are not recorded, referred or followed up. Institutions could address this by documenting the main concerns raised, assigning responsibility for each issue and reporting back on the action taken. NGOs may help communicate community and technical concerns, but the relevant public institution should remain responsible for providing a response.

The comparison shows that coordination challenges take different forms across the three destinations. In Victoria Falls, the large number of institutions involved can lead to overlapping procedures and difficulties in aligning their activities. Hwange benefits from established conservation partnerships, although coordination needs to extend beyond institutions and organisations centred on the national park. In Binga, links with national institutions are less frequent, leaving local actors with less access to the institutional support needed to address tourism and conservation issues. These findings support recent studies showing that multi-level governance is shaped by local conditions and that the same national policy may be implemented differently from one destination to another (Guo & Li, 2025; Novalia et al., 2025). They are also consistent with Zimbabwean studies that identify geographical differences in sustainability practices and continuing challenges surrounding community participation in Hwange (Mpofu & Van Der Merwe, 2025; Shereni & Rogerson, 2023).

This does not mean that each destination requires separate environmental or tourism legislation. Common national standards remain necessary to ensure consistency and public accountability. However, the support required to meet those standards will differ between destinations. Victoria Falls may benefit from clearer procedures for coordinating the many institutions already present, while Hwange requires stronger connections between park-centered partnerships and the wider district. Related research within the KAZA conservation network shows that local and sectoral partnerships vary with community agency, institutional context and power, supporting stronger links between local collaboration and higher governance levels (Tichaawa & Lekgau, 2025). In Binga, the priority is to improve access to national institutions and strengthen local administrative capacity. Applying the same administrative response across all three destinations could therefore place those with fewer resources and weaker institutional connections at a further disadvantage.

This study makes an empirical contribution by bringing together evidence from 39 interviews with government and parastatal officials, environmental and conservation organisations, tourism businesses and community representatives.

Considering these perspectives together shows how the same coordination problem can be experienced differently across the sector. Overlapping responsibilities within government may result in delays for tourism operators, limited opportunities for communities to influence decisions and additional pressure on NGOs to connect institutions and local stakeholders. The study therefore presents a broader account of how ecotourism governance operates in practice rather than examining it from the perspective of a single group. The comparison of Victoria Falls, Hwange and Binga also adds an important geographical and comparative contribution. Although all three destinations are governed under the same national legal and policy framework, coordination does not work in the same way in each place. Victoria Falls illustrates how the presence of many institutions can create overlapping procedures and make coordination difficult.

Hwange benefits from established conservation partnerships, but these relationships remain largely centred on the national park. In Binga, distance from national institutions and limited institutional presence reduce access to support

and opportunities to provide feedback. The findings therefore show that governance can vary considerably within one country, even where the same laws and policies apply (Guo & Li, 2025; Novalia et al., 2025).

The findings also have practical contribution, they suggest that Zimbabwe's immediate priority is not necessarily to create additional institutions, but to improve how the existing ones work together. This requires clearer responsibilities where mandates overlap, more regular and adequately resourced joint activities, stronger obligations to respond to concerns raised by local stakeholders, and greater support for destinations with limited institutional capacity.

The study shows that effective ecotourism governance depends on more than the existence of appropriate laws and organisations. It also depends on the working relationships through which institutions coordinate decisions, respond to local concerns and implement policy in different destinations.

The findings suggest four practical steps for improving coordination; at the national level, institutions responsible for tourism, environmental management and wildlife should develop a shared protocol for handling ecotourism proposals and recurring governance issues. This protocol should identify the lead institution, the information required from each agency, expected timeframes and procedures for resolving disagreements. Where a proposal requires approval from several agencies, assessments should be coordinated as far as the law allows to reduce unnecessary duplication for applicants. Coordination also needs to be strengthened at the destination level. Existing forums and partnerships should operate through agreed work programmes, designated responsibilities and sufficient budgets for implementation, rather than meeting only when a particular issue arises. The focus should reflect local conditions. In Victoria Falls, priority should be given to coordinating approvals, monitoring activities and responses to concerns raised by operators. In Hwange, conservation partnerships need stronger links with local government and community interests. Binga would benefit from more regular engagement and stronger connections between district institutions and national agencies.

Consultation should also be followed by a clear response, records of engagement should state the concern raised, the institution responsible for addressing it, the decision reached and any further action required. Communities and local businesses should be involved early enough for their knowledge to inform decisions, especially where proposed developments may affect land use, livelihoods or conservation responsibilities. The allocation of coordination resources should consider administrative distance and local institutional capacity, rather than being determined mainly by tourism volumes. More remote destinations may need additional technical assistance, visits from national officials and opportunities to participate remotely if they are to meet national requirements. NGOs and tourism businesses can continue to provide technical support and assist communication among stakeholders. However, responsibility for public decisions and for responding to concerns raised by stakeholders should remain with the relevant public institution.

CONCLUSION

This paper examined how relationships among institutions and stakeholders at different levels influence ecotourism governance in Victoria Falls, Hwange and Binga. Zimbabwe has an extensive set of laws, public agencies, local authorities and non-state organisations involved in tourism, environmental management, wildlife conservation and local governance. However, these arrangements do not always work together effectively during implementation.

Participants described overlapping responsibilities, competing institutional priorities, irregular joint activities and limited resources. They also reported that concerns raised locally did not always reach the institutions responsible for making decisions or receive a clear response. The comparison shows that these challenges differ across destinations, in Victoria Falls, the involvement of many institutions can result in overlapping procedures and difficulties in coordinating approvals and monitoring. Hwange benefits from established conservation partnerships, but these relationships remain largely centred on the national park and need stronger connections with local government, businesses and communities. In Binga, local actors have fewer regular links with national institutions and less access to technical support and decision-makers. The same national governance framework is therefore implemented under very different local conditions.

The findings do not point to an immediate need for additional institutions. Instead, they show the importance of improving how existing organisations work together. Responsibilities need to be clearer where mandates overlap, and joint activities require regular funding and agreed procedures. Approval and monitoring processes should be better coordinated, while communities and businesses should be involved early enough for their knowledge to inform decisions. Institutions should also report back on concerns raised during consultation.

The form of support provided should reflect local capacity, with less-connected destinations receiving greater assistance in accessing national institutions and meeting common standards. The study shows how coordination problems are experienced across institutional boundaries, through bringing together the experiences of government agencies, local authorities, communities, NGOs and tourism businesses.

Its comparison of three destinations also demonstrates that the effectiveness of multi-level governance depends on local institutional conditions as well as national laws and policies. For Zimbabwe, stronger coordination would improve more than administrative efficiency. It would help ensure that conservation priorities, tourism development and local interests are considered together. Ecotourism governance will be more effective and legitimate when institutions communicate consistently, follow through on joint decisions, respond to local concerns and remain accessible to destinations with weaker institutional connections.

LIMITATIONS AND FUTURE RESEARCH

This study was designed to generate analytical insights rather than findings that can be statistically generalised to all ecotourism settings in Zimbabwe. It draws on 39 semi-structured interviews with purposively selected participants.

Although the interviews included several stakeholder groups, individual accounts cannot be assumed to represent every view within an organisation or stakeholder category. Victoria Falls, Hwange and Binga also provided useful contrasts, but they do not reflect the full range of conditions found across Zimbabwe's ecotourism destinations.

Future research could examine whether similar coordination challenges occur in other protected areas, borderland and community-based tourism settings. Longitudinal studies would help establish how relationships among institutions change as tourism and environmental governance reforms are implemented.

Social network analysis could provide a more systematic picture of which actors interact, how frequently they communicate and where influence is concentrated. Participatory research could also explore how communities experience consultation, representation, feedback and accountability over time.

Abstract: Sustainable tourism affects host communities through interactions with tourists and other stakeholders, generating both benefits and costs for local residents. This study aims to examine how community involvement in community-based sustainable tourism development influences residents' overall well-being in Western Kenya, with particular attention to the mediating roles of support for tourism and community perceptions. The study addresses the limited empirical evidence on how these factors jointly shape residents' well-being in tourism contexts in developing regions. The study was guided by Social Exchange Theory and used a purposive sampling strategy. Quantitative data were collected using a structured questionnaire. A total of 400 questionnaires were administered, of which 310 complete responses were retained for analysis representing a 77.5% response rate. The data were analysed using a binary logistic regression model to assess the effects of community involvement, support for tourism, and community perceptions on overall well-being. The findings show that community involvement significantly improves residents' overall well-being, increasing it by 10.77%. Support for tourism and positive perceptions contributed an additional 1.5% and 0.5%, respectively. Interaction effects further revealed that community involvement combined with support increased well-being by 2.3%, while involvement combined with positive perceptions increased well-being by 6.8%. These findings provide empirical support for the application of Social Exchange Theory by demonstrating how participation, perceptions, and tourism support are associated with residents' well-being in the Western Kenyan context. These results suggest that active community participation, favourable perceptions, and stronger support for tourism are important drivers of improved well-being. The study, therefore, highlights the need for inclusive tourism policies and community-centred strategies that strengthen local participation and benefit-sharing mechanisms to enhance sustainable tourism development in Western Kenya.

Keywords: community participation, sustainability, tourism strategy, Social Exchange Theory, logistic regression, community-based model

INTRODUCTION

Community involvement in sustainable tourism development planning has long been recognized as a pathway for empowering residents to participate in decision-making and implement strategies that advance desired socioeconomic outcomes (Riyanto et al., 2023). As a bottom-up approach, community involvement addresses issues directly shaping the tourism experience and fosters a development environment aligned with local social and cultural contexts (Park et al., 2017). Importantly, such involvement protects the community's environment and cultural heritage while simultaneously enhancing socioeconomic well-being. These benefits explain why community-based sustainable tourism has attracted growing scholarly and policy attention (Nuanmeesri, 2022; Mohammed & Osumanu, 2022).

Across developing contexts, community-based tourism has demonstrated potential for poverty alleviation, livelihood diversification and improvements in local welfare (Mohammed & Osumanu, 2022; Priatmoko et al., 2025).

Tourism generates markets for local goods and services and provides diverse occupational opportunities that improve community well-being (Dogra et al., 2022; Wani et al., 2024). Achieving sustainability, however, requires balancing tourism's economic, environmental, and sociocultural dimensions (Li et al., 2021; Wani et al., 2023).

When practiced sustainably, community-based tourism reduces problems while maximizing benefits for local communities (Dogra et al., 2022). For these reasons, developing nations have increasingly embraced it as a strategy for advancing socio-economic resilience (Wani et al., 2024).

Despite its conceptual advancement, empirical evidence on the socioeconomic impacts of community-based sustainable tourism remains limited (Jugmohan & Giampiccoli, 2017; Wani et al., 2024). Rural communities, small islands, fishing villages, and indigenous groups could benefit substantially from such models (Wang et al., 2016; Watts et al., 2022). However, the success of these initiatives hinges on residents' active participation across decision-making, implementation, and evaluation processes (Wu et al., 2019; Rahman et al., 2024). Stakeholder-driven involvement not only fosters more effective, sustainable ecotourism but also enhances human well-being (Tseng et al., 2019). Indeed, community support is strongly shaped by residents' perceptions of tourism's economic, social, and environmental impacts (Dündar & Karacaer, 2024).

Tourism development can transform community values, lifestyles, and quality of life, often with both positive and negative outcomes (Rasoolimanesh et al., 2017; Sharpley, 2014; Mathew, 2022). Economically, it can create jobs, diversify income sources, and stimulate empowerment, but may also raise living costs and exacerbate property pressures (Dinis et al., 2019; Rasoolimanesh et al., 2015). Socially, tourism can enrich entertainment, recreation, and cultural identity (Mayaka et al., 2019; Su et al., 2017), while also causing congestion, crime, pollution, displacement, or cultural erosion (Alamineh et al., 2023; Látková & Vogt, 2012). On the cultural front, it can heighten global visibility and pride in local heritage (Gursoy et al., 2019), yet it must carefully balance preservation with tourism pressures (Ashworth & Page, 2011).

Both rural and urban contexts illustrate these dynamics. In rural areas, community-based tourism supports farming, services, and crafts while promoting cultural identity (Polukhina et al., 2021). Empirical studies confirm its potential for stable job creation, income growth, and poverty alleviation (Atun et al., 2019; Cheng & Zhang, 2020; Chen et al., 2022; Cunha et al., 2020) but also highlight risks such as income inequality and uneven spatial development (Zhang et al., 2023; Liu et al., 2022). In urban areas, tourism interacts with complex social and economic systems. While it can boost infrastructure, cultural tourism, and socio-economic well-being (Shin, 2010; Jaafar et al., 2020; Tan et al., 2023; Ma et al., 2020), excessive tourism threatens urban liveability, widening wage gaps, and limiting long-term benefits (Ananian et al., 2018; Ashworth & Page, 2011; Rasoolimanesh et al., 2017; Shi et al., 2020; Liu et al., 2023).

To explain these mixed outcomes, Social Exchange Theory (SET) offers a valuable lens. SET posits that individuals engage in exchanges to maximize benefits and minimize costs, making it well-suited to analyze residents' attitudes towards tourism. Community attachment,empowerment and a sense of belonging, increase residents' willingness to support and participate in tourism initiatives (Olya et al., 2018; Khalid et al., 2019; Strzelecka et al., 2017; Durrah et al., 2025). Similarly, residents' perceptions of economic growth, cultural enrichment, and social improvements positively influence support, whereas perceived costs reduce it (Chili, 2015; Pazhuhan et al., 2023; Megawati et al., 2025). Participation and inclusive governance further enhance legitimacy and sustainability (Choi & Murray, 2010; Dündar & Karacaer, 2024).

Against this backdrop, understanding the role of community involvement in shaping well-being through sustainable tourism becomes crucial. This study applies SET to explore how community attachment, perceived benefits, empowerment, participation, and environmental stewardship affect residents' support and overall well-being in Western Kenya. Applying SET to Western Kenya underscores the importance of community attachment, perceived benefits, empowerment, participation, and environmental stewardship in shaping residents' support for sustainable tourism. These factors collectively contribute to improved well-being, stronger engagement, and more effective, community-driven tourism development. The integration of SET not only contextualises local behaviour but also adds scientific value by linking psychosocial theories with empirical development outcomes. Therefore, this has paved the way for a probable research gap worth filling in this study.

