Geojournal of Tourism and Geosites

Year XIX, no. 3, vol. 67

Oradea - Gdańsk
2026

PUBLICATION REQUIREMENTS OF ARTICLES IN THE GEOJOURNAL OF TOURISM AND GEOSITES

The Editorial Board goes trough each article, which in then submitted to two referees' judgment. Names of referees are confidential to the Editorial Board. Authors may be asked to make revisions to their manuscript. If substantial revision is required manuscripts may be re-reviewed before a decision to accept/publish is made. Final acceptance of manuscripts for publication is at the discretion of the Editors.

Authors alone are responsible for the opinions expressed in their papers.

Citation: Abd Halim, M.H., Talib, N.K., & Saidin, M. (2026). Sungai Batu archaeological complex as an iconic heritage tourism site: Evidence of ancient trade in the northern part of peninsular Malaysia. *Geojournal of Tourism and Geosites*, 67(3), 1838–1852. https://doi.org/10.30892/gtg.67301-1813

Abstract: The research at the Sungai Batu Archaeological Complex (SBAC) aimed to document the original river jetty structure and port management of ancient Kedah, which dates back to the 6th and 5th centuries BC. It was built on the riverbank, while port management was built at the back of the river jetty structure. The existence of the river jetty and port management structure in SBAC is clear evidence of the international trade process that has occurred in this area between the ancient Kedah Kingdom and foreign traders. For primary data recording in the field, several methodologies have been used, which include excavation, and analysis. The results revealed evidence of in situ river jetty and port management structures built using bricks. The architecture was also found to be complete with floor, wall, corridor and staircase structures for the river jetty, while the port management structure revealed the architecture of the floor, wall, corridor and administration space. The evidence of in situ architecture allows for the first time the outstanding universal value (OUV) of the river jetty and port management site to be clearly determined based on academic studies. It is the most complete river jetty architectural form of early world civilisation since the 6th century B.C., ii) the most complete iron ingot export river jetty of early world civilisation and iii) the most complete ancient Kedah port complex. The OUV for port management sites was determined to be i) the earliest civilisations reveal the clearest and most complete evidence of port management architecture since the 5th century BC and ii) the first discovery of the architecture for managing iron export facilities in early world civilisations. This makes the archaeological evidence at SBAC the only one in Southeast Asia that is unique and can be nominated as a UNESCO World Heritage site for the World Heritage Site (WHS) category. To achieve this goal, the process of empowering the heritage tourism sector is actively carried out in collaboration between stakeholders and the local community so that it can produce a total of 17 identity tourism packages in the Kuala Muda district, Kedah, Malaysia. The involvement of stakeholders and local communities in tourism activities is a positive step to ensure that the heritage tourism sector in SBAC can be preserved and sustained.

Keywords: SBAC, heritage site, iconic tourism product, tourism

INTRODUCTION

The development of the Sungai Batu Archaeological Complex (SBAC) as a sustainable tourism site has been discussed scientifically by Abd Halim et al. (2024a) and Abd Halim et al. (2025a), which cover the offering of tour packages, the availability of tour guides and the application of digital technologies. The development of this area as a heritage tourism location is closely related to the very special outstanding universal value (OUV) revealed through academic studies.

In fact, based on these factors, SBAC was recognised as a national heritage site in 2012 (Ali et al., 2021 a,b) and developed as a heritage tourism site in Malaysia. Its recognition as a national heritage site has led to the establishment of a more structured tourism development and marketing plan to empower the heritage tourism sector. This allows for the first time in Kedah, Malaysia; there has been a systematic tourism development movement complete with living culture gallery facilities that include poster information, iron smelting demonstrations, hands-on excavations, and hands-on ancient brick, roof tiles and bead making (Abd Halim et al., 2024b). In addition, with the application of digital technologies such as AR, VR, hologram fans, and QR codes (Abd Halim et al., 2024a) also demonstrates the positive commitment played by stakeholders in ensuring that tourism sites in SBAC are conserved just like heritage tourism sites in other parts of the world (Hasan Khan, 2020; Labadi et al., 2021; Abdul Huq & Puthuvayi, 2024; Van der Zed et al., 2024; Abd Halim & Saidin, 2026). All these tourism marketing moves can be carried out based on systematic studies conducted at iron smelting workshop sites that represent evidence of the industry (Mohd Mokhtar, 2012: 2019; Abd Halim et al., 2025b), river jetty (Abd Halim et al., 2025c), and port management (Aminuddin, 2015; Ahmad, 2016; Yusof, 2016; Abd Halim, 2019) as evidence of trade, as well as ritual and Buddhist monuments (Abd Halim & Saidin, 2025a) as evidence of belief and religion in SBAC. This shows that archaeological studies in SBAC are special because it is the only area in the world that reveals clear and complete evidence of

industry, trade and religious beliefs in an area of only about 4 km² (Abd Halim & Saidin, 2025a). To balance the marketing of tourism, the availability of tourism infrastructure is also given priority. The availability of transportation infrastructure (Figure 1) and accommodation (Figure 2) to the heritage tourism area is seen to be on a good track and able to attract tourists to travel to this area (Yu et al., 2023; Zunic et al., 2023; Arsh et al., 2024). This is expected to be a trigger for the development of tourism activities that take place at SBAC, which is also able to maximise the tourist experience at a tourist location.

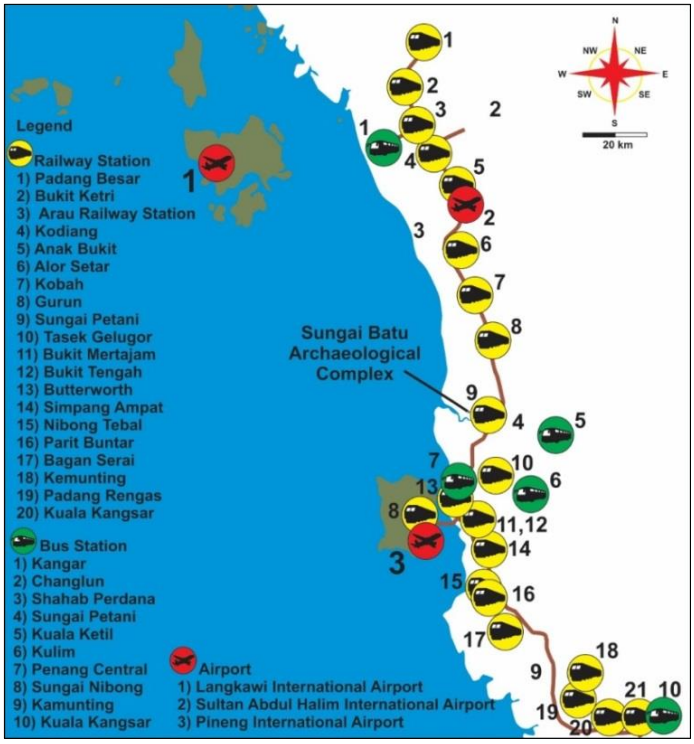

Figure 1. Availability of transportation systems to SBAC areas capable of developing tourism activities (Source: The authors)

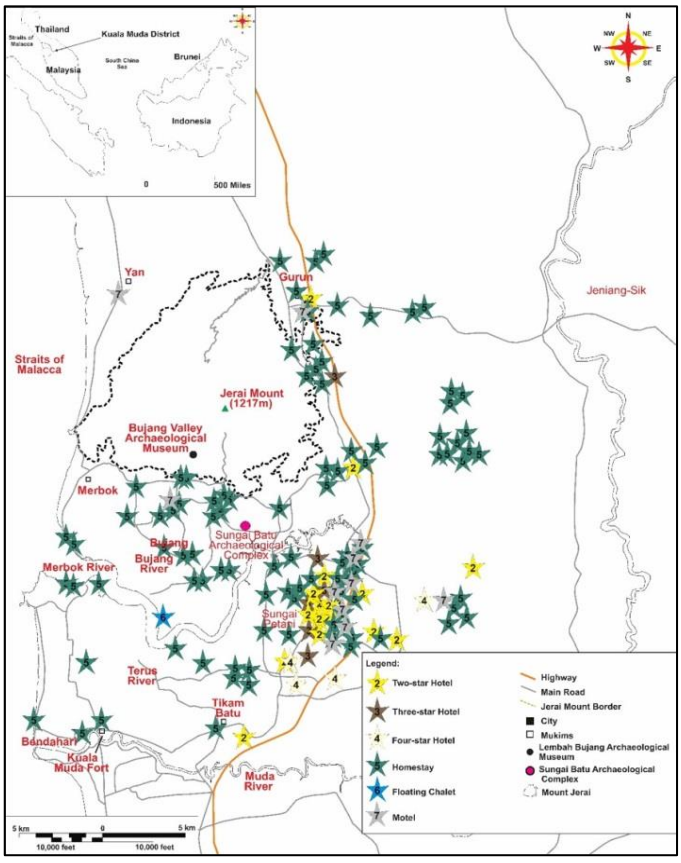

Figure 2. The availability of various types of accommodation in the nearby SBAC area is also able to offer more accommodation options to tourists (Source: The authors)

Additionally, there are eight border crossings near SBAC that have the potential to attract more tourists to the area (Figure 3). Some of the border gates include i) Wang Kelian-Wang Prachan border, ii) Padang Besar border, Perlis, iii) Bukit Kayu Hitam-Sadao border, Kedah, iv) Pengkalan Kubor-Tak Bai border, v) Rantau Panjang-Sungai Golok border, vi) Bukit Bunga-Buketa border, vii) Durian Burung-Ban Prakob border, Kelantan, and viii) Pengkalan Hulu-Betong border, Perak, Malaysia. Even with the role of stakeholders who formulate various programmes throughout the year to visit Kedah, 2025 is also expected to be able to attract domestic tourist visits (Nizam, 2024) in addition to being able to boost the influx of international tourists to tourist sites in Kedah (Hamid, 2024). This shows that the existence of special world-class heritage tourism sites with outstanding universal value and high value coupled with the availability of the best tourism infrastructure can be a catalyst for the development of heritage tourism, especially in ancient Kedah tourism sites. This is clearly recorded in other tourist sites that record the increase in the number of tourist arrivals to tourist areas due to tourism facilities that have been available (Gossling et al., 2018; Lei et al., 2023; Apriyanti et al., 2024; Hidalgo, 2024).

Figure 3. The border gate located in the northern part of Peninsular Malaysia has the potential to attract more tourists from Thailand (Source: The authors)

Tourism Marketing

According to Thomas & Langlitz (2018), John & Supramaniam (2024), and Basumatary & Sarma (2025), tourism marketing is a unique and methodological way to empower the tourist sector. This is because tourist sites are very close to local communities, so every element related to the development, empowerment, and marketing of a tourist location must include community involvement to ensure sustainability and success (Gubam & Nomishan, 2020). This approach is seen as a proactive step to maximise the empowerment of the tourism sector in an area (Ryan, 2002).

To achieve this goal, Poon (1993), Mendoncia et al., (2015) and Wang (2024) have outlined several issues related to integration, collaboration and networking activities at the local level as policy issues that need to be arranged and coordinated at the grassroots level to achieve the end goal of marketing a heritage tourism locality. After the issue is given special attention at the grassroots level, there is a need for a location that provides a tourism information centre which is used as an area that manages and monitors all activities related to packages and tourism, such as the recommendations of Ludmila & Kristina (2018) and Rachmawati et al. (2023). The purpose of its establishment is to centralise the tourism marketing process carried out while acting as an initial step to provide information related to tourist destinations directly to tourists so that the selection of tour packages becomes more effective. For these needs, tourism marketing in SBAC also involves the provision of a one-stop tourism centre in Sungai Merbok (Figure 4) which is available for various tourism facilities. To ensure that tourism marketing is able to attract tourists, especially for tour packages to heritage tourism sites, the provision of certified tour guides is a very necessary step (Rabotic, 2010; Setiawan & Wiweka, 2018). This is because a tour package to a heritage site is not a tour program to a tourist site other than because it is in the category of knowledgeable tourism, so the provision of a certified special tour guide is the most important asset in preserving the tourist location (Rabotic, 2018).

Figure 4. The One Stop Tourism Centre serves as a tourist information centre in Sungai Merbok (Source: The authors using a drone, 2021)

Therefore, UNESCO (2018); Bayram (2020); Malelak et al. (2022); and Dung (2024) stated that the local heritage has a direct connection with the community, so the provision of certified tour guides from among the local community is important to emphasise. This can also emphasise the principle of leaving no one behind in tourism marketing (Trupp & Dolezal, 2020; Butcher et al., 2021; de Jong & Vijgeberg, 2024; Abd Halim et al., 2025a; Priatmoko et al., 2025).

SBAC Authentic Data Research

Archaeological studies conducted at SBAC since 2009 have been able to record evidence of trade in this area based on the findings of the river jetty and port management structure. Although the archaeological study at SBAC has recorded the discovery of 11 river jetties structures and 18 port management sites, to complete this study, only archaeological evidence at the river jetty SB2J and port management SB2G sites (Figure 5) will be discussed more carefully to clarify the architecture, analysis of artefacts carried out and interpretations submitted.

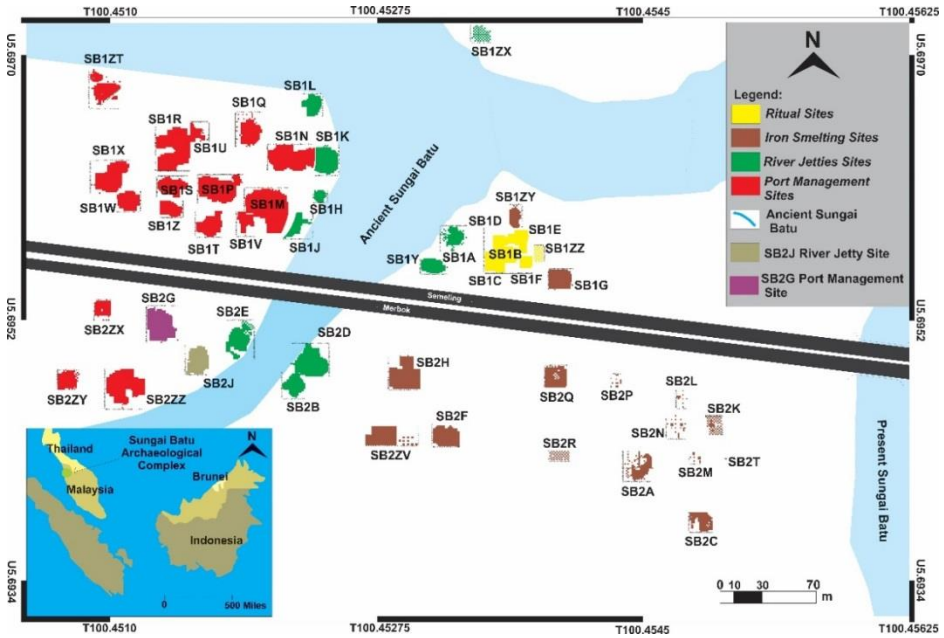

Figure 5. Location of SB2J river jetty and SB2G port management site in SBAC (Source: The authors)

SB2J River Jetty Structure

The SB2J site [05°41'42.0" N and 100°27'05.2" E] is located approximately 15 metres northeast of SB2E, 30 metres northwest of SB2G and 26 metres southwest of SB2ZZ (Figure 5). Excavations at the SB2J site have found bricks that

suggest bricks have been used as the raw material for the construction of monument structures at the SB2J site. The excavation process at the SB2J site involved a total of 173 squares, measuring 1x1 square meter (m²). After the excavation process was completed, digital photo recording at the SB2J (Figure 6) site was taken.

Digital photo recording was taken to be the main reference during the sketching process and the production of architecture plans for the appearance of the monument at the SB2J site. For the purpose of simplifying the process, Figure 7 is the floor map plan for the SB2J site. Excavations carried out at the SB2J site have involved an area of 247 m². Trench K19 and N10 are stratigraphic reference trenches for SB2J and have not been excavated. The stratigraphic layers in both trenches suggest that the monument structures at the SB2J site remain intact.

Figure 6. The side view of the SB2J site includes 173 squares, covering a total area of approximately 247 m² (Source: The authors)

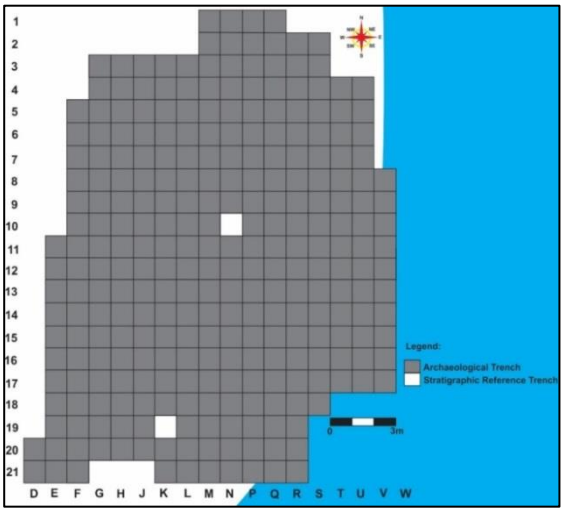

Figure 7. Floor map plan of SB2J (Source: The authors)

Researchers also conducted a study of the stratigraphic layers of the SB2J site (Figure 8). The researchers selected the walls of the site, located in the eastern part of the nearby ancient Sungai Batu, for the study of the stratigraphic layers. The results of the study also found that the SB2J site is still in situ and is not disturbed by human activities. Stratigraphic layers in the area with evidence of brick finds reveal a layer of clay. The SB2J site's clay layer serves as the base layer, indicating the absence of architectural structures beneath it.

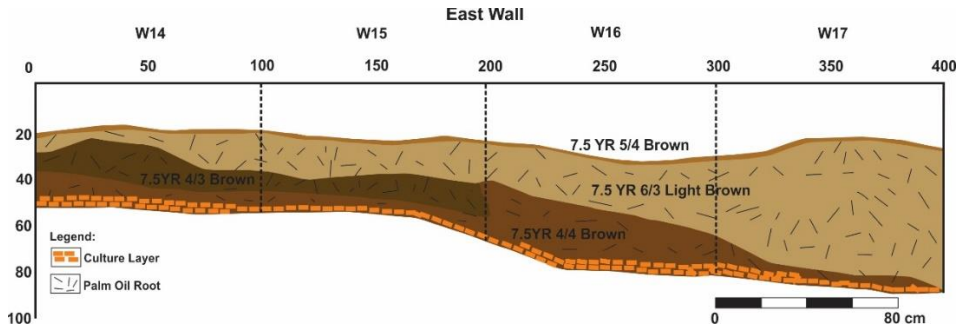

Figure 8. Stratigraphic layers at SB2J sites that are still in situ (Source: The authors)

The excavation results at the SB2J site have revealed the structure of floors, walls, corridors, staircase and roof tiles (Figure 9) as proof that the site is roofed. Based on the location and structure of the building, which was built sloping towards the ancient river, the site also plays the role of a river jetty in SBAC. The monument structure of the SB2J site was also built on land reclaimed in advance with brick fragments. The floor structure is in the central part of the site (Figure 9a). The horizontal construction of this part of the floor utilises bricks with an average size of 27x17x5 cm.

The area of this section is estimated at about 11 x 7 square metres. The arrangement of the floors on the site is clearly visible in the eastern part. The floor structure at this site also has similarities with other jetty sites, which are built orientated north–south and have a small strip of about 15 cm between each floor brick arrangement. The wall structure (Figure 9b) is found at the north and south ends of the main floor structure of the SB2J building.

The structure is intended to serve as a space separator between the floor structure and the corridor on the site. The length of the ruins of this wall structure measures 11 metres. The average brick size used to build the wall structure is around 17x16x5 cm, which consists of two layers of bricks. The SB2J site's main floor structure features corridor structures on its north, south, and west sides (Figure 9c). The corridor structure in the North and South is proposed to be the same length as the main structure of the SB2J monument, which is 11 metres long and about three metres wide, while the corridor structure in the western part measures 16x2.5 metres. The corridor structure at this site is built with an

average brick size of 18x17x5 cm and arranged in a stretchable manner between each brick arrangement. The proposal is to locate the floor staircase (Figure 9d) in the southern part of the SB2J site.

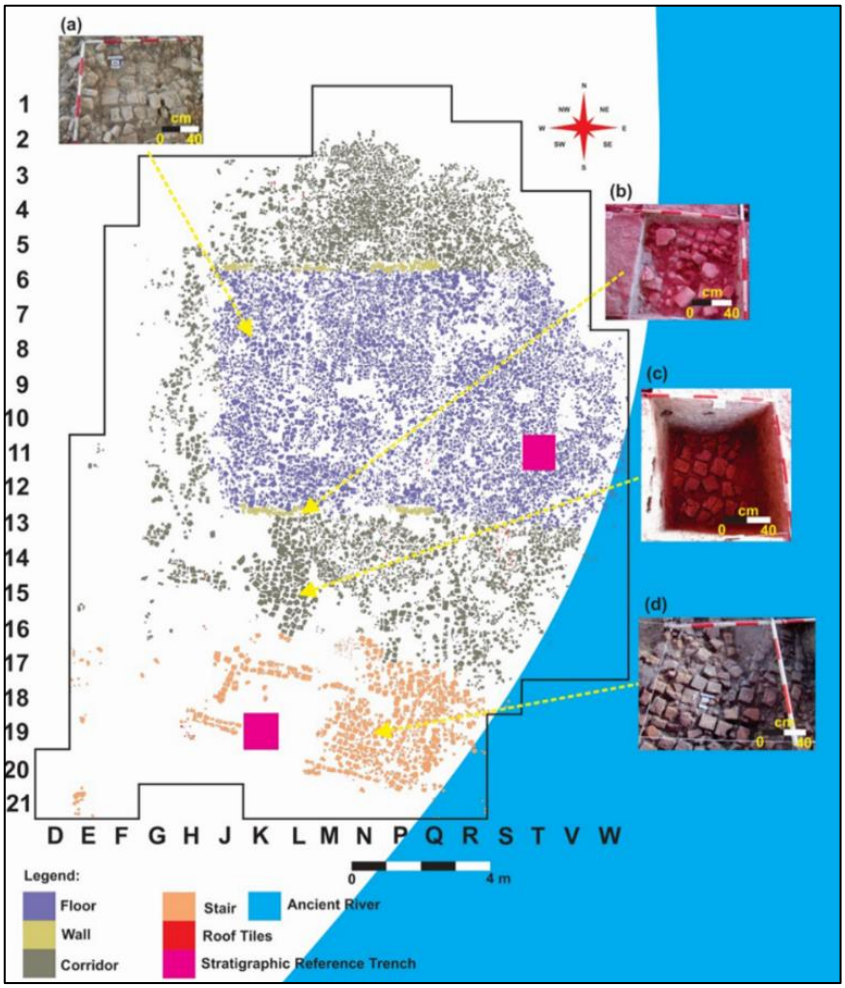

Figure 9. The architectural sketch plan of the SB2J river jetty at SBAC showcases the in situ structure, including the floor (a), wall (b), corridor (c), and staircase (d), making it the most complete ancient river jetty made of brick in Southeast Asia (Source: The Authors; small picture: The Authors, January 10, 2025)

The structure of the staircase was built with a 25° gradient towards the ancient river. The structure of the staircase at the SB2J jetty site was found to be connected to the corridor structure in the main building. The proposed structure will measure approximately 4 meters in length and 2.5 meters in width. The structure of the alternative pathways, which slopes towards the ancient river, consists of at least eight stacks of brick strips. The alternative route's floor features a brick arrangement that spans approximately 15 cm per row.

Based on the study of the architectural form of the SB2J site, Figure 10 is a reconstruction plan of the monument at the SB2J site. Based on the sketch, the SB2J site has similarities with the SB2E river jetty site, which has an alternative pathways structure to fluctuate from the river to the mainland. Excavations at the SB2J site also revealed the discovery of a pillar base in trench J5, spit 2, which suggested the existence of a roof structure at the site (Figure 11). This is reinforced by the discovery of the distribution of roof tiles on the north and south of the SB2J monument. Based on the pillar base found at the end of the floor structure, there are at least four pillars that support the roof structure at this site. Because there is no record of the discovery of the roof tiles on the altenative pathways, that suggests the structure is not roofed.

In addition, contour mapping carried out at the SB2J site also showed that the main monument structure of the site was built horizontally. However, in the southern part of the site, there is evidence of structures sloping towards the ancient river (Figure 12). It is likely that the structures built on the southern side of the SB2J site had a more obvious function with the ancient river.Pottery fragments were also found at the SB2J site, which is evidence of material culture in SBAC. A total of four brick samples were taken to obtain chronometric dating for the SB2J site. The four brick samples were taken from several different architectural structures, such as floors and staircase. The trench involved in the brick sampling process are L14 (Spit 5), P18 (Spit 8), N20 (Spit 9) and Q18 (Spit 4).

Charcoal samples from trench L14 (Spit 5) and P18 (Spit 8) were selected to obtain data on activities taking place at the site. However, until now only chronometric dating data from the trench L14 (floor structure) and P18 (staircase) have been obtained, which describe the site was built since the 4th to 6th century AD. This means that the river jetty floor structure was built since 518 AD (1.5±0.1), while the staircase structure was built since 318 AD (1.7±0.1).

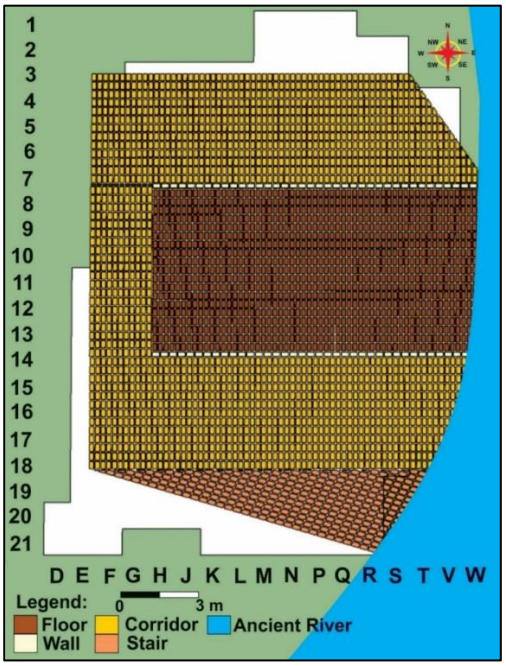

Figure 10. The SB2J site's proposed reconstruction architecture plan reveals that an ancient river served as the foundation for the main building structure

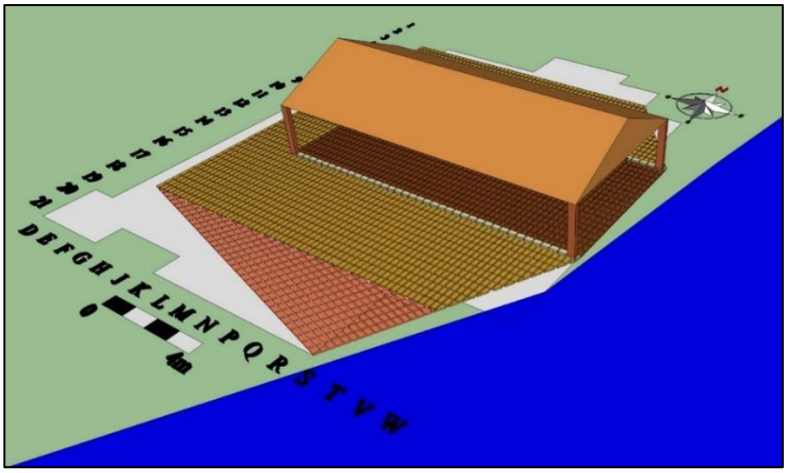

Figure 11. The proposed reconstruction architecture plan for the monument at the SB2J site is based on the findings of the floor structure, corridors, walls, staircase, roof tiles, and pillar base (Source: The authors)

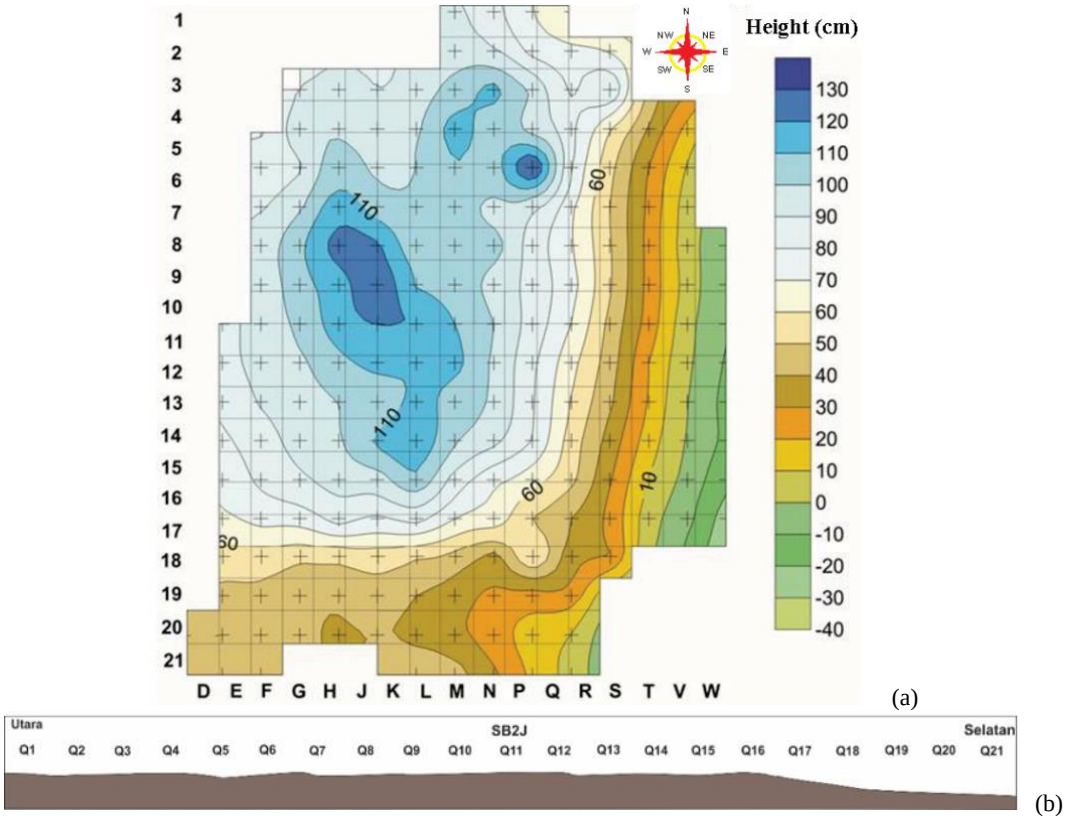

Figure 12. Contour mapping results (a) showing the structure at the SB2J site sloping towards the ancient Sungai Batu in the eastern. The cross-sectional results also indicate that the built structures at the SB2J site began to slope towards the ancient river in the southern part of the site (b) (Source: The authors)

SB2G Port Management Structure

In 2010, excavation took place at SB2G site, located at 05°41'42.2" N & 100°27.04.4 E (Figure 5). The mapping results revealed that the SB2G site was located 35 metres east of the SB2E site, 15 metres southeast of the SB2J site and 25 metres southwest of the SB2ZZ site. The SB2G site is behind the SB2E site, which is on the west bank of the ancient Sungai Batu.

After the excavation process was completed, a side view of the SB2G site was also taken (Figure 13). Digital photography for the SB2G site is intended to be used as a reference during the sketching process carried out there. In order to facilitate the work during the field study, the SB2G floor map plan has been produced (Figure 14). Based on the SB2G site plan, trench P45, R35-36, S35-36, S26-27, T26-27, B31-32, A41, B41, C31-32 and Y39 were not excavated, as the trench were used as stratigraphic reference trench for the SB2G site apart from the presence of oil palm tree stumps in the area.

Figure 13. View site of SB2G. A total of 407 trenches have been excavated at this site, involving an area of 513 m² (Source: The authors)

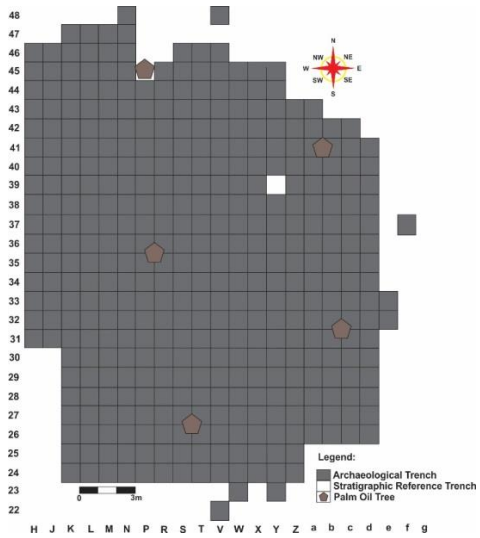

Figure 14. SB2G floor map plan involving 407 trenches with a total area of 513 m² (Source: The authors)

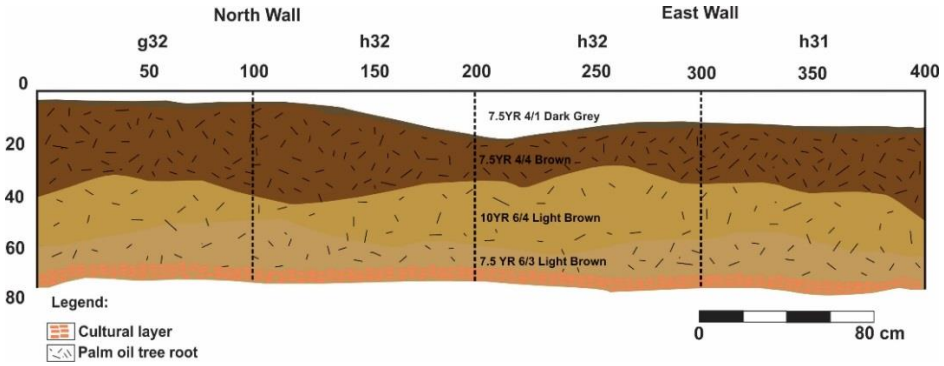
The stratigraphic data recording process was also conducted at the SB2G site. Stratigraphic data is important to examine to confirm that the SB2G site is still in situ and undisturbed during the last time it was abandoned by the community at SBAC. The results of a study of the soil stratigraphy of the SB2G site clearly show that it is not disturbed by human activities (Figure 15).

The building is therefore an undisturbed and still *in situ* structure. In addition, the results of contour mapping found that the main monument structure of the SB2G site was not built in a sloping condition (Figure 16). It is built horizontally.



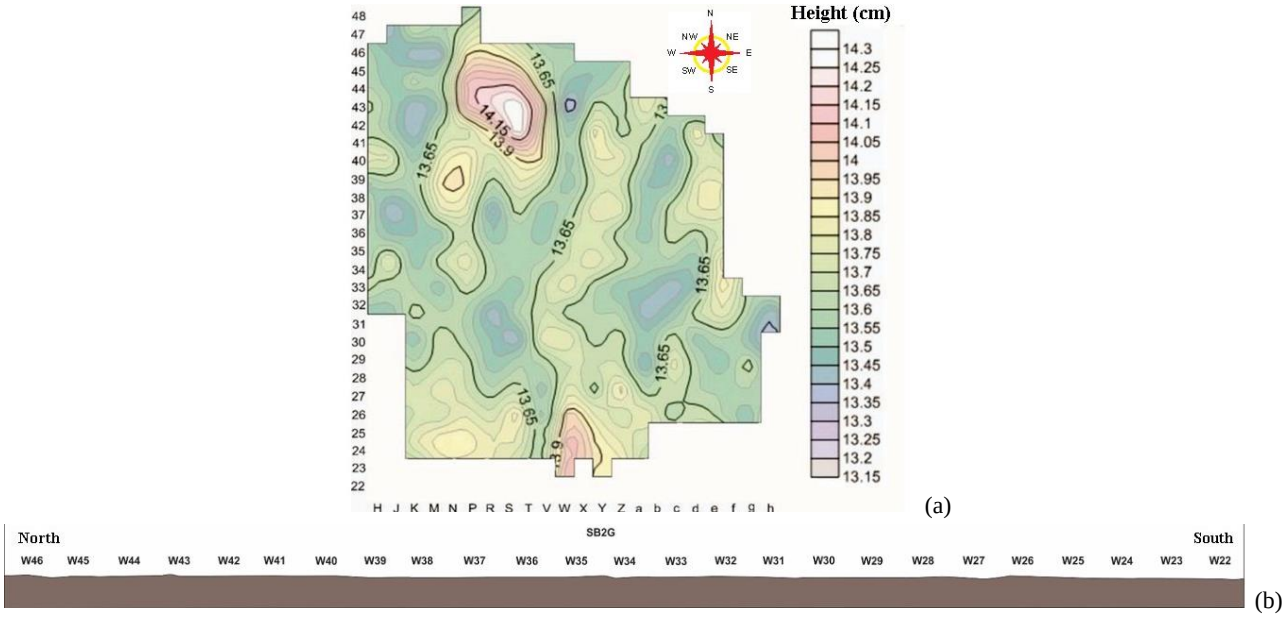


Figure 15. The SB2G sites exhibit stratigraphic layers. The cultural layer is found in the fourth layer, characterised by the discovery of bricks that represent the built structures of the site (Source: The authors)

(a)

(b)

Figure 16. The result of contour mapping (a) and cross-section (b) at the SB2G site clearly shows that the main monument is built horizontally, which is different from the river jetty site in SBAC (Source: The authors)

So the excavation process carried out at the SB2G site has revealed the structure of the floor, room space (administration), walls, roof tiles and pillar bases as evidence that it was roofed (Figure 17) and built on reclaimed land with broken bricks. The SB2G building's main floor structure faces north-south and features small, 15 cm-wide strips between each floor arrangement. The average brick size used to represent the floor structure is 27x16x5 cm. There are at least 45 strips of floor brick arrangement at the SB2G site that form the floor structure (Figure 17c).