We focused on community-based sustainable tourism practices among residents in Western Kenya, one of the regions where the country's development is being explored. Understanding the effects of community involvement in community-based sustainable tourism development on overall well-being can provide valuable insights into the interplays between local communities and sustainable tourism development from a specific geographical setting.

The aim of this study is to examine how community involvement in community-based sustainable tourism development influences residents' overall well-being in Western Kenya, with particular attention to the mediating roles of community perceptions and support for tourism development. More specifically, the study aims to contribute to the literature by addressing the following research questions:

i. To what extent does community involvement in community-based sustainable tourism development influence their overall well-being?

ii. Do perceptions mediate the relationship between involvement and well-being?

iii. What is the mediating effect of support for community-based sustainable tourism development on the nexus between community involvement and their overall well-being? By addressing these dynamics in a developing region context, this research responds to calls for more empirical evidence on the socioeconomic impacts of community-based sustainable tourism. It contributes to advancing both theory and practice.

MATERIALS AND METHODS

Study Area

The study was carried out in Western Kenya, covering Bungoma, Busia, Kakamega, Trans-Nzoia, and Vihiga counties, with a focus on Bungoma County due to its active tourism sector and diverse attractions. Bungoma (area ≈ 3,032.4 km²) hosts a range of cultural and natural sites (Mount Elgon National Park, Kitum Cave, Nabuyole Falls, Chetambe Fort, etc.) and a predominantly agricultural economy (County Government of Bungoma, 2023; Mamati & Omare, 2024; Downing et al., 2023; Kariithi, 2018). Local livelihoods combine farming with tourism-linked activities (guiding, hospitality, cultural performances, and handicrafts), making the county a suitable case for examining how community involvement in tourism relates to residents' well-being (Oduya, 2017). Figure 1 presents the study area in

Western Kenya, including the selected counties and the focal case of Bungoma County.Western Kenya, including the selected counties and the focal case of Bungoma County. Figure 2 shows selected original field photographs of tourism resources and community-related tourism activities linked to the study objectives.

Figure 2. Community-related tourism activity (Source: Photos by the author, taken during fieldwork, 2024)

Data Collection and Sampling

Data were collected using a structured questionnaire adapted from recent studies on community involvement, perceptions, tourism support, and well-being (e.g., Eslami et al., 2019; Gursoy et al., 2002; Riyanto et al., 2023). The questionnaire comprised four sections: (1) socio-demographic information (age, gender, education, monthly income (KES), residence, occupational engagement with tourism); (2) community involvement in tourism; (3) perceptions of sustainable tourism (positive and negative); and (4) overall well-being. Most attitudinal items used a 5-point Likert scale (1 = strongly disagree … 5 = strongly agree). Participants provided informed consent prior to completing the survey. A purposive, multi-stage approach targeted households and individuals engaged (directly or indirectly) in community-based tourism across the five counties, with Bungoma selected as a primary study site for its representativeness and accessibility. The sampling frame used 2019 Census household figures for the selected areas (N ≈ 358,796). Using Israel's (1992) formula for sample size estimation,

$$n = \frac{N}{\left(1 + N(e^2)\right)}$$

were n = sample size, N = target population size, e=level of precision (5%)

$$\text{Thus, } n = \frac{358{,}796}{\left(1+358{,}796(0.05^2)\right)} = 400$$

A total of 400 questionnaires were administered; 90 questionnaires were incomplete and therefore excluded, leaving 310 complete responses for analysis (final response rate = 310/400 = 77.5%).

Ethical considerations

Respondents were informed about the study's purpose and provided consent. Survey participation was voluntary and anonymous; no identifying data beyond institutional contact details for the corresponding author were recorded. Where required, local permissions and approvals were sought.

Analytical Approach

The study applied descriptive and inferential statistics in analysing the collected data. Specifically, the demographic and socioeconomic attributes of households were analysed descriptively using percentages and frequencies, as well as means and standard deviations. Community involvement, tourism support, perceptions, and overall well-being were analysed and presented in figures. The qualitative data were analysed synthetically by summarizing familiar thematic texts.

Regarding the effect of community involvement on the overall well-being of the households, the four-item questions were summed into a score, out of which 1-stronly disagree and disagree scores were merged to imply a negative response "no" denoted by zero, and agree and strongly agree were merged into a positive answer "yes" denoted by 1. This also applied to supporting community perceptions of sustainable community-based tourism and encouraging households to support it. Since the outcome variable (household well-being) was binary, the study employed a binary logistic regression model to analyse the effect of involvement in community-based tourism, as well as the mediating effects of support for tourism and perceptions of the community. Binary responses on overall well-being were used to provide a detailed view of the influence of community-based tourism involvement. The binary logistic model was applied in this study because it is helpful for analysing binary variables and is flexible in handling a mixture of continuous and categorical variables (Agresti, 2010; Jari & Fraser, 2009). Following Agresti (2010), the binary logistic regression model was specified as follows:

$$Wi = In\left(\frac{P\pi i}{1 - P\pi i}\right) = \beta 0 + \beta 1 Com - invo1 + \beta 2 Com - invo * Sup2 + \beta 3 Com - invo * Perc3 + \beta c Xc + \mu i$$

Where Wi denotes well-being, $Com - invo$ denotes community involvement, $Com - invo * Sup$ denotes interaction between community involvement and support for community-based sustainable tourism, $Com - invo * Perc$ indicates interaction between community involvement and community perceptions of tourism, $P\pi i$ denotes the probability of positive well-being, and $1 \neg P\pi i$ is the probability of negative well-being, $\beta 0$ denotes the intercept, $\beta 1, \beta 2, \beta 3, \beta c$ denotes coefficient estimates of community involvement, interaction between community involvement and support, community involvement and perceptions and household covariates (marital status, education level, gender, age, residence and average monthly income). The error term is denoted by μi . The subscript i denotes households $i = 1, \ldots, 310$.

RESULTS AND DISCUSSION

Descriptive and Summary Statistics

Table 1 provides a detailed description of the study variables. The social-demographic variables indicate that more than half (50.2%) of the sampled respondents were female, while 49.8% were male. The majority (75.7%) of households resided in urban regions. The majority (96.1%) of household heads have a tertiary level of education, with an average monthly income of KES 14,371.84. More than half (84.1%) of the sampled household heads were unmarried, while the majority (71.9%) engaged in community-based tourism as an economic activity.

Results show that 60.3% of respondents are involved in community-based tourism, and 64.5% are involved in its development. This highlights strong local engagement in sustainable tourism practices. Lastly, the majority (61.3%) of

respondents have a positive perception of community-based tourism development. Altogether, we can state that not only do respondents support this, but the majority are looking for positive changes and are ready for the challenge.

Effect of Community Involvement on Overall Community Well-being: Binary Logistic Estimation

The effect of community involvement, along with other household characteristics, on residents' overall well-being was modelled using a binary logistic regression. Table 2 presents coefficient estimates, marginal effects, standard errors, and corresponding significance levels. The likelihood ratio value of -207.334 indicates that the binary logistic model and the selected independent variables accurately fit the collected data, suggesting that the probability of positive overall well-being, along with the explanatory variables, collectively contributes to a comprehensive understanding of overall well-being in the community. The pseudo-R-squared value of 0.4987, with a statistically significant ($P < 0.05$) greater LR Chi-square value of 3.880, indicated that the estimated logistic regression model has adequate explanatory power; hence, the model's information is appropriate. Table 2 shows that community involvement significantly predicts' well-being ($\beta = 0.431$, $p < 0.05$).

Pseudo R^2	0.4987				
Log Likelihood	-207.334				
No. of Observations	310				

Community involvement was a significant positive predictor of residents' overall well-being at the 5% significance level. Specifically, community involvement had a positive effect on well-being ($\beta = 0.431$; $P = 0.018 \leq 0.05$). The marginal effect indicates that an increase in the number of community members involved in tourism results in a 10.77% increase in residents' overall well-being, holding other factors constant. This is because community involvement in community-based tourism reflects the extent to which residents participate in tourism-related activities, thereby influencing their overall well-being (Riyanto et al., 2023). These results align with previous studies (Abukhalifeh & Wondirad, 2019; Lee & Jan, 2019; Riyanto et al., 2023). The findings also revealed that support and positive perceptions of community-based tourism are significant positive predictors of residents' overall well-being. These findings align with those observed in recent studies (Chang, 2021; Han et al., 2023; Riyanto et al., 2023).

Interestingly, the marginal effects indicate that increases in support for and positive perceptions of community-based tourism development are associated with 1.5% and 0.5% increases in residents' overall well-being, respectively. Indeed, when the residents are informed or are privy to the perceived positive effects of sustainable community-based tourism, their lives are affected emotionally, materially, safety-wise, and health-wise, which ultimately influences their overall well-being (Andereck & Nyaupane, 2011; Woo et al., 2015; Eslami et al., 2019; Han et al., 2023; Kim et al., 2013).

The results indicated that household head age and community negative perceptions were significant negative predictors of residents' overall well-being. Specifically, the marginal effects indicate that a 100% increase in household heads and negative perceptions results in a decline in residents' overall well-being of 1.7% and 2.3%, respectively.

These results align with the findings of Rasoolimanesh et al. (2017), who found that a negative perception of the socioeconomic impact of community-based tourism leads to reduced community involvement and support for tourism, ultimately affecting overall well-being. Furthermore, the findings confirm the views of Hunt & Stronza (2014) that residents who are not fully involved in community-based tourism tend to hold a more negative attitude towards it, thereby negatively influencing their overall well-being. On the other hand, household gender had a positive and significant effect on residents' overall well-being (β=0.098; P=0.000≤0.05), implying that an increase in male-headed households by 100% results in an increase in residents' overall well-being by 2.4% as indicated by the marginal effects.

Mediating Roles of Tourism Support and Community Perceptions: Binary Logistic Estimation

The study also examined the mediating role of support and community perceptions in the impacts of community-based tourism development. In particular, the need to have a deeper understanding of how community involvement in community-based sustainable tourism development has pushed many researchers to investigate the role played by the community's perceptions and support for sustainable tourism development in influencing their involvement and their overall well-being (Nawijn & Mitas, 2012; Koh et al., 2020; Riyanto et al., 2023). Specifically, studies have started examining the mediating effect of community perceptions and support for community-based sustainable tourism development (Gannon et al., 2021; Han et al., 2023; Riyanto et al., 2023; Tosun et al., 2021). The study started by classifying community perceptions into positive and negative perceptions, where previous studies have observed a significant positive link between positive perceived socioeconomic impacts of tourism and residents' overall well-being (Eslami et al., 2019; Han et al., 2023; Kim et al., 2013; Riyanto et al., 2023; Woo et al., 2022).

Table 3. Mediating Effect of Community Perceptions and Support for Tourism Development on Overall Well-being (Source: Author's analysis using survey data, 2024) (Note: ***p < 0.01; **p < 0.05; *p < 0.1)

Variable	Coefficient	Marginal effect	Std. Err	Z	P-value>|Z|
Community involvement	0.275**	0.069**	0.576	0.48	0.033
Tourism support	0.003**	0.001**	0.388	-0.01	0.000
Positive perceptions	0.154	0.039	0.426	0.36	0.718
Negative perceptions	-0.021	-0.005	0.394	-0.05	0.957

Community involvement*Positive	0.271***	0.068***	0.545	0.50	0.020
Community involvement* Negative	-0.182	-0.045	0.486	-0.37	0.708
Household head gender	0.094	0.023	0.252	0.37	0.600
Household head age	-0.038*	-0.010*	0.133	-0.29	0.017
Household head marital status	-0.071	-0.018	0.342	-0.21	0.836
Household average monthly income	1.81e-6**	4.52e-7**	5.76e-6	0.31	0.053
Household head's education level	0.046	0.011	0.383	0.12	0.079
Constant	-0.134		0.943	-0.14	0.887
LR Chi2 (12)	4.32				
Prob > Chi^2	0.0105				
Pseudo R^2	0.2770				
Log Likelihood	-207.113				
No. of Observations	310				

On the other hand, inadequate planning and management of community-based tourism development led to negative perceptions, which ultimately impact the overall well-being of residents (Xu & Hu, 2021). How the community perceives the socioeconomic impacts of community-based tourism development influences their support, and this has a significant influence on their overall well-being (Eslami et al., 2019; Han et al., 2023; Jeon et al., 2016; Latip et al., 2018; Riyanto et al., 2023; Yu et al., 2018). Table 3 highlights the mediating roles of perceptions and tourism support in the relationship between involvement and well-being, with positive perceptions exerting the greatest influence.

Accordingly, the findings indicate a positive and significant mediating role of positive perceptions in the link between community involvement and residents' overall well-being ($\beta = 0.271$; $P \leq 0.05$). The marginal effects indicate that a 100% increase in the interaction between community involvement and positive perception results in a 6.8% increase in residents' overall well-being, holding all other factors constant. The findings align with the observations made by previous studies that sociocultural natural interactions with tourists are significantly associated with positive perceptions among residents, thereby promoting positive lifestyles, safety, and higher life satisfaction in non-material well-being domains (Carneiro et

al., 2018; Han et al., 2023; Hu et al., 2022; Xu & Hu, 2021). On the other hand, the results indicated a positive and significant interactive effect between community involvement and community-based tourism development on residents' overall well-being ($\beta = 0.092$; $P = 0.046 \leq 0.05$). The marginal effects indicate that a 100% increase in the interaction between community involvement and support for community-based tourism development results in a 2.3% increase in residents' overall well-being, holding all other factors constant. These findings corroborate previous studies showing that communities' perceptions of socioeconomic impacts influence their support and involvement in tourism (Dodds et al., 2018; Wani et al., 2024) but also provide new insights by quantifying effect sizes. Specifically, community involvement increased residents' well-being by 10.77% with additional effects from support (1.5%) and positive perceptions (0.5%).

Interaction effects between community involvement and support raised well-being by 2.3%, while involvement combined with positive perceptions increased it by 6.8%. These proportions are notably higher than those reported in earlier studies focusing on qualitative or non-context-specific analysis. The study extends Social Exchange Theory by empirically validating that perceived benefits (economic and social) significantly drive community members to exchange their support and involvement in tourism for improved well-being. This model-based, data-driven evidence from a rural Kenyan context offers a differentiated contribution to the literature and provides a replicable approach for other developing regions. For instance, the development of community-based tourism infrastructure increases social interaction and experiences as well as socioeconomic gains, thereby influencing overall well-being (Carrie et al., 2022; Jeelani et al., 2024; Wani et al., 2024).

CONCLUSION

Community involvement and residents' goodwill are paramount for the success and sustainability of any community-based tourism development. To evaluate residents' overall well-being resulting from community involvement, perceptions, and support for community-based sustainable tourism development precincts, this study drew on social exchange theory.

It incorporated various constructs related to residents' overall well-being, involvement, perceptions, and support for community-based tourism development. The study findings revealed a significant positive effect of community involvement on residents' overall well-being. The results further indicated a significant positive mediating effect of support and community perceptions of community-based tourism development. Most importantly, the study revealed that community perceptions of the socioeconomic impacts of community-based tourism development influence their involvement and support, which ultimately affect their overall well-being, as summarized in Table 4.

Additionally, the study synthesizes the research questions, key statistical findings, and recommended policy actions.

Table 4. Summary of Research Questions, Key Findings, and Policy Implications
(Source: Author's summary based on study findings, 2024)

Research Question	Findings	Policy Implications
To what extent does community involvement influence well-being?	Community involvement increases well-being by 10.77%.	Develop programs to boost local participation in tourism planning and implementation.
Do perceptions mediate the relationship between involvement and well-being?	Positive perceptions add 0.5%; when combined with involvement, they raise well-being by 6.8%.	Launch education campaigns to promote awareness of tourism's benefits.
What is the mediating effect of support on involvement and well-being?	Support alone adds 1.5%, and with involvement, increases well-being by 2.3%	Strengthen local support through inclusive policy frameworks and benefit-sharing mechanisms.

It can be inferred that involvement in community-based tourism improves residents' lives and demonstrates appreciation for their local heritage by fostering socioeconomic transformations (Kim et al., 2013; Riyanto et al., 2023; Wani et al., 2024). Therefore, the study presents a clear picture that enhanced involvement and support for community-based tourism development among residents can be an effective tool for poverty alleviation, thereby increasing social well-being among rural households. Based on the observed positive impact of community involvement, positive perception, and support for community-based tourism on residents' overall well-being, it can be posited that policies and programs should be conceptualized and implemented to enhance the development of community-based tourism.

However, more cautious policy strategies are required to promote increased community-based tourism development, in line with the ideal local government incentives. The aims of community-based tourism development should prioritize the preservation and protection of local heritage, the environment, the local economy, and everyday life, thereby enhancing residents' social well-being. At the top of these policy incentives should be a focus on aiding rural communities' social well-being by implementing community-based tourism development strategies in a more sustainable manner, including identifying the most effective ways to implement this while minimizing potential adverse effects.

Although this study yielded several insightful findings relevant to policymaking and academic discourse, a few limitations need to be addressed by forthcoming studies. To begin with, the study used a small sample from only one of the five counties in Kenya. A slightly larger sample size can improve the generalizability of this study's findings. Thus, future studies can focus on larger sample sizes. Secondly, future studies can examine how factors such as stakeholder perceptions and the local government's role influence community-based tourism development.

Author Contributions: For research articles with several authors, a short paragraph specifying their individual contributions must be provided, as follows: Conceptualization, S.O. and V. Sz. methodology, S.O.; software, S.O.; validation,

S.O., K.Sz. and V. Sz.; formal analysis, S.O.; investigation, S.O.; resources, S.O.; data curation, S.O.; writing—original draft preparation, S.O.; writing—review and editing, K.Sz. and V. Sz.; visualization, S.O.; supervision, V. Sz.; project administration, K.Sz.; funding acquisition, V. Sz. All authors have read and agreed to the published version of the manuscript.

Funding: This research was financed by the Doctoral School of Economic and Regional Sciences at MATE Hungarian University of Agriculture and Life Sciences and by the Research Group on Responsible and Resilient Food Consumption of MATE Hungarian University of Agriculture and Life Sciences.

Institutional Review Board Statement: The study was conducted in accordance with the Declaration of Helsinki, and approved by the Interim Ethical Committee of the Doctoral School of Economic and Regional Sciences, MATE Hungarian University of Agriculture and Life Sciences (protocol code: 7/2024, date of approval: 8/10/2024). **Informed Consent Statement:** Informed consent was obtained from all subjects involved in the study.

Data Availability Statement: The data presented in this study are available on request from the corresponding author.

Acknowledgements: The authors are grateful to Isaiah Maket Juma, PhD, for his invaluable support and assistance throughout the preparation of the manuscript.

Conflicts of Interest: The authors declare no conflict of interest.

Use of Generative AI: Not applicable.

Digital procurement, resilience and inclusivity in tourism msme supply chains: A comparative conceptual study of South Africa and Cameroon. *Geojournal of Tourism and Geosites*, 67(3), 2616–2626. https://doi.org/10.30892/gtg.67368-1880

Abstract: The tourism industry significantly contributes to economic growth, employment and inclusive development in Sub-Saharan Africa (SSA), with micro, small and medium enterprises (MSMEs) forming the backbone of tourism value chains. Despite their importance, tourism supply chains in the region remain fragmented and vulnerable to external shocks such as economic instability, health crises, climate-related disruptions and infrastructural constraints. Digital procurement has emerged as a strategic mechanism for improving operational efficiency, strengthening supply chain resilience, and promoting inclusive participation among historically marginalised groups, particularly women- and youth-led enterprises. However, limited research has examined digital procurement and its implications for supply chain resilience and inclusivity among tourism MSMEs in SSA from a comparative perspective. This conceptual paper comparatively examines digital procurement in tourism MSME supply chains in South Africa and Cameroon, focusing on its implications for resilience and inclusivity. Drawing on the Technology–Organisation–Environment (TOE) framework as an analytical lens, the study compares the technological, organisational, and environmental conditions that shape digital procurement opportunities and constraints in the two countries. The comparison highlights South Africa's more established digital ecosystem and Cameroon's developing but uneven digital environment, while recognising that MSMEs in both contexts continue to experience disparities in digital access, capabilities and institutional support. The analysis suggests that digital procurement's contribution to supply chain resilience and inclusivity is context-dependent and influenced by technological readiness, organisational capabilities, and the wider institutional environment. The study contributes to tourism supply chain and digital transformation literature by providing a context-sensitive comparative understanding of digital procurement in two distinct SSA settings. The findings offer practical insights for policymakers, tourism practitioners, and development agencies seeking to strengthen resilient and inclusive tourism MSME supply chains.

Keywords: digital procurement, supply chain resilience, inclusivity, tourism MSMEs, South Africa, Cameroon

INTRODUCTION

Tourism is globally recognised as one of the most rapidly expanding economic sectors, serving as a primary catalyst for socio-economic development in numerous Sub-Saharan African (SSA) nations. The sector significantly contributes to gross domestic product (GDP), employment generation, foreign exchange earnings, and poverty reduction.

Micro, small, and medium-sized enterprises (MSMEs) constitute the predominant force within tourism value chains (United Nations World Tourism Organisation [UNWTO] and United Nations Development Programme, 2017; World Tourism Organisation [UNWTO], 2018; 2023). In countries such as South Africa and Cameroon, tourism MSMEs are pivotal in providing accommodation, transportation, tour operations, food services, cultural experiences and ancillary services, thereby supporting local livelihoods and fostering economic diversification. Shaikha Al Nowais, Secretary-General Elect of the United Nations World Tourism Organisation (UNWTO) for the 2026–2029 term indicated that in 2024, the travel and tourism sector accounted for 10% of global GDP (Travel & Tourism News Middle East, 2025), while in Sub-Saharan Africa, the sector contributed 6.4% of regional GDP in 2025 (World Travel & Tourism Council, 2026).

Notwithstanding their crucial role, tourism supply chains in SSA confront substantial challenges. These include fragmented supplier networks, inadequate infrastructure, restricted access to financial resources, deficient organisational support and increasing susceptibility to systemic disruptions. Such disruptions encompass the COVID-19 pandemic, economic instability, climate-related events, and geopolitical uncertainties (Christie et al., 2014; Organisation for Economic Co-operation and Development [OECD], 2020; 2022).

These vulnerabilities underscore the imperative for tourism enterprises to cultivate resilient supply chain systems capable of anticipating, responding to, recovering from and adapting to disruptions.

Digital transformation has emerged as a critical strategic imperative for optimising organisational operations and supply chain management across diverse sectors (Shonubi, 2025). Within this paradigm, digital procurement is widely acknowledged as the application of digital technologies to streamline purchasing processes, enhance transparency, and improve supplier relationship management (Srai & Lorentz, 2019; Bienhaus & Haddud, 2018). Bienhaus & Haddud (2018) further posit that digital procurement tools, encompassing e-procurement platforms, electronic tendering systems, cloud-based procurement applications, and integrated enterprise resource planning systems, possess the potential to bolster coordination among supply chain actors and augment decision-making through enhanced visibility and data analytics capabilities.

Within the tourism sector, Bienhaus & Haddud (2018); Meyer et al. (2021); Zhao et al. (2023) observe that digital procurement practices can contribute significantly to supply chain resilience. This is achieved by facilitating quicker supplier identification, reducing transaction costs, enhancing communication flows and enabling more agile responses during periods of disruption through improved visibility, information sharing, and data-driven decision-making capabilities.

Furthermore, the International Trade Centre (2022) highlights that digital procurement may foster inclusivity by lowering market entry barriers and expanding participation opportunities for women- and youth-led enterprises, which frequently encounter structural impediments in accessing information, networks and formal procurement processes. As Dr. Hazel Gooding, United Nations (UN) Women South Africa deputy representative, articulated during the Women's Month 2025 celebration in South Africa, "When women have equal access to digital markets, entire communities thrive" (UN Women Africa, 2025). The integration of inclusivity considerations into digital procurement systems aligns with broader sustainable development goals aimed at mitigating inequalities and fostering equitable economic participation.

While the adoption of digital procurement has been investigated within broader MSME and public procurement contexts, existing scholarship predominantly focuses on technological adoption determinants and operational efficiency outcomes (Dumeh, 2025; Kaunda, 2025; Kalaba & Nakamba, 2026). Limited attention has been directed towards how digital procurement might influence both supply chain resilience and inclusivity specifically within tourism MSMEs in SSA. Crucially, comparative studies examining how disparities in digital infrastructure, organisational capabilities, and institutional environments shape digital procurement across African contexts remain scarce. This lacuna restricts a comprehensive understanding of whether the opportunities and constraints associated with digital procurement are uniform across countries or are shaped by their specific contextual nuances. To address these identified research gaps, this conceptual paper undertakes a comparative examination of digital procurement among tourism MSMEs in South Africa and Cameroon, with particular emphasis on its implications for supply chain resilience and inclusivity. South Africa is widely regarded as one of the continent's more digitally advanced economies, underpinned by relatively sophisticated information and communication technology (ICT) infrastructure and established digital business ecosystems (International Trade Administration, 2024). In contrast, Cameroon's digital development remains uneven across the country (World Bank, 2019; 2022), reflecting persistent infrastructural and institutional challenges that continue to influence digital participation. These contrasting contexts offer a valuable opportunity to investigate how differences in technological, organisational, and environmental conditions influence digital procurement adoption and its potential contribution to resilient and inclusive tourism MSME supply chains. The following objectives guide the present paper:

1. To examine digital procurement practices, opportunities, and challenges among tourism MSMEs in South Africa and Cameroon.
2. To compare the technological, organisational, and environmental conditions shaping digital procurement adoption among tourism MSMEs in the two countries.
3. To critically examine the implications of these similarities and differences for tourism MSME supply chain resilience and inclusivity.

This study offers three principal contributions. Firstly, it extends existing research on tourism digitalisation by specifically focusing on digital procurement and its potential implications for resilience and inclusivity. Secondly, it employs the Technology–Organisation–Environment (TOE) framework as an analytical lens to investigate how technological, organisational, and environmental conditions shape digital procurement among tourism MSMEs. Thirdly, by comparing South Africa and Cameroon, the study elucidates how variations in digital development, institutional environments, and MSME conditions may influence digital procurement opportunities and outcomes. In doing so, the paper provides context-sensitive insights that can inform policy interventions and investment strategies aimed at fortifying resilient, inclusive, and sustainable tourism value chains across SSA. The subsequent section reviews the pertinent literature on tourism MSME supply chains, digital procurement, supply chain resilience, and inclusivity. It then discusses the TOE framework as the theoretical lens guiding the comparative analysis. The paper proceeds to examine the South African and Cameroonian contexts and comparatively analyses the technological, organisational, and environmental conditions shaping digital procurement in the two countries. The discussion then considers the implications of these similarities and differences for supply chain resilience and inclusivity. The paper concludes by highlighting theoretical and practical implications, limitations, and directions for future research.

LITERATURE REVIEW

Tourism MSME supply chains

MSMEs form the bedrock of tourism economies across SSA, constituting approximately 80% of tourism businesses (Chamboko-Mpotaringa et al., 2025). Nevertheless, tourism MSMEs operate within highly fragmented and interdependent supply chains, frequently under resource-constrained conditions characterised by limited access to finance, weak organisational capabilities, inadequate infrastructure and varying degrees of informality, particularly within developing and

SSA contexts (Zhang et al., 2009; Kimbu & Tichaawa, 2020; Muluh & Lekgau, 2023; Chamboko-Mpotaringa et al., 2025). Chhetri et al. (2026) further observe that tourism supply chains encompass an interconnected network of suppliers, service providers, and intermediaries that deliver tourism experiences, ranging from accommodation and transport to catering, guiding, and craft production. For MSMEs, participation in these networks can facilitate collaboration, resource access, and value creation; however, their limited financial and organisational resources can also heighten their susceptibility to supply disruptions and external shocks (Rastegar et al., 2023; Seow et al., 2024). Consequently, for MSMEs, these chains represent both sources of opportunity and vulnerability. Within the African context, tourism MSMEs confront distinct structural impediments that constrain their effective participation in formal tourism supply and value chains.