The brick arrangement of the floor structure was found to have similarities with the river jetty floor and slightly sloping towards the ancient river in the eastern part. The arrangement suggests its function as a river jetty structure at the beginning and when the river level is shallow until the land is formed, causing it to change its function as an administrative space. Additionally, the left and right sides of the main floor structure do not serve as visible wall structures for space separation. The brick arrangement's orientation indicates the difference in space and function. The main building structure spans at least 13 metres in length and five metres in width. The corridor structures at the SB2G site are located on the north, south and west sides of the site (Figure 17a).

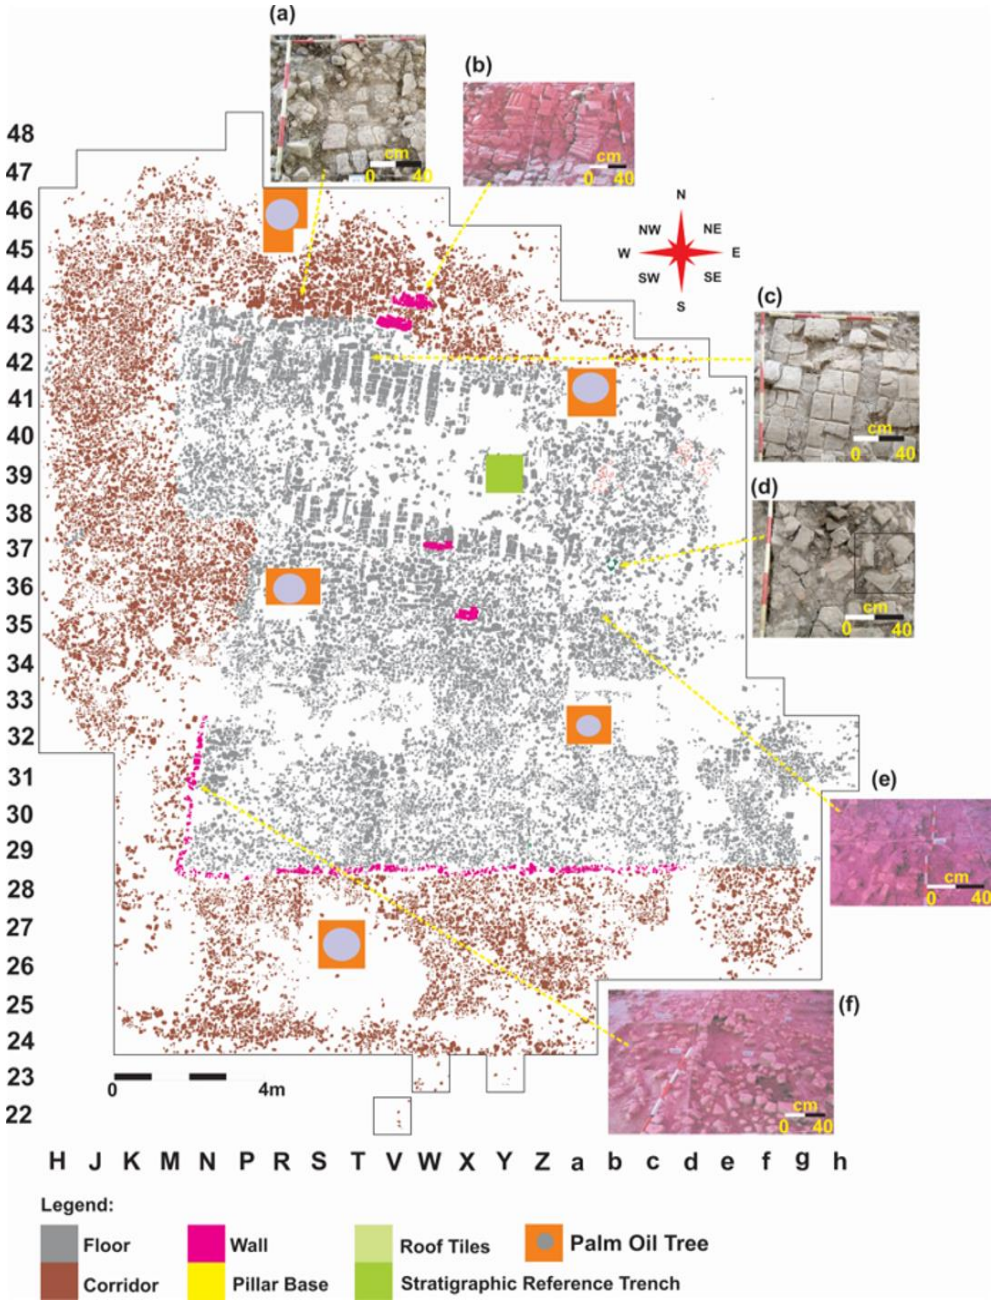

Figure 17. The architectural sketch plan of the SB2G port management site at SBAC showcases the in situ structure, including the corridor (a), wall (b), floor (c), pillar base (d), administrative space (e) and wall (f) making it the most complete ancient port management made of brick in Southeast Asia (Source: The Authors; small picture: The Authors, January 10, 2025)

The SB2G site arranges its corridor structure in an unsystematic manner, setting it apart from the main floor structure. This structure is expected to be a altenative route to the support monument, which is on the south side of the main structure of the site. This is because there is a wall structure that separates the corridor from the administrative building. The corridor

structures in the northern and southern sections measure 13 metres long and 1.2 metres wide, while those in the western section measure 2 metres wide. The size of the bricks used to represent the corridor structure at the SB2G site is 18x15x5 cm.

The discovery of stacked brick rubble believed to be a brick entrance gate structure (Figure 17b) was also found at the SB2G site. The brick entrance gate structure is in the corridor area at the north and south of the SB2G site. This brick entrance gate measures 130 cm long by using an average brick size of 17x16x5 cm. As there are two brick entrance gate, each pair on the north and south sides of the SB2G site suggests it is part of the brick entrance gate evidence of the SB2G monument structure. The southern end of the corridor structure at the SB2G site is proposed to be a rectangular structure that is proposed as an administrative space to the SB2G (Figure 17e). The port management structure measures 22x11 metres. A wall structure consisting of two layers of brick separates the administrative space from the corridor in this section (Figure 17f). So Figure 18a,b is a reconstruction plan and the appearance of the monument for the SB2G site, which has an earliest river jetty area of 6x17 m² in the north, while the second room has an area of about 22x11 m² in the south for the administrative area, as well as corridors in the north, south and west. The evidence of room space indicates that the SB2G monument initially functioned as a river jetty and later transitioned to port management in SBAC when the river became shallow. Excavations at the site also revealed 115 pieces of earthenware, which support the interpretation of the area as a river jetty and port management structure. The excavation also found a pillar base (Figure 17e) and roof tiles distribution (Figure 19), which allows interpretations to be submitted related to the architectural form of the pillar at the SB2G site. Pillar base at the SB2G site were recorded in trenches B37 and M38 at the end of the room structure at the SB2G site. Wooden poles are proposed to be used as roof supports at this site due to their flexible ability to accommodate heavy loads (Wiyana, 2016).

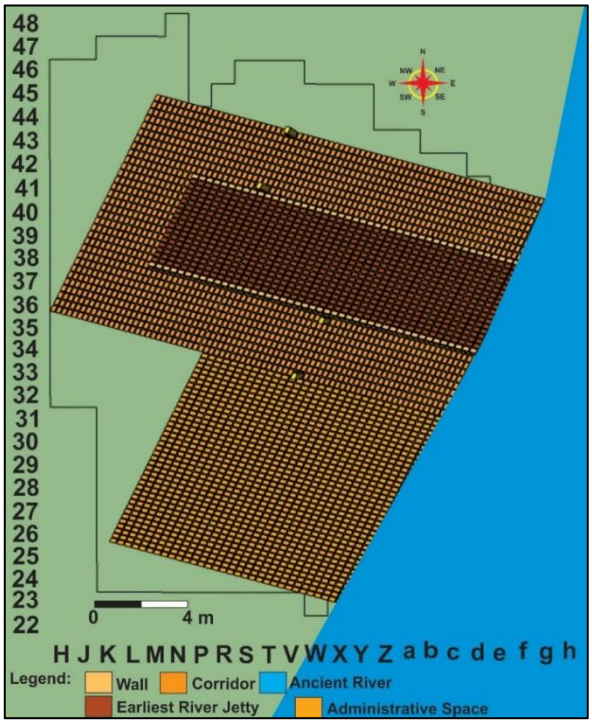

Figure 18a. The SB2G proposal plan was produced based on the remains of in-situ architecture at the site. The results of the study have confirmed its appearance as a river jetty and port management in SBAC (Source: The authors)

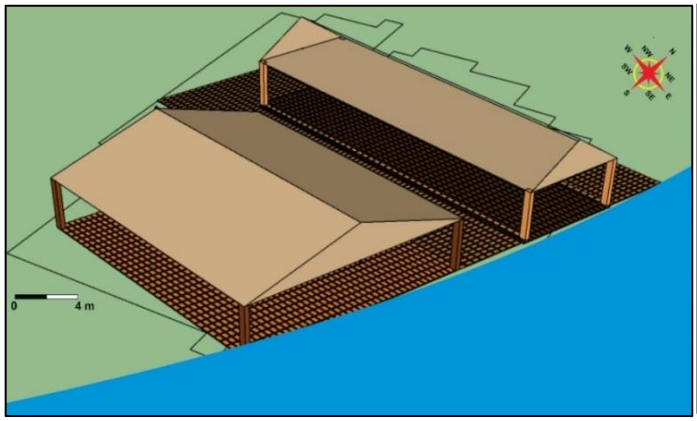

Figure 18b. The reconstruction plan for the SB2G monument is based on the findings of the river jetty floor, corridors, walls, administrative space, roof tiles, and pillar base structures (Source: The authors)

Figure 19. The distribution of roof tiles at the SB2G site in the northern part reinforces the related interpretation of the existence of roof structures at the SB2G site (Source: The authors)

However, the excavation results at the SB2G site did not record the discovery of the pillar structure because it was likely that it had been weathered. Based on the in-situ findings of the pillar base structure, it is proposed that the river jetty and port management monument at the SB2G site have four pillar base structures as roof supports. Therefore, Figure 16 shows the architectural form of SB2G, which has pillars and roofs based on the location of the pillar bases and the distribution of roof tiles at the site.To obtain data on the chronometric dating of the monument, a total of 11 brick samples were taken to obtain dating data. The sample brick will use the OSL method. The brick samples involved were d37 (Spit 3), d38 (Spit 3), d39 (Spit 3), e38 (Spit 6), X25 (Spit 3), M34 (Spit 3), M43 (Spit 3), N41 (Spit 4), P40 (Spit 4), X23 (Spit 3) and Z38 (Spit 3). The brick samples represent the floor, corridors, and administrative room structures at the SB2G site. However, until now, only two samples have provided dating data: sample d37 (Spit 3), which represents the corridor structure and indicates an age of about the 1st century BC, and sample d38 (Spit 3), which represents the floor structure and reveals that it was built in the 5th century BC. This construction occurred around the 5th century BC (Abd Halim & Saidin, 2025b). This site has functioned as a river jetty and port management on the riverbanks of the river, and when the sea level dropped, it caused land to form, causing the site to move away from the river. Consequently, the riverbank area underwent the construction of a new river jetty structure to facilitate effective trade activities. This coincides with the dating of the SB2E site on the banks of Sungai Batu (Figure 5), which was built in the 3rd century BC after the flow of the river decreased and was in the area concerned. This is reinforced based on geophysical mapping in the port management area in the northern part of SBAC, which was also built in the 5th century BC, which has revealed evidence of ancient river flow based on a low resistivity value of < 50Ωm (Ahmad, 2016).

Outstanding Universal Value (OUV)

Archaeological excavations carried out at the river jetty and port management site at SBAC have so far been able to reveal an exceptional outstanding universal value (OUV) that qualifies it to be nominated as a UNESCO World Heritage site. Table 1 summarises data relating to the OUV of the river jetty and port management sites, which to date have not been recorded in any other archaeological study in other parts of the world.

Based on the data, it is clear that SBAC has met the criteria for nomination as a UNESCO World Heritage site, although currently it is only recognised as a national heritage site in 2012 (Abd Halim et al., 2025a), in addition to being recognised as the oldest civilisation in Southeast Asia in 2016 during the Kedah Tua Festival held by five early world civilisation experts from Mesopotamia, Indus, Mesoamerica, China, and Greek-Rome (Anonymous, 2016).

Table 1. Outstanding universal value of river jetty and port management sites at SBAC (Source: The authors)

Site Classification	OUV	Description
River Jetty	Evidence of the most complete river jetty architectural form of early world civilisation since the 6th century B.C.	Based on the architectural appearance of the river jetty at SBAC, it has been suggested that it is the most complete structure that has ever been the subject of archaeological studies in the early civilisations of the world. Until now, archaeological studies at the world level have not recorded the existence of river jetty architectural structures that are still in situ structures of floors, walls, corridors, stairs, walkways, pillar bases and roof tiles in their architectural form.
	The most complete iron ingot export river jetty of early world civilisation	The dating of the river jetty structure corroborates the radiocarbon dating of the SB2H iron smelting site, which provides dating data to around the 6th century BC (Abd Halim et al., 2025b). Based on the dating data, it is clear that the Sungai Batu river jetty structure were erected for the purpose of exporting ancient Kedah iron ingots, especially since the 6th century BC (Abd Halim et al., 2025d). A comparative study of the iron smelting sites of the world civilisations to date also revealed no evidence of the river jetty, port management, ritual and Buddhist monument sites in the same area that shows the uniqueness and importance of the discovery in SBAC on the development of early world civilisations.
	The most complete ancient Kedah port complex	Archaeological studies conducted at the site on the edge of the ancient riverbank revealed 11 structures that served as river jetties (see Map 1). The results of excavations carried out at the site found that all the main monument structures were built in a directional manner and sloping towards the river, which suggested their function as a river jetty. The close spacing of the sites, which range from three to 15 metres apart, suggests that this area served as a port complex in SBAC. To date, archaeological studies of early river jetties, wharves, and harbours worldwide have not identified an area with as many river jetty structures suited for both river and sea environments. The Sungai Batu archaeological site is the only one in the world to date that has been able to reveal 11 sites of river jetty evidence that reveal the civilisation that took place in SBAC, which represents the ancient Kedah Kingdom and is representative of a highly civilised nation.
Port Management	The earliest civilisations reveal the clearest and most complete evidence of port management architecture	Most of the port sites identified are based on the discovery of trade artefacts such as beads, pottery, ceramics, glass and others. Evidence of port structures is incomplete as found in Mesopotamia, Indus, Egypt and China. Even if seen in studies in Southeast Asia, the port criteria are only identified based on the discovery of trade artefacts (Abd Halim, 2019). There is no data about the port itself and the role of the port management site. This makes the study at SBAC the only one in the world to date that reveals a clear and complete port management architecture
	First discovery of the architecture for managing iron export facilities in early world civilisations	Archaeological studies conducted in Mesopotamia, Egypt, Indus, China, Greek-Roman and Mesoamerican civilisations until now have not recorded the discovery of port management architecture used as the management of the iron ingot trade. To date, SBAC's port management is the only one in the world to reveal clear evidence of a port management architecture (Abd Halim & Saidin, 2025b). This makes SBAC the most complete centre of iron smelting and export management for the early civilisations of the world.

DISCUSSION

As the river jetty and port management site at SBAC have revealed a very special OUV, then the process of its development as a heritage tourism site was carried out vigorously after 2012. Even Abd Halim et al. (2022a; 2024a; 2025a) and Ali et al. (2021a, b; 2023) have discussed more detail about the marketing and development process of SBAC heritage tourism sites in the national tourism sector, emphasising the principles of sustainability and leaving no one behind. This can make the development of the tourism sector, especially in Malaysia, more efficient.

In addition, the heritage tourism sector in Malaysia, especially sites such as prehistoric sites in the Lenggong Valley (Rapidah et al., 2018; Talib et al., 2022: Abd Halim et al., 2025c), Gua Pelangi (Abd Halim et al., 2022b), and Neolithic sites in Guar Kepah (Abd Halim et al., 2024d), has also been developed as a sustainable heritage tourism product. Sustainability means that every tourism activity carried out emphasises the principle of preserving the heritage tourism site. At the same time, also involve the local community, either as a tour guide or as an association involved in providing tourism services. This shows that the marketing of heritage tourism is concerned with empowerment from the bottom up, which is specifically able to make heritage sites preserved based on the direct involvement of stakeholders, NGOs and the local community (Foncesa et al., 2025; Lawasi et al., 2025).

However, to ensure that a tourist location can attract domestic and international tourists, the implementation of several drastic measures is necessary to market the place or tourist destination to the general public. The five main components that need to be implemented in the travel offering movement are 1) destination attractions, 2) destination facilities and services, 3) destination accessibility (including transportation), 4) image, brand and perception and 5) price to visitors (Middleton & Clarke, 2001; Ali, 2022).

Therefore, the diversity of actors, roles and environmental factors is a main key that supports the development of a tourism area (Capone, 2006), so the heritage tourism development program in a planned manner should be designed and implemented. This is very closely related to the existing tourism service and product offerings and its relationship with business networks, interactions, resources and academic knowledge flow that should be given emphasis in advance so that delivery to end users can be done smoothly. For this reason, issues such as integration, collaboration and networking activities (Poon, 1993) need to be organised and coordinated at the grassroots level to achieve the end goal.

In fact, the involvement of local communities in tourism marketing initiatives (Ryan, 2002) is necessary to maximise the work of empowering the tourism sector in an area. At the Kedah state heritage tourism level, Malaysia has organised several activities to strengthen the heritage tourism sector, which include travel marts, town halls, carnivals, festivals and national and international conferences. The programme also involves the local community to strengthen community involvement in tourism development. To facilitate the work, cooperation with stakeholders (Machlouzarides, 2010) should be carried out, such as with the Kedah state, federal, the Kedah State Economic Planning Division (BPEN), Jerai Geopark, Sungai Petani Municipal Council (MPSPK), and the Tourismy; this is also the best step in marketing tourism destinations.

Additionally, utilising the latest technology (Abd Halim et al., 2024a; Yu et al., 2025) can positively impact the marketing process of tourist destinations, alongside the living culture gallery space that enables tourists to engage directly in demonstrations and hands-on activities. Digital marketing for tourist destinations, which includes analysing primary data studies, conducting marketing and promotion, developing strategic plans, and establishing branding, is the best approach for enhancing a tourist site. The use of virtual tourism methods is one of the effective methods that must be applied, as in many world tourism sites, such as the virtual centre of Alexandria and Kansas, United States (Aggour, 2017), in addition to several existing channels for promoting tourism destinations. In addition, a successful tourist destination also needs a tourist information centre that is able to manage all travel packages (Ludmila & Kristina, 2018) that are offered systematically. This is because the existence of the Tourism Information Centre is an initial step to provide information related to tourist destinations directly to tourists so that the selection of tour packages becomes more effective.

Providing tourism products and packages that prioritise the sustainability of tourist destinations should also be emphasised in developing the tourism sector. This is because if the sustainability of tourism products is not managed sustainably, then all tourism marketing programmes carried out will not be able to maintain the integrity of the tourism area, which ultimately has a negative impact on tourist visits. Therefore, the declaration of a tourist site as a UNESCO World Heritage site for the categories of World Heritage site for archaeology (WHS), global geopark (UGGp) and Man and Biosphere (MAB) is one of the best steps to preserve the tourist destination.

Tourism infrastructure at the global level also proves that all tourist destinations have maximised the construction of infrastructure such as hotel services, culinary, security and basic facilities at tourist locations (Cuka et al., 2015; Vinegar et al., 2015) to facilitate and provide maximum comfort to tourists. These elements must be given special attention to ensure that the tourist destination is able to attract tourists and become a successful tourist area.

Based on tourism marketing data for destinations, the world tourism site allows some good benefits to be taken for the development of heritage tourism marketing in SBAC. The management of the tourism information centre, product and package offerings, the availability of infrastructure, and the latest promotional activities are all necessary and can be of practical benefit to the development of the heritage tourism sector in this area.

CONCLUSION

Studies on primary evidence sites (trade and industry) in SBAC and the progress of destination marketing in its heritage tourism sector clearly demonstrate its importance to economic development in Malaysia in particular. To ensure that SBAC is able to attract tourists, the development of infrastructure in tourist areas, including accommodation and transportation, has become a priority and began to be developed in a planned manner. In fact, the SBAC has also been recognised as a

national heritage site in 2012, as Southeast Asia's oldest civilisation site in 2016, and is currently in the process of nomination as a UNESCO World Heritage Site through the Jerai Geopark concept. This is the backbone of the empowerment of the heritage tourism sector in SBAC, which is expected to develop this location on par with similar heritage tourism sites in other parts of the world.

Limitations of the study for futere study

The Sungai Batu Archaeological Complex area's heritage tourism study does not prioritize the involvement of stakeholders, NGOs, and the local community in the implementation of heritage tourism. This needs to be carried out as a comprehensive study along with accurate data related to the success of its implementation to measure the success of heritage tourism promotion offered.

Reframing roots tourism as a spatially structured heritage landscape: A multi-criteria evaluation of postcolonial heritage spaces in Con Dao, Vietnam. *Geojournal of Tourism and Geosites*, 67(3), 1853–1864. https://doi.org/10.30892/gtg.67302-1814

Abstract: In contemporary tourism research, roots tourism is increasingly recognized as more than a form of heritage visitation; however, its spatial organization within postcolonial heritage landscapes remains insufficiently examined. Existing studies have emphasized motivations, memory, identity, and heritage interpretation, while giving limited attention to the spatial configuration of heritage sites and their relationships within an integrated tourism system. This study conceptualizes roots tourism in Con Dao, Vietnam, as a spatially structured heritage landscape in which historical memory, commemorative practices, and visitor movement are organized across interconnected heritage spaces. Using an interpretive mixed-methods design, the research develops a multi-criteria evaluation framework to assess the functional and interpretive capacities of thirteen heritage sites. A three-round Delphi process involving 18 experts established the evaluation criteria, followed by the Analytic Hierarchy Process (AHP) to determine the relative importance of the criteria. These expert assessments were combined with evaluations from 28 participants, including professional tour guides and organized tour visitors, using a five-point Likert scale. The findings reveal that interpretive and commemorative capacity is unevenly distributed, forming distinct functional clusters, including core interpretive nodes, transitional and commemorative spaces, and peripheral visitor engagement areas. The analysis further demonstrates that the value of individual heritage sites is shaped not only by their historical significance but also by their spatial relationships and interpretive connectivity within the broader heritage network. By highlighting these spatial dynamics, the study advances understanding of roots tourism as an integrated heritage tourism system and provides a practical framework for destination planning, heritage interpretation, and sustainable management in postcolonial contexts.

Keywords: roots tourism; heritage landscape, spatial differentiation, functional clustering, postcolonial heritage, multi-criteria evaluation, Con Dao, tourism geography

INTRODUCTION

Over recent decades, tourism research has moved beyond conceptualizations of tourism as mere consumption and leisure toward perspectives that emphasize its social, cultural, and educational functions. Within this shift, heritage tourism has increasingly been understood as a spatially embedded practice of meaning-making and historical learning, mediated through interactions among people, memory, and place (Poria et al., 2003; Ahmad & Hertzog, 2016; Timothy, 2018). Heritage spaces are no longer viewed solely as repositories of the past; rather, they operate as active components of tourism landscapes, shaping how history is interpreted and experienced through embodied, affective, and spatial engagement (Harrison, 2012). From a tourism geography perspective, such spaces form interconnected spatial systems in which interpretation, accessibility, and visitor movement are organized across differentiated sites rather than occurring in isolation.

Research on memory tourism and dark tourism further illuminates tourism practices at sites associated with collective suffering, violence, and sacrifice. Encounters at such sites often activate moral reflection and emotional engagement that extend beyond the passive reception of historical narratives (Light, 2017; Dresler, 2023). Learning in these contexts unfolds through spatial encounter and regulated movement, situating visitors within ethically sensitive relationships with the past. From the perspective of collective memory theory, memory is not fixed but socially constructed through discourses and practices embedded in specific spatial settings (Olick & Robbins, 1998; Hirst & Echterhoff, 2012).

Heritage spaces such as prisons, detention camps, and memorials therefore emerge as contested arenas within tourism systems, where multiple narratives compete for interpretive authority (Macdonald, 2009; Zhang et al., 2018; Shreya et al., 2026). Yet, while these studies illuminate interpretive and ethical dynamics, fewer contributions systematically examine how such sites are spatially differentiated and functionally organized within broader destination structures.

The organization of heritage spaces that embody traumatic histories presents significant ethical and managerial challenges. Scholars have warned that commercialization or aestheticization of tragic memory may undermine interpretive integrity and reduce commemorative sites to consumable attractions (Stone & Grebenar, 2022; Dresler, 2024).

These concerns underscore the need for systematic approaches to evaluating how heritage spaces are structured, sequenced, and managed within tourism landscapes, particularly in relation to visitor movement and spatial connectivity (Lew & McKercher, 2006). In this regard, spatial differentiation–understood as the uneven distribution of interpretive, commemorative, and functional capacities across sites–becomes central to understanding how heritage tourism operates as a landscape-level system rather than as a collection of discrete attractions. Con Dao represents a paradigmatic postcolonial heritage landscape in Vietnam. Its network of colonial prison complexes, martyrs' cemeteries, commemorative monuments, and religious sites forms a multilayered memoryscape in which revolutionary, traumatic, and sacred narratives intersect spatially (Clark, 2013; Chung, 2025).

Although roots tourism in Con Dao has been widely developed, existing studies have primarily focused on visitor perception or symbolic memory discourse. The differentiated functional roles of individual heritage spaces and their spatial organization within the broader tourism landscape remain insufficiently examined. Moreover, limited attention has been given to how these sites collectively structure visitor routes, regulate experiential intensity, and form hierarchical patterns within the destination's spatial configuration. The aim of this study is to evaluate how heritage spaces in Con Dao function as spatially differentiated components of a structured heritage landscape within a postcolonial tourism context. Specifically, the study seeks (1) to develop a multi-criteria analytical framework for assessing the interpretive, ethical, and spatial-functional dimensions of heritage spaces; (2) to determine the relative importance of these dimensions; and (3) to analyze how heritage spaces are structured into distinct functional clusters across the heritage landscape.

By addressing these objectives, the research conceptualizes roots tourism not merely as commemorative visitation but as a spatially structured heritage tourism system that can be systematically evaluated and strategically organized in sensitive postcolonial contexts. In doing so, the study contributes to tourism geography by foregrounding landscape-level organization and functional differentiation as key analytical dimensions in the study of roots tourism.

LITERATURE REVIEW

Roots Tourism and the Shift toward Memory Education

In contemporary tourism research, roots tourism has moved beyond conventional heritage visitation to be understood as a spatially embedded practice associated with memory, identity, and historical interpretation. Rather than treating heritage as static objects of consumption, scholarship emphasizes spatial experience, movement, and interpretive mediation as mechanisms connecting visitors with the past (Poria et al., 2003; Ahmad & Hertzog, 2016; Timothy, 2018).

Heritage spaces thus function as nodes within broader tourism landscapes, shaping understanding through organization, accessibility, and design. From a tourism geography perspective, these nodes are relational rather than isolated, deriving significance through their position within destination-wide spatial configurations.

Recent syntheses of dark tourism and thanatourism research demonstrate a growing emphasis on authenticity, emotional engagement, and the governance of collective memory at sites of suffering (Hernández-Garrido et al., 2026). This shift highlights that meaning-making at traumatic or commemorative sites is shaped not only by historical content but also by interpretive framing and management practices. Accordingly, roots tourism in former prisons, memorials, and revolutionary landscapes must be approached as a structured encounter mediated by spatial sequencing and institutional regulation. Such mediation implies differentiated spatial roles among sites, rather than uniform interpretive functions across a destination.

Sites associated with violence or political struggle are typically experienced through curated routes and regulated access, influencing cognitive and emotional engagement (Biran et al., 2011; Light, 2017). Learning in such contexts unfolds through spatial choreography rather than isolated information transfer. Research on difficult heritage further shows that well-managed spatial organization can foster historical awareness and reflective engagement, whereas weak regulation risks commodification and spectacle (Dunkley et al., 2019; Farmaki, 2021; Stone & Grebenar, 2022). These findings suggest that the spatial structuring of visitor movement is not merely operational but constitutive of interpretive outcomes. These insights underscore the need to examine how heritage spaces are configured and connected within integrated tourism systems.

Within postcolonial destinations, roots tourism is shaped by the spatial politics of interpretation and identity formation. The organization and presentation of heritage spaces actively reproduce narratives of belonging and historical meaning (Clark, 2013; Winter, 2007; Shreya et al., 2026). Postcolonial heritage landscapes therefore represent spatially layered systems in which symbolic, political, and educational functions intersect across interconnected sites.

Heritage Spaces, Collective Memory, and Tourism Landscapes

Collective memory is socially constructed through practices embedded in specific spatial contexts (Olick & Robbins, 1998; Hirst & Echterhoff, 2012). In tourism settings, heritage spaces serve as arenas where memory is encountered through movement, spatial sequencing, and place-based narration. Spatial context thus becomes integral to the production and stabilization of collective memory within tourism environments.

Prisons, detention camps, and memorials often function as contested sites in tourism landscapes, where multiple narratives coexist and are mediated by layout, visitor circulation, and interpretive infrastructure (Macdonald, 2009; Waterton & Smith, 2010; Zhang et al., 2018). From a tourism geography perspective, individual sites derive meaning not only from intrinsic value but also from their connectivity within broader spatial systems (Lew & McKercher, 2006; McKercher & Lau, 2008; Till, 2012). Visitor understanding therefore emerges cumulatively across interconnected sites.

This cumulative process implies the existence of spatial differentiation, whereby certain sites act as interpretive anchors while others play supplementary or transitional roles within visitor itineraries.

Recent research highlights the relevance of route design and network analysis for structuring visitor mobility and accessibility. GIS-based modeling has been applied to optimize thematic routes and enhance spatial coherence within cultural tourism contexts (Akay, 2026). Although developed in urban settings, such approaches are pertinent to heritage landscapes characterized by dispersed yet interrelated sites. In postcolonial contexts, evaluating spatial connectivity becomes essential for understanding how memory is organized at the landscape scale. Even when formal GIS modeling is not employed, analytical attention to spatial clustering and route sequencing remains central to tourism geography.

Ethical Regulation and Interpretive Function of Heritage Spaces

Heritage sites associated with trauma operate within ethical boundaries shaped by historical significance and contemporary use. Spatial organization plays a critical role in regulating visitor behavior, emotional response, and interpretive engagement (Biran et al., 2011; Farmaki, 2021). Controlled circulation and interpretive zoning help preserve solemnity and prevent inappropriate consumption. Ethical regulation therefore manifests not only through discourse but through spatial arrangements that structure proximity, duration, and intensity of encounter. Studies of sacred landscapes further illustrate how ethical regulation is embedded in narratives, rituals, and local knowledge systems that guide visitor conduct (Setiyoningsih et al., 2026). Such moral frameworks operate alongside formal management mechanisms, reinforcing the ethical dimension of heritage interpretation. When spatial and interpretive regulation is weak, heritage sites risk becoming arenas of emotional spectacle rather than reflective engagement (Stone & Grebenar, 2022).

This risk is closely linked to spatial overexposure and insufficient differentiation among heritage functions. Interpretive capacity also depends on communication quality and experiential coherence. Research in museum contexts indicates that effective interpretive design–encompassing clarity, empathy, and narrative structure–enhances visitor engagement and reinforces educational outcomes (Chae, 2026). These findings suggest that interpretive capacity extends beyond informational provision to include experiential design. Within landscape-level analysis, interpretive capacity can therefore be understood as unevenly distributed across sites, contributing to differentiated functional roles.

From a planning perspective, heritage spaces function as managed territorial units within broader tourism systems. Their ethical and interpretive roles are intertwined with spatial capacity, visitor flow, and inter-site connectivity (Lew & McKercher, 2006). Evaluating heritage spaces therefore requires integrated frameworks combining ethical, interpretive, and spatial-functional dimensions. Such integration supports the analysis of heritage destinations as structured spatial systems rather than as isolated commemorative sites.

Research Gap and Analytical Framework

Although scholarship on memory tourism and dark heritage has expanded, much research remains focused on visitor emotions or single-site analysis. Less attention has been devoted to how multiple heritage spaces within one destination perform differentiated yet interconnected functions within a structured tourism landscape (Waterton & Watson, 2015; Light, 2017). In particular, limited empirical work has operationalized spatial differentiation and functional clustering as analytical categories within postcolonial heritage destinations.

Recent contributions emphasize authenticity governance (Hernández-Garrido et al., 2026), spatial route optimization (Akay, 2026), and ethical embedding in sacred landscapes (Setiyoningsih et al., 2026). However, systematic evaluation frameworks that integrate these dimensions within postcolonial heritage destinations remain limited.

In Con Dao, existing studies have examined the symbolic significance of individual sites but have rarely analyzed how these spaces collectively operate within an integrated heritage tourism system (Chung, 2025). Accordingly, this study conceptualizes heritage spaces as spatial units within a heritage tourism landscape and proposes an analytical framework evaluating their roles based on interpretive capacity, ethical regulation, spatial accessibility, and landscape connectivity. This framework provides the foundation for the multi-criteria evaluation approach presented in the following methodological sections. By doing so, the study advances a landscape-level perspective on roots tourism that aligns more explicitly with tourism geography while retaining sensitivity to memory and postcolonial contexts.

METHODS

Research Design

This study adopts an interpretive mixed-methods design that integrates qualitative expert knowledge with quantitative multi-criteria decision analysis to examine the functional and interpretive capacity of heritage spaces within the heritage tourism landscape of Con Dao. Mixed methods are employed to capture both the interpretive dimensions of heritage meaning and the need for systematic comparison across heterogeneous heritage sites (Ivankova & Wingo, 2018).

Rather than evaluating tourism performance in economic or satisfaction-based terms, the research focuses on the interpretive, ethical, and experiential functions of heritage spaces as components of a postcolonial tourism landscape. This approach aligns with critical tourism and heritage scholarship that conceptualizes heritage as a socially and politically embedded process shaped by power relations, interpretation, and spatial practice (Macdonald, 2009; Harrison, 2012).

The methodological design distinguishes between two knowledge sources: (1) a formal expert panel engaged in the Delphi–AHP process for criteria construction and weighting, and (2) a practitioner-based evaluation group composed of experienced tour operators and licensed local guides specializing in roots tourism in Con Dao. This distinction clarifies the analytical role of each dataset and addresses potential concerns regarding sample heterogeneity.

Study Area and Selection of Heritage Spaces

The empirical scope of the study includes 13 heritage spaces in Con Dao, selected to represent the principal layers of collective memory embedded within the island's tourism landscape. These include colonial prison complexes, formal commemorative sites, and locations associated with community-based and ritual practices (see Appendix).

Site selection was guided by two criteria: (1) historical and symbolic significance within the Con Dao heritage landscape, and (2) functional diversity in terms of visitor experience, spatial configuration, and interpretive form. Collectively, these sites constitute a multilayered heritage system that enables comparative analysis of differentiated functional roles within the broader tourism landscape (Waterton & Watson, 2015).

Expert Panel and Practitioner Knowledge Basis

The study draws on an expert panel comprising professionals in heritage management, tourism development, cultural interpretation, history, and experienced practitioners involved in guiding and organizing roots tourism activities. Experts were recruited through purposive sampling based on demonstrated professional experience and contextual familiarity with Con Dao. The experiential evaluation involved 28 practitioners who are not general tourists but specialized tour operators and licensed local guides with sustained professional engagement in Con Dao's roots tourism sector. Their inclusion reflects a practitioner-expert perspective grounded in repeated field-based interaction with heritage spaces rather than one-time visitor impressions. The relatively small size of this group (n = 28) reflects the limited population of professionals exclusively specialized in roots tourism within Con Dao. In methodological terms, the group constitutes a near-census of active operators in this niche segment rather than a convenience sample of general visitors. Accordingly, the findings represent professional interpretive consensus rather than statistically generalizable visitor perception.

Consistent with critical heritage and tourism approaches, expert knowledge is treated as situated and interpretive rather than as an objective measure of heritage value (Waterton & Smith, 2010; Harrison, 2012).

Development of Evaluation Criteria Using the Delphi Method

The Delphi method was employed to develop a structured set of criteria for assessing the interpretive and functional capacity of heritage spaces. Delphi is particularly suitable for complex tourism and heritage contexts where knowledge is distributed across expert groups and where no single indicator adequately captures spatial, ethical, and experiential dimensions (Hsu & Sandford, 2007). The process was conducted through three iterative rounds. In each round, experts reviewed proposed criteria, provided qualitative feedback, and reassessed their judgments in response to anonymized group input. Criteria were retained based on predefined agreement thresholds (≥70% convergence across rounds), ensuring conceptual clarity, stability, and relevance for heritage tourism analysis. Response stability between rounds was monitored to confirm convergence prior to finalization.

Weighting of Criteria through the Analytic Hierarchy Process

Following the establishment of the criteria set, the AHP was applied to determine the relative importance of each criterion group. AHP enables pairwise comparison within a hierarchical structure and is widely used in tourism and spatial planning to evaluate contexts characterized by multiple, incommensurable dimensions (Saaty, 2008).

Pairwise comparisons were conducted at the level of criteria groups rather than sub-criteria to preserve analytical coherence and avoid over-fragmentation in a context characterized by interpretive and ethical dimensions that are conceptually interrelated. Sub-criteria were treated as structurally embedded within their respective groups.

Consistency ratios (CR) were calculated to assess the reliability of expert judgments. All matrices achieved CR values below the accepted threshold of 0.10, indicating acceptable internal consistency (Saaty, 2008; Ishizaka & Labib, 2011).

Individual matrices were examined prior to aggregation to identify potential outliers, and no extreme inconsistencies were detected. Aggregation was performed using the geometric mean method in accordance with standard AHP procedures.

To examine robustness, a limited sensitivity check was conducted by introducing minor variations (±5%) in criteria-group weights. The relative ranking and clustering of heritage spaces remained stable, indicating that the differentiation patterns are not highly sensitive to marginal weight adjustments.