These include restricted access to finance, elevated borrowing costs, fragmented value chains, substantial market-entry barriers, and insufficient investment and business-readiness support (Adinolfi et al., 2018; South Africa National Department of Tourism, 2022; International Labour Organisation, 2022). These challenges are particularly pronounced among women- and youth-led enterprises, which frequently encounter additional financial, socio-cultural, institutional, and network-related barriers that impede their engagement in tourism entrepreneurship and formal value chains (Ribeiro et al., 2021; Tryphone & Mkenda, 2022; Mametja et al., 2023; Ofosu-Appiah et al., 2025). Digitalisation presents a potential avenue for addressing these fragmentation challenges. Evidence from South Africa indicates that digitally enabled and collaborative approaches can enhance coordination, connectivity, and visibility within tourism supply networks (Sifolo, 2025). However, the realisation of digitalisation's benefits is contingent upon the specific context in which tourism MSMEs operate.

Digital procurement in tourism MSMEs

Despite the increasing body of research on digital transformation within the tourism sector, digital procurement remains comparatively underexplored, particularly concerning tourism MSMEs and its implications for supply-chain resilience and inclusivity in SSA (Chamboko-Mpotaringa et al., 2025; Sifolo, 2025). Digital procurement is defined as the application of digital technologies and integrated electronic systems to support procurement activities, encompassing supplier identification, sourcing, purchasing, contract management, invoicing and payment (Bienhaus & Haddud, 2018; Srai & Lorentz, 2019). The evolution of procurement from traditional paper-based systems to interconnected digital systems has fundamentally altered how businesses manage supplier relationships, optimise costs, and enhance operational productivity (Shonubi, 2025). The transformative potential of digital procurement lies in its capacity to address inherent inefficiencies within tourism supply chains. Traditional and weakly digitalised tourism supply chain practices are often characterised by fragmented coordination, disconnected information flows, and limited visibility across supply networks (Sifolo, 2025). Digital procurement offers mechanisms to mitigate these limitations by integrating procurement activities, improving information exchange, and strengthening supplier coordination. Consequently, efficient procurement practices are essential as they can enable tourism MSMEs to reduce costs, enhance supplier coordination, improve service delivery, and strengthen long-term competitiveness and sustainability with their stakeholders (Kimbu & Tichaawa, 2020, p. 742; Sifolo, 2025). More recent evidence indicates that digitalised supply chains can support value co-creation, collaboration, and performance among South African tourism SMMEs (Sifolo et al., 2026, p. 1).

Digital procurement tools, such as e-procurement platforms, electronic tendering systems, e-marketplaces, supplier relationship management systems, cloud-based procurement applications and enterprise resource planning (ERP) systems, provide tourism enterprises with opportunities to streamline purchasing processes and enhance transparency (Patrucco et al., 2021). Evidence from large-scale tourism operations illustrates these potential benefits.

For example, TUI Belgium's implementation of Nezasa's TripBuilder reduced the time to make a new tour bookable from about one business day to one hour, while increasing itineraries created and bookings (Nezasa, 2025). The COVID-19 pandemic accelerated digital transformation across the tourism industry, necessitating the adoption of digital solutions by many businesses to maintain operational continuity (Sigala, 2020). For MSMEs in SSA, however, the transition towards digital procurement presents a more intricate scenario. Adoption is influenced not only by the perceived benefits of digital technologies but also by organisational readiness, technological infrastructure, digital capabilities, financial resources and the broader institutional environment (Afolayan et al., 2015; Chamboko-Mpotaringa et al., 2025).

Evidence from South Africa demonstrates that an awareness of technological benefits does not invariably translate into adoption. Schoeman and Seymour (2022, p. 257), for instance, observed that managers possessed "a clear understanding of the benefits of AI adoption," despite persistent factors inhibiting actual adoption. Similarly, inadequate digital infrastructure, limited digital skills, financial constraints, and organisational resistance can impede digital transformation among MSMEs. The benefits of digital procurement are therefore unlikely to materialise automatically. Their realisation is contingent upon the technological, organisational, and environmental conditions within which MSMEs operate. The literature suggests that successful digital procurement adoption is predicated upon a supportive ecosystem characterised by enabling policy frameworks, robust digital infrastructure, capacity-building initiatives, affordable technological solutions, and strong public-private collaboration mechanisms (International Trade Administration, 2024; OECD, 2021; Shonubi, 2025; Tchoffo et al., 2026; UN Women Africa, 2025). Although research on digital transformation and technology adoption in tourism is expanding, limited attention has been specifically devoted to digital procurement and its implications for tourism MSMEs in SSA. Comparative research, in particular, is scarce. This results in an insufficient understanding of how differences in digital infrastructure, organisational capabilities, and institutional environments shape digital procurement opportunities and constraints across various African contexts. A comparative analysis of South Africa and Cameroon therefore offers an opportunity to examine how these contextual differences may influence digital procurement and its implications for supply chain resilience and inclusivity.

Supply chain resilience in tourism

Supply chain resilience has emerged as a critical area of academic inquiry, driven by the escalating exposure to disruptions impacting global and localised supply networks. Resilience is generally understood as a system's capacity to anticipate, prepare for, respond to, recover from and adapt to unforeseen disturbances while sustaining essential functions (Ivanov & Dolgui, 2020). As previously established, tourism supply chains exhibit high vulnerability to disruptions due to their reliance on multiple interdependent actors operating across diverse geographical locations. Events such as pandemics, natural disasters, political instability, cyberattacks and economic crises can profoundly affect tourism operations and service delivery (Prayag, 2020). The COVID-19 pandemic starkly illuminated these vulnerabilities, exposing the inherent fragility of tourism systems globally and underscoring the imperative for resilience-building strategies (Buluk, 2023). Furthermore, climate-related disruptions exert additional pressure on tourism supply chains in SSA. Flooding, storms, and extreme weather events can impede accessibility, compromise infrastructure, disrupt logistics, and affect interconnected suppliers (Achu et al., 2026). Such disruptions reinforce the necessity for tourism MSMEs to cultivate capabilities for anticipation, response, recovery and adaptation.

The extant literature on supply chain resilience identifies several dimensions that enable organisations to withstand and recover from disruptions. Within the tourism sector, where businesses are acutely susceptible to disruptions, supply chain resilience has become a strategic imperative. Resilience is manifested through four interconnected capabilities: anticipation, which empowers organisations to identify risks and implement preventative measures prior to the occurrence of disruptions (Ponomarov & Holcomb, 2009); response, which facilitates flexible and coordinated actions during disruptive events (Hohenstein et al., 2015); recovery, which dictates the speed and efficacy of restoring operations post-disruption (Ponomarov & Holcomb, 2009); and adaptation, which enables organisations to learn from disruptions and reconfigure systems to enhance future preparedness (Chowdhury & Quaddus, 2017; Chowdhury et al., 2019). Collectively, these capabilities foster business continuity, operational stability, and long-term competitiveness in uncertain environments.

Digital technologies are increasingly recognised as pivotal enablers of supply chain resilience. Technologies that facilitate real-time information sharing, enhanced visibility, predictive analytics, and collaborative decision-making contribute significantly to strengthening organisational resilience (Bienhaus & Haddud, 2018; Ivanov & Dolgui, 2020; Zhao et al., 2023).

For tourism MSMEs in SSA, resilience is particularly crucial given the structural challenges characterising many operating environments, including infrastructure deficits, limited financial reserves, and increasing exposure to external shocks (South African National Department of Tourism, 2021, Muluh & Lekgau, 2023). Existing resilience research has predominantly concentrated on manufacturing and large organisational contexts, resulting in a knowledge gap concerning MSME experiences within developing tourism economies (Ivanov & Dolgui, 2020). Addressing this lacuna is vital because resilient tourism supply chains are indispensable for sustainable destination competitiveness, employment preservation, and community well-being. Consequently, understanding the mechanisms through which digital procurement may bolster resilience capabilities can furnish valuable insights for both researchers and practitioners.

Inclusivity in tourism supply chains

The concept of inclusivity has emerged as a salient discourse within tourism supply-chain research. This emphasis aligns with broader sustainable development objectives, particularly concerning the equitable distribution of tourism benefits (Scheyvens & Biddulph, 2018). Within the context of supply chains, inclusivity is defined by the active participation and equitable representation of marginalised enterprises and communities in both procurement and value creation processes (Scheyvens & Biddulph, 2018). Kimbu & Tichaawa (2020) posit that, in SSA, inclusive tourism necessitates the substantive involvement of MSMEs and historically marginalised groups, including women, youth and community-based enterprises. Nevertheless, tourism MSMEs frequently encounter impediments to meaningful engagement in established value chains. Adinolfi et al. (2018) observe that SMMEs in developing contexts experience "marginalisation or exclusion" and encounter difficulties in integrating into industry value chains. These challenges can be particularly acute for women-led enterprises. Empirical evidence from Ghana and Nigeria, for instance, underscores gender-based constraints that affect women's access to credit, markets, and other opportunities (Ribeiro et al., 2021). Similarly, in South Africa, women-owned tourism micro-enterprises confront limitations pertaining to financial resources, human capital, ICT infrastructure and institutional support (Mametja et al., 2023). Such barriers may impede their capacity for full participation in increasingly digitalised tourism supply chains. For digital procurement mechanisms to genuinely foster inclusivity, they must mitigate rather than perpetuate existing inequalities. Digital platforms possess the potential to enhance supplier visibility, expand market access, and diminish geographical barriers for smaller enterprises. However, the realisation of these benefits is contingent upon access to requisite infrastructure, affordable connectivity, appropriate skills, and robust institutional support (UN Conference on Trade and Development [UNCTAD], 2021; International Trade Center, 2022). Consequently, inclusive digital procurement necessitates a dual focus on both technological accessibility and the development of capabilities essential for MSMEs to participate effectively. Understanding the South Africa-Cameroon comparison necessitates an examination of the distinctive historical, economic, and institutional contexts that shape tourism supply chains and digital procurement opportunities in each country. The comparison is therefore instrumental in scrutinising context as a significant determinant influencing digital procurement, supply-chain resilience and inclusivity.

THEORETICAL FRAMEWORK

The TOE framework, posited by Tornatzky & Fleischer (1990), offers a robust analytical lens for comprehending organisational technology adoption. This framework postulates that decisions pertaining to technology implementation are

shaped by three interconnected contexts: technological, organisational, and environmental factors. The technological context encapsulates the characteristics of technologies accessible to an organisation, encompassing perceived benefits, compatibility, complexity, and relative advantage, all of which exert an influence on technology adoption decisions (Baker, 2012). Within the domain of digital procurement, technological considerations such as system usability, interoperability, cybersecurity, and perceived usefulness represent pivotal determinants of successful procurement digitisation (Bienhaus & Haddud, 2018). The organisational context pertains to internal characteristics that bear upon technology adoption, including organisational scale, leadership endorsement, financial provisions, technological proficiencies, and employee competencies (Baker, 2012).

MSMEs within the tourism sector frequently encounter organisational impediments linked to restricted financial capital, insufficient digital proficiencies, and a dearth of technical expertise, which may impede their preparedness to embrace digital procurement systems (Achieng & Malatji, 2022). The environmental context encompasses external factors such as industry characteristics, competitive pressures, governmental regulations, infrastructure availability and support from external stakeholders (Baker, 2012). In the context of Sub-Saharan Africa, disparities in digital infrastructure development, policy landscapes, and institutional support mechanisms may significantly influence the uptake of digital procurement among tourism MSMEs (Achieng & Malatji, 2022). The TOE framework has been extensively employed to elucidate organisational technology adoption across diverse sectors. Its multidimensional perspective renders it particularly apposite for the current study, given that the adoption of digital procurement among tourism MSMEs is unlikely to be solely contingent on technology. Rather, it is also shaped by organisational capabilities and the broader institutional and business milieu. Consequently, in this study, the TOE framework is deployed as an analytical lens to facilitate a comparative analysis between South Africa and Cameroon. The technological dimension will consider variations in digital infrastructure, accessibility, and technological readiness; the organisational dimension will examine MSME resources, skills, and capabilities; and the environmental dimension will address regulatory conditions, institutional support, and the wider business environment. This approach furnishes a structured foundation for investigating the potential divergence in digital procurement opportunities and constraints between the two nations.

Supply chain resilience and inclusivity as analytical outcomes

The TOE framework offers a valuable analytical lens for investigating the contextual factors influencing the adoption of digital procurement; however, this study extends beyond mere adoption conditions to critically examine the potential ramifications of such implementation. Consequently, supply chain resilience and inclusivity are conceptualised as primary analytical outcomes, rather than distinct theoretical constructs. Supply chain resilience is defined as the intrinsic capacity of a supply chain to anticipate, respond to, recover from, and adapt to disruptive events (Chowdhury & Quaddus, 2017). Within this operational context, digital procurement possesses the potential to bolster resilience through enhanced information visibility, improved supplier coordination and more effective communication channels. This, in turn, may empower tourism MSMEs to navigate and mitigate supply chain disruptions with greater efficacy (Ivanov & Dolgui, 2021).

Inclusivity pertains to the degree to which diverse stakeholder groups, particularly those historically marginalised from economic participation, can access and derive benefits from opportunities within tourism value chains (Scheyvens & Biddulph, 2018). Digital procurement may foster more inclusive participation by facilitating improved access to procurement information, market opportunities, and supplier engagement for MSMEs, including those spearheaded by women and youth (International Trade Centre, 2022). Nevertheless, the equitable realisation of these opportunities may be impeded by disparities in digital access, requisite skills, available resources, and the robustness of institutional support. Therefore, the TOE framework serves to structure the comparative analysis between South Africa and Cameroon, while resilience and inclusivity constitute the two principal outcomes through which the implications of digital procurement are rigorously scrutinised. This methodological approach enables the study to ascertain how variations in technological, organisational and environmental conditions across the two nations may influence the opportunities and constraints associated with digital procurement, and their consequent implications for fostering more resilient and inclusive supply chains within tourism MSMEs.