Evaluation Procedure, Reliability, and Data Analysis

The weighted criteria were applied to assess the 13 heritage spaces based on practitioner evaluations. Each practitioner evaluated the sites using a five-point Likert scale reflecting perceived interpretive clarity, ethical regulation, spatial accessibility, and experiential coherence.

Internal consistency of the practitioner-based evaluation instrument was assessed using Cronbach's alpha. The overall scale achieved an alpha coefficient above 0.80, indicating satisfactory reliability for exploratory spatial-functional assessment.

Inter-rater agreement was examined by analyzing variability across evaluators. Variance levels remained within acceptable bounds, suggesting convergence among practitioners despite differences in professional roles.

Although Likert-scale data are ordinal in nature, scores were treated as interval approximations for the purpose of comparative aggregation, a common practice in multi-criteria tourism research when scale categories are equidistantly defined. Interpretive claims are therefore limited to relative differentiation rather than absolute measurement.

Composite scores were calculated by integrating criteria weights and practitioner evaluations. Based on score patterns, heritage spaces were subsequently grouped according to their dominant functional characteristics within the overall

heritage tourism system. This analytical step supports the identification of differentiated spatial roles and informs the conceptualization of structured visitor routes within an integrated heritage landscape.

Methodological Limitations

Several limitations should be acknowledged. First, although the practitioner group represents a near-complete segment of roots tourism professionals in Con Dao, the sample size remains numerically limited and context-specific. The findings therefore reflect professional interpretive consensus rather than general visitor perception.

Second, the evaluation relies on structured expert judgment and practitioner assessment rather than direct measurement of visitor learning outcomes or behavioral change. Third, the AHP weighting procedure emphasizes relative importance at the criteria-group level and does not model dynamic spatial interactions between sites. Nevertheless, by integrating Delphi consensus-building, AHP consistency testing, practitioner-based evaluation, reliability assessment, and sensitivity checking within an interpretive mixed-methods framework, the study provides a transparent and replicable approach for evaluating the functional organization of heritage spaces within tourism landscapes. This methodological framework supports the analysis of roots tourism as a spatially structured form of heritage tourism in postcolonial contexts.

RESULTS

Criteria System for Evaluating Heritage Spaces within a Memory Landscape

The criteria system for evaluating heritage spaces in Con Dao was developed through a three-round Delphi process involving 18 experts from heritage management, tourism development, cultural interpretation, history and cultural studies, and professional practice related to roots tourism. The objective of the Delphi process was to establish a conceptually coherent and analytically robust criteria system capable of capturing the interpretive, ethical, and spatial-functional roles of heritage spaces within a sensitive postcolonial heritage tourism landscape such as Con Dao.

The initial pool comprised 26 candidate criteria synthesized from the literature on heritage tourism, difficult heritage, memory tourism, and heritage interpretation, complemented by contextual analysis of Con Dao and expert knowledge. In the first round, experts reviewed the relevance and conceptual fit of each criterion. Indicators primarily associated with general tourism performance–such as entertainment appeal, revenue generation, and current visitor volume–showed low consensus and high variance and were therefore excluded, as they were judged to shift the evaluation away from the interpretive and commemorative functions central to this study. In the second round, the refined list was further assessed for clarity, redundancy, and contextual sensitivity. Criteria related to large-scale group activities and experiential flexibility remained contested and were either removed or reformulated to emphasize contextual appropriateness and the specific requirements of sensitive heritage settings. The third round was conducted to confirm stability and consensus on the final system. All retained criteria met the predefined agreement thresholds for inclusion, indicating convergence across the expert panel. As a result, the final criteria system comprises 18 sub-criteria organized into six criteria groups, each representing a key dimension of heritage interpretation, ethical regulation, and spatial functionality.

This grouping structure supports evaluation of heritage spaces not merely as isolated physical sites but as interconnected spatial units within a broader heritage tourism landscape, where historical cognition, interpretive legibility, ethical limits, accessibility, conservation conditions, and route-based integration jointly shape visitor experience. The composition and functional dimensions of these six criteria groups are presented in Table 1.

Table 1. Criteria Groups for Evaluating Heritage Spaces in Con Dao
(Source: Authors' compilation based on Delphi expert consultations and literature review)

Criteria Group	Functional Dimension	Sub-criteria
G1. Memory Value and Authenticity	Foundations for historical interpretation	(C1) Historical–memory value; (C2) Authenticity and integrity; (C3) Representativeness of collective memory
G2. Interpretive Capacity and Infrastructure	Capacity of spaces to support interpretation	(C4) Quality of interpretation; (C5) Interpretive resources and materials; (C6) Organization of visitor routes and experiential rhythm
G3. Commemorative Ethics and Solemnity	Ethical regulation of heritage use	(C7) Sacredness and solemnity; (C8) Risk of entertainmentization/commercialization; (C9) Appropriateness of collective activities
G4. Accessibility and Safety	Practical conditions of visitor use	(C10) Accessibility; (C11) Safety of movement and experience; (C12) Suitability for specific visitor groups
G5. Carrying Capacity and Conservation	Sustainability of heritage use	(C13) Carrying capacity; (C14) Risk of deterioration and vulnerability; (C15) Conservation and monitoring capacity
G6. Route Connectivity and Collaborative Governance	Spatial and managerial coherence	(C16) Connectivity with other heritage spaces; (C17) Integration into interpretive programs; (C18) Stakeholder coordination

From a structural perspective, the six criteria groups form an integrated analytical framework rather than a collection of independent indicators. Groups G1 and G2 constitute the interpretive foundation of the system, defining the cognitive and narrative basis of heritage engagement. Group G3 functions as a regulatory dimension, establishing ethical boundaries for the use of sensitive heritage spaces. Groups G4 and G5 represent operational and sustainability conditions that shape the feasibility of heritage use within tourism systems.

Finally, Group G6 introduces a landscape-level perspective, emphasizing that heritage interpretation is reinforced when sites operate within coordinated spatial and managerial networks. This configuration ensures that evaluation

extends beyond attractiveness or economic performance and instead reflects the structured interaction between interpretive meaning, ethical regulation, and spatial organization within the Con Dao heritage landscape.

Criteria Weights and Structural Priorities

Following the establishment of the evaluation criteria through the Delphi process, the AHP was applied to determine the relative importance of the six criteria groups. Weighting was conducted at the criteria-group level in order to clarify how experts prioritize interpretive, ethical, operational, and spatial dimensions when conceptualizing heritage spaces in Con Dao as components of a sensitive postcolonial heritage tourism landscape. All pairwise comparison matrices satisfied the accepted consistency thresholds, confirming the internal reliability of expert judgments. The hierarchical structure of the AHP model comprised two levels: (i) the overall objective of evaluating the functional and interpretive capacity of heritage spaces within the Con Dao heritage landscape, and (ii) the six criteria groups identified. Experts conducted pairwise comparisons using Saaty's standard scale, and consistency ratios were calculated to ensure methodological rigor. The resulting weights for the six criteria groups are presented in Table 2.

The resulting weights reveal a differentiated priority structure rather than a uniform valuation of heritage attributes (Table 2). The highest weight was assigned to G3 (Commemorative Ethics and Solemnity) at 0.22, followed by G2 (Interpretive Capacity and Infrastructure) at 0.20 and G1 (Memory Value and Authenticity) at 0.18. Together, these three groups account for 60% of the total weighting, indicating that experts conceptualize heritage spaces primarily through ethical and interpretive dimensions rather than through operational or logistical considerations.

Table 2. Weights of Criteria Groups for Evaluating Heritage Spaces
(Source: Authors' calculations based on AHP results from expert pairwise comparisons)

Criteria Group	Core Focus	Weight
G3	Commemorative ethics and solemnity	0.22
G2	Interpretive capacity and infrastructure	0.20
G1	Memory value and authenticity	0.18
G5	Carrying capacity and conservation	0.16
G4	Accessibility and safety	0.14
G6	Route connectivity and collaborative governance	0.10
Total		1.00

The prominence of G3 suggests that, in the context of Con Dao, ethical regulation is regarded as a foundational condition for heritage tourism development. Sites associated with traumatic and revolutionary histories are expected to operate within clearly defined moral boundaries, which function not as peripheral constraints but as central structuring principles of the heritage landscape. G2 and G1 form the interpretive core of the weighting structure. While memory value and authenticity (G1) provide the historical basis for interpretation, experts prioritized interpretive capacity and infrastructure (G2) slightly higher, indicating that historical significance alone is insufficient without coherent narrative organization, spatial legibility, and appropriate interpretive resources. This ordering underscores the functional interdependence between intrinsic heritage value and its communicative articulation within tourism settings.

Operational dimensions–G5 (0.16) and G4 (0.14)–occupy an intermediate tier. Although assigned lower weights than ethical and interpretive dimensions, these groups define the practical feasibility and long-term sustainability of heritage use. Their positioning reflects an understanding that operational conditions enable, but do not define, the interpretive legitimacy of heritage spaces. G6, with a weight of 0.10, received the lowest relative importance.

However, this lower weight should not be interpreted as marginal significance. Rather, it indicates that spatial connectivity functions as a systemic enabler whose impact emerges through the cumulative integration of sites rather than through the intrinsic attributes of individual spaces. In destinations such as Con Dao, where heritage interpretation is structured through thematic routes and clusters of interconnected sites, connectivity contributes to landscape coherence even if it is not perceived as the primary determinant of site-level performance. Overall, the AHP results demonstrate a three-tier priority structure within the Con Dao heritage landscape: (1) ethical and interpretive foundations (G3, G2, G1); (2) operational and conservation conditions (G5, G4); and (3) systemic connectivity (G6). This hierarchy of weights provides the structural basis for subsequent composite evaluation and spatial differentiation of heritage spaces across the landscape.

Composite Evaluation and Spatial Differentiation of Heritage Spaces

Based on the criteria system and criteria-group weights established in the preceding sections, a composite evaluation of the 13 heritage spaces in Con Dao was conducted to examine their differentiated functional roles within the overall heritage tourism landscape. The analysis integrates AHP-derived expert priorities with practitioner-based experiential assessments, thereby combining normative orientation and field-based interpretive performance. The composite scores and classification results for the 13 heritage spaces are presented in Table 3.

As shown in Table 3, the composite assessment results reveal substantial variation in functional and interpretive capacity across the 13 heritage spaces, indicating an uneven spatial distribution of heritage performance within the landscape. The detailed scoring structure and classification levels are presented in Table 3.With an overall mean composite score of 3.14 (CD), the Con Dao heritage landscape as a whole falls within the "moderate potential" classification. However, this aggregate value conceals pronounced internal differentiation. Because ethical and interpretive dimensions

(G3, G2, and G1) together account for 60% of the total weighting structure, sites that perform strongly in these highly weighted criteria groups gain structural advantage in the composite ranking. Conversely, sites with adequate operational conditions but weaker interpretive density tend to occupy intermediate or peripheral positions within the spatial hierarchy.

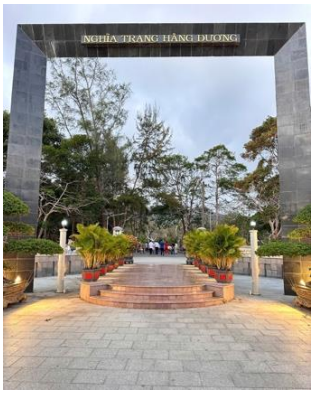
Note: B / W denotes the pre-weighting score and the corresponding weighted score, respectively. Heritage spaces are coded as follows: D1 – Con Dao Prison System (Phu Hai, Phu Son, Phu Tuong, Phu Binh); D2 – Con Dao Museum; D3 – Hang Duong Cemetery; D4 – Pier 914; D5 – Memorial to Con Dao Political Prisoners; D6 – Hang Keo Cemetery; D7 – Island Governor's Residence; D8 – Cow Shed (Trai Bo) Site; D9 – Former Communal Hall (Nha Cong Quan); D10 – An Son Temple and Cau Temple; D11 – So Co Site; D12 – So Lo Voi Site; D13 – Ma Thien Lanh Bridge Site; CD refers to the mean composite score across all heritage spaces

Core Interpretive Nodes

Two heritage spaces–the Con Dao Prison System (D1, 4.59) and the Con Dao Museum (D2, 4.39)–were classified as having very high potential. These sites achieved consistently strong performance across all six criteria groups, particularly in Commemorative Ethics and Solemnity (G3) and Interpretive Capacity and Infrastructure (G2), which carry the highest weights in the evaluation model.

Their composite dominance reflects structural centrality within the heritage landscape. The convergence of memory value (G1), interpretive clarity (G2), and ethical regulation (G3) produces a high degree of interpretive density, positioning these spaces as primary anchors for narrative orientation. In spatial terms, they function as core interpretive nodes from which thematic routes are structured and within which visitors acquire foundational historical frameworks.



Phu Hai Phu Son Phu Tuong Phu Binh

D1 – Con Dao Prison System D2 – Con Dao Museum

Figure 1. Core Interpretive Nodes within the Con Dao Heritage Landscape, Vietnam (Source: Authors, 2026)

Secondary and Transitional Spaces

A second cluster of sites–classified as high potential–includes Hang Duong Cemetery (D3), Pier 914 (D4), and the Memorial to Con Dao Political Prisoners (D5), with composite scores ranging from 3.63 to 3.94. These spaces demonstrate strong symbolic and commemorative value but comparatively lower performance in operational (G4), conservation (G5), and connectivity (G6) dimensions. Functionally, these sites operate as secondary or transitional nodes within the heritage landscape. While they reinforce and deepen interpretive engagement initiated at the core nodes, their comparatively weaker infrastructural coherence reduces their systemic centrality. The group of sites classified as moderate potential (D6–D10) further illustrates transitional roles. These spaces contribute to thematic diversification and narrative layering but do not independently structure visitor understanding. Their role is primarily supportive within organized routes.

D3 – Hang Duong Cemetery

D4 – Pier 914

D5 – Memorial to Con Dao Political Prisoners

D6 – Hang Keo Cemetery

D7 – Island Governor's Residence

D8 – Cow Shed (Trai Bo) Site

D9 – Former Communal Hall

D10 – An Son Temple and Cau Temple

Figure 2. Secondary and Transitional Heritage Spaces within the Con Dao Heritage Landscape, Vietnam (Source: Authors, 2026)

Peripheral and Fragmented Memory Spaces

At the lower end of the spectrum, So Co Site (D11), So Lo Voi Site (D12), and Ma Thien Lanh Bridge Site (D13) were identified as having low to very limited potential. These sites exhibit constraints related to conservation status, accessibility, interpretive infrastructure, and limited integration into structured routes. Rather than functioning as active nodes within the interpretive system, these spaces currently operate as peripheral or fragmented memory sites. Their limited performance in highly weighted criteria groups reduces their structural centrality within the landscape.

Spatial Hierarchy and Landscape Structuring Mechanism

While Table 3 distinguishes five statistical classification levels based on equal-interval scoring, the spatial hierarchy identified here reflects a functional interpretation of landscape roles. The analytical tiers therefore synthesize adjacent score categories into structurally meaningful clusters rather than strictly reproducing the numerical classification scheme.

Three interrelated tiers can thus be identified: (1) Core interpretive nodes (D1–D2), characterized by high interpretive density and strong ethical regulation; (2) Secondary and transitional spaces (D3–D10), which reinforce and extend narrative engagement across routes; (3) Peripheral or fragmented sites (D11–D13), with limited functional capacity under current conditions. This hierarchy emerges from the interaction between weighted criteria priorities and site-level performance patterns. Ethical and interpretive strength shapes centrality, while operational feasibility and route connectivity influence integration. The spatial distribution of these sites across Con Dao Island further illustrates the clustering and hierarchical relationships described above, as shown in Figure 1, 2, 3.

Figure 4 visually reinforces the differentiation between core nodes, secondary clusters, and peripheral sites, demonstrating that roots tourism in Con Dao operates as a spatially structured heritage system rather than a collection of isolated attractions.

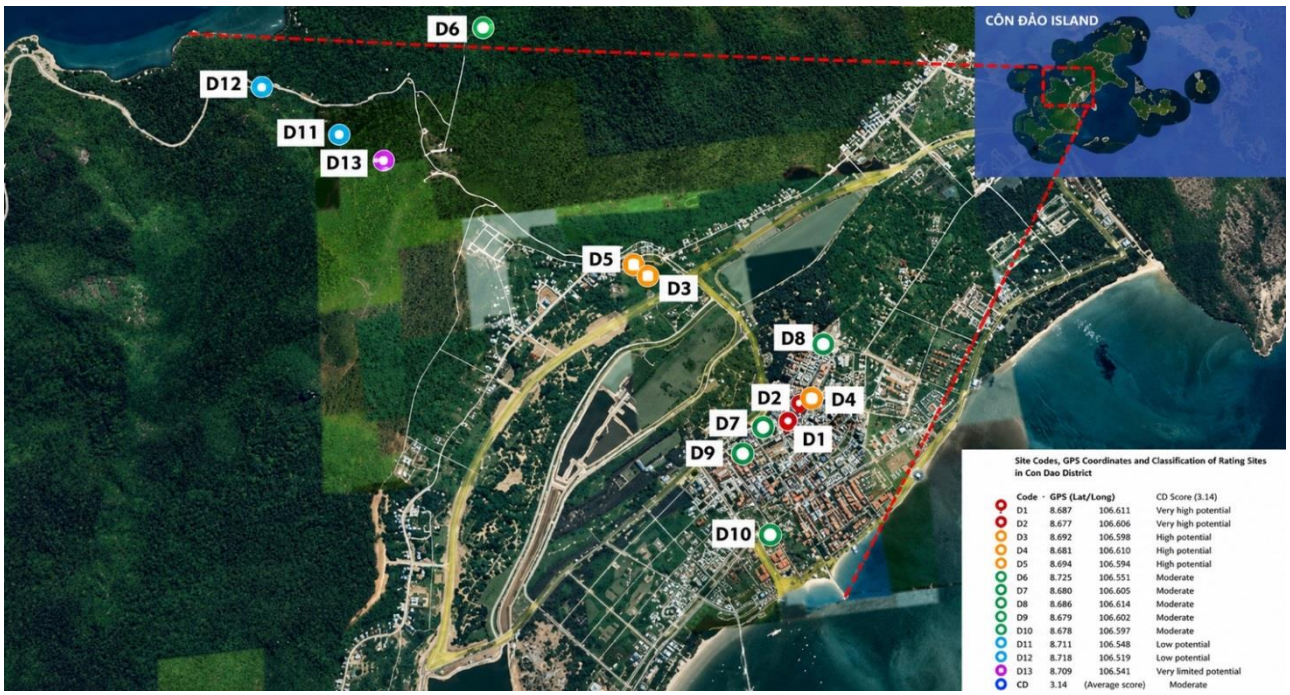

Figure 4. Spatial Distribution of the 13 Surveyed Heritage Sites in Con Dao Island, Vietnam (Source: Authors, 2026)

DISCUSSION

The findings demonstrate that roots tourism in Con Dao operates as a spatially differentiated and ethically structured heritage system rather than as a collection of historically significant sites. By integrating Delphi-based criteria construction, AHP weighting, and composite site evaluation, the study reveals how normative priorities translate into landscape-level hierarchy. The interaction between ethical centrality, interpretive capacity, and spatial organization produces a structured configuration in which heritage spaces assume differentiated but interdependent roles. This discussion situates the findings within debates on memory tourism, difficult heritage, postcolonial memory politics, and tourism geography, while clarifying their theoretical and applied implications. Importantly, the study moves beyond a dominant tendency in the literature to examine memory tourism through site-specific encounters and visitor emotions, by demonstrating how interpretive meaning and ethical regulation become structured across interconnected heritage spaces at the landscape scale.

Ethical Centrality as a Structuring Principle

The AHP results show that commemorative ethics (G3), interpretive capacity (G2), and memory value (G1) together account for 60% of the total weighting structure. This configuration indicates that heritage performance in Con Dao is defined primarily through moral legitimacy and interpretive coherence rather than through operational efficiency.

This finding is consistent with dark tourism scholarship emphasizing tensions between memorial significance and experiential consumption (Light, 2017). Research on moral emotions further demonstrates that engagement at sites of suffering unfolds through complex ethical registers rather than simple attraction mechanisms (Dresler, 2023). However, the present study extends this literature in two ways. First, rather than treating ethics as an external constraint on tourism development, the weighting structure indicates that ethical regulation functions as a primary determinant of heritage "capacity" and legitimacy. Second, while much dark tourism research remains centered on visitor affect and meaning-making within single sites, the Con Dao results show that ethical calibration shapes landscape-level centrality: sites become core nodes not only because they are historically significant but because they sustain ethical framing and interpretive coherence at a level that supports repeated, organized visitation.

Spatial Differentiation and Landscape-Level Interpretation

The composite results reveal a three-tier spatial hierarchy–core interpretive nodes, secondary/transitional spaces, and peripheral sites–emerging from the weighted interaction of ethical, interpretive, and operational criteria. This differentiation demonstrates that interpretive capacity is distributed across interconnected sites rather than embedded solely within individual attractions. This supports and empirically extends conceptualizations of heritage as a spatial process constituted through contemporary use and negotiation (Waterton & Watson, 2015). It also operationalizes Macdonald's (2009) notion of difficult heritage by demonstrating how spatial configuration shapes interpretive authority and narrative coherence. In particular, the findings suggest that "difficult heritage" is not only negotiated through interpretive content but through spatial allocation of roles–where certain sites are positioned as interpretive anchors, others as commemorative intensifiers, and others as peripheral traces requiring conservation-oriented approaches.

In contrast to route-optimization approaches in tourism geography that prioritize accessibility and efficiency (Akay, 2026), the present framework shows that route design in sensitive postcolonial contexts must be guided primarily by ethical and interpretive priorities. Spatial connectivity therefore functions not merely as a logistical variable but as a

mechanism of narrative sequencing and moral framing. This distinction is important because it shifts the planning logic from efficiency-based mobility to ethically guided route choreography, which is more consistent with the commemorative demands of postcolonial prison and martyrdom landscapes.

Co-Production of Meaning Through Structured Mobility

The integration of practitioner-based experiential assessments reinforces the argument that heritage meaning is co-produced through spatial engagement. Visitor learning outcomes depend not only on interpretive content but on how experiences are structured and sequenced (Packer & Ballantyne, 2016). Recent research on memory-making in tourism similarly highlights visitors' active role in attaching personal meaning to collective narratives (Pfoser & Stach, 2024).

The findings suggest that structured mobility–regulated pacing, controlled transitions, and thematic progression–constitutes a central mechanism through which interpretive realization occurs. Core nodes provide narrative anchoring; transitional sites deepen contextualization; peripheral spaces contribute thematic layering. This spatial choreography transforms dispersed heritage sites into an integrated interpretive system. Compared with approaches that equate learning with informational provision, this emphasizes that interpretive effectiveness depends on route rhythm and spatial sequencing, especially where ethical boundaries constrain visitor behavior and modes of engagement.

Emotional Regulation and Responsible Experience Design

The high weight assigned to solemnity and ethical regulation aligns with critical heritage scholarship warning against the commodification of traumatic memory (Farmaki, 2021). Emotional engagement, when responsibly mediated, can function as a catalyst for reflective understanding (Dresler, 2023). However, unmanaged affect risks transforming memory sites into spectacles detached from historical context. The spatial differentiation observed in Con Dao illustrates how emotional calibration is achieved through movement regulation, interpretive framing, and site-specific pacing rather than through amplification of affect. Ethical governance is thus embedded within spatial organization, shaping visitor flow, congregation patterns, and narrative emphasis. This reinforces a key implication for dark-heritage management: affective intensity should be regulated through spatial practice, not simply curated through narrative content.

Postcolonial Memory Politics and Functional Allocation

Within postcolonial contexts, spatial organization of heritage sites is inherently political. Decisions regarding route prominence, infrastructural investment, and interpretive focus actively shape contemporary narratives of identity and belonging (Cant et al., 2025). The evaluation framework developed here enables functional differentiation across the heritage landscape. Core interpretive nodes may support intensive educational programming, while fragile or peripheral sites may require conservation-oriented strategies or mediated interpretation. Such differentiation reduces the risk of uniform development models that could oversimplify layered and contested memories and provides a defensible basis for allocating interpretive resources and managing visitation intensity according to ethical sensitivity.

Methodological and Disciplinary Contribution

Methodologically, the study demonstrates how abstract theoretical constructs–ethics, authenticity, interpretive capacity–can be operationalized within a spatial multi-criteria framework. Unlike conventional AHP applications in tourism that emphasize attractiveness or economic performance, the weighting structure developed here foregrounds moral and interpretive dimensions. This reorientation illustrates how decision-analysis tools can be aligned with critical heritage perspectives rather than managerial optimization alone. From a disciplinary standpoint, the findings contribute to tourism geography by empirically illustrating how landscape hierarchy emerges from weighted normative priorities. Centrality is not determined solely by intrinsic historical value but by cumulative performance across ethically and interpretively weighted dimensions, which in turn structure route logic and the spatial distribution of visitor experience.

Synthesis

Overall, the study corroborates key arguments in memory tourism and difficult heritage research while extending them through spatial operationalization. By demonstrating how ethical and interpretive priorities generate hierarchical differentiation across interconnected sites, the research reframes roots tourism as a landscape-level system structured through moral calibration and spatial sequencing.

This spatially informed perspective bridges conceptual heritage theory and applied tourism geography, providing a foundation for strategic planning and responsible management in postcolonial heritage destinations.

CONCLUSIONS

This study reconceptualizes roots tourism in Con Dao as a spatially structured heritage system situated within a postcolonial memory landscape, rather than as a collection of commemorative or historical attractions. By integrating a criteria-based evaluation framework, hierarchical weighting through the AHP, and practitioner-informed experiential assessment, the research demonstrates how ethical priorities and interpretive capacity translate into measurable spatial differentiation across interconnected heritage spaces. The findings confirm that interpretive and commemorative functions are unevenly distributed and organized into a structured hierarchy. Core interpretive nodes anchor historical understanding; secondary and transitional sites deepen and extend narrative engagement; peripheral spaces contribute contextual layering or require conservation-oriented approaches. This spatial differentiation indicates that effective roots tourism depends not on the isolated enhancement of individual sites, but on ethically sequenced route design and landscape-level coordination.

Academic Contributions

The study advances heritage and tourism research in three principal ways. First, it shifts analytical focus from site-based memory encounters toward landscape-level structuring, thereby extending debates on memory tourism and difficult heritage into the domain of spatial hierarchy and system organization. Unlike predominantly descriptive or visitor-emotion–focused studies of memory tourism, this research provides a structurally operational model for examining how ethical priorities generate differentiated spatial centrality across interconnected heritage sites. Second, the study operationalizes abstract constructs–ethics, authenticity, and interpretive coherence–within a transparent multi-criteria evaluation framework. By aligning critical heritage theory with decision-analytic tools, it demonstrates how normative principles can be translated into structured, comparable, and context-sensitive assessment models. Third, the concept of functional clustering is advanced as an empirical mechanism for understanding how multiple heritage spaces collectively operate within an integrated tourism landscape. Rather than treating sites as independent attractions, the framework reveals how inter-site relationships shape interpretive effectiveness and governance priorities. In doing so, the research contributes to tourism geography by illustrating how weighted normative priorities shape spatial hierarchy, route logic, and heritage centrality, offering a replicable analytical approach for other postcolonial or conflict-related heritage destinations.

Practical and Policy Implications

From a planning perspective, the framework provides a defensible basis for differentiated management strategies. Rather than applying uniform development or visitation models, heritage managers can align interpretive depth, visitation intensity, conservation priority, and infrastructural investment with the functional role of each heritage cluster. Such differentiation is particularly important in postcolonial contexts where ethical sensitivity constrains commercial expansion and experiential design. By foregrounding ethical calibration and spatial sequencing, the model supports the design of structured heritage routes that balance commemoration, education, and sustainability. It also offers a strategic basis for allocating interpretive resources and regulating visitor flows in ways consistent with the symbolic integrity of sensitive heritage spaces.

Limitations and Future Research

Several limitations should be acknowledged. The experiential assessment relied on a relatively small and specialized participant group, and the findings therefore reflect context-specific professional insight rather than broad visitor generalization. In addition, while the study evaluates functional capacity and spatial organization, it does not directly measure long-term visitor learning outcomes, behavioral change, or governance dynamics.

Future research may expand participant diversity, conduct cross-destination comparative analysis, or apply sensitivity testing to alternative weighting structures. Further investigation into digital mediation, participatory governance models, and longitudinal patterns of visitor engagement would deepen understanding of how spatially structured heritage systems evolve over time and across different socio-political contexts.

Final Reflection

Overall, this study demonstrates that roots tourism, when conceptualized through an ethically grounded and spatially informed framework, operates as a structured heritage landscape in which centrality, integration, and marginality are analytically identifiable. The case of Con Dao shows that heritage spaces do not merely preserve historical traces; they actively organize visitor understanding through calibrated spatial relationships and normative prioritization.

By linking critical heritage theory with operational evaluation and route-based planning, the research provides both conceptual refinement and applied guidance for managing sensitive memory landscapes. In postcolonial contexts where tourism development intersects with collective trauma and identity formation, spatially differentiated and ethically calibrated approaches offer not only managerial direction but a principled foundation for responsible heritage governance.

Citation: Choudhary, V., Nag, A., Kankaew, K., & Sitikarn, B. (2026). From experience to responsibility: The contradiction influence of tourist recreational experience on wetland conservation behaviors. *Geojournal of Tourism and Geosites*, 67(3), 1865–1876. https://doi.org/10.30892/gtg.67303-1815

Abstract: Wetland ecosystem flourishes the biodiversity, local livelihood, and economy. However, the tourism activity in wetland can alter the ecosystem degradation. Thence, this study examines the psychological relationship of tourist recreational experience (TRE) on tourist satisfaction and environmentally responsible behavior (ERB). The tourist satisfaction (TS), meanwhile, was utilized as a mediator between TRE and ERB. The assessment was conducted through Stimulus-Organism-Response (SOR) theory lens in Pong wetland Himachal Pradesh, India. The quantitative method was administered by using partial least squares structural equation modelling (PLS-SEM) for data analysis. The questionnaires were employed collecting 219 valid data among domestic tourists at Pong wetland region. Whereas, the internal consistency of all constructs was assessed using Cronbach's alpha and McDonald's ω, with each construct scoring above 0.7. While, the overall Cronbach's alpha and McDonald's ω values were 0.967 and 0.969, respectively. The results indicated that recreational experiences significantly enhance satisfaction and positively predict environmentally responsible behavior. However, there was an unexpected negative direct effect of tourist recreational experience toward environmentally responsible behavior. This indicates that the hedonic recreational experiences may not straightaway translate into commitment to the environment without the mediating role of tourist satisfaction. The findings shed light on experience-satisfaction-behavior correlations in wetland tourism. Noting that, solely of the wetland recreational value has no psychologically impact on environmentally responsible behavior. Therefore, the destination management organization should project on nurturing the conservation activities that enhance visitor satisfaction. As such, the creation and design of nature-based recreation that satisfying, inspiring and mastering awareness on environmental conservation while establishing sustainable wetland governance. In addition to this, the local community participation in wetland management should be prioritized.

Keywords: environmentally responsible behavior, tourist recreational experience, wetland, attitude, satisfaction, SOR theory

INTRODUCTION

Wetlands are environmentally sensitive ecosystems that support a diverse species and offer significant impact on socio-economic as well as (Yiamjanya et al., 2024) nature-based tourism. Though, wetland does exist only 6% of the whole world, but its natural settings provide crucial social well-being (Van & Doo-Chul, 2025), recreational and educational benefits to visitors, increasing their admiration for nature. Furthermore, wetland habitats are widely perceived for SDG achieving goals (Stojanovic et al., 2025). It was metaphor as the earth's kidney that is one of the three primary ecosystems service for mankind. It is noticeable in current day that wetlands have more degradation and loss biodiversity (Wang et al., 2025). As Chatterjee et al. (2025) cited the wetlands were damage consistently from 1970 to 2015 with higher decline rate per year than natural forest. At the same time, tourism activity is regarded as wetland resource usage because of its attractiveness (Stojanovic et al., 2025). Addedly in the postmodern society, people prompted re-evaluation of tourism practices to a more integrated approach prioritizing biodiversity conservation alongside tourism development. Destination managers can support the sustainable development of recreational surroundings and enhance the scientific supply of park services by evaluating urban parks' environmentally responsible behaviour practices (Zhao et al., 2018).

Such a shift has the aim of restoring degraded ecosystems and biodiversity and creating sustainable economic opportunities for local communities. It aligns with evolving tourist behaviours and expectations in the context of the "new normal" (Afifi, 2021). Tourists typically sought to visit attractions in small groups in open-air locations like mountains, isolated islands and deserts. Such an aim is echoed by Skryl & Gregoric (2022), who stressed that through ecotourism and rural tourism, travellers favour remote locations, green and natural settings, fresh and pure air, and activities such as cycling, hiking, and trekking. Yet, wetland has gained more popularity among visitors especially nature-based tourists.

However, not every visitor has a positive in wetland spaces as Ausique et al (2025) stated the feeling of discomfort, rejection, and insecurity toward urban wetland because of socio-environmental factors and limitation in educational. Thence, the wetland conservation program initiative studies have recommended as in Vietnam found community involvement in managing wetland resources is vital (Van & Doo-Chul, 2025), the wetland scientific knowledge, infrastructure, and service quality are required in Kazakhstan (Dildabek et al., 2025), and activity-based instruction in school for natural sound mapping in Chile to stimulate students draw attention in the environment (Rabello-Mestre et al., 2026). At the same token, the tourism grows in these biodiversity locations, it is essential to comprehend the psychological and behavioral mechanisms that determine tourists' environmentally responsible behavior (ERB).

Though in India, the government has emphasized of its 93 Ramsar sites conservation tourism practices. The Pong Wetland in Himachal Pradesh is one of the projected sites. That exhibits biodiversity and historical sites such as Masroor Temple and Bathu Ki Ladi Temple, as well as the opportunities for bird watching and outdoor recreation. Despite a greater emphasis on wetland ecosystem preservation, the research on understanding the tourists' ERB is also crucial. Literally, this field of study still remains limited. Albeit, there were researches identified environmental attitudes, place attachment, and biospheric values as important predictors of ERB (Lee, 2011; Ramkissoon et al., 2013; Lin & Lee, 2019), whereas some studies pinpointed the recreational experience with nature can increase environmental awareness (Galley & Clifton, 2004; Ballantyne et al., 2011a). Nevertheless, the causal relationship between tourists' recreational experience and ERB in natural settings remains unclear (Lin & Lee, 2020). Secondly, the satisfaction has been hypothesized as a potential predictor of ERB (Lee & Jan, 2015a), but its mediated role in wetland tourism has yet to be empirically verified. Research on sustainability attitudes and biodiversity knowledge (Naparin & Karsudjono, 2025) underscores the necessity to investigate these internal factors. To address these gaps, this study adopts the Stimulus-Organism-Response (SOR) framework (Mehrabian & Russell, 1974), which holds that external stimuli generate internal evaluations that influence behavioral responses. Although it is widely employed in tourism and hospitality (Dogra et al., 2023), SOR is underexplored in wetland tourism specifically in India. This theoretical gap restricted our knowledge of how wetland-base experiences explain the conversation behavior.

Henceforth, we develop a structural model to investigate the relationships between recreational experience, satisfaction, and ERB among domestic visitors to the Pong Wetland, in India. This study also delves into satisfaction as a mediator of recreational experience and ERB. Ultimately, the theoretical expounding of ERB drivers by giving empirical information from a Ramsar-designated in an emerging economy, as well as informing managers who desire to establish recreational experiences that encourage sustainable preservation of wetlands will be addressed.

LITERATURE REVIEW

Stimulus-Organism-Response Theory

The Stimulus–Organism–Response (SOR) framework (Mehrabian & Russell, 1974) provides a foundational lens for understanding how external environmental cues shape individuals' internal states and subsequent behavioural responses. In tourism, SOR has been widely adopted to explain how attributes of the tourism environment function as stimuli that activate cognitive or affective evaluations, which then translate into outcomes such as satisfaction, behavioural intentions, and loyalty. This triplex structure has offered scholars a robust way to conceptualize the experiential pathways that connect destination attributes to visitor behaviour. Empirically, Cheng et al. (2016) illustrate that mediating variables generally represent the effects of visitor experiences to behavioral intentions. Zhou et al. (2022) discovered that experiencing inputs significantly influence tourists' internal appraisals, which then drive loyalty-related behaviors. Besides, the adoption of satisfaction as mediator is significantly between servicescape (S) and loyalty (R) in a healthcare setting (Suess & Mody, 2018), the memorable experiences (S) enhance destination attachment and overall satisfaction (O), resulting to the development of destination brand equity (R) base on customer (Guleria et al., 2024).

Collectively, these investigations demonstrate SOR's utility in recording multimodal experience processes and understanding how external factors influence behavioral responses. Although SOR has been widely utilized to explain behavioral intentions such as loyalty, revisit intention, and brand equity, its applicability to environmentally responsible behavior (ERB) is restricted, particularly in ecologically sensitive contexts alike wetland (Tang et al., 2025). Meanwhile, scholars studying ERB typically use alternative theoretical frameworks, such as the Theory of Reasoned Action and Theory of Planned Behavior (Lee et al., 2015; Lee & Jan, 2015b; Naparin & Karsudjono, 2025), the Value-Belief-Norm Theory (Lee & Jan, 2015a; Xu et al., 2018), Stakeholder Theory (Su et al., 2018), and the Theory of Goal-Directed Behavior (Han et al., 2018) rather than SOR. While these prior-mentioned theories provide useful insights into the attitudinal and normative drivers of ERB, they commonly ignore the senses and affective processes that arise from interaction with natural environments—mechanisms that are important to wetland tourism. Despite the strong conceptual alignment between SOR and the experiential aspect of wetland tourism, the theory has received little attention in this field.

In spite of that, no empirical study has used the SOR paradigm to explain ERB in wetland tourism contexts in India. This gap narrows our understanding of how recreational experiences behave as triggers, how satisfaction functions as an organismic state, and how these processes influence environmentally responsible behavior in fragile ecosystems.

Tourist Recreational Experience

Tourist recreational experience (TRE) is considered an integral driver of attitudes, satisfaction, and subsequent behavioral intentions in tourism research. It was defined as a multidimensional construct with emotional, cognitive, sensory, educational, entertaining, and hedonistic engagement (Pine & Gilmore, 1998; Schmitt, 1999; Kim, 2018; Câmara et al., 2023; Ge & Chen, 2024). The larger perspective views recreational experience as a holistic psychological

process impacted by interactions with place, nature, and interpretation, rather than just an activity-based encounter (Tang et al., 2024). In nature-based tourism, scholars (Xu et al., 2018) cited thoughts, emotions, and reflections that ecotourists develop when engaging in wetland-related activities. These experience components, particularly draw on the dynamic and multisensory qualities of wetland ecosystems, foster direct contacts with biodiversity, observation of ecological processes, and involvement with conservation narratives. In line with environmental psychology and ecotourism frameworks, such immersive nature-based interactions promote affective and cognitive restoration while strengthening environmentally responsible behavior through increased place connection and moral engagement (Ballantyne et al., 2011a; Ballantyne et al., 2011b). That is the emotional components such as admiration, empathy, and attachment to nature can foster deep psychological engagement and lead to behavioural motivation (Rasul et al., 2025). And the experiential quality constructs the foundation for environmental stewardship and influence visitors' willingness to act responsibly both during and after their visit. As evidence of a significant of emotion effect in tourism (Javed et al., 2020), community-based tourism verifies these dynamics: recreational experiences have been found to impact environmental attitudes, which in turn motivate environmentally responsible behavior (Lee & Jan, 2015b) activities experience exert satisfaction and behavioral intention (Ge & Chen, 2024). This can be inferred that the tourists' recreational experience and satisfaction could nurture behavior and attitudes toward endangered wetland habitats. Despite these findings, empirical understanding remains fractured. In particular, the structural links between recreational experience, ecologically oriented attitudes, satisfaction, and ERB have not been thoroughly investigated in wetland tourism. Given that wetlands offer unique dynamic and instructive environments, exploring these experiential pathways is critical for establishing effective nature-based tourism strategies that promote both visitor satisfaction and ecological responsibility. We anticipate that educational and emotional factors will influence ERB more significantly than hedonic factors, as the former promote conservation mindsets, whilst the latter may emphasize satisfying oneself. As well as, the multi-sensory immersion during visitation would generate holistic positive evaluations. Thence, our hypothesis is:

H1: TRE has a significant impact on Tourist satisfaction (TS)

H3: TRE has a significant impact on ERB

Tourist Satisfaction

Tourist satisfaction (TS) is regarded as an important indicator of destination loyalty and intent to return (Sahabuddin et al., 2021; Carvache-Franco et al., 2022). Satisfaction is typically portrayed in tourism literature as a mediating psychological mechanism that directs the influence of experiencing stimuli into behavioral results (Radovic et al., 2021; Carvache-Franco et al., 2022; Prayag, 2009). In tourism studies, satisfaction is defined as an emotional or cognitive appraisal (Liu et al., 2023) obtained by comparing actual experiences to pre-visit expectations, which is consistent with the foundations of expectancy-disconfirmation theory and norm theory (Javed et al., 2020; Beard & Ragheb, 1980; Yoon & Uysal, 2005). Where, the high-quality recreational experiences, particularly those that incorporate enjoyment, learning, and immersion, are consistently associated with higher levels of visitor satisfaction (Tribe & Snaith, 1998; Radovic et al., 2021; Haji et al., 2021). Visitors who are satisfied are more likely to recognize the importance of environmental conservation, especially in natural settings (Jiang et al., 2022). Similarly, in wetland tourism, satisfaction serves as a mediator between motivation, destination image, attitudes, and behavioral intentions (Lee, 2009). These findings suggest that satisfaction not only reflects the evaluative conclusion of recreational activities, but also acts as a crucial psychological state that converts experiencing encounters into future actions. Satisfaction levels impact visitors' decision-making to revisit and share positive things about the place (Lai et al., 2018).

Despite the importance of satisfaction in tourism behavioral models, its relevance in the nexus of recreational experience and environmentally responsible behavior (ERB) in wetland settings is understudied. Given that wetlands ecological sphere may induce psychological correlation between tourists' experiential attachment and their pro-environmental actions—however, scientific information on this approach is limited. We expect that satisfaction in a sensitive natural ecosystem creates a sense of reciprocal obligation. Therefore, our second hypothesis is:

H2: Tourists' satisfaction has a significant impact on environmentally responsible behaviour

H4: Satisfaction mediates the relationship between TRE and ERB

Environmentally Responsible Behaviour

Environmentally responsible behavior (ERB) refers to humans' intentional acts aimed at reducing environmental degradation and preserving ecological integrity (Zacher et al., 2023; Tan et al., 2023; Han et al., 2016; Lee, 2011; Confente & Scarpi, 2021) or interchangeably as pro-environmental behavior. It composes of four set of behavior including; environmental activism; nonactivist publicly but donation or complying to policy; private environmentalism as such green behavior; and other behavior like influencing (Zacher et al., 2023). Simultaneously, ERB in tourism is comprised of ecological knowledge, environmental attitude, place-based sensitivity, and recognized personal responsibility (Tang et al., 2025). These cognitive-affective components are expressed through behaviors such as following travel instructions, reducing waste, conserving resources, respecting wildlife, and supporting conservation projects (Chiu et al., 2014; Steg & Vlek, 2009; Zacher et al., 2023; Yu et al., 2024; Zhang et al., 2024).

ERB is thus regarded as a necessary foundation to preserving ecotourism growth and protecting endangered areas (Lee et al., 2013). A significant amount of research has identified different causes of ERB in multiple nature-based tourism environments. Place attachment and recreational involvement have been demonstrated highly predict ERB in wetland habitats (Lee, 2011; Xu et al., 2018) show that engagement and experience appreciation are antecedents of ERB in wetland parks. Although this research emphasizes the significance of experience-based and psychological drivers of

ERB, they only provide a partial comprehension of the complex mechanisms that link recreational activities with pro-environmental behavior. Notably, Figure 1 the structural associations between tourist recreational experience (TRE), tourist satisfaction (TS), and ERB in wetland based on SOR will be examined.

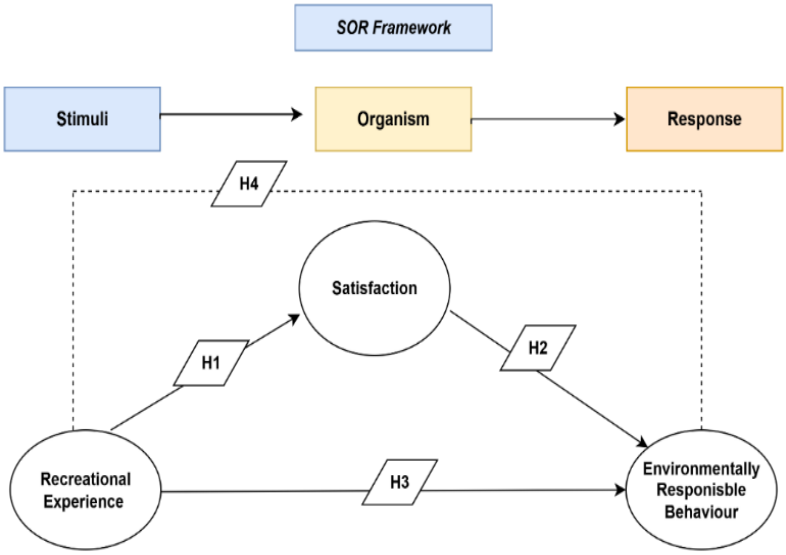

Figure 1. Conceptual Model (Source: Author's own creation)

METHODOLOGY

Research Design

The Quantitative research method and cross-sectional design have been employed to accomplish the research objectives, which are to examine the impact of TRE on ERB in wetland tourism destinations and the mediating roles of satisfaction. According to Apuke, (2017) quantitative research methods were selected for multiple reasons, including the potential of generalising the findings, addressing research questions through numerical data, and statistical analysis, etc. The study can be completed more quickly and cost-effectively, and a cross-sectional research design was used (Setia, 2016).

The questionnaires were constructed for data collection at Pong wetland site. Each measurement item used in the study was adapted and modified from the body of existing literature. The survey used a five-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree), as it is a common method for data collection that needs less time and effort than scales with more points (Likert, 1932). Tourist recreational experience is an exogenous variable, assessed using 12 indicators adapted from Ballantyne et al. (2011a); Lee & Jan (2015a); satisfaction is an intervening variable, assessed using 9 indicators adapted from (Lee, 2009); environmentally responsible behaviour is an endogenous variable, assessed using 5 indicators from (Xu et al., 2018)**.** The questionnaire was examined by domain experts and pretested with a small group of visitors to verify linguistic clarity, cultural appropriateness, and contextual accuracy before the final survey.

Study Area

This study focuses on Pong Wetland, also known as Maharana Pratap Sagar in Figure 2, one of India's largest artificial wetlands and a designated Ramsar site with diverse and unique biodiversity, located in the Kangra district of Himachal Pradesh (Kohli, 2015). It was established in 1975 on the Beas River. Pong Wetland likely serves as the first significant resting place for migrating birds from the Trans-Himalayan region during winter. This Ramsar site has been established as a sustainable tourism destination under the Swadesh Darshan Scheme 2.0.

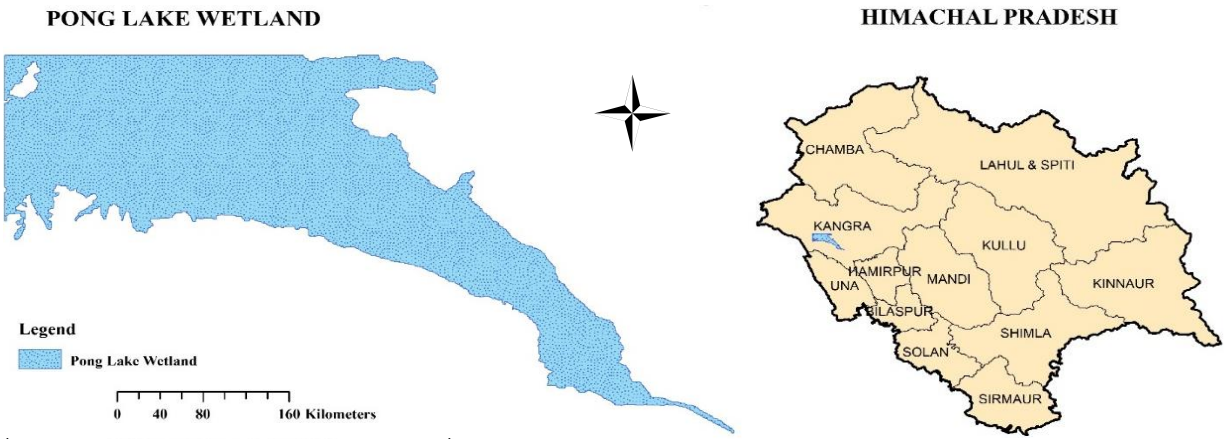

Figure 2. Pong Wetland (Source: Created by the authors using USGS Earth Explorer and ArcGIS10.5)

Sampling and Data Collection Procedure

The research methods were evaluated among visitors to the Pong Wetland (Ramsar site) in Himachal Pradesh, India. Before the final data collection, this study utilised an "a priori sample size calculator for structural equation models". The total number of responses required for the model's structure is sufficient for SEM, with 3 latent variables, 22 observed variables, an expected effect size of 0.30, a significance level of 0.05, and a statistical power of 0.80. The calculation shows that at least 119 responses are necessary to detect the effect **(**Westland, 2010**).** However, this study collected 219 valid responses, substantially exceeding this threshold and ensuring reliability, validity and adequate statistical power for hypothesis testing (Hair et al., 2014). The questionnaire was distributed offline at Pong Wetland. Data collection took place over three months, in October – December 2024, with respondents asked to complete the questionnaire. Before conducting the final survey, a pilot study was carried out with the first 30 respondents to verify clarity and reliability. The internal consistency of all constructs was assessed using Cronbach's alpha and McDonald's ω, with each construct scoring above 0.7. The overall Cronbach's alpha and McDonald's ω values were 0.967 and 0.969, respectively. Thus, the reliability of the questionnaire was established (Hair et al., 2019). The data was gathered among 230 domestic tourists using a convenience sampling technique, in which the respondents were chosen for their willingness and availability to participate while they were there. After initial screening, 11 unsatisfactory responses were eliminated, leaving a final sample size of 219 responses to be analysed with a response rate of 95.21%.

Data Analysis

Partial least squares structural equation modelling through SMART PLS 4.0 was applied to test both the measurement model (reliability and validity) and the structural model (path analysis) and the same was utilised to pilot-test as well as analyse the demographic profile of the respondents using Jamovi (version 2.3). For social sciences, conceptual model analysis, particularly in hospitality and tourism studies, partial least square path modelling is a reliable technique (Ali et al., 2018). Moreover, PLS-SEM is a useful tool for examining datasets with restricted observations (Hair et al., 2019). The research utilised the bootstrapping technique to estimate the statistical significance of both direct and indirect effects (Hayes, 2018). The methodology was conceptualized as shown in Figure 3.

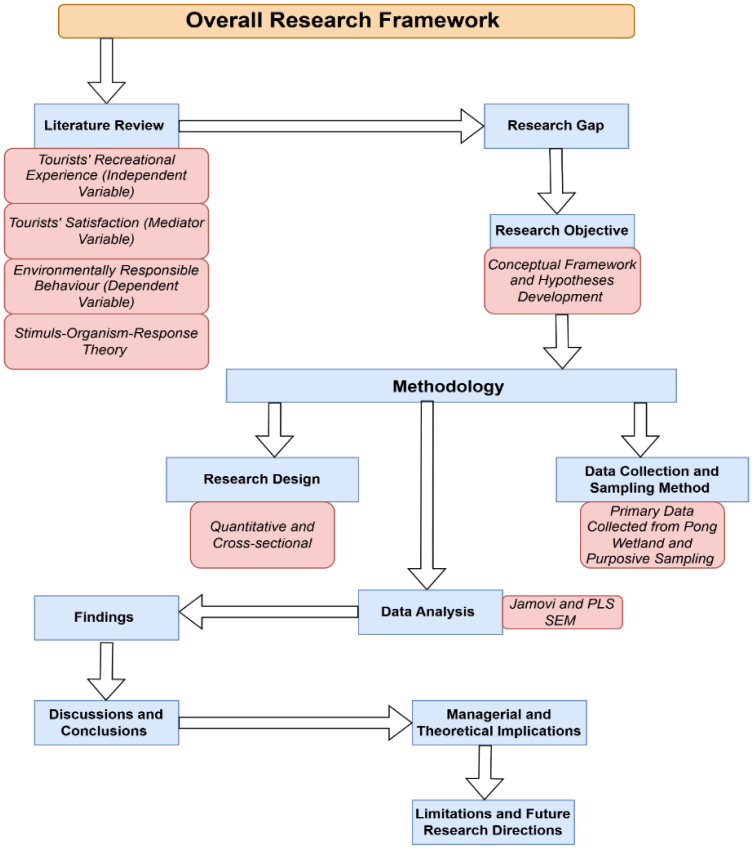

Figure 3. Research Framework

RESULTS

Descriptive statistics

Figure 4 shows the total of 219 responses data, it reveals that 63.0% of the tourists were male, while 37.0% were female. The largest group of tourists is aged 21-30 (68.5%), followed by those aged 31-40 (16.9%). Most are single (71.7%), with 27.4% married. In terms of educational background, 53.0% are postgraduates, 26.9% are graduates, and the majority are first-time visitors (48.9%). Additionally, 65.3% were accompanied by friends on this trip.

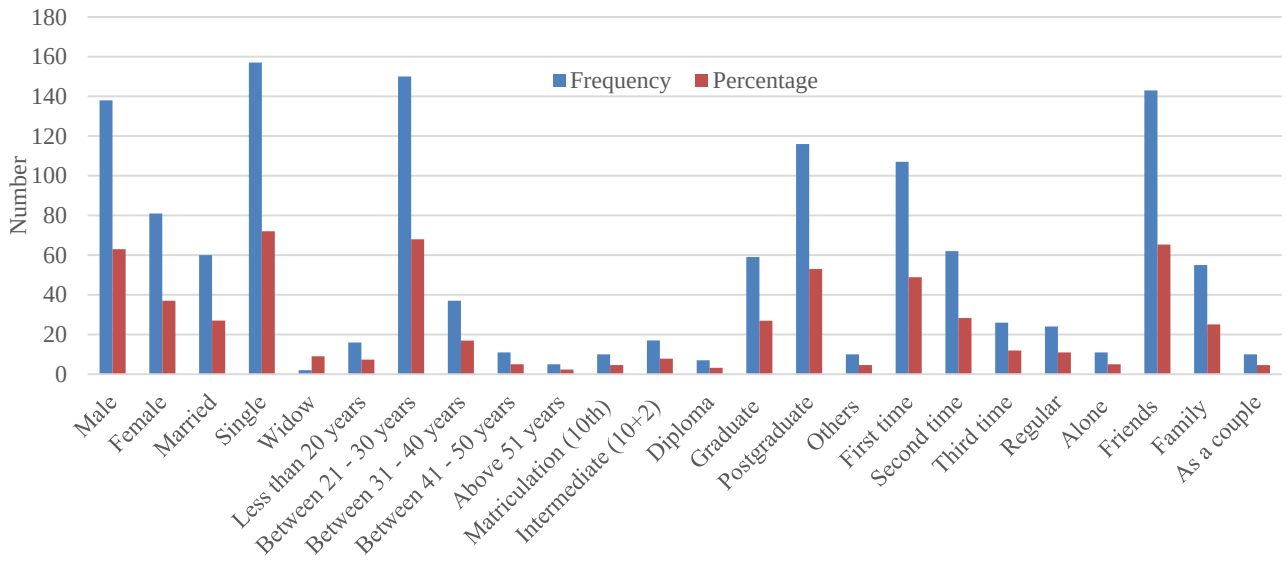

Figure 4. Respondents' Profile (Source: Author's own creation)

Assessment of the measurement model

To check the common method bias, Harman's Single Factor test was applied. The finding was that the first factor accounted for just 28.36% of the total variance, which is below the criterion of 50%. The implication is that there was no issue of common method bias (Fuller et al., 2016). The measurement model evaluation involves verifying construct reliability through measures such as Cronbach's alpha and composite reliability, along with assessing convergent validity (average variance extracted) and discriminant validity. The outer loadings of the 22 indicators ranged from 0.686 to 0.880, all exceeding 0.6. As shown in Table 1, Cronbach's alpha values were above 0.7, confirming that all constructs are reliable (Hair et al., 2014). The collinearity test results for the outer model revealed that all variance inflation factor values were under five, confirming the absence of multicollinearity and bias in the regression analysis.

Table 1. Construct reliability and validity (Source: Author's own creation)

Items		Factor loadings	VIF	Cronbach alpha	rho_c	rho_a	AVE
Tourists Recreational Experience				0.879	0.903	0.890	0.539
TRE1	"A fascinating and new experience"	0.728	1.591				
TRE4	"An amazing experience with water-based activities (Boating, Kayaking, Canoeing, etc.)"	0.710	1.705				
TRE5	"An emotional connection with the nature (flora-fauna)"	0.686	1.651				
TRE6	"A sheer pleasure as I got to see a wide variety of migratory birds"	0.748	1.708				
TRE8	"A refreshing experience as the air in the wetland was fresh and calming"	0.758	2.236				
TRE9	"Highly enjoyable as far as land-based recreational experiences were concerned (cycling tour, nature walk, etc.)"	0.734	2.102				
TRE10	"A very calming experience, as I felt a deep sense of peace within myself during the tour"	0.793	2.327				
TRE11	"A unique experience, where I witnessed a perfect balance between environmental preservation and recreational promotion"	0.714	1.892				
Tourists Satisfaction				0.908	0.925	0.914	0.580
TS1	"The recreational experiences offered at Pong Wetland (boating, bird watching, nature walks, etc)"	0.749	2.069				
TS2	"The tourist attractions (natural, cultural and religious), available at the Pong Wetland"	0.793	2.388				
TS3	"A thoughtful and worthwhile decision"	0.763	2.003				
TS4	"Time and money I have spent"	0.813	2.569				
TS5	"The environment of the destination"	0.806	2.489				
TS6	"The natural landscape at the Pong Wetland"	0.708	1.702				
TS7	"The Pong Wetland biodiversity"	0.622	1.687				
TS8	"The tourist facilities offered at the Pong Wetland (Information Centre, drinking water, washrooms etc,)"	0.792	2.428				
TS9	"Overall service distribution at the Pong Wetland"	0.789	2.310				
Environmentally Responsible Behaviour				0.890	0.919	0.904	0.695
ERB1	"I would talk to friends or relatives about environmental issues"	0.880	3.006				
ERB2	"I would try to persuade others to adopt environmentally responsible behaviour"	0.827	2.479				
ERB3	"I would report it to the wetland managers if I spotted improper behaviours"	0.864	2.657				
ERB4	"I would pick up the garbage that I see during my trip to Pong Wetland"	0.829	2.371				
ERB5	"I joined in community clean-up efforts"	0.763	1.806				

Additionally, the composite reliability (rho_c and rho_a) of all constructs was above 0.7 (Bagozzi & Yi, 1988; Dijkstra & Henseler, 2015), and the average variance extracted (AVE) was above 0.5, indicating that each construct explains at least 50% of the variance in its indicators (Hair et al., 2019). The AVE increased from 0.539 to 0.695. The AVE values of each construct are "Recreational Experience" 0.539, "Satisfaction" 0.580, and "Environmentally Responsible Behaviour" 0.695. Thus, the convergent validity was valid. To assess discriminant validity, using the Heterotrait-Monotrait ratio and Fornell-Larcker criterion in *italic numbers with* $\sqrt{\boldsymbol{AVE}}$ in ***italic bold***, Table 2. All HTMT values below the threshold of 0.9 or 1 (Henseler et al., 2015; Voorhees et al., 2016). Therefore, discriminant validity is valid.

Table 2. Heterotrait-Monotrait Ration (HTMT) and *Fornell-Larcker Criterion* $\sqrt{AVE}$ (*Italic numbers are Fornell-Larcker Criterion)

Constructs	TRE	TS	ERB
TRE	**0.734**	0.551	0.001
TS	0.590	**0.761**	0.336
ERB	0.132	0.367	**0.834**

Table 3. Explanatory Power (Source: Author's own creation)

Constructs	R-square	R-square adjusted	Q^2 predict
ERB	0.162	0.154	-0.011
TS	0.304	0.300	0.292

Table 3 presents the explanatory power of the models, highlighting the impact of predictor variables on each construct. The recreational experience accounts for 16.2% of the variance in tourists' satisfaction. Moreover, satisfaction explains 30.4% of the variance in environmentally responsible behaviour. The predictive validity of the structural model was confirmed through R-squared values for the endogenous latent variables of appreciation and actual visits, both of which exceeded the acceptable value of 0.10 (Chin et al., 2020). The Q2 prediction results show that the model has good predictive relevance for tourist satisfaction, indicated by the positive value (0.292). Conversely, the negative value for environmentally responsible behaviour (-0.011) suggests that the model has limited or no predictive power for ERB. This indicates that while the model predicts TS effectively, additional constructs are necessary to improve ERB prediction.

Structural Model

The structural model was evaluated using Model Fit (SRMR), f2, and path coefficients, as well as t-statistics and p-values, in SmartPLS 4.0. The model fit was excellent, with an SRMR (Standardized Root Mean Square Residual) value of 0.075. Effect size analysis showed that ERB → TRE ($f^2 = 0.058$) has a small effect, so ERB modestly explains the variability in the tourist recreational experience. Conversely, the effect size of ERB → TS is medium ($f^2 = 0.193$), indicating that environmentally responsible behaviour moderately contributes to tourist satisfaction. TRE → TS has a large effect size of $f^2 = 0.436$, suggesting that the recreational experience of tourists is a very strong predictor of tourist satisfaction.

Table 4. Hypothesis Testing Results (direct relationship) (Source: Author's own creation)
(Note: TRE: Tourist Recreational Experience: TS: Tourist Satisfaction: ERB: Environmentally Responsible Behaviour)

Construct (path)	β (path coefficients)	Std	T- statistics	p values	95% Confidence Interval (LICI-UICI)		Support
TRE→ ERB	-0.265	0.091	2.906	0.004	-0.445	-0.089	H1→ No (different sign)
TRE → TS	0.551	0.061	9.098	0.000	0.432	0.670	H2→ Yes
TS→ ERB	0.482	0.066	7.323	0.000	0.367	0.624	H3→ Yes

A bias-corrected and accelerated (Bca) bootstrap method with 5000 subsamples was employed to examine the relationship between tourists' recreational experience, satisfaction, and environmentally responsible behaviour in the Pong Wetland. The tourist recreational experience has a negative and significant effect on environmentally responsible behaviour (βTRE→ERB = -0.265, t = 2.906, p = 0.004; Table 4). This suggests that increased recreational engagement might decrease environmentally responsible behaviour. Therefore, H1 is not supported because of the different sign. This negative correlation raises the possibility that tourists may unawares experience psychological stress as a result of increased exposure to environmental responsibility. Conversely, it has a positive and significant influence on tourist satisfaction (βTRE→TS = 0.551, t = 9.098, p = 0.000; Table 5), supporting H2. The result emphasizes the necessity of creating environmental programs that lessen the immediate reliance on behavior and satisfying visitors. Additionally, satisfaction has a positive and significant impact on environmentally responsible behaviour (βTRE→ERB = 0.482, t = 7.323, p = 0.000), confirming H3.

Mediation Analysis

A mediator, according to Baron & Kenny (1986), is a variable that influences how the independent and dependent variables relate to one another. The results indicate that tourist satisfaction serves as a positive and significant mediator between the recreational experience and environmentally responsible behaviour of tourists (βTRE→TS→ERB = 0.266, t = 5.924, p = 0.000; Table 5). Notably, while the direct impact of TRE on ERB is negative, the indirect impact through satisfaction is positive, suggesting a competitive (inconsistent) mediation (Zhao et al., 2010). Therefore, H4 is confirmed. Consequently, three hypotheses are supported.

Table 5. Mediation Analysis (indirect effect) (Source: Author's own creation)

Construct	β (path coefficients)	Std	t- statistics	p values	95% Confidence Interval (LICI-UICI)		Result
TRE→TS→ERB	0.266	0.045	5.924	0.000	0.196	0.371	H4→ Yes

In Figure 5 depicts the structural equation model's hypothesized correlations between Tourist Recreational Experience (TRE), Tourist Satisfaction (TS), and Environmentally Responsible Behavior (ERB). The path coefficients and p-values reflect the strength and importance of these associations.

Figure 6 demonstrates that the importance-performance map analysis (IPMA) reveals clear differences among the constructs. Tourist satisfaction scores highly on both importance and performance, signifying it is a key factor influencing the target outcome and performs well. In contrast, tourists' recreational experience exhibits high performance but low importance, implying it has a smaller direct influence on the desired behavior outcome.

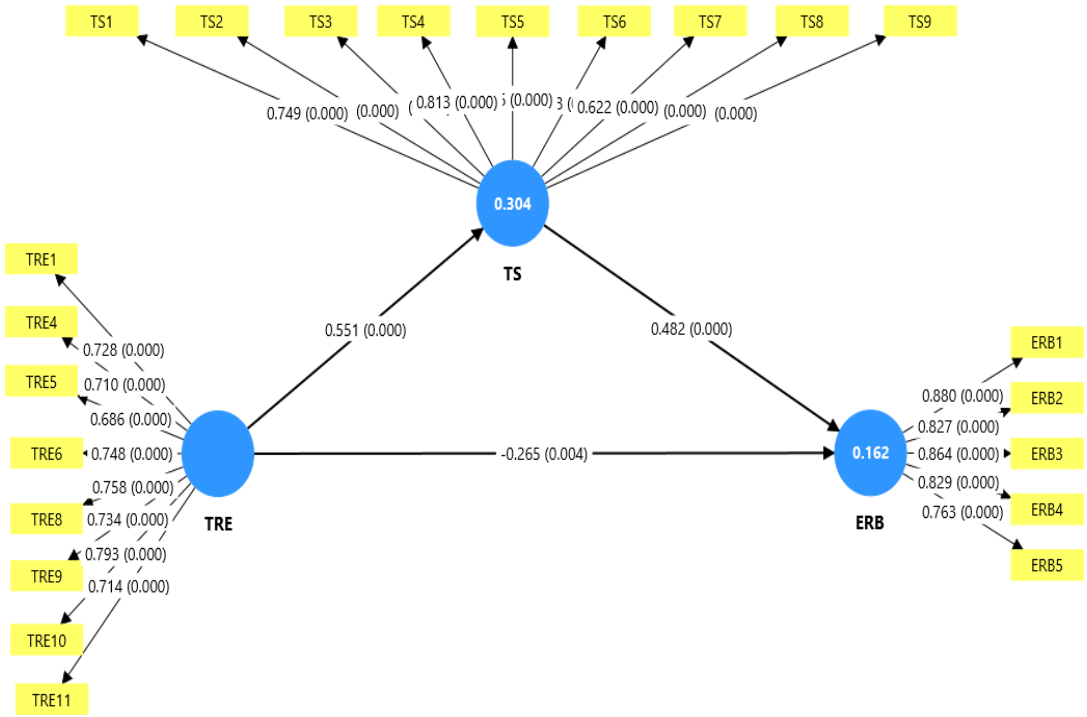

Figure 5. Path model results

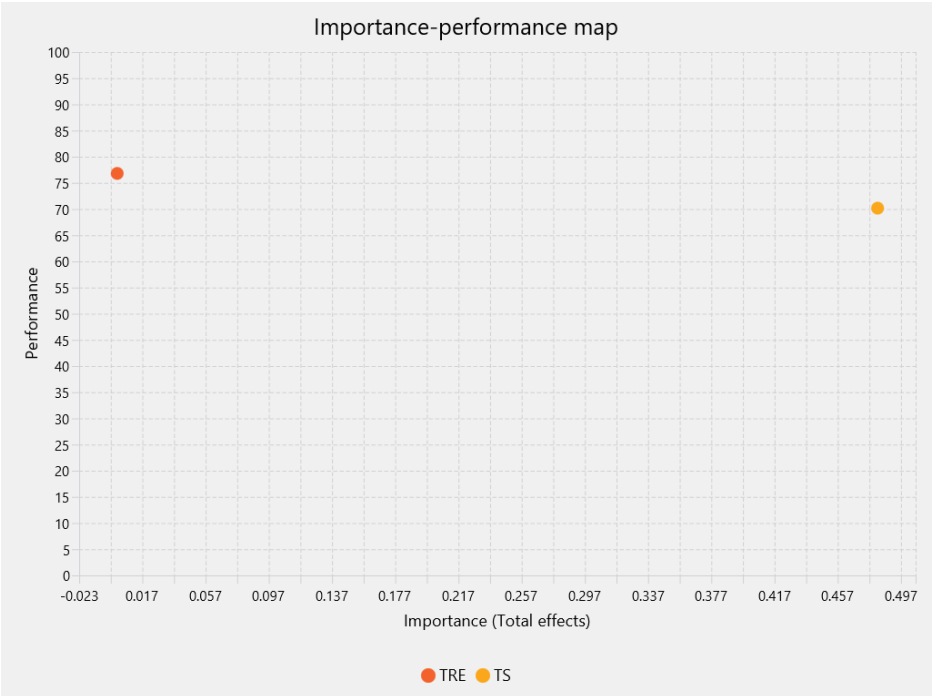

Figure 6. Importance-performance map analysis (IPMA)

DISCUSSION AND CONCLUSIONS

The findings confirm that tourist recreational experience (TRE) significantly contributes to tourist satisfaction (TS), which is consistent with previous research concluding that emotional, cognitive, and sensory experiences shape positive visitor evaluations in nature-based settings (Pine & Gilmore, 1998; Schmitt, 1999; Kim, 2018; Tang et al., 2025).

This finding is consistent with previous research demonstrating that meaningful nature experiences enhance tourists' attitudes and well-being (Ballantyne et al., 2011b; Xu et al., 2018). TS emerges as a major predictor of environmentally responsible behavior (ERB), reinforcing previous research showing satisfied visitors are more likely to appreciate, protect, and behave responsibly in natural settings (Chi & Qu, 2008; Jiang et al., 2022). This supports prior investigations suggesting that satisfaction influences behavioral intentions such as revisits, recommendations, and pro-environmental behaviors (Hultman et al., 2015; Hung et al., 2021).

Another significant theoretical variation is the negative direct effect of TRE on ERB, which puts into doubt the notion that pleasant experiences always encourage stewardship (Lee & Jan, 2015a; Ramkissoon et al., 2013). This indicates that higher involvement in recreational activities could reduce environmentally responsible behavior. This implies that recreational enjoyment alone does not convert into responsible behavior unless mediated by satisfaction or equivalent evaluative systems. This complexity contrasts with research that place experience as a direct antecedent of ERB (Lin & Lee, 2019; Xu et al., 2018), emphasizing the potential risks of establishing wetland tourism primarily around hedonic experiences. Overall, the data support the mediation function of satisfaction (Baloglu et al., 2004; Lee, 2009), which implies that TRE only contributes to ERB when visitors have positive appraisals of their experience. This highlights the importance for wetland managers to incorporate interpretative and conservation-oriented elements into recreational programs to guarantee that satisfying experiences foster responsible behavior rather than passive enjoyment.

Managerial, Theoretical Implications and Limitations

Our findings present an important challenge for managing wetland. The recreational experience itself does not directly initiative the environmentally responsible behavior. Hence, the development of recreational experiences must be planned carefully that not only entertainment is offered but also satisfaction levels are increased, and environmentally responsible behaviour values are promoted. Through enhancing satisfaction using interpretive programs, nature storytelling, or green infrastructure, tourism managers can enhance the likelihood that tourists translate their positive experience into environmentally friendly behaviour. It is recommended to cooperate with local community on the conservation program. As well as, collaboration with tourism operators, teachers, and social media influencers can also be a critical factor in raising awareness and creating a positive destination image.

The SOR theory illustrates its relevance to eco-tourism behaviour, particularly by indicating how satisfaction acts as a mediator of recreational experiences and environmentally friendly behaviour.

This research provides evidence of its applicability in explaining pro-environmental behavioural norms in natural tourism contexts. It adds to eco-tourism literature by conceptualising satisfaction as an important psychological process by which stimuli (experience) affect responsible responses, hence deepening the knowledge of sustainable tourist behaviour. This shows that satisfaction is not only a behavioural antecedent but also a psychological process that transforms recreational pleasure into significant, conservation-oriented actions.

This theoretical advancement enhances the understanding of sustainable tourists' behaviour in wetlands.

Though this research has yielded some useful findings, it does have a number of limitations, which are noted. In the first place, the study was undertaken in one wetland (Ramsar Site), Pong Wetland, within Himachal Pradesh, India. This could restrict the applicability of the findings to other natural environments. Secondly, the study utilised a cross-sectional survey design, where tourists' answers are captured at one point in time, and a quantitative method.

Thirdly, the study's main concern was tourists' recreational experience (Stimulus), impact satisfaction (Organism), and environmentally responsible behaviour (Response). Although this follows the SOR theory, future research can utilise destination image or environmental education (Stimulus), affect place attachment, or ecological concern (Organism), and reconsider intentions or word of mouth (Response). Lastly, this research did not apply any moderating variables.

Citation: Abuelhassan, A.E. (2026). Unboxing the antecedents of hotels employee proactive pro-environmental behavior. *Geojournal of Tourism and Geosites*, 67(3), 1877–1886. https://doi.org/10.30892/gtg.67304-1816

Abstract: This study focuses on employee proactive pro-environmental behavior (EPPB) rather than task-related pro-environmental behaviors. EPPB encompasses actions that promote sustainability and environmentally friendly practices beyond job tasks. Such behaviors reflect a proactive approach to environmental stewardship. This study applies social identity theory to examine the new combined effects of green organizational identity (GOI) and corporate social responsibility (CSR) on employee environmental concerns (EECs) and EPPB within the hospitality industry. It also examines the extent to which environmentally specific servant leadership (ESSL) moderates the indirect effects of CSR and GOI on EPPB through EECs. A sample of 406 supervisor-subordinate dyads from 7 five-star and 8 four-star hotels was collected using a two-wave data collection procedure. AMOS analyses indicate that ESSL moderates the indirect effects of CSR and GOI on EPPB through EECs. The study extends the existing literature that examined the effects of CSR and GOI on employee pro-environmental behaviors individually. This study explores the intricate relationships between CSR and GOI and their combined effects on proactive environmental behaviors. In addition, the study provides a novel, more integrated perspective on the roles of CSR and GOI in influencing ECs. As such, the findings of this study contribute to our understanding of the complex relationships and mechanisms involved in the CSR and GOI effects on ECs and EPPB. Finally, this study offers novel practical insights for the service industry, which poses significant environmental risks due to its operations.

Keywords: corporate social responsibility, green organizational identity, environmental concerns, proactive pro-environmental behavior, environmentally specific servant leadership

* * * * * *

INTRODUCTION

In the hotel industry, proactive behaviors of employees are a critical source of competitive advantage for success and sustainability (Abuelhassan et al., 2024; Ndlovu et al., 2026). Most organizations in the hospitality industry adhere to the standards of environmental sustainability that are established on the basis of strict regulations (Durrah et al., 2026; Ferdos et al., 2026; Khreis et al., 2025b). Based on the pro-environmental behavior literature, there are two main types of pro-environmental behaviors: task-related and proactive (Karatepe et al., 2021).