METHODOLOGY

This conceptual study employed an integrative literature review to examine existing knowledge on tourism supply chains, MSMEs, digital procurement, resilience and inclusivity in SSA, with particular attention to South Africa and Cameroon. An integrative approach was considered appropriate because it allows theoretical and empirical literature from related fields to be brought together and critically synthesised to identify key concepts, relationships and gaps in existing knowledge (Snyder, 2019). The review aimed to integrate multidisciplinary knowledge rather than aggregate empirical effects. It drew together scholarship from tourism supply chain management, digital procurement, resilience and inclusive development. Particular attention was given to comparing South Africa and Cameroon to examine how differences in technological, organisational and environmental conditions may shape digital procurement opportunities and its implications for resilience and inclusivity. Relevant literature was identified through targeted searches of Web of Science, Scopus and Google Scholar, supplemented by citation chaining and hand-searching of key journals in tourism, hospitality and supply chain management. Search terms and combinations used embodied tourism and hospitality, supply chains, value chains, procurement, MSMEs/SMEs, digitalisation, resilience, and inclusivity, with specific attention to Sub-Saharan Africa, South Africa and Cameroon. Boolean operators such as AND and OR, together with truncation where appropriate, were used to combine key concepts and broaden or refine searches. The review focused primarily on literature published between 2015 and 2026 to capture contemporary developments in digitalisation, tourism supply chains and MSME participation. Earlier seminal studies were retained where they provided important theoretical or conceptual foundations.

Literature was selected purposively based on its theoretical contribution, conceptual relevance and contextual applicability to SSA. The search prioritised studies providing substantive insights into tourism or hospitality MSMEs and on issues related to supply chains, value chains, procurement, digitalisation, resilience, inclusivity, and associated challenges and opportunities. Consideration was given to evidence from SSA, with specific attention to South Africa and Cameroon. Literature from other developing-economy contexts was also considered where it provides concepts and theorist ha can be transferred.

The selected literature was analysed thematically and synthesised iteratively to identify, compare, and integrate recurring concepts, patterns and relationships across the literature with the aid of ChatGPT and Rayyan. This methodology was considered appropriate for the integrative nature of the review because it brought together evidence from diverse theoretical and empirical studies to support conceptual development. The analysis focused on recurring themes relevant to the study, including tourism MSME supply chain challenges, digital procurement practices, technological and organisational capabilities, environmental conditions, supply chain resilience, inclusivity, and emerging opportunities. The study examined similarities and differences between the South African and Cameroonian contexts and drew on evidence from the broader Sub-Saharan African literature and other developing economy contexts to provide additional contextual and theoretical insights.

The literature was critically compared and integrated to identify relationships among the key concepts and to inform the development of the study's proposed conceptual framework and research propositions. The analysis followed a four-step interconnected process. Firstly, the literature was examined to identify and clarify the key constructs and their definitions. Second, emerging themes were compared across studies and contexts to identify similarities and differences. Then, relationships among the concepts were mapped and integrated to develop a preliminary conceptual framework that links the factors influencing digital procurement adoption with supply-chain resilience and inclusivity outcomes. The final stage involved integrating the identified themes into a comparative analysis of South Africa and Cameroon. The synthesis examined how technological, organisational and environmental conditions differ across the two contexts and how these differences may shape digital procurement adoption and its implications for tourism MSME supply-chain resilience and inclusivity.

RESULTS

The following section presents the results for the South African and Cameroonian contexts. South Africa provides a relatively established setting for tourism and digital business compared with many SSA economies. The country has an advanced ICT infrastructure and has established digital business systems, although access to these opportunities remains uneven across enterprises and locations (International Trade Administration, 2024). Tourism MSMEs operate within this relatively developed environment but differ considerably in their capacity to participate effectively in digital markets. Despite the availability of digital infrastructure, digital inequality remains relevant to South African MSMEs. Mbatha (2024: 65) finds that "a digital divide is hampering the adoption of technology by SMMEs", with technology costs, limited financial resources and inadequate technical knowledge among the barriers to adoption. Tourism-specific evidence similarly indicates that digital transformation among MSMEs is shaped by infrastructure, skills, financial capacity and organisational readiness (Chamboko-Mpotaringa et al., 2025). South Africa can therefore be understood as a context where the challenge is not simply the availability of digital technologies, but whether tourism MSMEs possess the resources and capabilities required to participate effectively in digitally mediated supply networks. This provides an important basis for comparison with Cameroon, where the digital and institutional environment is at a different stage of development.

Cameroon represents an emerging digital context where tourism contributes to economic development, but where digital infrastructure development remains uneven (Zoa, 2026). The country has made digitalisation an important development priority, but significant structural and institutional constraints remain. A World Bank assessment identified high broadband prices, limited institutional capacity, and weaknesses in digital policy and regulation as constraints on the development of Cameroon's digital economy (World Bank, 2022). While mobile technology adoption has increased substantially, challenges relating to internet penetration, affordability, digital skills, and institutional support persist (World Bank, 2022, p. 48; World Bank, 2019). There are nevertheless signs of institutional change. Cameroon enacted a Personal Data Protection Law in 2024, indicating progress towards strengthening the governance of its digital environment. However, the World Bank's (2022) assessment reports that several reforms relating to telecommunications, cybersecurity and cybercrime remained under review, while some planned institutional capacity-building programmes had yet to commence. Thus, Cameroon should not be characterised simply as digitally "underdeveloped". Rather, it represents an evolving digital ecosystem in which technological expansion is occurring alongside continuing institutional and regulatory development. Recent evidence shows growing adoption of digital financial services in Cameroon. World Bank Global Findex data indicate increasing use of mobile phones and computers for payments and transactions, though access remains uneven. Affordability persists as a barrier, with mobile data costs cited by non-smartphone owners as a reason for non-ownership (World Bank, 2025). These conditions matter for tourism MSMEs because digital procurement requires not only platform availability but also affordable connectivity, suitable devices, digital payment capabilities and an enabling institutional environment for trusted transactions. Examining Cameroon alongside South Africa provides valuable insights into how differing digital ecosystems shape procurement practices and resilience outcomes.

The comparison therefore reveals different conditions for digital procurement adoption. South Africa provides a relatively more established digital and institutional environment, although inequalities in access, affordability, and MSME capabilities remain. Cameroon represents a more rapidly evolving but uneven digital environment, where connectivity, affordability and institutional capacity remain significant considerations. These differences suggest that digital procurement cannot be understood as a uniform process across SSA. Its adoption and potential contribution to resilience and inclusivity are likely to depend on the technological, organisational and environmental conditions within which tourism MSMEs

operate. The contextual differences between South Africa and Cameroon can be summarised across the technological, organisational and environmental dimensions relevant to digital procurement adoption. Table 1 highlights these differences and their analytical significance for understanding the potential contribution of digital procurement to resilience and inclusivity among tourism MSMEs. The comparison suggests that digital procurement opportunities cannot be separated from the contexts in which tourism MSMEs operate. South Africa and Cameroon differ in their technological readiness, MSME capabilities and institutional environments. These differences provide the basis for the comparative analysis of how digital procurement may contribute to resilience and inclusivity in the two contexts.

Table 1. Comparative Context of Digital Procurement in Tourism MSMEs in South Africa and Cameroon

Dimension	South Africa	Cameroon	Analytical significance
Digital infrastructure	Relatively more developed digital infrastructure	Developing but uneven digital infrastructure	**Technological context:** influences digital readiness
Internet and mobile connectivity	Relatively higher levels of connectivity and digital access	Expanding but uneven access with affordability and connectivity constraints	**Technological context:** influences access to digital platforms
MSME digital capabilities	Relatively stronger digital ecosystem but uneven capabilities among MSMEs	Greater constraints in digital skills and enterprise capabilities	**Organisational context:** influences readiness and effective technology use
Institutional and regulatory environment	More established digital business and regulatory environment	Developing digital institutional and regulatory environment	**Environmental context:** shapes enabling conditions for adoption
Digital procurement readiness	Greater enabling conditions for digital procurement adoption although uneven across MSMEs	Emerging opportunities but constrained by infrastructure and enterprise readiness	**TOE interaction:** influences adoption opportunities and constraints
Women and youth participation	Participation opportunities exist but structural and digital inequalities remain	Participation opportunities exist but structural and digital barriers remain	**Inclusivity:** determines who can access and benefit from digital opportunities
Urban-rural digital divide	Digital disparities remain between locations and enterprises	Geographic disparities in connectivity and access remain significant	**Inclusivity and technology access:** may limit participation of rural MSMEs
Tourism MSME environment	Relatively established tourism and MSME ecosystem	Developing tourism MSME ecosystem with greater informality and capacity constraints	**Contextual difference:** affects how digital procurement practices may be transferred between settings
Potential resilience implications	Stronger digital foundations may support information sharing, coordination and response to disruptions	Potential benefits depend more strongly on improvements in connectivity and MSME capabilities	**Resilience:** digital procurement benefits are context-dependent

Comparison between South Africa and Cameroon shows how differences in technological, organisational and environmental conditions shape digital procurement opportunities among tourism MSMEs.

Rather than viewing one country as digitally advanced and the other as digitally disadvantaged, the comparison portrays different levels of readiness and different limitations within changing digital environments. The TOE framework provides a useful lens for interpreting these differences.

Technological conditions

South Africa has a relatively advanced digital infrastructure and higher levels of digital maturity, providing a stronger platform for adopting digital procurement technologies. Nevertheless, access and effective use remain uneven particularly among smaller and rural tourism enterprises. Recent research confirms that South African tourism SMMEs continue to experience challenges in effectively adopting digital technologies despite recognising their potential benefits (Chamboko-Mpotaringa et al., 2025). Sifolo (2025) similarly demonstrates that digital adoption remains a challenge within South African tourism supply networks, although digitally enabled interventions can improve connectivity, coordination and market visibility. Cameroon's digital environment is developing but remains more uneven. Broadband expansion, increasing internet traffic and growing digital services demonstrate ongoing digital transformation. However, affordability, connectivity and access remain vital limitations, especially outside major urban areas (World Bank, 2021; World Bank, 2022). These differences suggest that technology readiness acts as an important contextual condition: whereas South African tourism MSMEs may be better positioned to adopt more sophisticated digital procurement practices, many Cameroonian MSMEs may first require stronger foundations in affordable connectivity and accessible digital services.

Organisational and MSME conditions

The organisational dimension revealed that technological availability alone does not guarantee effective adoption. Tourism MSMEs necessitate financial resources (encompassing the acquisition of digital systems, equipment, subscriptions, and implementation costs), digital proficiencies, managerial capabilities, and organisational readiness to integrate digital tools into their procurement activities. In the South African context, while a comparatively robust digital ecosystem offers increased exposure to digital technologies, considerable disparities persist in the capabilities of tourism SMMEs to utilise them

effectively. This is attributable to variations among enterprises in terms of financial resources, digital skill levels, technical capabilities and organisational readiness (Chamboko-Mpotaringa et al., 2025). These organisational constraints are potentially more pronounced in Cameroon, where the broader digital ecosystem remains in a nascent stage of development. Furthermore, evidence from women-owned tourism enterprises indicates that the availability of institutional support does not necessarily translate into enterprise-level awareness and subsequent utilisation (Njinyah & Pendati, 2021). The comparative analysis therefore suggests that organisational readiness is pivotal in translating digital access into meaningful procurement participation (Ntimane, 2025). Consequently, digital procurement initiatives that overlook MSME capabilities may inadvertently exacerbate, rather than mitigate, disparities between digitally capable and less-prepared enterprises.

Environmental and institutional conditions

The environmental contexts of the two countries also diverge significantly. South Africa operates within a comparatively more developed digital business and regulatory framework, notwithstanding persistent challenges related to regulation and digital access (World Bank, 2018). Conversely, Cameroon is in the nascent stages of reinforcing the institutional foundations requisite for comprehensive digital transformation. Notably, broadband affordability, regulatory evolution, and institutional capacity remain pivotal considerations within Cameroon's digital transformation agenda (Hurpy, 2021). These contextual disparities hold considerable implications, as digital procurement is contingent upon an enabling environment that transcends the individual enterprise. The efficacy of MSME participation in digital supply networks is influenced by reliable infrastructure, supportive regulatory frameworks, affordable connectivity, accessible digital payment systems, and robust institutional support. Consequently, the advancement of procurement digitalisation may be more readily achievable in environments where these enabling conditions are firmly established. In nascent digital environments, such as Cameroon, augmented focus may be necessitated on fortifying both technological infrastructure and institutional capacity. This observation corroborates the TOE framework, which posits that the external environment can either facilitate or impede technology adoption, even when individual enterprises acknowledge its potential advantages.

Implications for supply chain resilience

A comparative analysis suggests that digital procurement can enhance the resilience of tourism supply chains; however, its efficacy is context dependent. Digital technologies offer potential benefits through improved information accessibility, enhanced supplier visibility, and more effective coordination, thereby enabling enterprises to respond robustly to disruptions. Empirical evidence from South Africa provides some substantiation for this potential. Sifolo (2025), for instance pointed out that digitally enabled interventions augmented tourism supply-network coordination and connectivity within Gauteng and KwaZulu-Natal. It is important to note, however, that her study focused on broader digitalisation rather than digital procurement specifically. In the context of Cameroon, the potential resilience benefits may be more contingent upon advancements in connectivity, affordability and the digital capabilities of enterprises (Harilal & Tichaawa, 2026).Consequently, digital procurement should be conceptualised as a resilience enabling mechanism rather than an inherent source of resilience. Its contribution to the anticipatory, responsive, recovery, and adaptive capacities of tourism MSMEs is thus mediated by the prevailing technological, organisational and environmental conditions.

Implications for inclusivity

Digital procurement presents a dualistic landscape of opportunities and risks for the advancement of inclusive tourism. While digital platforms offer the potential to enhance the visibility of smaller suppliers, streamline access to procurement opportunities and connect MSMEs with wider tourism markets, their benefits are not uniformly distributed. Disparities in access to connectivity, digital literacy, and financial resources pose significant barriers, precluding certain enterprises from leveraging these opportunities. Digital divides persist across Africa, particularly affecting impoverished and remote communities, with gender-based discrepancies in internet usage representing an additional concern (World Bank, 2023).

This analysis therefore underscores a critical tension: digital procurement, while capable of fostering inclusion, also bears the potential to perpetuate existing inequalities. In both South Africa and Cameroon, the pursuit of inclusive digital procurement necessitates interventions beyond mere technological implementation. It requires affordable access, targeted skills development, robust institutional support and concerted efforts to facilitate the participation of smaller, rural, women-led, and youth-led enterprises. The variations observed between the two nations further indicate that such interventions must be tailored to specific local contexts, rather than being applied uniformly across SSA. In conclusion, the comparative analysis reveals that South Africa and Cameroon operate within distinct digital and institutional environments within SSA. South Africa, characterised by a relatively mature ecosystem, nonetheless contends with persistent inequalities in access and MSME capabilities. Conversely, Cameroon exemplifies an emergent digital ecosystem where connectivity, affordability and institutional capacity remain more pronounced constraints. The central finding of this comparison is therefore that the capacity of digital procurement to enhance resilience and inclusivity is intrinsically contextual. While technological availability is a crucial factor, its ultimate outcomes are shaped by organisational preparedness and the broader institutional framework.

CONCLUSION

This conceptual study critically examines the role of digital procurement within the supply chains of tourism MSME supply chains in South Africa and Cameroon, with a specific focus on its implications for resilience and inclusivity. Employing the TOE framework as an analytical lens, the study posits that the potential advantages of digital procurement are contingent upon technological readiness, organisational capabilities, and the broader institutional

milieu. In South Africa, the operational context is characterised by a comparatively more developed digital ecosystem; however, persistent disparities in access, digital literacy and MSME capabilities remain evident.

Conversely, Cameroon presents an evolving digital landscape where issues of connectivity, affordability, and institutional capacity continue to exert significant influence over digital engagement. The comparative analysis indicates that digital procurement possesses the capacity to enhance supply chain resilience through improved visibility, coordination, and information exchange, whilst simultaneously fostering opportunities for broader MSME participation. Nevertheless, the realisation of these benefits is not inherent.

Without sufficient digital skills, accessible and affordable connectivity, organisational preparedness, and robust institutional support, digitalisation risks exacerbating existing inequalities rather than mitigating them. Consequently, digital procurement strategies within SSA ought to be context-sensitive and complemented by targeted interventions aimed at supporting smaller, rural, women-led, and youth-led enterprises. Future empirical research could extend this comparative analysis by investigating the practical adoption of digital procurement among tourism MSMEs in South Africa and Cameroon and assessing its subsequent impact on resilience and inclusive participation.

This study contributes to the extant literature on tourism digitalisation and supply chains in three principal ways. Firstly, it demonstrates the utility of the TOE framework in elucidating contextual variations in digital procurement among tourism MSMEs, rather than focusing only on digital adoption. The comparative analysis reveals differential interactions among technological readiness, organisational capabilities and environmental conditions across distinct national contexts. Secondly, the study expands the discourse on digital procurement beyond conventional considerations of efficiency and cost reduction, by exploring its potential ramifications for supply chain resilience and inclusivity. The analysis posits that digital procurement may enhance coordination, visibility, and responsiveness, whilst concurrently fostering opportunities for broader MSME participation. Nevertheless, the realisation of these outcomes is contingent upon the specific conditions underpinning adoption. Thirdly, the comparative approach underscores the critical importance of context in the application of digital transformation concepts to SSA tourism. Findings and practices derived from digitally mature environments are not automatically transferable to nations characterised by divergent infrastructural, organisational, and institutional conditions. Consequently, this study offers a context-sensitive perspective on understanding digital procurement within African tourism supply chains. For policymakers and tourism practitioners, the findings suggest that digital procurement strategies ought to differentiate according to national and MSME readiness. In the South African context, a greater emphasis may be required on strengthening MSME digital capabilities, affordability, and the effective utilisation of extant digital infrastructure. Conversely, in Cameroon, priorities may encompass expanding affordable connectivity, fostering digital skills development, and fortifying the institutional environment that underpins digital business and MSME participation. Across both nations, digital procurement initiatives should integrate technological investment with MSME capacity building and inclusive participation. Particular attention should be directed towards smaller, rural, women-led, and youth-led enterprises, which may otherwise encounter difficulties in participating within increasingly digital tourism supply networks. Consequently, a context-sensitive approach is more likely to ensure that digital procurement contributes not only to operational efficiency but also to the development of more resilient and inclusive tourism supply chains.

Demographic drivers of pro-environmental behaviour in agritourism: The roles of age, gender and income. *Geojournal of Tourism and Geosites*, 67(3), 2627–2638. https://doi.org/10.30892/gtg.67369-1881

Abstract: Agritourism is increasingly positioned as a practical route to encourage more responsible environmental behaviour by bringing tourists into direct contact with farms, local landscapes, and everyday sustainability practices. Building on established measurement work on key pro-environmental constructs, this paper takes a narrower and more applied step by testing whether gender, age, and income meaningfully differentiate tourists' environmental awareness, concern, values, knowledge, attitudes, and pro-environmental behaviour in agritourism settings. A quantitative survey was administered to tourists participating in agritourism activities in Kashmir, India, India. Using purposive sampling, 700 tourists were approached and 560 usable responses were obtained (80% response rate). Gender differences were assessed using an independent-samples t-test, while age (below 30 years, 31–50 years, above 50 years) and income groups were examined using one-way ANOVA. The findings show a limited but informative role of demographics. Gender differences were significant only for environmental awareness, where female tourists reported higher awareness than male tourists. Age differences were significant for environmental attitude (stronger among tourists below 30 years) and for pro-environmental behaviour (highest among tourists aged 31–50 years). Income-based differences were significant for environmental knowledge, environmental attitude, and pro-environmental behaviour, with higher-income groups reporting consistently higher scores. Thus, the results provide segmentation-ready evidence that can help agritourism operators and destination planners tailor sustainability communication, experience design, and pricing or behavioural nudges to visitor groups with different constraints and response tendencies.

Keywords: agritourism, pro-environmental behaviour, demographics, gender, age, income, sustainable tourism

INTRODUCTION

Tourism is no longer being measured based on the number of visitors that it brings, but also on the type of visitors that it is attracting to a disaster-prone destination (Alloh et al., 2024). Due to the increasing visibility of climate and biodiversity pressures in people's daily lives, destinations and tourism operators face increasing pressure to promote low-impact decisions, responsible consumption, and the well-being of local ecosystems (Badia et al., 2024). Similarly, Agritourism is one of the promising areas of this change, as tourists will stop merely sightseeing, but they will be involved in agriculturally based activities, have local food experiences, and experience the rural lifestyle (Ting & Cheng, 2017).

Since agritourism is based on the actual landscapes, labour, and utilisation of resources, it can render the environmental issues less abstract and more personal (Ohorodnyk & Finger, 2024). The experience of agritourism has suggested that agritourism participation can be linked to both the public sphere and the private sphere sustainable behaviours, suggesting that the experience may not only reinforce greener practices during the process of travel but may also extend to other areas (Brune et al., 2022). Simultaneously, agritourism is frequently framed as a rural sustainability and local wellbeing avenue, where environmental protection is connected to the local developmental goals (Ciolac et al., 2019).

An important factor as to why agritourism is important in sustainability is that it is able to turn the concept of environment into a slogan into a sight and touch experience for the tourists (Shi & Liao, 2025). As visitors see how the resources are saved, waste management, soil management and how food is produced in seasons, they are introduced to sustainability as a collection of daily choices and not a far-fetched policy argument (Wu et al., 2024; Zhang et al., 2024).

Research on farm tourism and other tourism in a rural setting demonstrates that these experiences have the potential to bridge personal values and environmentally responsible decision-making, which supports the idea that sustainability is partially related to what individuals value and how they understand their contribution to visiting (Hassan et al., 2024). In a broader sense, tourism studies have long held that internal factors (including knowledge, attitudes, and values) are significantly connected to intentions and behaviour, albeit the level of connection depends on the situation and the kind of behaviour under investigation (Gao et al., 2016). That is, the psychological pathway is substantive, but it does not work in empty space.

This is where the role of demographic differences comes in as a practical factor. Tourism managers seldom enjoy the privilege of creating a single sustainability message or a single green experience that will be equally effective on all. Age, gender, and income usually determine the affordability of the tourists, their priorities, responsibility interpretations, and their readiness to abandon routine behaviours (Pinho & Gomes, 2024). Within the hotel and destination contexts, it has been observed that there are systematic circular attitude differences as well as environmental behaviours across socio-demographic lines, some of the results indicated that women expressed greater circular behaviours compared to men and willing to pay higher to access greener establishments may also differ depending on their socio-demographic background (Rodríguez et al., 2020). On the same note, gender work in tourist settings has demonstrated that the connections among individual elements and pro-environmental behaviour may vary between men and women so that they indicate that what drives green behaviour may not be the same among men and women (López-Bonilla et al., 2020). The issue of income is also significant as it may serve as an enabler (possibility to afford greener alternatives) and be a barrier (price sensitivity and competing needs). Indicatively, studies on green product purchasing behaviours of tourists show that there is a noteworthy variation in the environmentally friendly purchasing behaviour across income classes (Pekerşen & Canoz, 2022). More recent findings on the relevance of socio-demographics (such as age, gender, and income) in explaining or moderating sustainable travel decisions and associated behavioural patterns are also reported in India (Naik et al., 2025). Combined, the literature direction is clearly pointed that demographic segments may vary, but the trend of variations may be situation-specific and has to be verified in the context under investigation.

It is in this context that the current paper takes a very narrow and pragmatic approach. The most important constructs in the pro-environmental behaviour chain such as Environmental Awareness, Environment Concern, Environment Value, Environmental Knowledge, Environmental Attitude and Pro-environmental Behaviour have already been discussed in previous research work in terms of their concept divisions as well as the relationship of one with another (Ansari et al., 2021; Bilynets & Knezevic Cvelbar, 2022; Fatoki, 2019; Foroughi et al., 2022; Li et al., 2022).

There have been least studies that might have studied the role of demographic variables. Thus, this study focuses on whether there are any significant differences in the mean scores of these constructs across significant demographic groups in an agritourism setting. The study would create practical demographic segmentation knowledge to agritourism operators and destination planners by isolating the variation in demographic in this manner.

These understandings can be used to make the communication of sustainability more accurate, experience design, and pricing or behavioural nudges so that the practitioners can better reach out to groups with the highest response rates and also account for the limits and incentives that could be driving less responsive groups.

The rest of the paper will be structured in the following way. Section 2 demonstrates the theoretical framework and hypotheses of the study. Section 3 describes the research design, sampling method, construct measurement and the analytical methods. In section 4, the findings of the empirical research are reported. In Section 5, the results will be discussed, the most important limitations identified, and the way future research should be carried out.

Theoretical Framework

Agritourism provides a setting where tourists encounter the natural environment and food production systems in a direct, experience-based way (Alloh et al., 2024; Karthik & Gajanand, 2017). Unlike conventional tourism, where sustainability may remain a background message, agritourism makes environmental issues visible through land-based activities, local food consumption, and interaction with rural communities (Jamaliah et al., 2021).

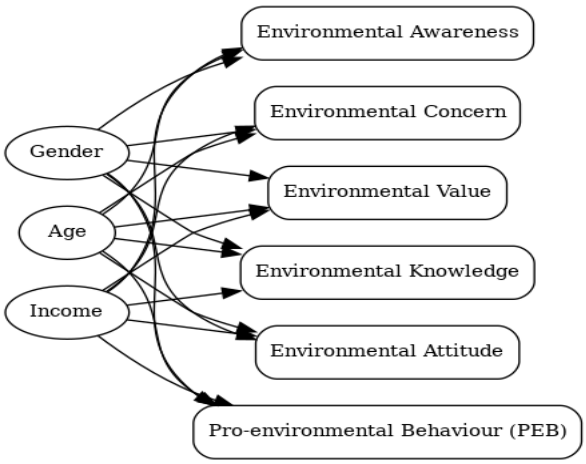

Figure 1. Research Framework

This matters because pro-environmental behaviour in tourism is shaped not only by what people believe in principle, but also by what the setting makes salient and easy to practise (Brune et al., 2022). The present model (Figure 1) is intentionally framed as a segmentation model, not a causal behavioural model. The model assumes that gender, age, and income function as distal determinants that can create meaningful differences in tourists' environmental orientations and actions. This is consistent with the broader literature, which recognises that demographic characteristics often shape socialisation, resources, and constraints, and therefore influence environmental attitudes and behaviours (Stern, 2000). In tourism settings, socio-demographic profiling has been used to explain why some tourists exhibit stronger environmentally responsible or circular practices than others, suggesting that demographic segmentation is useful for sustainability planning (Rodríguez et al., 2020).

Hypotheses development

Gender-based differences in pro-environmental factors and behaviour

A large body of literature suggests that gender can shape pro-environmental attitudes and behaviour, although the direction and strength of this effect vary across settings. Early work by Zelezny et al. (2000) showed that women often report stronger environmental concern and a greater tendency towards environmentally responsible behaviour than men. More recent evidence also supports this pattern. For example, Li et al. (2022), in a study from China, found that women showed higher environmental concern and engaged in several greener everyday practices than men. Within tourism and hospitality, Han et al. (2009) reported that the relationships between green attitudes, hotel image, and behavioural intentions were generally stronger among female guests in a green hotel context. Similarly, Moise et al. (2021) found that gender moderated the effects of hotel green practices on guest responses, suggesting that women may respond more positively to environmentally responsible hospitality initiatives in some contexts. At the same time, the evidence is not fully consistent. MacDonald & Hara (1994) found only weak gender differences in environmental concern, with males showing slightly higher concern in their sample of college students. In another study, Mostafa (2007) reported significant gender differences in green purchase behaviour among Egyptian consumers, showing that such variation is highly context-dependent rather than universal. Patel et al. (2017), using evidence from India, also reported that men displayed higher pro-environmental behaviour than women in their sample. Taken together, these findings suggest that gender may influence pro-environmental factors and behaviour, but the pattern is shaped by cultural context, type of behaviour, and research setting. In view of these mixed findings, the following hypothesis is proposed:

H1: Male and female tourists do not differ significantly with respect to pro-environmental factors (environmental awareness, environmental concern, environmental value, environmental knowledge, environmental attitude) and pro-environmental behaviour.