This study focuses on examining employee proactive pro-environmental behavior (EPPB) instead of task-related behaviors. Task-related behaviors at work are actions directly associated with fulfilling job requirements (Darvishmotevali & Altinay, 2022; Karatepe et al., 2021). On the other hand, EPPB at work involves employees' proactive measures taken to foster environmental practices beyond their job responsibilities (Bissing-Olson et al., 2013; Durrah et al., 2026). EPPB at work takes pro-environmental actions to a higher level. They involve self-initiated efforts to identify and implement innovative solutions for environmental challenges, actively seeking opportunities to improve sustainability practices beyond what is expected in one's job role. Such behaviors demonstrate a proactive and forward-thinking approach toward environmental stewardship (Bissing-Olson et al., 2013). EPPB refers to the voluntary efforts made by employees to engage in environmentally sustainable behaviors beyond their usual environmental work tasks (Bissing-Olson et al., 2013).

EPPB involves employees taking an active and self-starting approach to their environmentally friendly work practices (Bissing-Olson et al., 2013; Durrah et al., 2026). Engaging in proactive pro-environmental behaviors might involve offering valuable suggestions for the environment, pinpointing environmental issues, creating inventive solutions for environmental challenges, and tackling barriers to enhance current environmental processes (Bissing-Olson et al., 2013; Durrah et al., 2026). Employee pro-environmental behaviors are influenced by various internal factors, such as their values, attitudes, and beliefs, including employee environmental concerns (EECs) (Haldorai et al., 2023). EECs refer to employees' awareness, attitudes, and beliefs regarding environmental issues and the importance of taking proactive measures to address them (Haldorai et al., 2023). Additionally, external situational factors also play a role, such as interpersonal interactions with

leaders, for example, environmentally specific servant leadership (ESSL) (Xu et al., 2022), and organizational factors such as corporate social responsibility (CSR) and green organizational identity (GOI) (Shiri & Jafari-Sadeghi, 2023).

The social identity theory (Tajfel et al., 1979) offers valuable insights into how hotels adopting CSR and cultivating GOI can influence EECs, ultimately leading to pro-environmental behavior (Raza et al., 2021). When hotels prioritize CSR and GOI, they create a distinctive social group that employees can identify with, fostering a shared commitment to environmental behaviors. This sense of group affiliation enhances employees' sense of belonging and strengthens their pro-environmental awareness by highlighting the importance of pro-environmental preservation. ESSL, characterized by leaders prioritizing the environment's well-being, plays a crucial moderating role (Xu et al., 2022).

Such leaders inspire and empower employees to adopt pro-environmental values and behaviors, reinforcing the alignment between the organization's sustainability goals, such as CSR and GOI, and employees' environmental motivations, like EECs. By recognizing the interplay between the social identity perspective, CSR, GOI, and ESSL, hotels can effectively cultivate a culture of environmental responsibility (EECs) and harness the collective power of employees to drive meaningful change toward a more sustainable future by EPPB (Fatnassi et al., 2026; Khreis et al., 2025a; Ndlovu et al., 2026). ESSL has been widely acknowledged as a significant factor in shaping employees' pro-environmental behaviors (Badar et al., 2016). However, scarce research has ventured into testing the moderating role of ESSL (Darvishmotevali & Altinay, 2022), the CSR-EPPB relationship, and the GOI-EPPB relationship via EECs.

The study model (Figure 1) aims to address this gap in the scholarly landscape, further advancing the understanding of CSR, GOI, ECs, EPPB, and ESSL. Finally, the implications of the findings extend beyond academia, as they hold substantial relevance for the hospitality industry, providing valuable insights for practitioners and managers in fostering sustainable practices (Durrah et al., 2026; Fathy et al., 2025; Khreis et al., 2025).

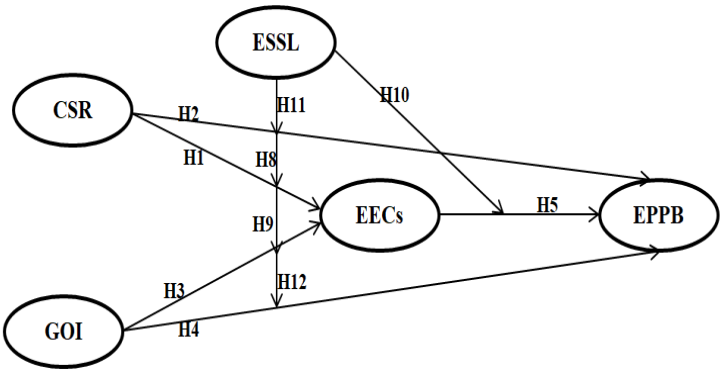

Figure 1. The Research Model

LITERATURE REVIEW

The Relationship between CSR, EEC, and EPPB

Drawing on the social identity theory (Tajfel et al., 1979), an organization actively engages in CSR practices showing its interest to prioritize environmental sustainability. it sends a clear message to employees that the organization values and prioritizes environmental responsibility (Shiri & Jafari-Sadeghi, 2023). CSR initiatives often involve raising awareness about environmental issues like climate change, pollution, and resource conservation (AlSuwaidi et al., 2021). By providing information and education, companies can help employees better understand these concerns and their environmental impact (AlSuwaidi et al., 2021; Su & Swanson, 2019). Organizations committed to CSR are likelier to engage employees in environmental sustainability activities such as organizing volunteer environmental programs, sustainability initiatives, or environmental campaigns (Cheema et al., 2020; Shiri & Jafari-Sadeghi, 2023). Active employee environmental involvement fosters a sense of ownership and empowerment, making them more invested in environmental concerns (AlSuwaidi et al., 2021; Su & Swanson, 2019).

H1: CSR positively impacts employees' EECs.

The second hypothesis suggests that CSR may positively affect EPPB. According to the social identity theory (Tajfel et al., 1979), when an organization shows dedication to CSR, especially in terms of environmental sustainability, it communicates to its employees the critical nature of environmental responsibility (Rhou & Singal, 2020). CSR initiatives in environmental practices can raise employees' awareness about environmental issues and their impacts (AlSuwaidi et al., 2021; Rhou & Singal, 2020). By actively engaging in CSR programs, employees become more informed about the importance of environmental behavior (Cheema et al., 2020; Su & Swanson, 2019). When an organization places a high emphasis on CSR, it establishes a normative benchmark for its workforce. Employees may experience societal pressure to conform their conduct to the organization’s values and participate in green practices (AlSuwaidi et al., 2021; Cheema et al., 2020).

Based on the social identity theory, when employees perceive their company as socially responsible, they are more likely to feel a sense of pride and loyalty (Shiri & Jafari-Sadeghi, 2023), which can translate into greater motivation to engage in pro-environmental behaviors (AlSuwaidi et al., 2021). When organizations implement CSR practices regarding environmental responsibility and encourage employees to participate, they provide role models for employees to follow (Cheema et al., 2020; Rhou & Singal, 2020). Employees may be inspired by their organization's actions and emulate them in their behaviors, including pro-environmental activities (Song et al., 2019). Finally, CSR environmental initiatives often

involve providing employees with environmental resources, training, and support to engage in pro-environmental behaviors (Rhou & Singal, 2020). Employees with the necessary environmental tools and knowledge are likelier to take proactive steps toward environmental sustainability (AlSuwaidi et al., 2021). Literature evidence supports that perceived CSR motivates employees to engage in green innovation. These behaviors encompass activities such as generating and implementing novel green ideas. Moreover, employees will likely proactively develop and implement ideas to reduce their organization's environmental impact (Shah et al., 2021; Shahzad et al., 2020).

H2: CSR has a positive effect on employee EPPB.

The Relationship between GOI, EEC and EPPB

Developing a comprehensive GOI can significantly enhance employees' awareness of environmental issues, concerns, and behaviors toward the environment (Haldorai et al., 2023). Based on the social identity theory (Tajfel et al., 1979), when an organization is acknowledged for its environmentally responsible practices and values (Song & Yu, 2018), it can impact EECs and EPPB in various ways. A robust GOI aids in aligning employees' values with the company's environmental concerns (Haldorai et al., 2023). Employees who believe their company prioritizes sustainability and environmental responsibility are likelier to have a positive attitude toward environmental concerns and embrace environmental initiatives promoting sustainability (Haldorai et al., 2023). This shared purpose creates a strong sense of community and encourages a culture of environmental responsibility within the organization (Soewarno et al., 2019). Organizations with a green identity tend to provide their employees with resources, training, and information on environmental issues (Peng et al., 2020). This approach increases employees' awareness about environmental concerns, they become better equipped to understand the importance of sustainability (Zhang & Huang, 2019).

H3: GOI has a positive impact on EECs

The social identity theory (Tajfel et al., 1979) posits that when individuals within a workforce align themselves with an organization that embodies an environmentally sustainable identity, it may foster an enhanced sense of pride and intrinsic motivation. They feel proud to be associated with a company that prioritizes environmental responsibility and takes concrete actions to address sustainability challenges (Haldorai et al., 2023). This pride and inspiration can translate into increased engagement and commitment to environmental concerns, leading to proactive participation in green initiatives and a willingness to go the extra mile to contribute to sustainability goals (Soewarno et al., 2019). An organization that emphasizes environmental stewardship can exert a beneficial influence on the attitudes and behaviors of its employees regarding environmental issues (Haldorai et al., 2023). By establishing norms and expectations that promote eco-friendly behavior and by rewarding such behavior, employees are more likely to adopt environmental concerns leading to advocate for environmentally responsible practices (Peng et al., 2020; Soewarno et al., 2019). This can translate into proactive actions to conserve energy, reduce waste, make responsible consumption choices, and promote sustainability both inside and outside the workplace (Song et al., 2019).

H4: GOI has a positive impact on EPPB

The Mediating role of Employee Environmental Concerns

The social identity theory and the existing literature suggest that EECs can positively mediate the CSR-EPPB and GOI-EPPB relationships. The literature sugessts that employees with strong environmental concerns show high attitudes and beliefs about the importance of environmental issues (Cheema et al., 2020; Kim et al., 2016). Thus, they tend to be motivated and engage in green behaviors proactively (Zhang & Huang, 2019). Their environmental concerns are mediated by bridging the relationship between environmental and organizational goals (CSR and GOI) and their proactive actions. Employees who are environmentally concerned are more likely to interpret CSR initiatives and GOI as genuine and meaningful, which increases their motivation to engage in pro-environmental behavior (Haldorai et al., 2023; Shiri & Jafari-Sadeghi, 2023). Employees who are environmentally concerned and perceive their organization as socially responsible are likelier to take proactive steps toward environmental sustainability (Shiri & Jafari-Sadeghi, 2023; Soewarno et al., 2019). Therefore, they can achieve the organizational environental goals by initiating actions such as proactively conserving energy, advocating for sustainable practices, reducing waste, or participating in environmental initiatives inside and outside the workplace (Xu et al., 2022).

H5: EECs have a positive impact on EPPB

H6: EECs positively mediate the relationship between CSR and EPPB.

H7: EECs positively mediate the relationship between GOI and EPPB.

The Moderation Role of Environmentally Specific Servant Leadership

The study suggests that ESSL moderates the effect of CSR and GOI on EECs. Leaders have a crucial impact on the relationship between an organization's environmental initiatives and goals and its employees' environmental awareness, concerns, behaviors, and performance (Luu, 2019; Tuan, 2021). Leaders who exhibit high ESSL create supportive environments that enhance these connections. They provide information, practices, resources and training to support employees in addressing environmental concerns (Aboramadan et al., 2021; Tuan, 2020, 2021). Thus, Leaders with high ESSL are able to strengthen the effect of CSR and GOI on EECs by enhancing their subordinates' awareness of CSR and GOI initiatives and practices (Javed et al., 2024; Zafar et al., 2023). Conversely, leaders with low ESSL diminish the effectiveness of CSR and GOI on EECs on EECs by not supporting environmental practices and initiatives, failing to involve employees in green decision-making, and providing insufficient support, encouragement, and resources

(Aboramadan et al., 2021; Tuan, 2020, 2021). Accordingly, leaders with high ESSL act as potent stimulators, enhancing the effects of CSR and GOI on EECs. Leaders with low ESSL serve as isolators, diminishing the connection between subordinates' environmental concerns and both CSR and GOI initiatives and practices.

H8: ESSL moderates the CSR-EECs relationship

H9: ESSL moderates the GOI-EECs relationship

The literature suggests that ESSL can influence the relationship between EECs and EPPB in multiple ways. Leaders with high ESSL, rather than those with low ESSL, appreciate subordinates' environmental concerns and value their perspectives on environmental issues by providing environmental support and empowerment (Badar et al., 2023). This approach motivates employees with environmental concerns to engage in proactive behaviors (e.g., EPPB) (Abuelhassan et al., 2024). Leaders with high ESSL are role models for proactive environmental behaviors by exhibiting environmentally responsible behaviors. They demonstrate the importance of green interests through their actions and decisions, inspiring their subordinates to follow suit (Aboramadan et al., 2021). Therefore, leaders with high ESSL create a supportive environment that enhances the relationship between EECs and EPPB. They encourage their subordinates to elevate their environmental concerns to be proactive in green behaviors. On the other hand, leaders with low ESSL neglect the importance of providing employees with the necessary resources, tools, and opportunities to engage in pro-environmental behaviors (Aboramadan et al., 2021; Tuan, 2020). They decrease allocating budget and time for green initiatives, promoting training programs, or providing access to environmentally friendly technologies and practices (Badar et al., 2023). Leaders with low ESSL can weaken the relationship between EECs and EPPB. They do this by reducing support and resources and fostering an environment that does not prioritize environmental contributions. As a result, they fail to create a supportive atmosphere that encourages employees to engage in proactive green behaviors when environmental concerns arise. In contrast, leaders with high ESSL can enhance the impact of EECs and EPPB by empowering, inspiring, and supporting employees with environmental concerns, encouraging them to adopt proactive green behaviors. Accordingly,

H10: ESSL moderates the EECs-EPPB relationship

The moderated mediation analytical paradigm suggests that the relationship between an independent variable (such as CSR or GOI) and a mediator (like EECs) can be influenced by a specific moderator (for instance, ESSL in hypotheses H8 and H9). In this context, the indirect relationship linking the independent variable to a dependent variable (such as EPPB) through the mediator is typically affected by the same moderator (Preacher et al., 2007). Additionally, hypothesis H10 posits that ESSL moderates the relationship between EECs and EPPB. Therefore, the following hypotheses are proposed:

H11: ESSL moderates the CSR- EPPB indirect relationship via EECs.

H12: ESSL moderates the GOI- EPPB indirect relationship via EECs.

MATERIAL AND METHODS

Data Collection Process

Five-star and four-star hotels in the KSA were approached for participation in a research study, out of which 7 five-star and 8 four-star hotels agreed to take part in the survey. Once the human resource departments of these hotels were approved, questionnaires were distributed among the employees and their leaders. The respondents were required to answer the questionnaire items and submit them to the designated person in charge. In the study, the author distributed 512 questionnaires to employees and their supervisors. This was done in person, with 224 questionnaires going to five-star hotels and the rest to four-star hotels. At Time 1, the author collected 476 valid employee questionnaires over two weeks. Time 2 (one month after Time 1), distributed 476 questionnaires to the employees who had returned their questionnaires. The author collected 444 valid questionnaires during this phase. Two months after Time 1, the author collected 456 questionnaires from 96 supervisors. The author assigned unique codes to each questionnaire to match the employees' and supervisors' questionnaires. The author obtained 406 sets of questionnaires from both employees and supervisors, which accounts for 79.3% of the original 512 questionnaires distributed.

Measurements and Analysis

The study utilized the Likert scale ratings from the sources of the constructs. The study used Su & Swanson's (2019) five items to measure CSR and rated them on a seven-point Likert scale. Using a five-point Likert-type scale, the study assessed GOI with six items from Mittal & Dhar (2016). The four items of EECs were taken from Kim et al. (2016) using a 7-point scale. For EPPB, the study utilized the three items developed by Karatepe et al. (2021) and rated them on a 5-point scale. For ESSL, the study used the twelve items created by Luu (2020) and rated them on a 5-point scale. To ensure discriminant validity, the study used the square root of the average variance extracted (AVE) values. For evaluating convergent validity, the study utilized factor loadings, composite reliabilities (CR) and AVE. Finally, the author conducted confirmatory factor analysis (CFA) and tested our hypotheses using AMOS 21.

RESULTS

Construct Validity

Table 1 presents the means, standard deviations, and correlations among study constructs. All constructs correlate positively with each other ($p< 0.01$). The study used the AVE values to ensure discriminant validity. Fornell and Larcker suggested that every variable should have an AVE value greater than its correlation values with other variables. Our results, shown in Table 1, indicate that in this study, the square root of the AVE values of each variable was higher than all their correlation coefficient values, proving the study's discriminant validity.

Table 1. Descriptive Analysis, Variance Inflation Factor, Correlation, and Discriminant Validity

Variables		Mean (SD)	Correlation				
			1	2	3	4	5
1	ESSL	3.19 (1.305)	**(0.825)**				
2	CSR	4.65 (1.723)	0.590**	**(0.805)**			
3	GOI	3.93 (1.024)	0.511**	0.387**	**(0.729)**		
4	EECs	4.71 (1.590)	0.793**	0.524**	0.658**	**(0.815)**	
5	EPPB	4.01 (0.872)	0.349**	0.306**	0.341**	0.468**	**(0.865)**

Notes: N = 406, p<0.01= **

To assess the study's convergent validity, the study analyzed the loadings of the items belonging to the five constructs (Table 2). The loadings were all significant ($p < 0.01$) and higher than 0.50. The lowest loading was for GOI2, with a value of 0.708, while the highest was for EPPB1, with a value of 0.906. The finding found that all five constructs had CR values of over 0.60, with the highest value of 0.962 for ESSL and the lowest value of 0.872 for GOI.

The high significant factor loadings and CR values indicated that the five constructs had no convergent validity issues. Additionally, all of the study's constructs had AVE values exceeding 0.50, further demonstrating convergent validity (Hair et al., 2010). Finally, the CFA findings using AMOS showed a good fit ($\chi 2$ [pdf] = 476.451 [395], $\chi 2$/pdf =1.206, CFI = 0.991, RMSEA= 0.023, AGFI= 0.916, GFI = 0.929, NFI = 0.949), which confirmed the construct validity.

Table 2. The Convergent Validity and Loadings

Variables and Items	AVE	CR	Loadings
Environmentally Specific Servant Leadership	**0.681**	**0.962**	
ESSL1			0.805**
ESSL2			0.830**
ESSL3			0.814**

Employee Proactive Pro-Environmental Behavior	**0.747**	**0.899**	
EPPB1			0.906**
EPPB2			0.812**
EPPB3			0.873**
Notes: ** =P<0.01			

Two tests were conducted to check for any potential common method bias (CMB) in the proposed model. Firstly, we performed a one-way analysis of variance (ANOVA) to investigate the CMB of the supervisor survey. The result of the ANOVA was insignificant (F = 1.274, p = 0. 061), suggesting that supervisors rated their subordinates' EPPB independently. The author conducted Harman's single-factor test to test the CMB of the employee survey. The analysis revealed no CMB problem in the study, as the most significant variance explained for all constructs' items was 47 %, less than 50% (Podsakoff et al., 2003). Therefore, we concluded that no CMB issue was present in the study.

Hypotheses Testing

The findings presented in Table 3, Step 1, indicate that CSR significantly influences EECs (β = 0.306, p < 0.01) and EPPB (β=0.200, p < 0.01), thereby supporting H1 and H2, respectively. Based on the findings of H3 and H4, GOI positively impacts both EECs and EPPB. The results presented in Table 3 (Step 1) show that GOI significantly affects EECs (β = 0.471, p < 0.01) and EPPB (β = 0.236, p < 0.01), providing support for H3 and H4, respectively. The findings presented in Table 3 (Step 2) demonstrate that EECs significantly influence EPPB (β =0.326, p < 0.01). Therefore, H5 is supported. The results of the analysis, shown in Step 2 of Table 3, indicated a positive indirect effect of CSR (β = 0.100, p < 0.01) and GOI (β = 0.153, p < 0.01) on EPPB through EECs. Therefore, the findings fully supported both H6 and H7.

Table 3. The Results of Hypotheses

Variables	Environmental Concerns				Proactive Pro-Environmental Behavior							
	Direct Effect				Direct Effect				Indirect Effect			
	β	SE	Bootstrapping		β	SE	Bootstrapping		β	SE	Bootstrapping

Notes: Corporate social responsibility = CSR, green organizational identity = GOI, environmentally specific servant leadership = ESSL, employee environmental concerns = EECs, employee proactive pro-environmental behaviour = EPPB, *= p<0.05, ** = p<0.01, N = 406

The finding revealed that the ESSL-CSR interaction (β = 0.137, p < 0.01; Figure 2), ESSL-GOI interaction (β = 0.316, p < 0.01; Figure 3), and ESSL-EECs interaction (β = 0.327, p < 0.01; Figure 4) are significantly positive, supporting H8, H9, and H10 respectively. The findings show that ESSL significantly moderated the indirect association between CSR and EPPB through EECs (H11, β = 0.095, p < 0.01), as well as the indirect relationship between GOI and EPPB via EECs (H12, β = 0.146, p < 0.01).

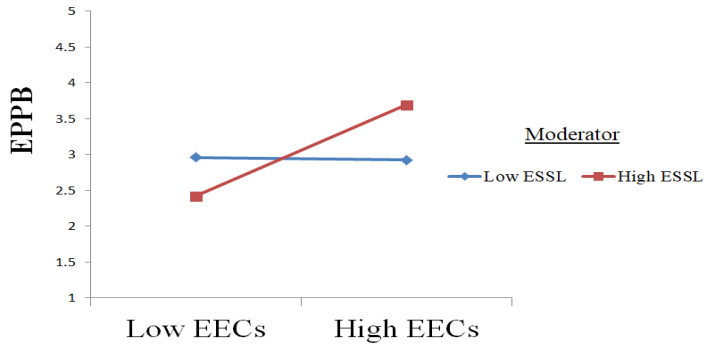

Figure 4. ESSL Moderates EECs-EPPB Relationship

DISCUSSION

Theoretical Contributions

The findings highlighted several novel theoretical contributions within the context of CSR, GOI, ECs, ESSL, and EPPB. First, the study asserts its pioneering contribution in unraveling the intricate dynamics of CSR and GOI, particularly in their influence on ECs and EPPB (Fatnassi et al., 2026; Ferdos et al., 2026; Khreis et al., 2025c). The study goes beyond previous research (Shiri & Jafari-Sadeghi, 2023; Zafar et al., 2023) that investigated the individual impacts of CSR and GOI on employee pro-environmental behaviors. This study delves deeper into the complex relationships between CSR and GOI and their joint effects on proactive environmental behaviors. Also, it offers a novel and more comprehensive understanding of how CSR and GOI shape ECs. Therefore, these findings enhance our knowledge of the intricate interactions and mechanisms underlying the effects of CSR and GOI on ECs and EPPB, providing valuable insights into the dynamics of sustainable behavior within organizations (Bissing-Olson et al., 2013; Durrah et al., 2026).

Second, the study fills a critical void in the literature by examining the mechanisms through which CSR and GOI impact EPPB via EECs. It advances our understanding of the underlying processes that explain how organizational factors (e.g., CSR and GOI; Nourafkan et al., 2024; Pham et al., 2023) influence EPPB (Bissing-Olson et al., 2013; Durrah et al., 2026). This theoretical contribution provides valuable insights into the pathways through which CSR and GOI translate into tangible environmental outcomes (Nourafkan et al., 2024; Shiri & Jafari-Sadeghi, 2023; Song et al., 2019), highlighting the

importance of fostering EECs as a mediating mechanism (Darvishmotevali & Altinay, 2022). Also, it provides further support for the tenets of the social identity theory (Tajfel et al., 1979) through the mediating role of ECCs in CSR and GOI's effects on pro-environmental behaviors. Previous research has focused on examining the relationship between CSR and task-related pro-environmental behaviors, mainly through the mediating mechanism of personal environmental norms (AlSuwaidi et al., 2021). Third, this study recognizes the importance of ESSL in influencing employees' pro-environmental behaviors. While previous research (Aboramadan et al., 2021; Javed et al., 2024) has highlighted its significance, no studies have examined its moderating role in the relationships between CSR and GOI with EPPB through EECs. The study applies social learning theory to explain how ESSL can moderate the relationship between pro-environmental organizational factors (CSR and GOI) and employees' pro-environmental tendencies and attitudes (EECs). It also found that ESSL, in collaboration with CSR and GOI, interacts with employees' EECs to encourage proactive engagement in pro-environmental behaviors. This research supports recent findings in the hospitality industry on the potential impact of ESSL in promoting environmentally responsible behaviors (Darvishmotevali & Altinay, 2022; Javed et al., 2024).

Finally, our study contributes to the literature on proactive employee behaviors (Abuelhassan & AlGassim, 2022) by providing empirical evidence for the flourishing of EPPB in the hospitality industry. We examine and evaluate the role of green-oriented organizations in promoting proactive individuals' green behaviors.

We also depict the roles of organizations and leaders in shaping employees' EECs to promote EPPB. Our research findings advance our understanding of the importance of all members of an organization, including policy-makers, leaders, and employees, in boosting EPPB by revealing causal relationships between them.

Managerial Contributions

The practical contributions of this research are relevant to organizations, experts, and policy-makers in the hospitality industry. First, the study recommends that policy-makers implement laws and regulations to promote and support environmental initiatives, including impact assessments and waste management systems, in the hospitality industries. Specifically, these could consist of technological standards for emissions and discharges and technological-specific standards for water, electrical, and thermal energy consumption. The study asserts that large industries' responsibility regarding environmental sustainability is more crucial than individuals' responsibility. In other words, at the management level, green strategies and practices could significantly impact the creation of a genuinely sustainable effort.

Promoting CSR and GOI through green consumerism and eco-friendly products will foster individual responsibility and encourage more efforts in environmental protection. For CSR, hospitality management should prioritize eco-friendly operations, community engagement, and ethical sourcing to enhance EECs and encourage EPPB. On the other hand, for GOI, hospitality management should focus on integrating sustainable practices, promoting environmental values within the organizational culture, and emphasizing sustainability in day-to-day operations to develop a strong GOI. This can create a sense of environmental concern among employees and motivate them to engage in environmentally proactive behaviors.

Second, the study highlights that EECs positively impact EPPB and act as a mediator between CSR and EPPB as well as between GOI and EPPB. Therefore, hospitality management needs to recognize the significance of EECs as a pathway through which CSR and GOI can influence EPPB. Organizations can enhance the impact of CSR and GOI initiatives on EPPB by strengthening EECs. For instance, hospitality management can implement strategies such as raising awareness, educating on environmental issues, offering training programs, organizing workshops, and sharing information on sustainable practices. These efforts can help employees develop a deeper understanding of environmental concerns and encourage them to adopt proactive pro-environmental behaviors. Also, we suggest that hotels integrate environmental concerns and values into employee selection, recruitment, performance evaluation, and motivation processes.

To promote pro-environmental behavior, employee recruitment and selection standards and job descriptions should emphasize the significance of environmental concerns and values. Intrinsic and extrinsic rewards can be essential tools to promote and incentivize employees' environmental concerns and values.

Finally, the research findings indicate that ESSL moderates the indirect relationships between CSR and PPB via EECs, and GOI and PPB via EECs. Therefore, hospitality management must recognize the importance of ESSL in shaping the relationships between organizational factors, EECs, and EPPB. Supporting and empowering ESSL can enhance the impact of CSR and GOI on employees' EECs and EPPB. Hospitality management should prioritize the development of ESSL skills among leaders in the hospitality industry. ESSL involves demonstrating environmental consciousness, providing support and resources for sustainable practices, and setting an example for employees.

By promoting ESSL, hospitality management can foster a culture of sustainability and encourage employees to engage in EPPB. For instance, hotels may prefer to promote employees with the same vision and values regarding environmental protection during the promotion process. By using promotion criteria, organizations can communicate the importance of environmental protection to prospective leaders, encouraging ESSL development.

CONCLUSION

Collectively, the findings support the notion that CSR, GOI, and EECs all play important, albeit complementary, roles in facilitating proactive pro-environmental behaviors in hospitality employees. By simultaneously rather than separately investigating CSR and GOI, this research offers a more complete understanding of how organizational values and identity impact individual-level green behaviors. The results also help to clarify the complex relationships between the dynamics of CSR and GOI that promote EECs, which in turn promote EPPB. Hence, the present study contributes to a more nuanced understanding of proactive environmental behavior in service contexts.

The results also underscore the importance of ESSL as a moderator variable that mediates the relationships between CSR, GOI, EECs, and EPPB. Environmentally focused leaders, in concert with green-oriented organizational practices, help foster powerful environmental cognitions, which, in turn, motivate hospitality employees to go beyond their prescribed job responsibilities and participate in voluntary pro-environmental behaviors.

Abstract: This study aims to evaluate the usability of a personalized Augmented Reality (AR) application in a museum tourism context and to examine how such digital tools support Generation Z (Gen Z) visitors' interaction with cultural exhibits. Specifically, it seeks to assess whether personalized AR can deliver consistent and positive user experiences across different visitor groups. A personalized museum AR application, "Explore Muse", was developed and implemented in a museum setting. Usability evaluation was conducted using the System Usability Scale (SUS) with 52 Gen Z participants. Descriptive statistics, reliability analysis, and factorial ANOVA were employed to examine overall usability performance and the influence of demographic variables. The findings indicate that the personalized AR application demonstrates a good level of perceived usability among Gen Z visitors. Reliability analysis confirms the internal consistency of the usability measurement, supporting the robustness of the evaluation results. Further analysis reveals no significant differences in usability perceptions across demographic characteristics or prior AR experience, suggesting that the system delivers a stable and consistent user experience for diverse visitor groups. These results underscore the effectiveness of personalization in supporting inclusive and engaging digital interactions within museum tourism contexts. From a tourism and heritage management perspective, the findings provide empirical evidence supporting the integration of personalized AR technologies to enhance visitor engagement and experience quality in cultural tourism settings.

Keywords: Augmented Reality, museum tourism, visitor experience, usability evaluation, personalization, Generation Z

INTRODUCTION

Museums play a central role in cultural tourism by functioning not only as repositories of heritage but also as key destinations for learning, interpretation, and experiential consumption. As important nodes of cultural communication and knowledge dissemination, museums are rich in historical content; however, traditional display media often struggle to meet the evolving experiential expectations of contemporary museum visitors (King et al., 2025). In response to broader shifts in smart tourism and visitor behavior, museums have increasingly turned to digital technologies to enhance cultural communication and enrich the quality of the visitor experience. Among these technologies, Augmented Reality (AR) has emerged as a prominent innovation in museum tourism and digital heritage interpretation (Cipparrone et al., 2025). AR technologies enable the overlay of digital content onto physical spaces, allowing museums to design interactive and immersive environments that transform visitors from passive observers into active participants (Hatami & Rashidi, 2025). Beyond improving access to cultural assets, AR facilitates digital reconstruction, simulated historical settings, and immersive storytelling, thereby strengthening interactive communication between museums and visitors (Kefi et al., 2024; Shu, 2025). As museums increasingly compete within the cultural tourism market, AR technologies are becoming strategic tools for improving visitor satisfaction, engagement, and overall experience quality.

Within diverse museum visitor groups, the Generation Z (Gen Z) who are born between the mid-1990s and early 2010s, exhibits obvious technological behavior and a high level of digital engagement expectations (Benítez-Márquez et al., 2022). As digital natives, Gen Z museum visitors value interactivity, personalization, and ease of use in technology-mediated experiences, and they tend to evaluate cultural offerings through both experiential and functional lenses (Chang & Chang, 2023; Peter et al., 2025). This specific profile gives both chances and difficulties to the museums that want to implement new technologies because they should go beyond being able to engage with visitors at a personal level, and need to ensure usability and visitor's long-term cultural engagement. In the context of smart tourism, these

considerations are particularly critical in museum tourism settings, where visitor satisfaction and experience quality directly influence revisit intention and cultural value creation (Li et al., 2024; Pimentel et al., 2025).

Despite the growing body of research on AR applications in museums, empirical evidence examining how personalized AR applications support visitor engagement and experience remains limited. Existing studies have largely focused on technical development or conceptual discussions of AR's advantages, offering comparatively fewer insights into systematic approaches for evaluating design effectiveness and usability from a visitor-centered perspective (Dargan et al., 2023; Li et al., 2025). Moreover, while the System Usability Scale (SUS) is a well-established and widely validated instrument within Human-Computer Interaction (HCI) research, its systematic application in evaluating AR-based interpretive tools in museum tourism contexts remains underexplored (Genc et al., 2023; Graser et al., 2024). This gap highlights the need for empirical studies that bridge technological evaluation with museum tourism research.

In this context, the present study develops a personalized museum AR application, "Explore Muse", and evaluates its usability among Gen Z museum visitors, a key group within contemporary cultural tourism. By employing the SUS as a standardized assessment tool and examining the influence of demographic factors, the study aims to generate empirical insights into visitor interaction with personalized AR technologies and to assess the applicability of usability evaluation methods in museum tourism environments. Accordingly, the study addresses the following research questions (RQ):

- RQ1: How do Gen Z museum visitors perceive the overall usability of a personalized AR application in a museum tourism context?
- RQ2: To what extent does the SUS serve as an effective instrument for evaluating usability in interactive AR-based tourism settings?
- RQ3: Do usability evaluations differ significantly across visitor demographic characteristics?

Beyond addressing methodological gaps, this study contributes to museum tourism literature by providing empirical evidence on the usability of personalized AR applications and by enhancing understanding of how Gen Z visitors engage with digitally mediated cultural experiences. By combining standardized usability evaluation with demographic analysis, the study offers a replicable framework for assessing personalization digital tools in cultural tourism contexts (Mahajan & Taggar, 2025). From a practical perspective, the findings aim to inform museum managers and designers in developing AR experiences that are not only technologically functional but also meaningful, inclusive, and aligned with contemporary museum tourism strategies (Zhang et al., 2024).

LITERATURE REVIEW

AR Development in Museum Tourism

AR enables more interactive and immersive experiences because it provides viewers with superimposition of the virtual world on the real one (Arena et al., 2022). Nowadays, AR has found extensive application in the museum tourism to assist in preserving cultural heritage sustainably and communicating through the effective representation of cultural heritage (Logan, 2025) The more recent projects on AR use in museum tourism have touched upon its application in exhibits and interactive screens and cultural communications by use of various technologies that optimize the experience of the visitors (Hsieh et al., 2025; Khor & Mubin, 2024). These attempts are useful practical examples of the digital communication of museums and reflect the great potential of AR in the cultural interaction and engagement.

An example of this is (Ahmed et al., 2025) designed and planned a mobile application called MUSEON referring to the ontological theory of gamification learning, and tested the perception of 86 discriminatory visitors about the effectiveness of the MUSEON based on a 3-tiered evaluation model (M3). Gozali et al., 2024 developed a mobile application using Immersal software development kit (SDK), which helps users to use the surroundings of the Bandung Geological Museum. (Xu et al., 2024) presented two physical AR prototypes, which are meant to be used in the display of cultural objects, named Postcard AR and CubeMuseum AR, and conducted three user tests that helped to optimize the overall design quality. Another paper by (Jung et al., 2020) showed a VR/AR-powered visualization platform called JejuView that is intended to provide the visitors with an immersive and intuitive experience of the cultural heritage of the Jeju Island.

AR Usability Evaluation

In the ISO 9241-11 framework, the concept of usability is defined as the level of effectiveness, efficiency, and overall contentment with which the assigned users can complete certain tasks through the system (ISO, 1998). Usability testing is a methodology inherent in HCI research, and is mainly preoccupied with the degree to which the users can use and interact with a system (Nielsen, 2010). It points out the need to study real users since they perform real work to identify any problem of usability, determine their level of satisfaction and guide future design evolution (Meyer et al., 2021). The significance of usability testing in the context of AR research is supported by the extensive use of methods of this type over time, which streamlines the user-centered design and enhances the quality of the interaction in general (De Paolis et al., 2023).

In museum tourism settings, usability evaluation is essential in determining the role of AR technologies in helping visitors to engage in the situation, understand information, and experience interaction (Bekele et al., 2018). Standardized usability measurement tools have also been used in the past to assess usability and this includes the following: heuristic evaluation checklists (Nielsen, 1993), the System Usability Scale (Jordan et al., 1996), and the User Experience Questionnaire (UEQ) (Laugwitz et al., 2008). Although these methods have produced meaningful findings into the AR interface performance, most of the studies focus on overall users, ignoring the unique digital behaviors and user expectation of the Gen Z. As a result, the literature regarding the empirical studies of AR usability evaluation in museums is limited to be specific to Gen Z, which is a prime opportunity to be filled via further research.

Generation Z Visitor Engagement Studies

Gen Z visitors have grown up within digital environments, which shapes their expectations for interactivity, immersion, and personalized engagement when encountering cultural content (Onjewu et al., 2025). In response the new expectations, museums have increasingly introduced AR-based storytelling, interactive installations, and visually distinctive spaces designed to encourage social sharing and active participation, particularly among younger visitors (Diez, 2021).

These practices are not merely aesthetic enhancements; rather, they reflect a broader shift in museum tourism toward experience-oriented interpretation, where visitors co-construct meaning through digital interaction rather than passively consuming information (Zhu et al., 2025). Despite this growing adoption of AR-driven experiences, empirical research remains limited in explaining how such technologies shape Gen Z visitors' usability perceptions and subsequent engagement with museum tourism content. Existing studies have tended to emphasize technological affordances or experiential appeal, while paying comparatively less attention to how usability influences interaction quality, learning processes, and sustained cultural involvement among digitally native visitors (Škola et al., 2024).

Addressing this gap is critical for aligning AR innovation with visitor-centered museum tourism strategies. Accordingly, further empirical research is needed to systematically examine the relationship between AR usability, Gen Z visitor responses, and cultural engagement within museum tourism settings (Hwang et al., 2024; Singh & Ahmad, 2024).

MATERIALS AND METHODS

Research Design

This study develops a virtual AR application named "Explore Muse" to create 3D artifacts animation through Unity with C# programming language. The main design idea is to transform traditional museum visits into self-directed journeys, which enables users to explore digital artifacts overlaid on the physical environment through their smartphone cameras.