Age-based differences in pro-environmental behaviour

Age is widely used as a demographic variable in sustainability research because different life stages are often associated with different values, routines, responsibilities, and consumption habits (Farmaki et al., 2026; Sadeque et al., 2026). However, the relationship between age and pro-environmental behaviour is far from straightforward. Some studies suggest that younger consumers may be more receptive to green appeals, especially where environmental behaviour is linked with identity, innovation, and social influence (Khairy et al., 2026). Lee (2008), for instance, showed that young consumers can be an important segment for green marketing. In hospitality research, Han et al. (2009) found that age had a moderating role in the relationship between green attitudes and behavioural intentions in a hotel setting. These findings indicate that younger groups may be especially responsive to green communication in some market environments. Other studies point in a different direction. Wang et al. (2021), using cross-national evidence from 31 countries, found a positive relationship between age and pro-environmental behaviour, with older people more likely to participate in environmentally responsible actions. Sun et al. (2019) also found that age affects green consumption behaviour, although its effect operates within a broader system of demographic and environmental influences. In tourism specifically, Wang et al. (2020) reported that age significantly influenced green purchase attitudes towards green hotel selection in China. By contrast, Akehurst et al. (2012) argued that psychographic factors are often more important than socio-demographic variables in explaining green purchase behaviour, which suggests that age alone may not be a reliable predictor in every context. Patel et al. (2017) likewise found that middle-aged consumers scored higher on pro-environmental behaviour than both younger and older groups, reinforcing the idea that age effects are present but not uniform. Given this mixed yet meaningful evidence, the following hypothesis is proposed:

H2: Tourists across different age categories differ significantly in mean pro-environmental behaviour.

Income-based differences in pro-environmental behaviour

The role of income in pro-environmental behaviour remains one of the most debated issues in this literature. One line of research suggests that higher income can support greener behaviour because it reduces the financial burden associated with eco-friendly products, green premiums, or sustainable service choices (Buckley et al., 2025; Wang & Zhang, 2020). Khare (2015) found that income influenced environmentally friendly behaviour among Indian consumers, while Wang et al. (2020) reported that income significantly affected both green purchase attitudes and behavioural intention towards green hotel selection in China. These studies support the argument that financial capacity may make it easier for consumers to translate environmental concern into action, particularly when sustainable choices involve higher cost or perceived sacrifice (Pang & Jiang, 2026). Yet another line of evidence suggests that income is neither simple nor consistently positive as a predictor of green behaviour. Akehurst et al. (2012) concluded that psychographic variables were more relevant than socio-

demographic ones in explaining ecologically conscious consumer behaviour. Sun et al. (2019) similarly found that while several demographic factors matter, overall consumption levels did not have a significant impact on green consumption in their multilevel model. More recent evidence further complicates the picture. Berthold et al. (2023) found that higher income was associated with lower willingness to engage in certain pro-environmental behaviours, while subjective financial scarcity also reduced willingness to act sustainably. This suggests that both objective resources and subjective financial experience can shape environmental behaviour in different ways (Voss et al., 2026). Therefore, the effect of income appears to be context-sensitive and dependent on the type of behaviour being measured. In light of these mixed findings, the following hypothesis is proposed:

H3: Tourists across different income categories differ significantly in mean pro-environmental behaviour.

METHODOLOGY

This paper investigates how key demographic variables shape tourists' pro-environmental behaviour in agritourism settings in Kashmir, India. In line with the study's central purpose, the analysis focuses on whether age, gender, and income significantly differentiate tourists' pro-environmental behaviour, rather than re-examining the already well-established causal links among environmental values, beliefs, attitudes, norms, perceived behavioural control, and behavior (Forleo & Bredice, 2025; Majid et al., 2025). This focus is practically important because agritourism operators and destination planners need clear segmentation-based evidence to design sustainability messages, visitor experiences, and behavioural interventions for different categories of tourists. To address this objective, the study adopted a quantitative survey design and gathered systematic evidence from tourists who had participated in agritourism activities in the region. The target sample comprised 700 domestic and international tourists, and purposive sampling was used to ensure that all respondents had direct experience of agritourism in Kashmir. Before the main survey, the questionnaire was piloted with 80 respondents to assess clarity, relevance, and logical flow in line with the studies (Malik et al., 2025; Mehraj et al., 2025; Mehraj & Qureshi, 2022a; Qureshi & Mehraj, 2022; Tanzeela et al., 2024). Based on the pilot feedback, minor revisions were made to improve the final instrument. The structured questionnaire consisted of two main sections. The first section captured the demographic profile of respondents, including age, gender, nationality, education, occupation, and income. The second section measured the major pro-environmental constructs using established scales drawn from earlier studies.

Figure 2. Methodological Flow Diagram (Source: Prepared by the authors)

Specifically, pro-environmental values were adapted from Stern et al. (1999), pro-environmental beliefs from Dunlap et al. (2000), pro-environmental attitude from Kaiser et al. (1999), social norms from Cialdini et al. (1990), environmental conscientiousness from Hirsh (2010), perceived behavioural control from Ajzen (1991), and pro-environmental behaviour

from Kaiser (1998). All items were rated on a five-point Likert scale ranging from 1 = strongly disagree to 5 = strongly agree. Of the 700 questionnaires distributed, 560 valid responses were received, giving a response rate of 80 per cent. In line with the study's segmentation objective, respondents were grouped by age into below 30 years (26 per cent), 31-50 years (50 per cent), and above 50 years (24 per cent). Gender was evenly distributed between male (50 per cent) and female (50 per cent) respondents. Monthly income was classified into five brackets: below ₹20,000 (15 per cent), ₹20,000-₹50,000 (30 per cent), ₹50,001-₹100,000 (25 per cent), ₹100,000-₹200,000 (20 per cent), and above ₹200,000 (10 per cent). For the statistical analysis, an independent-samples t-test was used to examine gender-based differences, while one-way ANOVA was applied to test differences across age and income groups. Thus, the study seeks to identify which categories of tourists display higher or lower levels of pro-environmental behaviour in agritourism settings and to generate practical insights for more targeted and effective sustainability strategies as showin in Figure 2.

RESULTS

Analysis for Gender

To examine whether Environmental Awareness, Environmental Concern, Environmental Value, Environmental Knowledge, Environmental Attitude, and Pro-environmental Behavior differ based on gender, an independent sample t-test was conducted. The results, presented in Table 1, indicate that Environmental Awareness is the only construct where a statistically significant difference was observed between male and female respondents ($t = -2.43$, $p = 0.015$). Females ($M = 3.75$, $SD = 1.07$) reported higher environmental awareness compared to males ($M = 3.52$, $SD = 1.15$), suggesting that women tend to be more environmentally conscious in agritourism settings. The Levene's test for equality of variances ($F = 5.75$, $p = 0.017$) indicates that variance was not equal, so adjustments were made in the t-test calculations. For Environmental Concern, there was no statistically significant difference between males and females ($t = -0.718$, $p = 0.473$), with mean scores of 3.61 ($SD = 1.05$) for males and 3.67 ($SD = 1.06$) for females, indicating that both genders exhibit similar levels of concern for environmental issues. Similarly, Environmental Value showed no significant difference ($t = 0.542$, $p = 0.588$), with males ($M = 3.66$, $SD = 0.967$) and females ($M = 3.61$, $SD = 0.956$) reporting comparable perceptions of sustainability importance in agritourism. The results in Table 4.24 also show no significant gender differences in Environmental Knowledge ($t = -0.383$, $p = 0.702$), with males ($M = 3.68$, $SD = 1.00$) and females ($M = 3.71$, $SD = 0.990$) demonstrating similar levels of knowledge regarding sustainability in agritourism. Likewise, Environmental Attitude did not show a significant difference between males ($M = 3.53$, $SD = 1.00$) and females ($M = 3.59$, $SD = 1.04$), with $t = -0.648$ and $p = 0.518$, indicating that both genders hold comparable attitudes towards environmental sustainability.

For Pro-environmental Behavior, the results show no statistically significant difference ($t = -0.088$, $p = 0.930$), as both males ($M = 3.62$, $SD = 1.05$) and females ($M = 3.62$, $SD = 1.05$) reported identical levels of environmentally responsible actions in agritourism settings. Overall, the findings in Table 1 suggest that gender plays a role in Environmental Awareness, with females demonstrating higher awareness levels than males, while there are no significant differences in other environmental constructs, including Concern, Value, Knowledge, Attitude, and Pro-environmental Behavior. These results indicate that while awareness-based interventions may need to be customized based on gender, other sustainability initiatives can be implemented uniformly across male and female tourists in agritourism settings.

Table 1. Independent Sample t-Test Results for Gender

Constructs	Gender	Mean	Std. Deviation	Levene's Test		T	Sig..
				F	Sig..		
Environmental Awareness	Male	3.52	1.15	5.75	.017	-2.43	.015
	Female	3.75	1.07				
Environmental Concern	Male	3.61	1.05	.004	.951	-.718	.473
	Female	3.67	1.06				
Environmental Value	Male	3.66	.967	.193	.660	.542	.588
	Female	3.61	.956				
Environmental Knowledge	Male	3.68	1.00	.248	.618	-.383	.702
	Female	3.71	.990				
Environmental Attitude	Male	3.53	1.00	1.174	.279	-.648	.518
	Female	3.59	1.04				
Pro-environmental Behavior	Male	3.62	1.05	.164	.685	-.088	.930
	Female	3.62	1.05				

Analysis for Age

To assess whether Environmental Awareness, Environmental Concern, Environmental Value, Environmental Knowledge, Environmental Attitude, and Pro-environmental Behavior vary across different age groups, a one-way ANOVA test was conducted. The results, presented in Table 2, provide insights into whether significant differences exist among three age groups: below 30 years, 31-50 years, and above 50 years. The analysis reveals that Environmental Attitude and Pro-environmental Behavior show statistically significant differences across age groups. Environmental Attitude ($F = 5.96$, $p = 0.003$) differs significantly, with respondents below 30 years ($M = 3.84$, $SD = 0.793$) reporting higher environmental attitudes than those in the 31-50 years ($M = 3.46$, $SD = 1.07$) and above 50 years ($M = 3.52$, $SD = 1.05$) age groups. This suggests that younger tourists are more likely to hold positive environmental attitudes in agritourism settings. Similarly, Pro-environmental Behavior ($F = 4.25$, $p = 0.015$) exhibits significant differences, where

respondents aged 31-50 years (M = 3.71, SD = 1.12) report higher engagement in pro-environmental actions compared to those under 30 years (M = 3.38, SD = 0.953). This indicates that middle-aged tourists demonstrate stronger environmentally responsible behaviors in agritourism, possibly due to greater life experience and awareness of sustainability practices. For Environmental Awareness (F = 2.07, p = 0.126), Environmental Concern (F = 1.31, p = 0.269), Environmental Value (F = 0.044, p = 0.957), and Environmental Knowledge (F = 1.50, p = 0.224), no significant differences were found across age groups (p > 0.05). This suggests that age does not play a significant role in shaping awareness, concern, value, or knowledge related to environmental sustainability in agritourism. Overall, the findings in Table 2 indicate that younger tourists exhibit stronger environmental attitudes, while middle-aged individuals demonstrate higher pro-environmental behaviors. However, awareness, concern, knowledge, and value remain consistent across age groups, suggesting that sustainability efforts in agritourism appeal broadly across different age demographics. These insights can guide targeted sustainability initiatives, ensuring that awareness campaigns focus on attitude development among older groups while reinforcing behavioral commitment among younger tourists.

Table 2. One-way ANOVA Results for Age

Constructs	Age	Mean	Std. Deviation	F	Sig..
Environmental Awareness	<30 yrs	3.80	1.01	2.07	.126
	31-50 yrs	3.60	1.18		
	above 50 yrs	3.54	1.11		
	Total	3.62	1.12		
Environmental Concern	<30 yrs	3.72	1.01	1.31	.269
	31-50 yrs	3.56	1.07		
	above 50 yrs	3.69	1.06		
	Total	3.63	1.06		
Environmental Value	<30 yrs	3.66	.829	.044	.957
	31-50 yrs	3.64	1.01		
	above 50 yrs	3.63	.965		
	Total	3.64	.961		
Environmental Knowledge	<30 yrs	3.83	.920	1.50	.224
	31-50 yrs	3.64	.992		
	above 50 yrs	3.68	1.05		
	Total	3.69	.998		
Environmental Attitude	<30 yrs	3.84	.793	5.96	.003
	31-50 yrs	3.46	1.07		
	above 50 yrs	3.52	1.05		
	Total	3.56	1.02		
Pro-environmental Behavior	<30 yrs	3.38	.953	4.25	.015
	31-50 yrs	3.71	1.12		
	above 50 yrs	3.65	1.00		
	Total	3.62	1.05		

Analysis for Income

To assess whether Environmental Awareness, Environmental Concern, Environmental Value, Environmental Knowledge, Environmental Attitude, and Pro-environmental Behaviour vary across different income groups, a one-way ANOVA was conducted. The results are summarised in Table 3, comparing five income categories: below ₹20,000, ₹20,000–₹50,000, ₹50,001–₹100,000, ₹100,001–₹200,000, and above ₹200,000. The findings show that Environmental Knowledge, Environmental Attitude, and Pro-environmental Behaviour differ significantly across income groups. Environmental Knowledge displays a statistically significant difference (F = 2.74, p = 0.028), with mean scores rising steadily across income brackets. Respondents earning above ₹200,000 report the highest knowledge levels (M = 3.95, SD = 0.86), compared to those earning below ₹20,000 (M = 3.50, SD = 0.99). This suggests that higher-income tourists may have greater exposure to sustainability information or may be more familiar with sustainability concepts relevant to agritourism experiences.

A similar pattern is observed for Environmental Attitude (F = 3.11, p = 0.015). Tourists in the highest income bracket show more favourable environmental attitudes (M = 3.80, SD = 0.94) than those in the lowest bracket (M = 3.38, SD = 1.07). This indicates that income-based segmentation may be relevant for attitude-building interventions, especially for groups that score comparatively lower on environmental attitude. Most importantly, Pro-environmental Behaviour also shows significant income-based variation (F = 4.48, p = 0.002). Behavioural engagement increases with income, with the lowest-income group reporting the lowest behavioural score (M = 3.30, SD = 1.02) and the highest-income group reporting the highest (M = 3.95, SD = 0.98). One plausible interpretation is that some pro-environmental actions in agritourism (such as paying for eco-activities, purchasing local sustainable products, or opting for greener services) may be easier to adopt when tourists face fewer financial constraints. For Environmental Awareness (F = 0.62, p = 0.650), Environmental Concern (F = 0.41, p = 0.802), and Environmental Value (F = 0.29, p = 0.883), no statistically significant differences were found (p > 0.05). This indicates that, regardless of income level, tourists hold broadly comparable awareness, concern, and value orientations, while differences emerge more strongly in knowledge, attitude, and actual behaviour. Overall, Table 3 suggests that sustainability efforts in agritourism resonate across income groups at the level of general awareness and concern, but income-based segmentation becomes more important when the focus shifts to knowledge depth, attitude strength, and behavioural uptake.

Table 3. One-way ANOVA Results for Income

Constructs	**Income**	**Mean**	**Std. Deviation**	**F**	**Sig.**
Environmental Awareness	below ₹20,000	3.55	1.10	0.62	.650

The demographic tests show a clear “mixed picture”, which is exactly why it is sensible to test differences rather than assume that all visitor groups behave the same way. For H1 (gender), the results indicate a statistically significant difference only for Environmental Awareness (female tourists scoring higher), while Environmental Concern, Environmental Value, Environmental Knowledge, Environmental Attitude, and Pro-environmental Behaviour do not differ significantly by gender. In other words, H1 is largely supported, but not fully, because awareness does vary by gender. For H2 (age), the one-way ANOVA shows that Pro-environmental Behaviour differs significantly across age groups, so H2 is supported. For H3 (income), the one-way ANOVA indicates that Pro-environmental Behaviour differs significantly across income categories, so H3 is also supported. Notably, the income analysis also suggests meaningful differences for Environmental Knowledge and Environmental Attitude, even though the core hypothesis focused on behaviour.

DISCUSSION

This research was purposefully limited by a specific objective to establish whether there are significant differences in pro-environmental behaviour of tourists in an agritourism context by gender, age, and income, as opposed to re-evaluating a well-established logic of values, beliefs, attitudes, norms, control that prevails in the research in environmental behaviour (Salim et al., 2022). The significance of that decision is practical as it is not sufficient that the operators of agritourism should know what predicts behaviour in general, but rather what visitor groups have dissimilar reactions, and that a one-size-fits-all sustainability policy will perform worse (Patwary et al., 2023).

Beginning with gender, what is interesting about the results is, in fact, that it is modest. The environmental awareness amongst female tourists is higher but they do not have statistically significant greater concern, knowledge, attitude, and pro-environmental behaviour in the agritourism visit per se (Mehraj, et al., 2025). A possible way to interpret it is that awareness is commonly more of a more cognitive and more self-reported disposition whereas behaviour in a destination is determined by the situational characteristics of what is convenient, what is expected to be done on-destination socially, and what experience design predisposes to do easily. In cases where the setting is very strong structuring behaviour (farm rules, guided activities, waste systems, local-produce prompts), the gender gaps may reduce as everyone is nudged towards the same direction by the environment (Jeaheng et al., 2026).

This is in line with more general literature that indicates that demographic influences on pro-environmental behaviour are contextual and can be influenced by social expectations and opportunity structures rather than individual disposition. In the case of agritourism, the message that should be practiced is that gender differences might be more applicable to an awareness-building communication, but behavioural design on-site might not need to be radically different between male and female tourists as long as the aim is to increase actual eco-actions (Papp-Váry & Hajeer, 2026).

The results of the age comparison are more subtle and, actually, more realistic than the typical young people are greener argument. The environmental attitude is highest among the tourists who are below 30 years of age, whereas the pro-environmental behaviour is reported to be higher among the 31-50 category of tourism.

Such division is in line with a general trend in sustainable tourism studies that individuals may have high pro-environmental ideologies, but behavioural choices are influenced by lived restrictions, habits, perceived costs, and the short-term costs of acting in a sustainable way (Sharma & Gupta, 2020). Younger tourists might have more sustainability principles and identity-based stances, which can be reflected in the attitudes, but might not necessarily translate into behaviour in a destination situation, particularly when behaviour is associated with trade-offs or effort. Middle aged visitors, on the other hand, can be more apt to exert behavioural follow through since they are more inertially habitual and more generally more inclined to planning routines and (often) more able to assimilate small expenditures.

Notably, generation stories may get sloppy when they overload the generational stereotypes. Tourism studies warn against assumed age effects, they are to be tested and that a lot of so-called generational differences fail when you start to look at the larger period effects and situational impacts (Chen & Cheung, 2025). Your results are well consonant to that warning: here age is important, but in a particular sense, and not in all the constructs of the environment.

Switching to income, the findings indicate that income is not closely correlated with the variables of awareness, concern and value which are a baseline orientation but is correlated to depth of knowledge, strength of attitude and pro-environmental behaviour. That trend is behaviourally sound in the tourism. The agritourism context has some sustainable behaviours that are correctly free (conforming to regulations, not littering, not damaging the ecology of the farm), whereas other actions can be more easily accomplished when tourists are able to pay a premium (buying locally grown organic food, participating in fee-based eco-tourism, selecting greener service options) (Mehraj & Qureshi, 2022). Income disparities are more likely to be conspicuous where behaviour is concerned with financial trade-offs. Once again, the broader literature has been identifying that demographic and socioeconomic factors influence pro-environmental behaviour in part due to social and structural limitations, rather than in part because of willingness.

In the case of agritourism, this is important, since it implies an issue of fairness as well as marketing: when sustainable options are charged so that they are not accessible to visitors with lower incomes, then green tourism may be seen as something people believe in ideally but cannot perform in reality at the present. In all three demographics, this trend supports one of the major ideas of sustainable tourism research, it may not always be the most difficult task to create positive attitudes, but bridging the gap between positive orientations and systemic behaviour (Woolf et al., 2026).

It is then where the design of interventions would be important. Tourism is also becoming an area of research that focuses on the effectiveness of behavioural interventions and choice architecture, and proactive prompts to make tourists make carbon-intensive decisions and follow pro-environmental follow-through (Liu et al., 2025). Similarly, the design and interpretation of messages might be relevant: effective interpretation messages have been found to enhance pro-environmental reactions of tourists in a heritage environment and the same reasoning can be used agritourism where learning, meaning, and place-based identity are the focus of experience (Khan et al., 2024). To put it briefly, your demographic outcomes are not differences on a table. They indicate where the operators need to be more message based (to acquire awareness and attitude) and less friction reducing and behavioural designing (to acquire actual behaviour).

CONCLUSION

This research paper investigates the existence of differences in age, gender, and income among tourists in the context of pro-environmental behaviour in agritourism environments in kashmir, India.

The main contribution is that it does not consider demographics as background information, but rather as pragmatic segmentation variables that can inform on-ground sustainability decisions in agritourism. Instead of retesting the known relationships between the values, beliefs, attitudes, norms and behavioural control, the research separated demographic variation to provide an answer to a more practical question, that is, which visitor groups behave.

First, this setting does not have a lot of gender differences. The women tourists are more environmentally aware; however, the study does not find any gender differences in concern, value, knowledge, attitude, or pro-environmental behaviour. It implies that the agritourism settings might already offer a relatively normalised behaviour scheme that minimises gender disparities in real eco-behaviours. The gender factor seems to have the greatest impact at the level of awareness, which is commonly shaped by exposure, attention, and information processing and not by situational constraints (Mehraj et al., 2025; Mehraj & Qureshi, 2020).

Second, there is age variance that is significant yet construct-varying. The younger tourists (under 30) show a better level of environmental attitudes, whereas the middle-aged tourists (31-50) show a better level of pro-environmental behaviour. This trend confirms the fact that positive attitudes are not always associated with consistent behaviour in tourism situations, like time, effort, habit and perceived cost are the factors that influence what tourism visitors actually do (Pícha & Navrátil, 2019). It also conforms to the larger warning that claims of age need to be approached with caution and should not be forced into oversimplistic generational narratives (Subramaniam et al., 2020).

Third, the difference in incomes is the most convincing at the behavioural level, where the pro-environmental behaviour, attitudes and environmental knowledge are higher in higher income groups. Simultaneously, the awareness, concern, and values seem to be rather similar regardless of the income group, meaning that lower-income tourists do not seem to be generally less eco-conscious, but simply have fewer opportunities to make sustainable decisions that might mean premium payment or reduced convenience. This supports the view that structural feasibility, rather than motivation alone, also influences pro-environmental behaviour (Kaur et al., 2026).

The findings, combined, go towards giving the study the practical motivation: demographic segmentation can assist the agritourism operators in determining where to focus. The larger point is that agritourism can be used as a powerful tool in the sustainability platform, but only to the extent that the experience created encourages the visitor to transition to a more precise action rather than remaining in an overall positive state. The growing literature on tourism argues that the attitude-behaviour gap needs to be filled with prompts and interventions, but not merely more information (López-Bonilla et al., 2020; Steg et al., 2014). The immersive and educative nature of Agritourism makes it ideally placed to do just that, so long as its sustainability plans are aimed at the behavioural implications of various classes of visitors.

Implications of the study

The findings of the study have practical and operational implications, as agritourism operators make day-to-day decisions on the design of experiences, prices and communication which have a direct impact on visitor behaviour (MacInnes et al., 2025). The results indicate that a one-size-fits-all sustainability message sent to the group of tourism consumers will be less effective than a more targeted strategy that acknowledges the influence of demographics on what visitors observe, how they perceive sustainability signals, and what they can physically, practically, and effectively do on a visit (He & Filimonau, 2020). The first implication is related to experience design and behavioural friction. Gender differences are insignificant in actual behaviour, so operators would be more concerned with default-green systems, which would make the sustainable choice the one of least effort among all. This involves well-defined waste disposal locations, visible refill locations, and organised instructions in dealing with the farms as well as simple cues when doing an activity. These factors minimize the motivation and assist in transferring the positive attitudes into practice. Tourism behavioural intervention studies indicate that high-carbon decisions decrease when prompted and choice structures are designed adequately, and sustainable choices are reinforced without necessarily employing persuasive tactics (López-Bonilla et al., 2020). In the case of agritourism, a similar shift is to ensure that the visits are structured in such a way that pro-environmental behaviour of low effort occurs naturally in the experience flow.

The second implication is the message strategy based on the demographic segment, particularly age. The attitude score of younger tourists is higher than that of the 31–50 age bracket, but the behavioural score of the younger tourists is lower due to which the operators should work towards persuading the under-30 tourists to change attitude to action.

This can be implemented in the sense of providing younger visitors with identity-related and actionable actions and participation that is observable and visible, critical of the visit, little conservation actions, and brief explanations that relate farm activities to outcomes that tourists are interested in. In comparison, the 31-50 segment already exhibits comparatively better behaviour and thus, the message can be reinforcing and commitment-based, i.e. offering loyalty-based incentives to encourage repeat eco-actions or family-sustainable activities that bring behaviour out in the open and make it sharable. A third implication is associated with income and fair sustainability design. As pro-environmental behaviour is income-dependent, operators must not construct sustainability as a new premium experience.

Provided that the most sustainable choices can be obtained only with the help of paid upgrades, less affluent visitors might be willing to be supportive in attitude, but incapable of being able to act completely sustainably, which can silently contribute to the difference between the intentions towards green and the actual green behaviour.

This is a method that employs segmentation but not sustainability as exclusivity. It is also part of the broader argument that socioeconomic conditions can impact behaviour in part because of feasibility and constraint, but not exclusively due to values (Kaur et al., 2026). The fourth implication is one to interpretation and learning design.

Agritourism is a form of education, and recent research in tourism cases indicates that interpretation messages can significantly lead to an increase in pro-environmental reactions, through influence on how visitors interpret their presence in the place they are exploring (Wang et al., 2025). In the case of agritourism in Kashmir, India, interpretation can be integrated into a little bit practical means: brief, informative, why this practice is important, explanations when you go and see a farming demonstration, the signs that will relate consumption of local food to environmental results, and the stories of staff people who will relate sustainability to the livelihood of the people.

Well done, interpretation minimizes abstract preaching, and instead, it creates place-based meaning.

Lastly, the research has an implication on destination planning and targeting. These findings can be used by tourism planners to target campaigns: campaigns should resonate with female tourists more by focusing more on awareness, younger audiences should be encouraged by the design to behave sustainably, and differentiated products may be required to ensure sustainability is inclusive and still financially viable. All in all, the findings contribute to the assumption that sustainable tourism outcomes are best achieved when the operators combine persuasive communication with behavioural design, as opposed to using either of them (Mehraj & Kaur, 2022).

Limitations and scope for future research

There are a number of limitations in this study, which must be considered during the interpretation of the findings. One, the study is cross-sectional and self-reported, which implies that the study focuses on perceived orientations and reported

behaviours at a single point in time. The research on sustainable tourism has repeatedly that self-reports have the possibility of inflating behaviour, particularly when social desirability leads to sustainability, and future research would be more robust with behavioural observation or post-visit follow-up. Second, the sample was in Kashmir agritourism locations, which was through judgmental (purposive) sampling. It is suitable to make sure that the participants are relevant with regard to experience, but it restricts the degree to which the research findings can be extrapolated to other agritourism environments. This could be useful for future research in several ways. Recreation in other states in India and in other types of rural tourism would help ascertain the question of whether the demographic trends are unique to Kashmir or universal.

The researchers could also examine whether properly tailored interventions, like interpretation-based messaging or behavioural prompts, would lead to demographic bridges in behaviour, based on previous studies that have emphasised the usefulness of target interventions in influencing sustainable tourist decisions.