It is compatible with Android devices which have OS version 7.0 (API Level 24) or above, and includes AR Foundation and Vuforia SDK to enable marker-based tracking, real-time rendering, and touch to AR response (Linowes & Babilinski, 2017). The AR portal is based on a looped workflow consisting of: (1) camera initialization, (2) marker detection, (3) target-image matching, (4) 3D model rendering, and (5) continuous tracking and it repeats itself until the user leaves the session. As illustrated in Figure 1, when any target is identified, the system triggers real time rendering and constant tracking, which means that the virtual objects can be maintained in visual consistency and live responsive as the user renders his device. This AR application aims to provide a fast and dependable user experience by reducing latency and jitter causes by being lightweight on asset management, and dynamically modulating performance. Subsequently, this study adopts a quantitative cross-sectional design to evaluate the usability of the "Explore Muse" among Gen Z visitors at the Yanshi museum in China. The study design is a mixture of structured usability testing with post-experience surveys of SUS, which would be followed by reliability testing and a factorial ANOVA (Barnum, 2021). After the AR app is developed, there is a one-group post-test study where the subjects go through the "Explore Muse", followed by a standardized SUS questionnaire. Based on a previous study that uses the SUS scale, a target population size of 50 will be selected to provide adequate statistical power to perform a descriptive and inductive analysis (Lacoche et al., 2022). The objective of this design aims to collect direct user perceptions of the AR application's usability without the influence of a control group or pre-test bias.

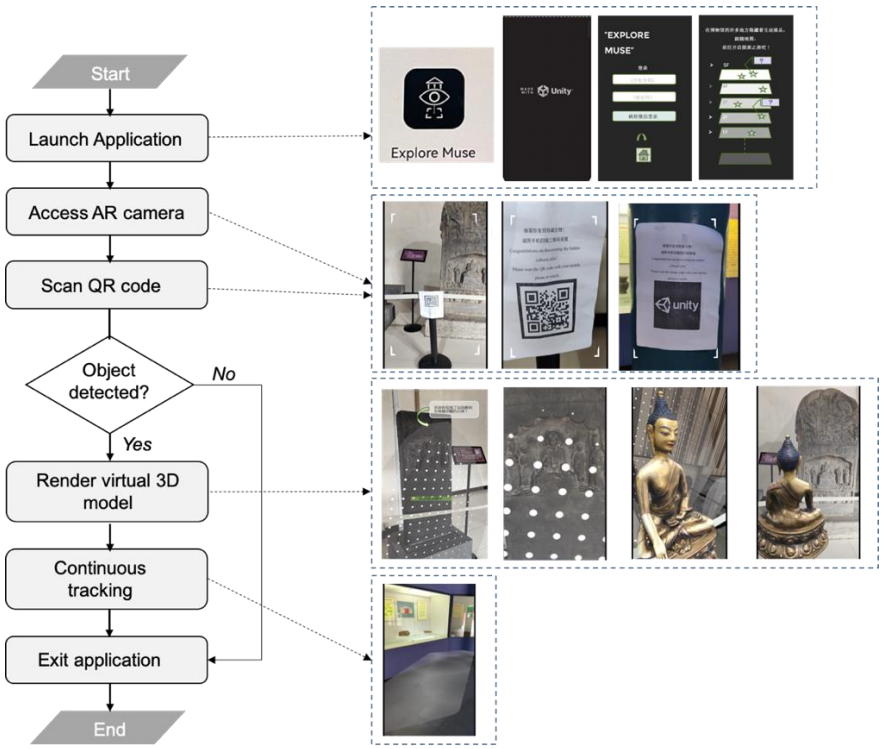

Figure 1. Flow chart of AR portal and usage demonstration (Source: Authors' own work)

Participants

The target participants in this study are members of Gen Z who belong to the cohort born roughly from 1995 to 2010. Participants are randomly recruited from a sampling pool that integrated both online and offline channels, including university forums, social media platforms (e.g., WeChat and QQ), and onsite promotion during visits to the Yanshi Museum in China. The inclusion criteria required participants to be between 15 and 30 years old and have basic proficiency in smartphone usage. Additionally, the sample selection is balanced in terms of gender and educational background to reflect the diversity of Gen Z. Prior experience to AR technology is recorded for reference but is not a requirement for participation. This sampling strategy ensured that participants are representative of typical Gen Z museum visitors, making the results more reliable and meaningful for understanding emerging generation visitors usability perceptions of AR technologies.

Instrument

This study uses the standardized SUS questionnaire as the primary tool for usability testing. The questionnaire is divided into two sections. The first section consists of ten SUS items rated on a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree) (Likert, 1932). Odd-numbered items express positive statements about the AR application, whereas even-numbered items are negatively worded. The second section collects demographic information, including participants' age, gender, education level, and prior experience with AR. These data are used to contextualize the SUS results and to examine whether individual characteristics influence perceived usability. Each response is scored using the conventional SUS calculation method (Brooke, 1996), as shown in following Equation 1.

$$\text{SUS Score} = 2.5 * \{ \sum(5 - P) + \sum(N - 1) \} \quad (1)$$

Where P = positive statement score, N = negative statement score.

In the case of positively expressed statements, the determination of each item score is in the form of subtracting 1 of the rating chosen. The value of negatively phrased statements is determined by subtraction of the selected rating and 5. A sum of item scores divided by 2.5 is used to get the total score and the final value is obtained as the multiplication of the result by 2.5 a final SUS value. The score less than 50 means there is a bad system usability and is usually unacceptable. The values between 50 and 70 will be moderate usability whereas the values over the 70 will be good usability with a higher value indicating greater perceived ease of use (Orfanou et al., 2015).

Data Collection and Analysis

Before the experiment, all eligible participants were provided with an ethical statement and signed consent form to ensure voluntary participation and confidentiality. Participants were then invited to install the "Explore Muse" AR application on their mobile phone. Subsequently, they were encouraged to freely explore the AR content for approximately 10-15 minutes, allowing for a natural and self-directed journey. Upon completing the exploration, participants are invited to completed an online questionnaire via Wen Juanxing, a widely used online survey platform in China. During the session, researchers remained available to assist with technical issues and provide non-intrusive support without influencing participants' responses. After completing the survey, participants were thanked for their contribution, marking the end of the testing session. All collected data are exported to Microsoft Excel for preliminary cleaning, including the removal of incomplete or invalid responses. Four approaches of data analysis are performed: (1) Descriptive statistics. The central tendency (mean) and Standard Deviation (SD) analyses are computed mainly using Statistical Package for the Social Sciences (SPSS) software 31.0. (2) SUS scores are calculated according to standard method, resulting in usability scores ranging from 0 to 100. (3) To assess the internal consistency of SUS items, Cronbach's alpha (Cronbach's α) is computed using Python. (4) A factorial ANOVA is conducted in SPSS software 31.0 to examine whether participants' demographic variables had significant effects on usability score.

All four variables are treated as between-subjects factors, and interaction effects are included in the model. A significance threshold of $p < .05$ is applied for all statistical tests (Lacoche et al., 2022).

Table 1. Demographic information of Gen Z participants (Source: Authors' own work)

Demographic Variable		Number (n)	Percentage (%)
Gender	Male	25	48.08
	Female	27	51.92
Age	15-18 years old	4	7.69
	19-25 years old	24	46.15
	26-30 years old	24	46.15
Education Level	High school education or below	4	7.69
	College or bachelor's degree	25	48.08
	Master's degree	19	36.54
	Doctoral degree	4	7.69
Prior AR experience	Have used	30	57.69
	Not used	22	42.31

RESULTS AND DISCUSSION

Demographic Descriptive Statistics

A total of 60 participants completed the survey, of which 52 valid responses were retained after excluding invalid questionnaires. As shown in Table 1, among the 52 Gen Z participants, 48.08% identified as male (n = 25) and 51.92%

as female (n = 27). The majority were between the ages of 19 and 30. Specifically, 7.69% were aged 15-18 (n = 4), 46.15% were aged 19-25 (n = 24), and another 46.15% were aged 26-30 (n = 24). The average age of all participants was approximately 24.35 years with a standard deviation of 3.66 (SD = 3.66), suggesting a relatively moderate variation in age distribution and indicating a representative sample of Gen Z visitors. Regarding educational level variable, 7.69% had a high school education or below (n = 4), 48.08% hold a college or bachelor's degree (n = 25), 36.54% hold a master's degree (n = 19), and 7.69% hold a doctoral degree (n = 4). In addition, 57.69% participants (n = 30) have used AR applications before, 42.31% participants (n = 22) have not used any AR applications before this survey. The demographic distribution of participants are illustrated in Figure 2. Those demographic characteristics indicate that the sample was diverse in terms of gender, age, education level, and prior AR experience, providing a balanced foundation for subsequent analyses.

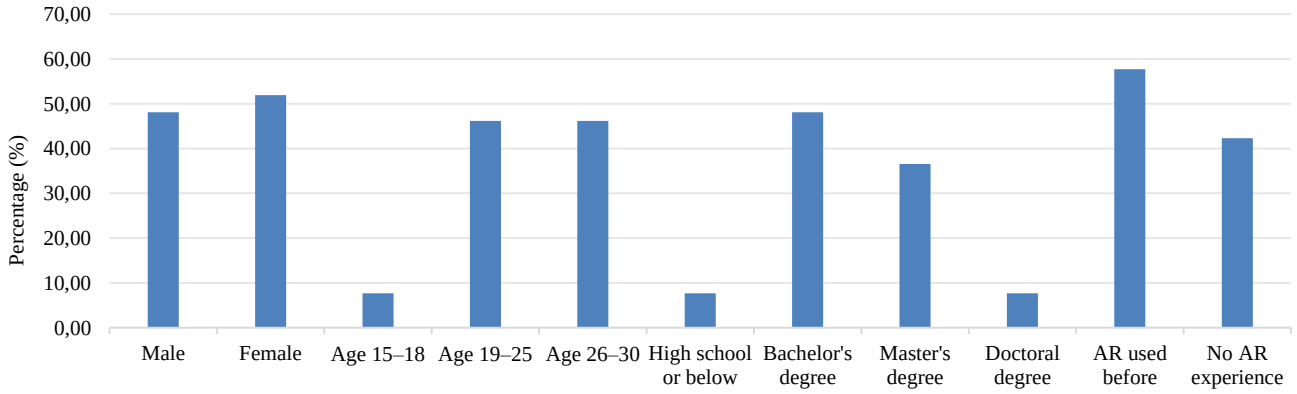

Figure 2. Demographic distribution of 52 participants (Source: Authors' own work)

SUS Score Analysis

As shown in Table 2, The total SUS score reached 3707.5, with an average score of 71.30. According to established SUS interpretation benchmarks, a score above 70 generally indicates acceptable usability and is considered "good" in terms of user experience (Bangor et al., 2008). This suggests that Gen Z participants perceived the application system as usable and functionally coherent. The standard deviation of SUS scores was 10.10, indicating a moderate level of variability in participants responses. While the average usability score suggested a generally positive perception, the distribution of scores reflects a degree of subtle inconsistency among 52 participants. As illustrated in Figure 3, the majority of scores fell between 60 and 80, with a peak around the mean value of 71.30. The distribution closely resembles a normal curve, indicating consistent usability perceptions across overall users. The red dashed line represents the overall mean, suggesting that most users rated the system within the "acceptable" to "good" usability range according to standard SUS interpretation benchmarks.

Table 2. Overall SUS scores analysis (Source: Authors' own work)

Participant Number	SUS Score	Mean	SD	Category
1-5	62.5/67.5/67.5/75/60	66.5	5.76	Acceptable
6-10	55/80/62.5/65/75	67.5	10	Acceptable
11-15	80/55/72.5/62.5/85	71	12.33	Good
16-20	82.5/55/67.5/65/55	65	11.32	Acceptable
21-25	67.5/67.5/75/67.5/55	66.5	7.20	Acceptable
26-30	52.5/55/57.5/60/60	57	3.26	Acceptable
31-35	85/80/82.5/75/82.5	81	3.79	Good
36-40	80/72.5/70/75/72.5	74	3.79	Good
41-45	80/82.5/82.5/80/72.5	79.5	4.11	Good
46-50	82.5/80/80/75/80	79.5	2.74	Good
51-52	87.5/82.5	85	3.54	Excellent
Average Score in Usability Testing		71.30		Good
Standard Deviation		10.10		variability

Table 3. Internal consistency and reliability test result (Source: Authors' own work)

SUS Item	CITC	Cronbach's α if Item Deleted	Cronbach's α	SUS Item	CITC	Cronbach's α if Item Deleted	Cronbach's α
1	0.481	0.718	0.749	6	0.424	0.727	0.749
2	0.694	0.692		7	0.445	0.724	
3	0.144	0.773		8	0.434	0.727	
4	0.396	0.731		9	0.396	0.731	
5	0.422	0.727		10	0.37	0.735	

Internal Consistency and Reliability Test

To assess the internal consistency and reliability of the SUS questionnaire, Cronbach's α was calculated. As shown in Table 3, the resulting reliability coefficient was 0.749, which is above the commonly accepted threshold of 0.7, indicating that the SUS evaluation instrument in this study has acceptable reliability and good internal consistency (DeVellis & Thorpe, 2022). The result supporting its suitability for further data analysis.

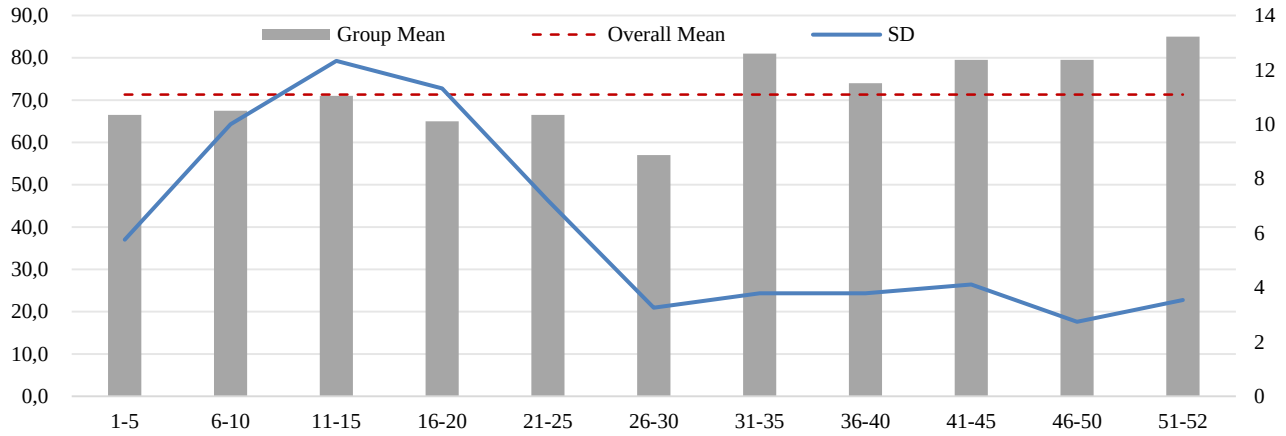

Figure 3. Distribution of SUS score among 52 participants (Source: Authors' own work)

The Corrected Item-Total Correlation (CITC) analysis further supported the reliability of the instrument, with most items showing moderate to strong correlations with the overall SUS score (ranging from 0.37 to 0.69). Among them, Items 2, 5, 6, and 7 exhibited particularly robust correlations (CITC > 0.40), indicating that participants' responses were generally coherent and consistent across different usability dimensions (Nunnally & Bernstein, 2010).

Demographic Variables Factorial ANOVA

A factorial ANOVA was conducted to examine whether gender, age, education, and prior AR experience had significant effects on perceived usability scores, as measured by the SUS scale. The analysis included both main effects and two-way interaction effects among the four demographic variables. As shown in Table 4, the results of the main effects are summarized as follows: (1) Gender, $F(1, 34) = 0.049$, $p = 0.826$; (2) Age, $F(1, 34) = 0.504$, $p = 0.483$; (3) Education, $F(1, 34) = 0.222$, $p = 0.802$; (4) Prior AR experience, $F(1, 34) = 0.125$, $p = 0.726$. Additionally, the model explained approximately 22.0% of the variance in SUS scores, suggesting that demographic attributes such as gender, age, educational level, and prior AR experience contributed marginally to variations in usability perceptions.

Similarly, the interaction terms showed no notable variations across conditions (all $p > 0.05$), indicating that the combined effects among these factors were limited in shaping usability ratings. These results demonstrated that Gen Z participants across different demographic profiles evaluated the AR application in a relatively consistent manner.

DISCUSSION

In response to RQ1, the findings indicate that Gen Z visitors generally perceive the personalized AR application as usable and supportive of their museum visit experience. The average SUS score of the 52 participants was 71.30 that falls within the standard interpretation rule of being considered as "Good" level. Most of the scores were in the range of 60-80 with the highest point in the range of 71.30. The curve is highly similar to a normal curve meaning that the results were consistently done with equal perspectives of usability by the participants. The overall usability evaluation suggests that "Explore Muse" functions as an accessible and intuitive interpretive tool, enabling visitors to engage with cultural content without cognitive or operational barriers. The relatively concentrated distribution of usability perceptions further indicates that visitors shared comparable experiences when interacting with the application, reflecting a stable level of interaction quality across the sample. Consistent with prior museum tourism research, these findings indicate that

usability is closely linked to visitors' sense of involvement and perceived cultural engagement when digital technologies are embedded into exhibition environments (Pentescu, 2023). Regarding RQ2, the results demonstrate that a standardized usability evaluation approach can effectively capture visitor interaction quality in AR-based museum environments. The internal consistency resulted in Cronbach 0.749 level, which showed that the SUS scale is acceptable. Most of the items were found to have moderate to strong correlations with the overall SUS score (all between 0.37 and 0.69), as the values reported by CITC. Echoing previous findings (DeVellis & Thorpe, 2022; Deshmukh & Chalmeta, 2024; Ntoa, 2024), the internal consistency of the usability assessment indicates that visitors responded coherently across different dimensions of system interaction, such as learnability, efficiency, and confidence during use. This consistency suggests that usability perceptions among museum visitors are not fragmented impressions, but rather reflect an integrated evaluation of their overall experience with the digital interpretive tool. From a museum tourism perspective, these findings are particularly relevant because they show that usability evaluation instruments originally developed in HCI research can be meaningfully applied to cultural and tourism settings.

When adapted to interpretive technologies, such tools offer a structured way to assess how visitors experience digital mediation during their visits. This contributes to bridging the methodological gap between technical evaluation and experiential assessment in museum tourism research, where systematic evaluation of digital tools remains relatively limited.

With respect to RQ3, the absence of significant differences in usability perceptions across demographic variables suggests that the personalized AR application delivered a relatively homogeneous experience among Gen Z visitors. Factors such as gender ($F(1, 44) = 0.45$, $p = 0.507$), age ($F(2, 44) = 0.38$, $p = 0.685$), educational level ($F(2, 44) = 0.54$, $p = 0.588$), and prior AR experience ($F(1, 44) = 0.07$, $p = 0.791$) did not substantially influence how visitors evaluated the AR system. This finding implies that personalization within the AR application may have mitigated potential disparities in digital familiarity or prior exposure, resulting in a more inclusive and balanced visitor experience. These results align with earlier studies in immersive digital media and tourism contexts, which similarly reported limited demographic effects on perceived usability and experience quality (Othman et al., 2022; Mohamad Rosman et al., 2023). From a museum tourism management perspective, this suggests that well-designed personalized AR applications can support equitable access to digital interpretation, reducing the risk of excluding certain visitor segments. Such inclusivity is particularly important for museums seeking to engage younger visitors while maintaining broad accessibility and experience consistency.

CONCLUSION

This study examined the usability of a personalized AR application within a museum tourism context, with a specific focus on Gen Z visitors. By developing and empirically evaluating the "Explore Muse" application, the research contributes to a growing body of literature exploring how digital interpretation tools shape visitor experiences in contemporary museums (Almashyakhi, 2022; Trivedi, 2024; Schapsis et al., 2025). The findings indicate that personalized AR applications can deliver consistently positive usability experiences among Gen Z visitors, regardless of demographic characteristics or prior exposure to AR technology. This suggests that usability perceptions within this digitally native generation tend to be relatively homogeneous, highlighting the potential of personalization to support inclusive and accessible digital experiences in museum tourism settings (Tang & Zhou, 2025). Rather than acting as a technical constraint, usability functions as an enabling condition that allows visitors to engage more meaningfully with cultural content. From a methodological perspective, the study demonstrates the applicability of standardized usability evaluation approaches in museum tourism research.

By combining the System Usability Scale with demographic analysis, the research offers a replicable framework for assessing visitor interaction quality with AR-based interpretive tools. This approach extends traditional usability testing into three-dimensional cultural environments and provides empirical grounding for evaluating digital heritage applications beyond purely technical performance (Zhang et al., 2024). The study also carries practical implications for museum managers and designers. The results emphasize that effective AR implementation should prioritize usability and personalization as core design principles, particularly when targeting younger visitor segments. Well-designed AR systems can support engagement without creating digital barriers, thereby enhancing overall visitor experience quality and contributing to sustainable museum tourism development (Mahajan & Taggar, 2025). Despite these contributions, the study is subject to certain limitations. The sample size and focus on a single generational group may limit the generalizability of the findings.

Future research should extend the analysis to broader visitor segments and employ multi-method evaluation approaches, combining standardized usability measures with behavioral or qualitative data to capture more nuanced interaction processes.

Further studies could also examine how advanced AR features (e.g., personalization, gamification, or multimodal interaction) influence visitor engagement and usability, as well as explore longitudinal effects of AR use on learning and sustained cultural interest (Cheng et al., 2025). Such efforts would deepen understanding of how AR technologies can be sustainably integrated into museum tourism and cultural heritage interpretation.

Leveraging ai and user-generated content in sport tourism: How engagement and familiarity drive purchase intent for food brands in emerging markets. *Geojournal of Tourism and Geosites*, 67(3), 1896–1907. https://doi.org/10.30892/gtg.67306-1818

Abstract: This study investigates the complex role of Artificial Intelligence (AI) and User-Generated Content (UGC) in enhancing Online Brand Equity (OBE) within the food industry, focusing on the emerging sport tourism markets of Saudi Arabia and Egypt. It specifically explores how AI-driven digital environments and word-of-mouth reshape brand loyalty among fans and tourists during major global sporting events. Employing a quantitative research design, the study utilizes a primary dataset collected via questionnaires from 606 consumers across both countries. The participants were specifically screened to include consumers who actively follow or participate in sport tourism activities, ensuring the data reflects the intersection of sports travel and food brand consumption. The theoretical model posits Brand Familiarity as a moderating variable and Consumer Engagement as a mediating variable, with data analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM). Results and Discussions: The findings validate that UGC is pivotal in strengthening OBE, with a marginally stronger effect in Egypt compared to Saudi Arabia. Notably, Consumer Engagement mediated the relationship between brand promotion and OBE differently in each country: Saudi consumers favored low-engagement, brand-initiated promotions, while engagement fully mediated the effect in Egypt. In both contexts, Brand Familiarity acted as a psychological anchor, reinforcing trust when fans seek familiar food brands like 'Blabn' or 'Baheeg' during sporting events. This research contributes actionable insights for food industry marketers by providing a robust, comparative model for leveraging UGC in emerging tourism markets. It highlights the necessity of tailoring engagement strategies based on specific cultural preferences and the regional sport tourism calendar. The study proves that while digital tools are global, the psychological path to loyalty varies significantly across borders. Marketers are encouraged to launch UGC-driven campaigns during major events to convert spectator enthusiasm into sustainable brand advocacy.

Keywords: Emerging Tourism Markets, User-Generated Content (UGC), Online Brand Advocacy (OBA), Customer Engagement, Brand Familiarity, Online Brand Equity (OBE)

* * * * * *

INTRODUCTION

User-generated content (UGC) is recognized today as one of the most potent sources that influence and even transform consumers' brand perception, sentiment, and behaviors in online social contexts. For instance, a few studies underlined the significant influence of such content on consumers' buying decisions in the realm of experience-driven industries, especially the food sector, where the power of online reviews, star ratings, and people's sharing their eating experiences is immense in attracting new customers (Wilk, 2020). With the changing face of digital communication, consumers are no longer a passive group getting fed with information by a brand; they even create and share content themselves which not only changes the image of the brand but also affects consumer preferences and the extent of their brand loyalty.

Therefore, by functioning as a medium for expression and freedom of opinion, user-generated content opens the door to individuals going one step further than being consumers and becoming content co-creators (Gandhi & Ubba, 2025). Thus,

TripAdvisor is one of the platforms which promotes this idea by providing a virtual environment where users may display their skills, accumulate social capital, and be part of communities of people who share their interests (Mathew, 2021). In other words, UGC is not only a means to obtain information but also a channel through which people are able to create socially acceptable online identity, therefore, self-presentation turns out to be the main reason for posting content (Scholz et al., 2019).

Besides these changes in behavior, the way we experience digital content has been radically altered, especially in the aftermath of the COVID-19 pandemic. Through the increased closeness of different groups and communities, reliance on online channels was greatly stimulated, particularly, the majority of networks to which content is accessed are through mobile phones (Wilk, 2019). On top of that, this phenomenon is clearly visible in the case of Egypt and Saudi Arabia, the pace of digital adoption is so fast here that it surpasses many other countries. In Egypt, it is estimated that mobile users account for almost 110 million, alongside 96.3 million internet users and close to 50 million social media users. On the hand, Saudi Arabia recorded around 48.1 million mobile subscriptions, 33.9 million internet users, and 34.1 million active social media users (González-Rodríguez et al., 2021). Such statistics not only confirm how digital platforms have become an integral part of people's daily lives but also UGC is the key driver of brand-marketing and communication in both of these markets (Rezaee, 2023). In the specific context of Sport Tourism, this digital adoption plays a crucial role. As Egypt and Saudi Arabia host major global sporting events, tourists rely heavily on UGC to discover food brands that align with their event experiences. This makes the food sector an integral part of the sport tourism ecosystem in these emerging markets.

LITERATURE REVIEW

1. User-Generated Content (UGC)

Social media and digital platforms have revolutionized the interaction of brands with people in Egypt and Saudi Arabia. Egyptian brands mainly use Facebook and Instagram for their interaction with the audience. While in Saudi Arabia, Twitter and Snapchat are the top-most communicative channels. Citizens of both countries are very much inclined towards sharing their experiences on the internet in the form of ratings, recommendations, or reviews, and this has had a significant impact on their perception of brands (Burmann & Zeplin, 2005; Alalwan et al., 2017). One of the main factors which has led to a significant increase in the creation and sharing of user-generated content is the highly interactive environment on social media, throughout which people spread their content, i.e. reviews and comments describing their experiences with specific products or even giving general information about them (Roma & Aloini, 2019).

There coexist many different platforms, each with their separate nature, and the companies are going through various strategies to figure out the best way to utilise this content. This phenomenon can especially be largely seen when the case of discussion is open social media platforms like X, which used to be called Twitter (Rezaee, 2023; Guillen et al., 2025). In the same manner, on closed or semi-closed social media networks, for instance, private Facebook groups or WeChat in China, marketers should concentrate on personal relationships which are formed in these virtual worlds, as stated in the research by (Wijaya et al., 2023). This condition is very significant in Egypt, where consumers are heavily dependent on digital content for their buying decisions. As a result, with social media and review platforms becoming pervasive, brands that are operating in Egypt need to be conscious of this issue and give it their proper attention (Roma & Aloini, 2019). The significance of user-generated content in influencing the views is obvious, and by its nature, it has a major influence on more extreme behaviors, such as being a brand advocate online.

2. Online Brand Advocacy (OBA)

In Egypt, the brand trust that customers have is the main factor that influences how much the customers will support the brand. Also, online word-of-mouth (eWOM) and reviews are the most influential channels for the brand's reputation (Wilk et al., 2019; Hutzinger, 2021). The case in Saudi Arabia is a bit different; there, support is more strongly associated with the brand's prestige and rarity, which, in turn, leads to the creation of a different kind of relationship. In both areas, people are inclined to react positively to authentic and genuine content, particularly when it is their social and cultural values that are being mirrored (Aljarah et al., 2024). According to social exchange theory, the relationship with consumers is created by companies through social interaction, where consumers give to brands good feedback and support in return for a feeling of being valued, emotional satisfaction, or gratitude (Acharya, 2020). The rise in digital communities in Egypt has made online brand endorsement a key factor as Egyptian consumers have become more engaged in discussions, writing reviews, and giving recommendations that help the decision of buying (Wijaya et al., 2023).

3. Customer Engagement (CE)

Basically, customer engagement is the mental condition when a customer mentally, physically, or emotionally interacts with the brand and co-experiences the activities with the brand (Wijaya et al., 2023) Such interaction tremendously influences people's perception of the brand, their trust in it, and hence, their loyalty over time (Liao et al., 2024; Colicev et al., 2019). A few days ago, it was recognized that customer engagement is not only one kind of behavior but rather the combination of actions, thoughts, and feelings of the customer towards the brand (Kim et al., 2012; Kar et al., 2024).

To companies, it is crucial to develop a strong connection with their customers, as this deepens brand loyalty and makes people more likely to interact with the brand. Engaged customers are also very supportive and even become online brand advocates; thus, they contribute to the increase of the brand's value. In a market like Egypt, where the brand reputation largely depends on digital interaction among consumers, the influence of customer engagement on user-generated content and brand advocacy is still a vital and fascinating issue (Liao et al., 2024; Colicev et al., 2019).

Establishing a strong relationship with customers is a must-have for companies, especially with the proliferation of mobile-first platforms and the increase in influencer marketing campaigns in Saudi Arabia. Such campaigns are designed to establish genuinely engaging and valuable relationships between people and brands (Aljarah et al., 2024). In this sense, engagement serves as a link that connects the content with customer feedback. Hence, it is very important to figure out the impact of customers' previous knowledge about the brand on their trust and brand loyalty (Kim et al., 2022; Sutiadiningsih et al., 2024).

4. Brand Familiarity (BF)

Visibility and familiarity are the two aspects that mostly affect brand familiarity, which in turn lead to trust of the brand and the willingness to be its advocate. Namely, in Egypt and Saudi Arabia, familiarity is very much dependent on visibility (Agina et al., 2025) In Egypt, brands that are rooted deep and have a local heritage are the ones that get more familiarity, recognition, and even visibility. As an example, Baheeg and Laban brands have evolved and become so popular that many people now know and trust them. In Saudi Arabia, the old and well-established brands employ recognition and visibility to gain familiarity. When the brands start using influencer advertising to connect with the consumers, then trust gets built, which is why they are increasing consumer interaction and engagement (Goh, et al., 2013; AlRahman, 2025). Brand familiarity comes from the consumers' past experiences with a brand, the ads they have seen, or their interactions with it. It is a measure of how much a consumer knows, recognizes, or remembers a brand Familiarity is one of the main factors that influence consumers' choices (Al Zein et al., 2025). It lowers a consumer's perceived risk, views the brand with greater trustworthiness, and enhances trust in the brand (Kim et al., 2022). Schema theory explains the cognitive methods that consumers employ for encoding and recalling memories related to brands. These frameworks influence and shape consumer preferences, attitudes, decision-making, and loyalty (Aljarah et al., 2024). Within Sport Tourism, Brand Familiarity acts as a psychological anchor. Fans visiting for events often seek food brands they 'know' through social media to reduce perceived travel risks. Schema theory suggests that seeing a familiar brand like 'Blabn' or 'Baheeg' in a sporting context reinforces the consumer's trust and enhances their willingness to engage and advocate for the brand online. In the Egyptian market, competing firms are equally consistent and purposeful with user-generated content, cultivating the kind of brand loyalty that starts with familiarity and progresses to trust and advocacy, thereby enhancing market share and loyalty.

5. The impact of user-generated content (UGC) information dimensions and online brand advocacy

Normative According to (Hermanto et al., 2023), user-generated content (UGC) mirrors the opinions and views of former customers. Favorability is one of the most commonly described representation techniques in the normative dimension and can be calculated in terms of the likes and dislikes of a given product. Successful branding of a company on social media hinges on the positivity of comments and feedback a consumer provides (Goh et al., 2013). Trust in a brand and positive user-generated content (UGC) improve social media branding (Makrides, 2019).

Favorability is the social standing of a product or service offered within a peer group (Li, 2020). We recommend that you carry out the following operations: Online user reviews are considered a prominent signal of valuable user-generated content (UGC) by (Hermanto et al., 2023). The user-generated content (UGC) pieces have a massive influence on the view of potential buyers (Lu, 2014). A body of research in the eWOM area reveals that informational text attributes, that is, length, subjectivity, readability, and the emotional tone (positive or negative), can be used as the main characteristics for evaluating the quality of the information (Zhao et al., 2022). Negative reviews may elevate the level of uncertainty and the feeling of risk associated with making purchases online. This is because consumers, according to the negativity bias, tend to consider unfavorable information more than positive ones (Labrecque et al., 2022).

The research supporting this notion, indicates that shorter or more vague messages are usually regarded as less persuasive and of lower quality, whereas longer and more detailed texts help to dispel ambiguity and bolster the confidence in the decision-making process (Bevan et al., 2020). Purely subjectively oriented statements based only on personal preferences may look as if the communicators are concealing something from the consumers, thus leading to a decrease in credibility and trust (Scholz et al., 2019; Yu et al., 2021). Additionally, research concerned with how easily messages can be read indicates that extensively complicated materials might give a sense of higher authority; however, at the same time, they can lower the practical use of the materials and negatively impact product sales (Shen, 2022). Besides content characteristics, peer interactions have a decisive influence on the formation of consumer demand as well; for instance, on a platform like YouTube, users can get close to their peers through interactive communication and the comments (Kim, 2010). The first of these findings to be underlined is that both the quality and social aspect of UGC have the most considerable impact on consumer trust and their choice of buying.

6 .UGC and online brand advocacy and customer engagement:

Previous research has been studied cognitive consistency theory. The theory of cognitive consistency also postulates that customers, when they are subjected to psychological pain seek the harmony between their thoughts and their behavior and try to avoid the dissonance cognitive (Donsbach, 2008). Therefore, if a customer notices good while others are bad in accompanying (e.g., customer involvement), he or she will be more likely to do, other compatible actions with his or her beliefs, attitudes and behaviours (e.g., online brand advocacy) (Aljarah et al., 2024).

Theoretically, data support this position. (Samala & Singh, 2019) found in their study that customers who engage with a brand are more likely to promote it. Exposing customers to digital content marketing may lead them to brand involvement (Aljarah et al., 2024), which in turn may generate a belief-confirmation experience like online brand advocacy.

Therefore, it is logical that customer engagement acts as a facilitator between digital content marketing and online brand advocacy. Hence, we propose the subsequent hypothesis

7. UGC and online brand advocacy And Brand familiarity

Schema theory gives an insightful explanation of the impact of brand familiarity on consumer reactions. Consumers depend on mental frameworks (schemas) which are formed from their past experiences and these enable them to process familiar brand stimuli faster and with less cognitive effort, whereas unfamiliar stimuli need more evaluation and adjustment (Alba & Hutchinson, 1987). Therefore, knowing a brand is one that lessens uncertainty, increases trust, and makes it easier for good words and customer advocacy to spread (Acharya, 2020; Colicev et al., 2019). Recent research has similarly acknowledged that brand familiarity leads to customer engagement because it opens the customer's mind to the already existing mental connections, which in turn increases the brand's credibility and the customer's perceived value (Aljarah et al., 2024). Hence, using schema theory as a basis, the present research foresees that consumer advocacy behavior through digital content marketing will be affected by brand familiarity to different extents.

8. Customer engagement and OBA and brand familiarity

Brand familiarity has been identified as a key factor that brand marketers need to consider when they are targeting consumers through digital content marketing and social media. When consumers have little knowledge of a brand, digital content communication has a direct effect on brand advocacy since users are in need of more informational cues and are willing to try new experiences (Acharya, 2020). On the contrary, in situations where consumers are highly familiar with the brand, they can rely on their existing mental representations and previous experiences of trust, thus content marketing may have a reduced effect on the increment of brand advocacy (Aljarah et al., 2024).

The discoveries imply that brand familiarity may strengthen the relationship of digital content marketing and brand advocacy or it may weaken it, depending on the consumer's prior knowledge and trust in the brand. Consequently, the theory mentioned below is proposed: Continuing with the argument from the prior paragraph, one can clearly infer that User-Generated Content (UGC), Online Brand Advocacy (OBA), Customer Engagement (CE), and Brand Familiarity (BF) are interpersonal interaction models that significantly determine customer behavior in the digital market.

However, extant research has predominantly treated these factors as separate variables or single-market contexts, thus the interplay of these variables across culturally diverse but digitally connected regions like Egypt and Saudi Arabia still remains unexplored. This study answers that gap by creating a detailed model that looks into how user-generated content influences online behavioral advertising, environmentally friendly consumer behavior, customer engagement as a mediator and brand familiarity as a moderator. The comparative approach provides the valuable insight into cross-market consumer engagement and advocacy behavior in the food industry.

Research Model: (The effect of user-generated content on online brand advocacy mediated by customer engagement and moderated by brand familiarity).To address this gap, the study proposes the following hypotheses:

H1: User generated content (UGC) Information positively effect on Online brand advocacy.

H2: The positive effect of UGC and online brand advocacy mediated by customer engagement.

H3: The positive effect of UGC and customer engagement moderated by brand familiarity.

H4: The positive effect of UGC on online brand advocacy moderated by brand familiarity

The theoretical framework of the study is illustrated below in Figure 1.

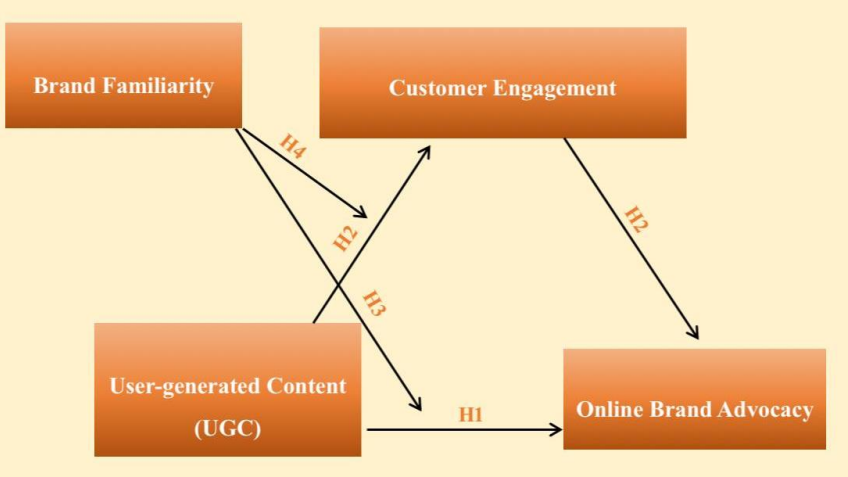

Figure 1. The study's conceptual model

METHODOLOGY

This study employed a quantitative method which is a research method where a participant discusses 3 food brand stores in Egypt and Saudi Arabia which were (1- Wahmy, 2- Blabn, 3- Baheeg) based on online surveys that primarily deal with the

collection and analysis of numerical data to explain phenomena, forecast, or test hypotheses by means of a convenience sample technique. Quantitative research frequently entails statistical analysis and is based on measurable units to arrive at conclusions that are capable of being verified and repeated, thereby ensuring objectivity, through the survey of 606 persons. The participants were specifically screened to include consumers who actively follow or participate in Sport Tourism activities and events in Egypt and Saudi Arabia, ensuring the data reflects the intersection of sports travel and food brand consumption."

The researchers relied on the questionnaire as the primary instrument for gathering data to analyze the relationships in the research model. The participants' answers were recorded on a five-point Likert scale (5 Strongly Agree and 1 Strongly Disagree). The scales used to measure the variables were taken from the literature and adjusted to be suitable for Arabic speakers. User-generated content is the independent variable. Customer Engagement, is the mediator, and Brand Familiarity, is the moderator. Finally, Online Brand Advocacy is the dependent.

RESULTS

This research led the way to combine survey data with an innovative statistical method named partial least squares-based structural equation modeling (PLS-SEM) implying tool PLS 3.3 to deal with the problem of data normality. PLS-SEM was chosen as the primary analysis method because of its capabilities in managing situations of small sample sizes and non-normal data which are characteristics of exploratory research.

Additionally, it is a perfect method to be used in a study with such a complex model as this one that aims at detangling the effects of variables customer engagement as a mediator and brand familiarity as a moderator. Their use here is strongly supported by the complexity of the model and the need for indirect effect measurement through mediation.

Furthermore, PLS-SEM can accept data from any distribution and, thus, it is an appropriate instrument for an exploratory study like this one. "Normalcy-related problems" signify the issues that emerge when individuals or societies attempt to live according to what they consider norms or average practices. These problems include the social pressure to conform, the feeling of inadequacy when one cannot meet societal standards, the discrimination of those who oppose the norm, and the suppression of one's individuality under the guise of conformity.

To determine the reliability and validity of the measurement approach, a comprehensive testing program was conducted. Multiple indicators confirmed the discriminant and convergent validity of the model. Cross-loadings, Composite Reliability, Cronbach's Alpha, the Average Variance Extracted (AVE), and the Fornell-Larcker criterion were used to conduct reliability and validity tests. Collinearity among formative indicators was also tested using the variance inflation factor (VIF). Sample profile in total, 606 survey responses were used in the analysis collected from the learners to test the pre-determined hypothesis. According to the descriptive analysis for demographic variables, the results illustrate that most of the sample is female (55%), while males account for only (45%).

As for age, the results show that the age of the majority is ranging between (20-29) years old, with (53.9%), followed by the age (30-39) years old (19.3%). In addition, the analysis showed that the income of the majority ranges between (11.000-30.000) per month (33.5%), followed by those whose income is (31.000-50.000) per month with (26.1%). for the country, the majority are from Egypt with (80.6%) and only (19.4%) are from Saudi Arabia. Finally, concerning the education level, the majority are college graduates (39.9%), followed by those who are graduates (36.6%).

Egypt Model

First, for the Egyptian model, the measurement model has strong internal reliability and validity, as shown in Table 1 and Table 2 . All the Cronbach alpha values are 0.7. Moreover, every composite dependability (CR) value exceeds 0.8. The rho_A1 values of all latent variables are less than 1. Each of the AVE values in Table 1 is higher than 0.5. The square root of the AVE values is compared to the latent variable correlations in the Fornell-Larcker discriminant validity criterion.

Table 1 shows that, in accordance with the Fornell-Larcker criterion, the square roots of the AVE for each construct (which indicates convergent validity) are greater than their greatest correlation value with any other construct.

There are no cross-loadings displayed in Table 2, and loadings are around 0.7. Additionally, Table 2 indicates that the VIF proves that none of the measures are greater than five. The diagonal figures in Table 1 meet the Fornell-Larcker discriminant validity requirement because they are greater than their greatest correlation value with any other notion. The model's convergent and discriminant validity are confirmed by the absence of cross-loadings and well-loaded dimensions on their constructs, with 0.45 being the lowest loading see Table 2.

Structural model

The significance and direction of the hypothesised relationships were tested using the bootstrap method with 5000 subsamples. PLS-SEM indices, for model fit, involved SRMR=0.09 ≤ 0.12 and NFI=0.711.

Figure 2 and Table 3 show that the UGC, positively significantly, affect OBA with (β= 0.769). So, UGC is responsible for 63.5 % of the variation that happens in the OBA.

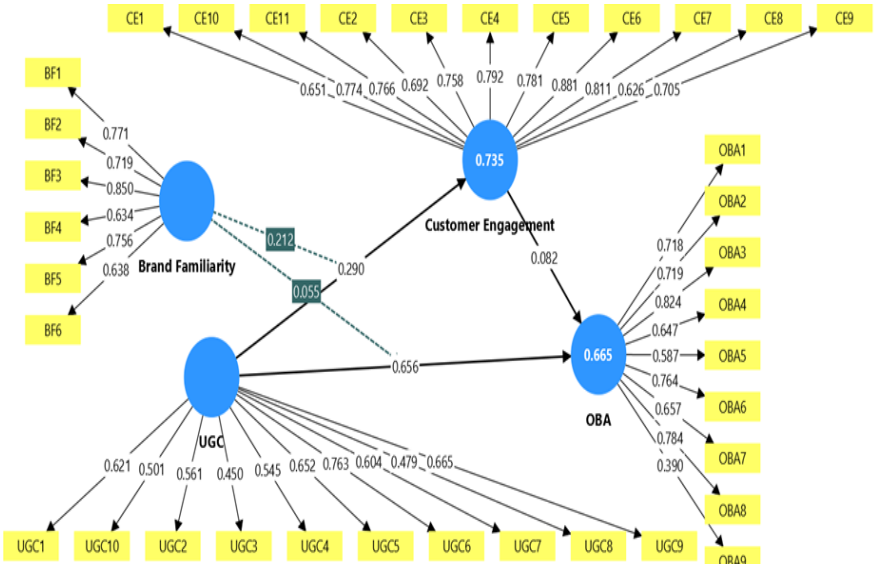

Figure 2. Model tested (Source: Smart PLS 3.3 output)

Direct and indirect relationships

First, for the direct relationship, Figure 2 and Table 3 show and confirm that UGC positively affects OBA. Hence H1: User-generated content (UGC) Information positively affects Online brand advocacy is accepted. Second, for testing mediation/ moderation relationships, bootstrapping with 5000, was conducted. Table 3and Table 4 is used in the mediation and moderation analysis. Table 4 shows significant indirect relationship between UGC and OBA (β=0.017, t= 3.317) through customer engagement, it ensures the mediation of customer engagement in the UGC and OBA relationship, indicating a full mediation. Hence, the mediation hypotheses H2: The positive effect of UGC and online brand advocacy mediated by customer engagement is accepted. In addition, Table 4 indicates a significant positive relationship between UGC and customer engagement (β=0.009 t= 4.119) moderated by brand familiarity, it ensures the moderation of brand familiarity in the UGC and customer engagement. Hence, the moderation hypotheses H3: The positive effect of UGC on customer engagement moderated by brand familiarity is rejected. Moreover, Table 4 also indicates a significant positive relationship between UGC and OBA (β=0.005, t= 2.129) moderated by brand familiarity, it ensures the moderation of brand familiarity in the UGC and OBA. Hence, the moderation hypotheses H4: The positive effect of UGC on online brand advocacy moderated by brand familiarity is accepted.

Table 3. Direct Relationships

Hypothesis		Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T-Statistic (|O/STDEV|)	P values	Accept / Reject
H1	UGC -> OBA	.769	.774	.092	8.366	0.000	Accepted

Table 4. Specific Indirect effects

		Original Sample (O)	**Sample Mean (M)**	**Standard Deviation (STDEV)**	**T-Statistic (|O/STDEV|)**	**P values**	**Mediation / Moderation**
H2	UGC -> Customer Engagement-> OBA	0.017	0.005	0.127	3.137	0.000	Mediation accepted
H3	UGC x Brand Familiarity -> Customer Engagement	0.009	0.02	0.079	4.119	0.000	Moderation accepted
H4	UGC x Brand Familiarity -> OBA	0.005	0.005	0.038	2.129	0.000	Moderation accepted

Saudi Arabia Model

First, for the Saudi Arabia model, the measurement model has strong internal reliability and validity, as shown in Table 5. All the Cronbach alpha values are 0.7. Moreover, every composite dependability (CR) value exceeds 0.8. The rho_A1 values of all latent variables are less than 1. Each of the AVE values in Table 5 is higher than 0.5. The square root of the AVE values is compared to the latent variable correlations in the Fornell-Larcker discriminant validity criterion. Table 5 shows that, in accordance with the Fornell-Larcker criterion, the square roots of the AVE for each construct (which indicates convergent validity) are greater than their greatest correlation value with any other construct. There are no cross-loadings displayed in Table 6, and loadings are around 0.6. Additionally, Table 6 indicates that the VIF proves that none of the measures are greater than five. The diagonal figures in Table 5 meet the Fornell-Larcker discriminant validity requirement because they are greater than their greatest correlation value with any other notion. The model's convergent and discriminant validity are confirmed by the absence of cross-loadings and well-loaded dimensions on their constructs, with 0.097 being the lowest loading.

Structural model

The significance and direction of the hypothesized relationships were tested using the bootstrap method with 5000 subsamples. PLS-SEM indices, for model fit, involved SRMR=0.07 ≤ 0.12 and NFI=0.612.

Figure 3 and Table 3 show that the UGC, positively significantly, affect OBA with (β= 0.687). So, UGC is responsible for 60.2 % of the variation happens in the OBA.

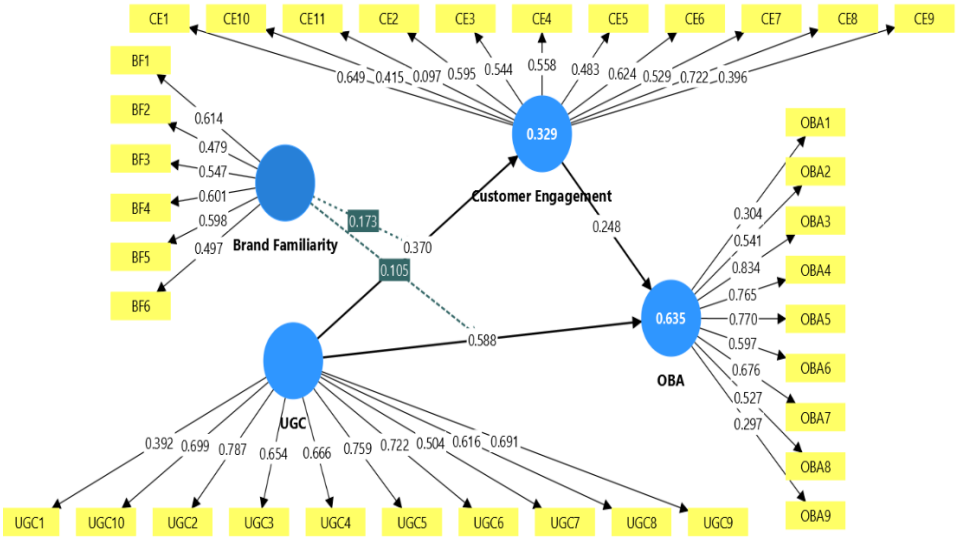

Figure 3. Model tested (Source: Smart PLS 3.3 output)

Direct and indirect relationships

First, for the direct relationship, Table 7 confirms that UGC positively affects OBA. Hence H1: User-generated content (UGC) Information a positive effect on Online brand advocacy is accepted. Second, for testing mediation/ moderation relationships, bootstrapping with 5000 was conducted. Table 4 is used in the mediation and moderation analysis.

Table 8 shows an insignificant indirect relationship between UGC and OBA (β=0.091 t= 1.175) through customer engagement, indicating no mediation effect. Hence, the mediation hypotheses H2: The positive effect of UGC and online brand advocacy mediated by customer engagement is rejected. In addition, Table 8 indicates a significant positive relationship between UGC and customer engagement (β=0.117, t= 2.337) moderated by brand familiarity, which ensures the moderation of brand familiarity in the UGC and customer engagement. Hence, the moderation hypotheses H3: The positive effect of UGC on customer engagement moderated by brand familiarity is accepted.

Moreover, Table 8 also indicates a significant positive relationship between UGC and OBA (β=0.055, t= 2.155) moderated by brand familiarity, which ensures the moderation of brand familiarity in the UGC and OBA. Hence, the moderation hypotheses H4: The positive effect of UGC on online brand advocacy moderated by brand familiarity is accepted.

Table 7. Direct Relationships

Hypothesis		Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T-Statistic (|O/STDEV|)	P values	Accept / Reject
H1	UGC -> OBA	0.687	0.681	0.112	6.160	0.000	Accepted

Table 8. Specific Indirect Effects

		Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T-Statistic (|O/STDEV|)	P values	Mediation / Moderation
H2	UGC -> Customer Engagement-> OBA	0.091	0.101	0.078	1.175	0.240	Rejected
H3	UGC x Brand Familiarity -> Customer Engagement	0.117	0.135	0.088	2.337	0.081	Moderation accepted
H4	UGC x Brand Familiarity -> OBA	0.055	0.04	0.048	2.155	0.098	Moderation accepted

Comparing Saudi Arabia and Egypt, some of the significant differences and similarities between the role of User-Generated Content (UGC) towards Online Brand Advocacy (OBA) can be identified. In Egypt, the findings validate a stronger direct role exhibited by UGC towards OBA (β=0.769), explaining 63.5% variation in OBA, as opposed to Saudi Arabia, which exhibits a lower level of impact (β=0.687), explaining 60.2% variation.

In addition, customer engagement fully mediated the relationship between UGC and OBA in Egypt, while the moderation effect was not significant in Saudi Arabia, uncovering that customer engagement was not a necessary mediating variable. However, brand familiarity provided a significant moderation effect in the relationship between UGC and customer engagement as well as between UGC and OBA, affirming brand awareness is a significant driver of strengthening these relationships. Overall, while UGC is predominantly affecting both realms of OBA in a positive way, Egypt portrays a stronger and direct influence with the customer interaction being a pivotal mediating factor, compared to Saudi Arabia where its influence was constrained.

DISCUSSION

User-generated content (UGC) impacts online brand advocacy directly as a result of which researchers suggest that consumers are more willing to trust and support a brand when they find authentic content from other users (Aljarah et al., 2024). Also, UGC through emotional and cognitive connections can escalate advocacy (Bahtar & Muda, 2016).

But, the quality and the personality of UGC matter, as bad writing or negative content may reduce the power of such content (Zhao et al., 2022). The research in Egypt confirmed the effect of UGC on customer engagement, which later resulted in advocacy, where consumer engagement was the full mediator of the relationship, and consumers were more likely to advocate when they felt emotionally and cognitively engaged (Rachbini, 2023; Marbach et al., 2019; Sureddy et al.,2026). The authors have shown that brand familiarity contributes to the strengthening of the UGC influence on both engagement and advocacy, as familiar brands evoke quicker and deeper engagement when supplemented with user-driven content (Colicev et al., 2019). Although brand familiarity usually escalates the influence of UGC on brand advocacy, excessive familiarity may lower the rate of response to new UGC (Schivinski et al., 2020).

The degree of a consumer's trust impacts the effect of customer engagement on brand advocacy, with the brand familiarity through either facilitating or hindering the connection between engagement and advocacy (Aljarah et al., 2024) User-generated content (UGC) impacts online brand advocacy directly as a result of which researchers suggest that consumers are more willing to trust and support a brand when they find authentic content from other users (Aljarah et al., 2024). Also, UGC, through emotional and cognitive connections, can escalate advocacy (Bahtar & Muda, 2016). But, the quality and the personality of UGC matter, as bad writing or negative content may reduce the power of such content (Zhao et al., 2022). The research in Egypt confirmed the effect of UGC on customer engagement, which later resulted in advocacy, where consumer engagement was the full mediator of the relationship, and consumers were more likely to advocate when they felt emotionally and cognitively engaged (Ayele & Singh, 2024).

The authors have shown that brand familiarity contributes to the strengthening of the UGC influence on both engagement and advocacy, as familiar brands evoke quicker and deeper engagement when supplemented with user-driven content (Colicev et al., 2019). Although brand familiarity usually escalates the influence of UGC on brand advocacy, excessive familiarity may lower the rate of response to new UGC (Schivinski et al., 2020). The degree of a consumer's trust impacts the effect of customer engagement on brand advocacy, with the brand familiarity through either facilitating or hindering the connection between engagement and advocacy (Aljarah et al., 2024)

Implications

1. Theoretical implications

The paper is a significant theoretical contribution as it establishes the fact that user-generated content (UGC) is a major driver of online brand advocacy (OBA), whereby customer engagement is the most important mediating factor. The findings

of the research extend cognitive consistency theory (Donsbach, 2008; Ruiz-Equihua et al., 2023) by demonstrating that when consumers are positively engaged with UGC, they adopt more active advocacy behaviors in line with their attitudes (Aljarah et al., 2024). Besides that, the brand familiarity as a moderating factor enriches schema theory (Lang, 2000), since consumers accessing familiar brands from their pre-existing mental frameworks which, in turn, makes the influence of UGC on engagement and advocacy more potent. The findings further underscore that UGC is not only a source of trust and authenticity but also a theoretical link that connects consumer participation, engagement, and advocacy in the digital realm.

2. Practical implications

The results from a managerial standpoint indicate that food industry marketers should vigorously promote such as customer reviews, testimonials, and interactive videos as a strategic tool to influence advocacy behaviors positively. To be most effective, brands need to create customer experiences that not only invite customers to share genuine stories but also emotionally engage with the content, hence, turning engagement into advocacy.

For food industry marketers, leveraging Sport Tourism calendars is essential. Brands should launch UGC-driven campaigns during major sporting events to capture the emotional engagement of fans, thereby converting spectator enthusiasm into Online Brand Advocacy (OBA). The thing is that it would be of no small consequence to mention the point that investing in the establishment and ongoing of brand recognition is absolutely necessary as it has been shown that familiar brands have a positive impact both, engagement, and, advocacy levels. Simply put, this implies that new brands have to get their name out and win the trust via the consistent use of UGC strategies while already established brands can leverage their familiarity to obtain better results from digital marketing. Overall, it can be said that the appointment of managers to the board of directors is to implement UGC-driven strategies which not only merge engagement initiatives with trust-building procedures but also ensure customer loyalty and advocacy in the long run in competitive markets.

CONCLUSION

The research prominently presents how the towering impact of User-Generated Content (UGC) that is mostly responsible for Online Brand Advocacy (OBA) in the food industry is made to be very clear. It mainly focuses on the markets of Egypt and Saudi Arabia. The findings suggest that UGC positively influences brand advocacy; however, the routes differ between the two countries. Customer engagement in Egypt was found to be a full mediator between OBA and UGC, therefore indicating that brands need to focus most on interactive experiences and co-creation activities so as to convert user content into advocacy behaviors. Egyptian consumers are more likely to be influenced by authentic content that emotionally connects with them, and as a result, they become more engaged and loyal.

While UGC influences OBA significantly in Saudi Arabia, customer engagement did not mediate this relationship, therefore a more direct influence of UGC is suggested. Nevertheless, brand familiarity was very powerful in both cases as a moderator, indicating that positive consumers with a prior association to a brand are the ones who will do advocacy behavior upon seeing UGC. The passage stresses the importance for brands to invest in familiarity and trust-building activities through, for example, quality communication strategies that are consistent.

Besides that, the study points out that authenticity, emotional connection, and cultural aspects are the key elements when one is looking to get the most out of UGC. Food brands must be in a position to not only motivate UGC but also control it in a way that they strengthen brand-consumer relationships and at the same time increase brand equity, especially in highly competitive and digital-oriented markets. The research paper is a great resource for mastering concepts related to online consumer behavior. It establishes the connections among UGC, customer engagement, brand familiarity, and brand advocacy and offers a wide range of suggestions for the marketing professionals who want to effectively employ UGC to brand loyalty and sustainable advocacy in a digitally competitive market place.

Limitations and future research

The research did not address several aspects that could be relevant to other magazines about restaurants and beverages in Egypt and Saudi Arabia. Future research should consider these financial aspects and include other types of projects in different fields, potentially utilizing different geographical areas, while taking into account competitive pressures and market changes. By using both qualitative and quantitative research methods, clearer understanding may emerge about the influence of non-cash support services given by governments on the performance and innovation of entities.

To focus mainly on the comprehension of the role of support services in the creative process as well as in the growth of startups businesses in various sectors, the paper propounds that subsequent research should explore the mediating and modifying factors as well as the effect of financing and assistance on the enterprises at different phases of their development. In most research, it is quite common to acknowledge that there are certain limitations. The primary point is that this research only looked at the influence of user-generated content (UGC) on online brand promotion (OBA), where customer interaction was the mediator and brand knowledge was the mediator. Subsequent research might provide a new model to investigate various variables, e.g., by considering gender, age, sociocultural values, and emotional attachment, technology knowledge, and the influence of artificial intelligence, thus possibly unfolding a deeper understanding of consumer behavior across different contexts. Moreover, an added measurement was utilized in this research to assess online brand marketing, which is not merely a local examination of brand advocacy, information sharing, or liking, but is rather more focused on understanding how consumers perceive the content type. The article proposes that subsequent inquiries would benefit from exploring this issue interaction more in-depth to users; so that, the researchers could get a more detailed

and nuanced view, which could be easily generalized to the different marketing fields. Thirdly, a large portion of the study sample came from one generation, and thus the results of the study might not be applicable to other generations.

The reason for this is that there are significant differences between generations in the way they use technology and in their trust in the opinions of content creators. Hence, it is advisable for subsequent research to investigate the different generations. Additionally, this research was limited to the food industry in Egypt and Saudi Arabia only. We, therefore, propose that subsequent research assess other industries such as fashion or cosmetics where the user-generated content is electrifying brand promotion. Consequently, exploring different cultural or geographical contexts can be a way to understand the significance of socio-cultural differences in consumer interaction and advertising behavior.

Citation: Zimik, A.S.S., & Kang, S.W. (2026). Constructed environment as a catalyst for tourism excellence and stakeholder engagement in northeast India. *Geojournal of Tourism and Geosites*, 67(3), 1908–1917. https://doi.org/10.30892/gtg.67307-1819

Abstract: In light of prevailing industry trends, the growing popularity of tourism, emerging regional challenges, and evolving policy frameworks, the constructed environment is examined as a practical and strategic foundation for advancing sustainable tourism development in Northeast India. This study emphasizes the role of the constructed environment in delivering performance excellence across the region's tourism sector. Grounded in a comprehensive review of Scopus-indexed literature, the research is guided by two primary objectives: first, to analyze the contribution of the constructed environment to tourism development in Northeast India; and second, to assess stakeholder awareness and engagement in regional tourism initiatives. A descriptive research design was adopted. Primary data were collected from 2,469 tourists across 29 selected destinations, while stakeholder perceptions were evaluated using an Opinion Synthesis Matrix. Analytical modeling was conducted using SPSS to assess the fit, validity, and feasibility of the proposed conceptual framework. The findings confirm the feasibility of the proposed model, as evidenced by multiple fit index criteria, demonstrating its practical applicability from the tourists' perspective. Insights derived from the Opinion Synthesis Matrix further highlight the need to align stakeholder strategies with tourist expectations to sustain tourism development through improvements in the constructed environment. The study underscores the necessity for greater stakeholder attention to deficiencies in both tangible and intangible components of the constructed environment across destinations. By systematically identifying existing gaps, the research provides a basis for corrective interventions and enhanced stakeholder awareness. A key contribution of this study lies in strengthening both the conceptual understanding and practical implementation of constructed environment principles among diverse tourism stakeholders, thereby supporting more sustainable and performance-driven tourism development in the region.

Keywords: Constructed Environment, Stakeholder, Model Fit, Opinion Synthesis Matrix, development

INTRODUCTION

Tourism has emerged as a significant area of academic inquiry and global research interest (Sofronov, 2018; Jangra et al., 2021). In addressing the diverse challenges and opportunities within the tourism sector, the concept of the Constructed Environment (CE) has gained prominence as a critical analytical framework (Zimik et al., 2026). While the CE has already demonstrated notable influence across tourism-related industries, this study aims to deepen scholarly engagement by systematically evaluating its potential and practical applications. A distinctive contribution of this research lies in its focus on stakeholder perspectives—particularly those directly involved in tourism—highlighting the necessity of integrating their insights into development strategies (Zimik, 2026).

The study undertakes a focused examination of Northeast India, a region of strategic importance due to its geographic, cultural, and ecological diversity (Jamir, 2024; Tasung, 2024; Nath & Saikia, 2025). By considering both tourist expectations and their implications for quality of life and regional development, the research adopts a comprehensive and context-sensitive approach (Donaire et al., 2024; Font & McCabe, 2017; Alsaloum et al., 2024).

The CE framework, encompassing both tangible (infrastructure, architecture) and intangible (cultural practices, policy environment) dimensions, is employed to explore innovative and conscious strategies for sustainable tourism growth. A notable strength of the CE lies in its capacity to integrate advanced technologies and forward-looking strategies—components that are essential but often underutilized in traditional tourism planning (Zimik & Barman, 2025). By illuminating the multifaceted role of the CE, this study aims to provide actionable insights that enhance tourism development in Northeast India, fostering competitiveness with more developed regions while promoting sustainable and inclusive growth.

Background

Although the Northeast region of India constitutes only about eight percent of the country's total area; tourism has proven to be a key contributor to the regional economy (Ahmad et al., 2026). This prominence is largely attributed to the

* Corresponding author

region's abundant natural resources, rich cultural diversity, and a wide range of tourism trends that continue to evolve. Figure 1 show the selected 29 destinations in northeast India selected for the study. However, the region also faces persistent challenges, including prolonged monsoon seasons and complex geographical terrain, which have hindered consistent tourism growth and infrastructure development. Despite the increasing inflow of tourists and rising investment interest—which have catalyzed growth in tourism and related industries (Nguyen, 2021; Rasool et al., 2021)—there remains a lack of focused research addressing the infrastructural shortcomings and identifying optimal strategies for policy-making and investment.

Figure 1. Selected 29 Destinations in Northeast India (Source: Compiled by authors; image sources accessed via Google Images in 2026)

The absence of a clear framework for sustainable development limits the potential of the tourism sector to operate efficiently and achieve long-term growth. To bridge this gap, the present study selected 29 representative tourist destinations across the region for in-depth exploration. These sites were analyzed to better understand their current status, infrastructural needs, and the potential of targeted policy interventions to enhance tourism performance and regional economic development.

LITERATURE REVIEW

To support and strengthen the research framework in the field of tourism, a systematic approach was employed. Data were collected from the Scopus database, which served as the primary source for identifying scholarly contributions related to tourism (Timur et al., 2025). The collected data were then processed using VOSviewer software to generate a comprehensive bibliometric analysis. This approach provided a broader perspective on existing tourism research, highlighting thematic concentrations and identifying potential gaps that the current study aims to address (Beegum & Aboobaker, 2026; Kaldeh et al., 2025). A key insight emerging from the review is the urgent need for a well-defined and integrative conceptual framework that encompasses the diverse facets of the tourism industry in the region. Various research contributions indexed in Scopus were critically examined to inform this framework.

For instance, Feng et al. (2024) emphasize that tourist demand is closely linked to the structure and efficiency of the tourism network. Their study applies trend flow analysis and the spatial mismatch index to illustrate demand distribution patterns. Similarly, Wang et al. (2024) employed the DPSIR model, concluding that a thriving tourism industry requires robust inter-sectoral support. In parallel, studies in green tourism management have gained momentum. Qasim et al. (2024) conducted extensive empirical research, collecting and analyzing substantial data to evaluate the effectiveness of sustainable tourism practices. These studies collectively inform the present research, offering foundational insights for further exploration and application in the context of Northeast India.

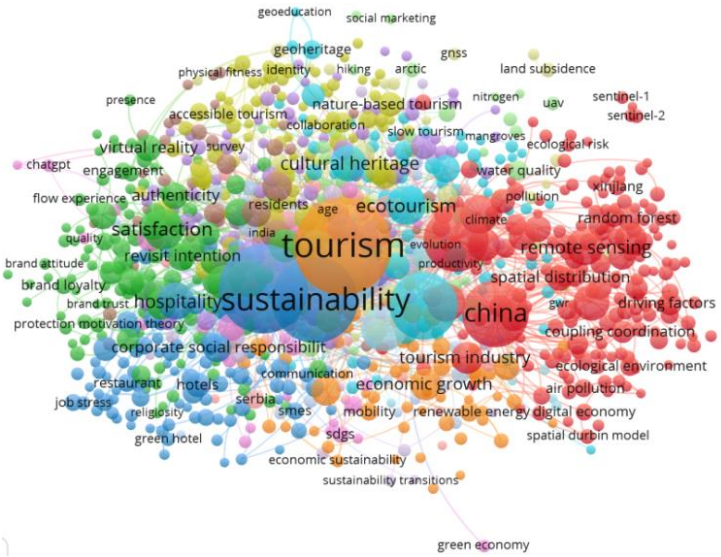

Figure 2. Research Contribution in Tourism Industries (Source: SPSS report from Scopus Data Base)

To align with the selected study area, Abidin et al. (2024) identified eco-tourism as a sustainable and effective strategy for improving community welfare, particularly in low-income regions as shown in Figure 2.

Their study employed the QSPM to prioritize actionable initiatives. Similarly, Ahmad et al. (2024) examined the impact of tourism on local communities and well-being using a combination of NVivo software for qualitative data analysis and the SWOT matrix framework, supported by an interview-based methodology. Recognizing the growing importance of intangible assets in tourism development, Tonini et al. (2022) emphasized the role of digital and social technologies as powerful marketing tools. Their study demonstrated how visual and digital media can significantly enhance tourism appeal and industry engagement. In an effort to move beyond traditional frameworks, Ajmera (2017) integrated the TOPSIS and MADM methodologies to overcome the limitations of conventional SWOT analysis.

His findings revealed that incorporating new technologies and adaptive administrative models offers an ideal path for tourism development. Stakeholder awareness and commitment to infrastructure development—supported by effective policies and strategic investments—are essential for sustainable progress (Sautter & Leisen, 1999; Alvarez, 2025; Tran, 2025). Tourist demand is dynamic and constantly evolving, requiring destinations to manage their systems with heightened attention, responsiveness, and proactive engagement from host stakeholders (Bisht et al., 2025; Christou et al., 2025; Nicolau, 2025). Despite these advancements, a review of the literature revealed a clear gap: no significant research to date has addressed the implementation and potential of the CE concept within the context of Northeast India. This gap justifies the need for further investigation, forming the basis for the present study's focus on CE as a strategic framework for sustainable tourism development in the region.

Objectives

1. To analyse the role of the constructed environment in facilitating tourism development in Northeast India.
2. To assess the level of awareness and engagement among various stakeholders involved in tourism development within the region.

METHODOLOGY

Figure 3 portraits the methodology steps adoption of the research design, formulated in response to the objectives identified and the gaps observed in the existing body of literature. A mixed-methods approach—comprising both quantitative and qualitative techniques—was employed to ensure a comprehensive understanding of the research problem. Primary data were collected from tourists who had visited 29 selected destinations across Northeast India with 2462 respondent for the analysis. This data collection aimed to assess the current status of the CE from the perspective of end users—tourists. Their opinions, based on past visits and comparative experiences with other destinations, were instrumental in evaluating satisfaction levels and the perceived economic and non-economic benefits of tourism infrastructure (Yuan et al., 2021; Villamor et al., 2025). In parallel, the consciousness and competence of key tourism stakeholders—including government officials, contractors, labor associations, investors, and local communities—were assessed through semi-structured interviews (Novianti & Syahid, 2026; Khater et al., 2025; Basyar et al., 2025; Salazar et al., 2025).

The responses were systematically organized and analyzed using an Opinion Synthesis Matrix (OSM), offering insights into stakeholder engagement as relevant to CE development (Günther et al., 2024; Barros et al., 2021; Owojori & Okoro, 2022; Tumpa & Naeni, 2025; Kish & Miller, 2025). As illustrated in Figure 3, the adoption of a mixed-method approach is particularly significant in addressing the complexity of the study. It offers greater flexibility for comprehensive investigation and analysis, especially when incorporating perspectives from both stakeholders and tourists (Pagliara et al., 2025; Jena, 2025; Esposito et al., 2025). To enrich the scholarly context of the study, a bibliometric analysis was conducted using data sourced from the Scopus database, supplemented by books, journal articles, and other credible academic sources.

The integration of literature-based findings with primary field data allowed for a multi-dimensional analysis, thus enhancing the validity and depth of the study in light of its stated objectives.

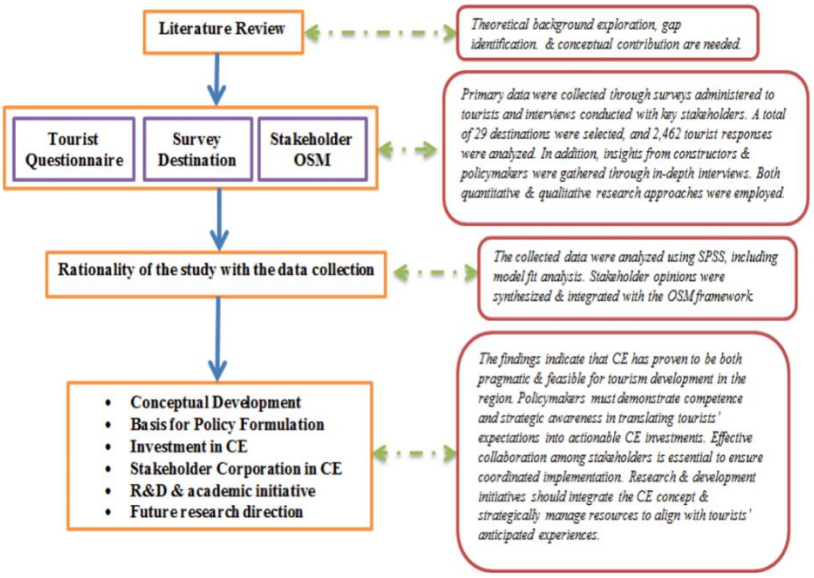

Figure 3. Research Design Flow Chart (Source: Author Compilation)

FINDING AND DISCUSSION

To investigate the complex interrelationships between the CE and various aspects of tourism development, a SEM approach was employed. This method enabled the analysis of both latent variables (unobservable constructs) and observed variables (measurable indicators), thereby offering a comprehensive view of the underlying structure of tourist perceptions and experiences. For this study, several latent variables were identified, reflecting key dimensions of the tourist experience.

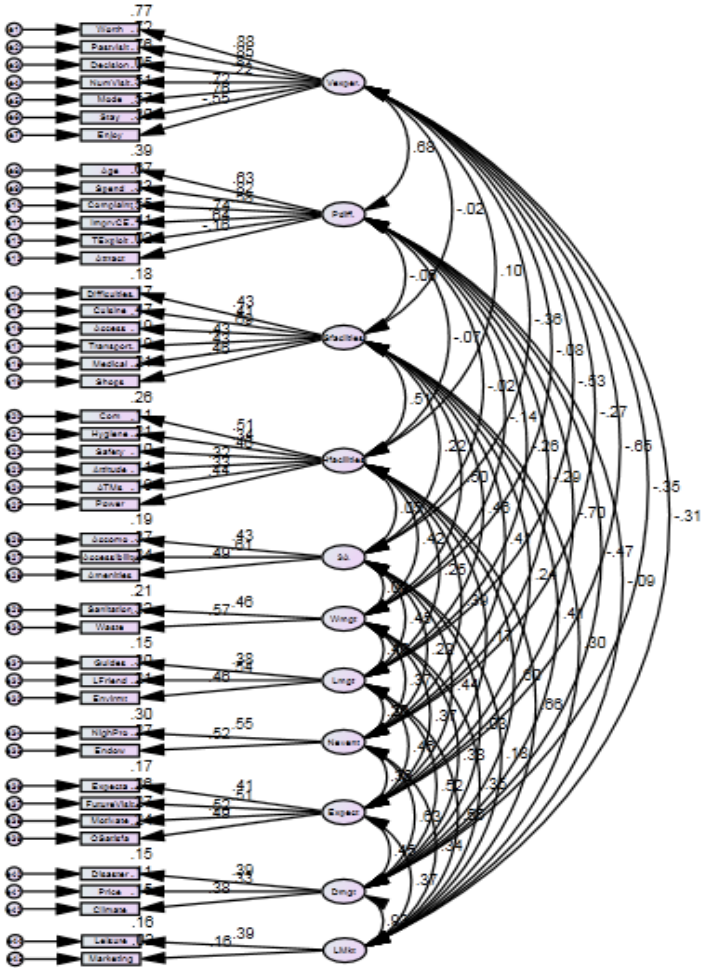

Figure 4. Model of CE (Source: Hypothetical AMOS -Based Report)

Data for each construct were gathered directly from tourists who had visited selected destinations in Northeast India. Given the limited existing research on CE within the Northeast Indian context, this study marks a significant initial effort to classify and quantify the impact of tourism infrastructure and management practices in the region.

These include: Visitor Experience Tourist Personal Difficulties and Challenges Service and Hygiene Facilities Accessibility, Amenities, and Attractions (3A's) Waste Management Systems Local Management Practices Visitor Expectations Nighttime Events and Activities Leisure Market Offerings Damage Management and Preservation Efforts These variables collectively represent critical components of the CE and their influence on tourism satisfaction and sustainability.

The responses obtained from tourists were analyzed and visually represented in Figure 4, which illustrates the SEM diagram and highlights the relationships between key variables. This model provides a valuable framework for understanding how the CE influences overall tourism development and visitor satisfaction in the region.

The proposed CE model demonstrates a strong model fit, effectively bridging theoretical foundations with empirical insights derived from primary data. The model not only validates key constructs relevant to the tourism sector but also illustrates the practical feasibility of CE concepts in promoting sustainable tourism development across Northeast India.

As depicted in the model, it encapsulates tourist experiences and perceptions, emphasizing the sensory and emotional responses elicited by their visits to the destinations. These insights offer a nuanced understanding of how the built and managed environment contributes to overall satisfaction and engagement. However, the successful enhancement and maintenance of the CE are contingent upon active state intervention and heightened consciousness among policymakers. The roles and responsibilities of diverse stakeholders—including government agencies, infrastructure developers, local communities, and tourism operators—are instrumental in shaping the effectiveness of CE-related initiatives.

To further investigate stakeholder awareness and capacity, the study incorporates findings from semi-structured interviews, as detailed in the methodology. These responses were synthesized into OSM, which captures key skill attributes, perceptions, and levels of commitment toward tourism development. This matrix serves to assess whether the implementation of CE frameworks is not only feasible but also supported by the necessary institutional and community competence required for long-term success in the region. To validate the robustness of the proposed CE model, a range of model fit indices were assessed and are presented in Table 1. These indices confirm the appropriateness of the structural model and reinforce its empirical alignment with the theoretical framework.

Table1. Model Fit Indices (Source: Hypothetical AMOS -Based Report)

Fit Index	Model Values	Threshold	Interpretation
CMIN/DF	2.53	<3	Acceptable model fit
RMSEA	0.059	<0.08	Good fit and close to ideal range
CFI	0.93	0.90-0.95	Acceptable to good fit as it falls between 0.90 (good) and 0.95 **(**excellent**)**
TLI (NNFI)	0.91	>0.9	Good- specified model
SRMR	0.062	>0.08	Good fit with low residual in the differences
GFI	0.89	>0.9	Marginal acceptable
AGFI	0.86	>0.9	Slightly below the threshold and complexity accepted

The feasibility of the CE model is examined in Table 1, which demonstrates its strong potential to support the strategic development of tourism in the region. To ensure robustness and credibility, multiple fit indices were applied and validated against established scholarly standards. The results, derived from data collected from tourists across 29 destinations, confirm a satisfactory model fit and reinforce its practical applicability. Evaluating this model represents a distinctive contribution, particularly given the limited empirical research conducted in the domestic context of Northeast India. The findings offer valuable insights for policymakers, encouraging more responsive and evidence-based tourism planning. The strong model fit underscores the importance of aligning CE strategies with evolving tourist demands, positioning the constructed environment as a strategic instrument for sustainable destination management.

By examining both tangible and intangible dimensions of the constructed environment, the study highlights the need for more rigorous and professional research to guide policy formulation. The framework proposed can serve as a strategic compass for policymakers, helping transform tourist destinations into more competitive, efficient, and smart systems. With sustained commitment and strategic investment in CE, Northeast India has the potential to shift from being among the least preferred destinations to becoming one of the most attractive tourism regions.

Furthermore, resource planning must align with the evolving expectations and dynamism of tourists. Timely allocation of financial resources and efficient project execution are critical for effective destination management. Delays in project completion—currently a significant challenge in the region—have contributed to cost overruns and budget deficits, underscoring the need for stronger governance and monitoring mechanisms.

An additional contribution of the study is its emphasis on the use of local resources in CE development. Strengthening local resource management and promoting self-reliant supply chains can reduce dependence on imports, a challenge presently faced by the region. Enhancing local sourcing and supply chain resilience will not only support sustainable tourism development but also stimulate regional economic growth.

The results also underscore the importance of bringing tourism-related activities into the scholarly spotlight—particularly the roles of contractors, local communities, management authorities, and policymakers, all of whom are central to the objectives of this study. To capture ground-level realities, various critical parameters were explored through direct engagement with respondents. These include funding availability, technological capacity, stakeholder

competence, skill levels, project scheduling, and operational challenges. These dimensions are essential for enabling a functioning and sustainable CE, especially in the tourism context of Northeast India. Stakeholders—ranging from worker associations, contractors, and local community groups to NGOs—were surveyed using customized questionnaires tailored to their specific roles and responsibilities within the CE ecosystem. Infrastructural development requires strategic and continuous management of the 4Ms: Money, Men, Machine, and Materials. This underscores the necessity of timely project planning, formal documentation, and streamlined execution processes.

Delays in fund allocation and disbursement were identified as key constraints, often leading to operational setbacks or underperformance by contractors. These challenges are further compounded by prolonged monsoon seasons and difficult terrain, which intensify the need for destination planning around accessible transport hubs such as railway stations and highways. A spontaneous and transparent flow of funds, along with awareness of tourist expectations during construction periods, is crucial. Both voluntary and paid labor forces are actively engaged in tourism development, and their coordination with other government departments is vital for ensuring industry sustainability.

Current policy and investment strategies are largely reactive, informed by past challenges and economic considerations, but often lack a forward-looking, integrated CE framework. Tourists consistently demand high-quality infrastructure and amenities, reinforcing the importance of CE as a foundational pillar for tourism development. However, the seasonal nature of tourism-related employment and income raises concerns about long-term investment returns, warranting greater attention from both public and private sectors.

Moreover, the environmental impact of unchecked tourism growth—such as habitat degradation and overcrowding—requires urgent intervention. Security and visitor confidence can be improved through CCTV surveillance and youth engagement programs, which foster a safe and welcoming environment. While scholarly and expert recommendations have long highlighted the need for strategic improvement in tourism infrastructure, such insights have rarely been translated into actionable policy. A shift toward policy consciousness and executional accountability is urgently needed to align tourism growth with sustainable development in the region.

The study presents a hypothesis-driven analysis that justifies the advancement of the CE as a strategic instrument for tourism development. It advocates for a systematic and calculated approach to resource management, infrastructure maintenance, and logistics and supply chain coordination, with the aim of overcoming domestic inefficiencies and expanding the sector in a structured manner. Through this lens, CE enables each destination to be managed under the guidance of competent and conscious policymakers, ensuring development that is context-specific and locally grounded. Empirical evidence from the model's fit indices supports the validity of CE as a strategic framework, offering policymakers a sound analytical basis for formulating responsive and forward-looking policies.

The study also highlights the importance of collaborative engagement among constructors, workers' associations, NGOs, and bureaucratic institutions. Insights generated through the OSM reveal multiple operational and structural challenges affecting development projects across the region. A key objective of CE is to align development initiatives with tourist psychology and expectations. However, the study finds that much of the technology currently used in the region is outdated and requires modernization, automation, and professional training to match contemporary advancements. Persistent logistical constraints—such as prolonged delays, overdependence on imports and inter-state supply chains, and seasonal disruptions caused by monsoons—further complicate project execution.

These factors increase project costs, extend timelines, and place additional pressure on workforce capabilities and innovation. Infrastructure maintenance remains another pressing concern. For instance, maintenance efforts at Dzukou Valley have been minimal over the past two decades, despite the site's growing tourism significance. While some urban destinations benefit from policy initiatives such as the Act East Policy and Smart Cities Mission, remote and ecologically sensitive areas continue to face neglect. This disparity calls for a reassessment of planning priorities, particularly in logistics and connectivity. Transportation challenges are especially acute in Sikkim, where road connectivity remains the primary mode of access, posing serious risks during adverse weather conditions.

Similarly, ecotourism destinations such as Loktak Lake, Kaziranga National Park, and various destinations in Meghalaya require development approaches that are closely integrated with local communities to ensure ecological balance and sustainability. CE emphasizes the need for professional coordination and effective collaboration, even in short-term development initiatives, to position destinations as smart and competitive.

It promotes a systematic planning framework that aligns infrastructure development with tourist expectations, seasonal fluctuations, and projected visitor flows—taking into account both monthly and annual cycles. Given that many destinations in Northeast India are located in rural and tribal-dominated areas, the study underscores the importance of empowering local communities to understand and implement CE at the micro level.

By fostering localized participation and capacity-building, CE can establish performance benchmarks for stakeholders and strengthen grassroots ownership of tourism development. Ultimately, the study positions the Constructed Environment not merely as a physical infrastructure concept, but as a strategic and academic framework essential for advancing sustainable, inclusive, and competitive tourism development in the region.

The extent to which both tangible and intangible dimensions of the CE are integrated across the 29 selected destinations depends largely on policy effectiveness, stakeholder competence, and sound decision-making capacity. The findings indicate that strategic policy direction and institutional capability are critical in strengthening CE's role in tourism development. As illustrated in Figure 4, the elements of CE are highly interrelated and require coordinated collaboration. Achieving balance among these interconnected components provides a strategic advantage, enabling destinations to design CE strategies that respond effectively to emerging trends and contextual demands.

This integrated support system enhances adaptability and long-term sustainability. The implementation of CE is grounded in scholarly validation, as demonstrated by the empirical findings of the study. With stronger academic engagement and evidence-based guidance, CE can be more effectively operationalized.

The research confirms that CE functions as a catalyst for sustainable tourism development by offering practical and structured mechanisms to understand tourist expectations and achieve sectoral excellence in alignment with global standards. Furthermore, stakeholders involved in CE—including policymakers, constructors, worker associations, and allied institutions—are encouraged to collaborate under a unified platform.

Such coordinated engagement strengthens strategic responsiveness, improves execution capacity, and enhances professional competence in project implementation. Through integrated action and shared accountability, CE can more effectively address regional challenges and elevate the competitiveness of tourism destinations.

CONCLUSION`

Tourism in Northeast India has demonstrated significant potential and garnered growing interest on the global stage. However, sustainable and innovative approaches are essential to ensure the region's long-term tourism development. The rapid expansion of the tourism industry, coupled with inconsistent stakeholder performance, presents critical challenges that must be addressed. In this context, the CE emerges as an ideal and rational framework to guide the sustainable growth of tourism in the region. By systematically examining the opinions, awareness, and competencies of various stakeholders, this study contributes to both academic scholarship and practical knowledge.

Recognizing tourists as the central focus of the industry, the research incorporates both micro and macro perspectives of tourist psychology. Data collected from multiple destinations were analyzed within the CE conceptual framework, with model fit indices (presented in Table 1) affirming the robustness of this approach. The CE model effectively integrates academic rigor with practical implementation, offering a pragmatic pathway to enhance the wellbeing and sustainability of tourism industries in NER. The study highlights the importance of aligning management policies and development projects with tourist expectations and psychological needs.

Addressing systemic failures and delays requires a heightened level of professionalism and stakeholder consciousness—core objectives underscored throughout this research. Ultimately, this study concludes by advocating for the institutionalization of CE principles as a foundational strategy for sustainable tourism development in Northeast India. By fostering a deeper understanding of tourist behavior and reinforcing stakeholder collaboration, the CE model promises to significantly advance the region's tourism sector in both sustainable and competitive terms.

Appendix: Opinion Synthesize Matrix (Source: Primary data collected via open interview from the field visit)

No.	Particular	Opinions	Summary
1	Contractor	1. The workforce available in the region is adequately skilled and demonstrates strong potential for innovative design and creativity in CE-related projects. 2. The monsoon season, which commences after spring and continues for approximately three months, significantly hampers construction activities. This seasonal constraint often leads to project delays and affects the timely completion of CE developments for visitors. 3. Destinations located far from railway and road connectivity, such as Dzuko, Aizawl, and Shirui, experience considerable challenges in the maintenance and timely development of CE due to logistical constraints. 4. The timely availability of financial and material resources is critical for successful project completion. Contractors frequently encounter substantial difficulties due to delayed disbursement of funds and late supply of materials, posing a serious risk to the sustainability and quality of CE. 5. Locations such as Kangla, Kamakhya, Jorethan, and Sella Pass require minimal construction interventions, primarily because of their strategic positioning along highways and comparatively lower pressure from leisure tourism. Consequently, CE maintenance in these areas is relatively manageable. 6. Road infrastructure plays a pivotal role in enhancing tourist satisfaction at major destinations including Gangtok, Elephant Falls, Loktak Lake, Kangla, Neer Mahal, Sibsagar, and Aizawl. While two-lane roads have been developed in several areas, the expansion to four-lane highways is strongly recommended to accommodate increasing tourist inflow. 7. A significant proportion of resources are dependent on imports, which contributes to procurement delays. These delays are particularly pronounced in rural destinations, affecting the timely delivery of goods and services. 8. The policies formulated by relevant authorities demonstrate a clear commitment toward sectorial development through CE initiatives. 9. The systematic development of road infrastructure is expected to substantially increase tourist arrivals in the region. 10.It is essential that policy formulation processes incorporate tourist opinions and feedback to ensure sustainable and demand-driven development.	Contractors face considerable challenges in completing development projects due to delayed funding and resource provision, the disruptive effects of the monsoon season, and high transportation costs associated with remote railway access. Many CE projects are further constrained by limited financial allocation, although the workforce demonstrates the necessary skills and expertise to execute tasks efficiently. Minimal construction is required at locations such as Imphal and Sella Pass, owing to their strategic positioning along highways and relatively low appeal to leisure tourists. CE (road infrastructure) plays a crucial role in enhancing tourist satisfaction, particularly at destinations like Gangtok and Loktak Lake, with the expansion of road capacity strongly recommended. CE project timelines are also impacted by procurement delays, reliance on imported resources, and logistical challenges in rural areas. Despite these obstacles, laborers exhibit notable competence and adaptability for making CE pragmatic. Policymakers recognize the significance of CE (tourism-driven development, and infra-structure improvements) combined with the integration of tourist feedback, are essential for maximizing positive outcomes and attracting increased visitor inflow.

2	Worker Association	1. Proper training in new automated technologies is recommended, along with the replacement of outdate machinery with modern automated equipment to enhance operational efficiency and improve CE. 2. CE projects require diverse and short-term engagement of various skilled labourers. This necessitates a high level of professionalism, effective coordination, and systematic workforce management. 3. The successful implementation of CE requires clearly defined competencies and adherence to standardized project timelines. However, such structured time-bound project practices are not widely adopted in the region. 4. Workers demonstrate diligence and a strong work ethic in carrying out their assigned responsibilities, contributing positively to project execution.	Most volunteers and workers lack formal training, affecting task efficiency. Additionally, the transient and diverse nature of development projects results in short-term workforce engagement, impacting continuity and expertise. Despite these challenges, the labour force demonstrates strong competence, diligence, and work ethic, consistently completing projects on schedule and showing high commitment in overcoming obstacles. All would align in making the CE improve in the region.
3	Stakeholders	1. There is a noticeable lack of effective follow-up mechanisms after policy formulation, which limits the successful implementation of planned initiatives of CE in the region for the sector sustainable development. 2. CE directly benefits from the growth of the tourism industry, generating significant positive impacts on regional development. 3. Infrastructure enhancement (CE) is imperative to ensure higher levels of tourist satisfaction and sustainable destination management. 4. The engagement of local communities during policy formulation is crucial, particularly as many destinations are inhabited by tribal populations whose participation ensures inclusive and sustainable development. 5. Policies are formulated based on tourism activity requirements and comprehensive analysis of various reports, resulting in broad community consensus and contributing to CE development. 6. Tourism has significantly contributed to job creation, revenue generation, and the development of amenities and recreational facilities in the North-Eastern region. 7. Tourists seek well-maintained CE, including quality infrastructure, adequate amenities, warm hospitality, hygienic food services, and reliable telecommunication facilities. 8. Rapid progress in road construction is being undertaken to enhance accessibility and attract more tourists, particularly to remote destinations such as Dzuko, Kaziranga, Kanchenjunga, Tawang, and Gangtok, where road transport remains the primary means of access. 9. Despite proposed policies and planned projects, delays in completion frequently arise due to factors such as the pandemic, local interventions, untimely funding, supply chain disruptions, and monsoon conditions. 10.With adequate departmental support and developmental initiatives, numerous unexplored destinations can be brought into prominence beyond the currently selected sites. However, additional support from CE is required to facilitate this expansion. 11.Tourism industries boost revenue and generate employment opportunities through CE initiatives such as homestays, hotels, recreational services, and the sale of local products. 12.The enhancement of CE provides a vital platform for showcasing local culture, promoting indigenous products, and creating employment opportunities. 13.Tourist opinions encompass diverse preferences and expectations; therefore, CE must be sufficiently developed to address a wide range of needs. 14.Increased tourist influx has led to environmental concerns, including the exploitation of natural resources and rising pollution levels, particularly in Loktak, Umiam Lake, Kaziranga, Dzuko, and Shirui. 15.Strengthening CE will yield positive outcomes for both the tourism industry and local communities. 16.Local governments should prioritize effective promotion and partnership strategies to advance sustainable tourism development.	The development of CE faces several challenges, including limited interdepartmental collaboration and slow follow-up after policy implementation. While tourism industries benefit directly from CE, the enhancement of infrastructure is essential to meet tourist expectations and ensure satisfaction. Tourism policies are generally well-designed, supporting activities effectively, but active engagement of local communities, particularly tribal groups, is crucial during policy formulation to ensure inclusivity. Policies based on tourism needs and comprehensive reports help build community consensus, while constructors and worker associations strive to meet tourist demands. Tourism has positively contributed to job creation, revenue generation, and the development of amenities across the North-Eastern region. However, challenges persist, including inadequate infrastructure, project delays caused by external factors, and the environmental impact of increasing tourist influx, causing the CE to be un-organized. To address these issues, targeted road and facility development, particularly in destinations such as Tawang, is vital. The local government should prioritize promotion, partnerships, and comprehensive policies that balance tourism growth with environmental sustainability and community well-being.

Assessment of the potential of eco-cultural heritage in the development of sustainable tourism in Azerbaijan (on the example of Shusha city, Tugh, Taghlar and Azykh villages). *Geojournal of Tourism and Geosites*, 67(3), 1918–1925. https://doi.org/10.30892/gtg.67308-1820

Abstract: This study examines the utilization of cultural, ecological, and ethno-cultural heritage in the development of sustainable tourism in Azerbaijan, with a particular focus on the spatial organization of the natural-ecological, cultural, and ethno-cultural heritage potential in the Karabakh region. It also outlines methodological approaches for transforming areas with concentrated eco-cultural and ethno-cultural potential into tourism destinations. The research explores the applicability of modern methodological frameworks at the local level in promoting cultural and eco-cultural tourism. A multi-criteria assessment of existing resources is conducted using the Fuzzy Analytic System (FAS) method. Through integral calculations within the FAS method, the competitive advantages and strengths of destinations rich in cultural and eco-cultural heritage across the study region are identified. The study further analyzes the role of stakeholders in the formation of the city of Shusha as a cultural and creative tourism center, evaluating both advantages and challenges using the FAS method. Additionally, the advantages of efficient resource utilization in the development of the villages of Tugh, Taghlar, and Azykh as eco-cultural, ethno-cultural, and ecological tourism centers are substantiated. The principles guiding the planning of the research area and the zoning of its primary functional components were established, and key priorities for tourism development were identified. The results of the integrated assessment were substantiated as a central component for future tourism development, emphasizing the active participation of local communities in settlement processes, comprehensive management of cultural heritage resources, enhanced opportunities for official designation, and improvements in infrastructure and accessibility. Therefore, it is clear that the FAS method helped to identify areas of priority within the decision-making process for the project. The research was carried out based on an evaluation of cultural and eco-cultural potential in the region. Additionally, the framework ensures sustainability in tourism development.

Keywords: cultural, ecological, eco-cultural, ethno-cultural, FAS method, Shusha, Tugh, Taghlar, Azykh

INTRODUCTION

Eco-cultural heritage tourism promotes the conservation of natural, cultural and ethnic heritage (ethno-heritage), as well as the sustainable use of registered heritage through the tourism sector, ensuring its ecological and social sustainability. This type of tourism provides visitors with the opportunity to travel to natural and cultural heritage sites and contributes to the protection of the environment and the development of local communities. Eco-cultural tourism (ECT) combines environmental protection, promotion of cultural heritage, development and sustainability of local communities. Eco-cultural tourism destinations on a global scale can be noted both in destinations where natural and cultural heritage is concentrated, which are included in the UNESCO heritage, and in other countries.

Thus, national parks combining Maori culture and natural heritage in New Zealand, destinations covering indigenous culture and natural heritage in Costa Rica, Bali Island in Indonesia, Serengeti National Park in Tanzania, etc. can be noted (Demkova et al., 2022). At the same time, the Shusha and Khojavend regions, which were selected as research areas, are rich in cultural, ethno-cultural, eco-cultural, and ecological heritage, and the city of Shusha, Turshsu settlement, Tugh, Yukhari and Ashaghi Taghlar, Azykh estate complex, the surroundings of Gulabli village, as well as the archaeological heritage of the Aghdam region are suitable for organizing eco-cultural tourism destinations.

RELEVANCE OF THE RESEARCH

It is relevant in terms of environmental protection, the application of sustainable development in the transformation of cultural and ethno-cultural heritage into tourism products, increasing the activity of local communities in the tourism business, and expanding the concept of "green" tourism. Eco-cultural tourism consists of the protection of natural resources and ecosystems, tourists' discovery of natural wealth, the use of local culture and traditions, historical-cultural, artistic and creative heritage. Supporting the concepts of sustainable development in global tourism makes it necessary to involve local communities, which in turn stimulates economic development and promotes local eco-cultural heritage to a wider audience, ensures a balance of protection and use, and protects it for future generations without harming the ecological and cultural heritage. It should also be noted that the encroachment of natural and cultural heritage in the study area, and the complete destruction of some of them, has led to the emergence of "grey" zones from an ecological and economic point of view. In this regard, the application of the eco-cultural heritage concept in the development of sustainable tourism in the region would be more effective in terms of restoring and protecting existing resources.

METHODS

The conducted studies show that research on eco-cultural heritage mainly reveals three scientific approaches, which are ecological, cultural and community oriented. In addition, the concept of sustainability is taken as the basis for the use of eco-cultural heritage as a tourism product. The following theoretical and methodological approaches can be noted in the research on the use of eco-cultural heritage in tourism:

- **The theory of sustainable development** is widely used in the transformation of eco-cultural heritage into a tourism product, which researchers note the need to protect natural, ecological, cultural, traditions, as well as improve the socio-economic well-being of local communities (Weaver, 2016).
- **Theory of ecosystem services**. This theory is based on the assessment of ecosystem services of natural areas and heritage objects. Thus, the mentioned theory requires the protection and development of the natural environment in the formation of eco-cultural tourism products, which is similar to the concept of ecological and "Soft" tourism. This approach offers tourists the opportunity to use natural and cultural heritage in a regulated manner without harming nature, and to jointly benefit from natural and cultural heritage (Honey, 2019).
- **Theory of cultural and traditional heritage protection**. This approach promotes the preservation of cultural heritage, traditions and local lifestyles in tourist destinations, and the protection of cultural property (Hao et al., 2019).
- **Holistic theory (Holism)**. This approach emphasizes the inextricable link between cultural and natural heritage and is based on the advantage of joint use in eco-cultural tourism. Thus, eco-cultural heritage tourism seeks to ensure the protection and use of both natural and cultural values, considering the mutual effects of nature and culture (Jopp et al., 2022).
- **Theories of natural heritage promotion and community development**. This theory is aimed at increasing the value of natural heritage and its protection. It is aimed at regulating natural tourism activities in relation to the sustainability of natural heritage and ecosystems and preventing disruption of their self-recovery processes. At the same time, the benefits of eco-cultural tourism activities to local communities include not only tourism revenues, but also social, cultural and economic benefits for the local population, support and stimulation of their development (Rotherham, 2013).

In addition, eco-cultural tourism studies have highlighted the importance of sustainable tourism strategies, increasing the role of local communities, protecting cultural heritage and presenting it as a tourism product, in many ecological, ecotourism, cultural and ethno-tourism studies.

LITERATURE REVIEW

Studies conducted in the field of cultural and ecological tourism highlight the concept of a combined approach and, in some cases, the possibility of joint use. From the analysis of the literature, research on eco-cultural tourism began at the beginning of the 21st century and provided the formation of destinations based on the principles of the concept of sustainable development. According to Cajee, eco-cultural tourism encompasses the concept of sustainability by forming the basis of environmental, cultural and economic sustainability (Cajee, 2014). Here, the advantages of using tourism services by communities and protecting the environment in the form of regional development are shown (Jopp et al., 2022).

Rotherham based on the development concepts and examples of eco-cultural tourism, noted the advantages of cultural heritage, the use of local traditions as a tourism product and proposed a "circular solution" model in the destination (Rotherham, 2013). Tiberghien, Bremner and Milne noted eco-cultural tourism as the advantages of attractive factors, tourist behavior, environmental protection and ensuring the participation of communities (Tiberghien et al., 2017).

Hao, Wang and Ren put forward the concept of joint use of existing resources in the formation of eco-cultural tourism products, which allows for the creation of new innovative products. The authors attached special importance to such models as geographical environment, landscape-ecological factors, socialization, increasing the role of communities, transformation of cultural and traditional heritage into a tourism product, and advantages in the global market as UNESCO heritage (Hao et al., 2019). Dargahov, Talibov and Mammadov support the concept of transformation of eco-cultural heritage into a tourism product by considering the environment, eco-landscape, lifestyle of communities, demand for cultural and ethno-culture in the global market and propose "green" and "circular solutions" tourism models (Dargahov et al., 2021). Institute of Economics Ministry of Science and Education of the Republic of Azerbaijan analyze the institutional foundations of the post-conflict economy, focusing on structural transformation, infrastructure restoration, human capital development, and regional economic integration through a systematic approach. The authors identify priority areas for

economic growth based on the theory of comparative advantage and propose strategic development models for their implementation. Within this framework, the tourism sector is highlighted as a priority area of the economy, and the economic effects of its attractive factors are comprehensively examined (Institute of Economics, 2023).

Gavurova and others proposed a hybrid model integrating multi-criteria analysis for the assessment of regional sustainable tourism development. Their approach emphasizes the importance of incorporating sustainability-oriented criteria into regional tourism evaluation frameworks. The mathematical analysis, based primarily on expert assessment methods, prioritizes multi-criteria indicators when comparing alternative development scenarios. The expert-based evaluation model for determining the level of sustainable tourism in a region was developed and empirically tested using data structured around four principal groups of criteria: cultural, ecological, tourism-specific, and socio-cultural indicators (Gavurova et al., 2025).

DISCUSSION

Cultural tourism on a global scale allows for the development of urban destinations, the transformation of historical and cultural heritage into a tourism product. Cultural tourism accounts for 35-40% of international tourist flows and the annual growth rate is 3-5%. Analysis of World Tourism Organization data shows that UNESCO heritage and traditional cultural tourism destinations have retained their importance in cultural and ethno-cultural tourism (Eggleton et al., 2023).

The peak in inbound tourist arrivals to Azerbaijan was recorded in 2019, reaching approximately 2.8 million visitors. Following the COVID-19 pandemic, the recovery process progressed gradually, albeit with comparatively modest indicators. Over the past four years, the tourism sector has not fully regained its pre-pandemic performance levels, and a substantial growth rate in inbound tourism has yet to be observed.

Table 1. Dynamics and main indicators of tourists visiting Azerbaijan (The State Statistical Committee of the Republic of Azerbaijan, 2025)

Indicators	2019	2020	2021	2022	2023	2024	2025
Total number of foreigners arriving for tourism purposes (thousand persons)	2863.5	519.4	461.7	1058.1	1402.6	1855.1	2081.4
Leisure and entertainment	1164	164.9	132.4	398.5	858.3	1161.6	1243.1
Business	850.5	150.4	176.7	340.5	156.6	261.0	270.3
Visiting relatives and friends	519.9	98.5	90.5	154.8	160.7	203.8	250.6
Cultural and other tourism activities	265.2	88.9	53.9	150.3	207.1	208.5	274.2
Treatment and health	63.9	10.2	8.2	14.0	19.9	23.2	43.2
Spending by incoming tourists (thousand manats)	2971.4	414.7	492.6	1340.2	2439.2	3403.5	4334.2
GDP share of the tourism sector (%)	4.5	1.9	2.1	2.9	4.1	4.7	4.6

Analysis of international tourist flows in Azerbaijan shows that in the post-pandemic period, an increase in the dynamics of arrivals was observed (Imrani et al., 2025). The number of people arriving in the country for tourism exceeded 2.1 million people in 2025, which is 67.5% compared to 2019, the highest period of tourist flows. Among tourists arriving in the country, those arriving for recreation and entertainment purposes amounted to 1243.1 thousand people (Figure 1). Among those arriving for recreation, cultural tourism indicators are determined by the dynamics of foreign tourists arriving in the cities of Baku, Sheki, as well as reserves under the State Tourism Agency (STA). In particular, the number of tourists visiting the country for cultural tourism purposes reached more than 274 thousand in 2025, exceeding the peak level recorded in 2019. This trend is consistent with the broader tourism–economic development nexus, wherein sustained growth in tourist arrivals correlates with expansion in the sector's contribution to national GDP (Sokhanvar et al., 2018).

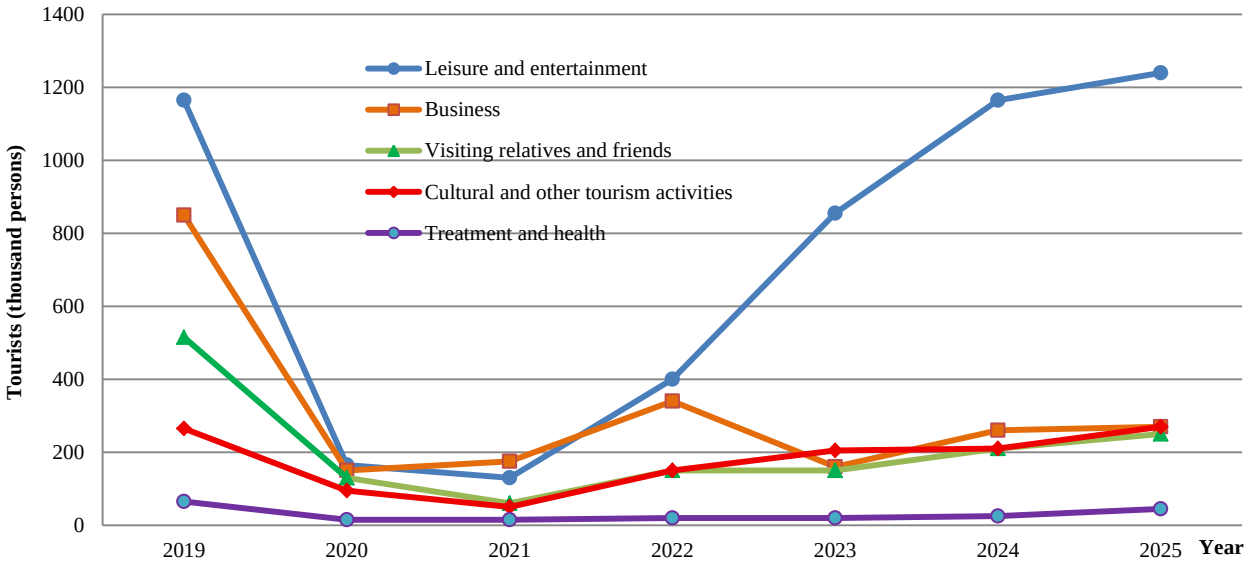

Figure 1. Structure of Inbound Tourist Arrivals by Purpose in Azerbaijan (Source: SSCRA, 2025)

At the same time, it is possible to determine the dynamics of visitors to historical and cultural reserves and archaeological monuments under the Ministry of Culture based on the analysis. Thus, the number of visitors to reserves under the STA amounted to 663.5 thousand people in 2024, which is a 35% increase compared to the previous year. 460.3 thousand incoming tourists were foreign tourists. Foreign tourists visiting the country amounted to 2.4 million people in 2024, of which 19.2% traveled to cultural tourism facilities (SSCRA, 2025).

Along with this, an increase in the dynamics of tourists visiting historical and cultural reserves under the Ministry of Culture is also observed, which can be considered an indicator of the increase in tourists visiting the country with cultural motives. The number of tourists visiting the 13 historical and cultural reserves under the Ministry of Culture was 223.4 thousand people in 2024, of which 102.6 thousand were foreign tourists. It should also be noted that the main part of those visiting historical and cultural reserves falls on the Gobustan Historical and Artistic Reserve, which is 132.4 thousand (State Tourism Agency of the Republic of Azerbaijan, 2025).

It should also be noted that the number of tourists visiting the Icherishahar (Old City in Baku) historical and cultural reserve, which is included in the UNESCO intangible heritage, was 235.6 thousand people in 2024. It can be noted that more than half of the tourists visiting the museums and other historical heritage of the Old City were foreign tourists. Also, the number of tourists visiting the city of Shusha, which has the status of a historical and cultural reserve, was 78.4 thousand people in 2024 (State Service for Protection, Development and Restoration of Cultural Heritage, 2025).

It is clear from our research that the development of cultural tourism destinations in the country, especially the presentation of historical and cultural reserves under the STA as a tourism product, and the implementation of a digital market have allowed tourists to be attracted. In addition, although 13 historical and cultural reserves under the Ministry of Culture have been restored, low indicators of marketing planning and lack of information have affected the low number of visitors (State Service for Protection, Development and Restoration of Cultural Heritage, 2025).

The advantage of the cultural and natural heritage potential in the Karabakh economic region, which is the study area, and its favorable location for organizing tourism activities ensure the development of tourism in the region. In this regard, the organization of tourism activities requires a multi-criteria assessment (MCA) of the existing potential using the FAS methodology. The multi-criteria assessment approach using the FAS methodology allows us to determine the comparative advantages of cultural, ethno-cultural, ecological, and other resources in tourism (Perles-Ribes et al., 2024). The formation of tourism-recreation zones in such regions parallels the broader practice of establishing special economic zones as a mechanism for stimulating regional tourism development (Plisetsky, 2012).

The assessment of tourism potential using the FAS methodology is an analytical analysis approach based on factors, assets and investments. In assessing the potential in the study region, preference was given to the rating and integral approach method, which determines the advantages of the FAS method of resources. Development directions are determined using the assessment of the cultural and creative heritage potential of the city of Shusha. Thus, it is carried out based on the FAS method and the analysis of indicators shows prospects.

The use of the FAS method in assessing the potential of the city of Shusha allows for the development of a basic concept including relief, climate, landscape, upper and lower infrastructure, hospitality and cultural characteristics of the population, security situation, legislation and state policy.

The mild climate in the city of Shusha in summer, cold in winter, high dry and comfortable indicators in the summer months, the presence of a dry climate and rich oxygen have led to its formation as a mountain-climatic resort. The fact that the city of Shusha covers an area of 4.5 km^2 on the plateau of the same name and is surrounded by forests and forest-steppe landscapes creates an attractive landscape in terms of tourism (Dargahov et al., 2023). The infrastructure of Shusha city was vandalized and destroyed during the occupation. The infrastructure is being restored, which consists of the restoration of the city's main energy supply, utilities, communications, and internal city roads.

Currently, the city's Karabakh street has been reconstructed, and a certain part of the main museums and buildings has been restored. Four mosques, one church, three museums, and 14 historical and architectural buildings have been restored in the city, which are presented to tourists visiting the city (Dargahov et al., 2023).

In determining the weight coefficient of factors in accordance with the FAS methodology, resource assessment and analysis capabilities have been determined based on integral approach methods. Here, the weight coefficient of cultural heritage indicators determines the cultural tourism opportunities of Shusha city. In this regard, based on the FAS methodology, the city's tourism potential and cultural tourism opportunities are assessed based on integral score indicators and added value creation. The integral assessment is calculated by the following formula (Baltagi, 2021):

$$P = \sum (W * Q)$$

P-Integral evaluation index;

W-Weight coefficient;

Q-Quantitative indicator.

Based on the above formula, the results of the factor analysis can be calculated:

$$P = (0.25 \times 9) + (0.15 \times 7) + (0.20 \times 6) + (0.10 \times 8) + (0.10 \times 5) + (0.10 \times 7) + (0.10 \times 6)$$

$$P = 2.25 + 1.05 + 1.20 + 0.80 + 0.50 + 0.70 + 0.60 = 7.10$$

The horizontal X-axis represents the factors applied in the multi-criteria evaluation and constitutes a nominal variable. The vertical Y-axis ranges from 0 to 2.5 points and is calculated as the product of the assigned weight and the corresponding quantitative value.

Table 2. Weighting coefficient and evaluation of cultural tourism potential in Shusha city

Factors	Weighting coefficient (W)	Quantitative score (Q)	Evaluation (WxQ)
F1 (Exotic nature and landscape)	0.25	9	2.25
F2 (Historical and cultural heritage)	0.15	7	1.05
F3 (Creative heritage and art)	0.20	6	1.20
F4 (Accessibility & Infrastructure)	0.10	8	0.80
F5 (Tourism infrastructure)	0.10	5	0.50
F6 (Tourism Services & Facilities)	0.10	7	0.70
F7 (Safety & Political Stability)	0.10	6	0.60
Total:	**1**	**48**	**7.10**

From the analysis of the table, although Shusha city has a high cultural tourism potential and has historical and cultural heritage and security as its strengths, the weak infrastructure and digital marketing and shortcomings do not fully support the development of tourism. Therefore, it is important to organize cultural events at an international level in the city, promote investments in tourism infrastructure (hotels, catering and transport), strengthen digital marketing and branding activities, and involve the local population in cultural tourism activities.

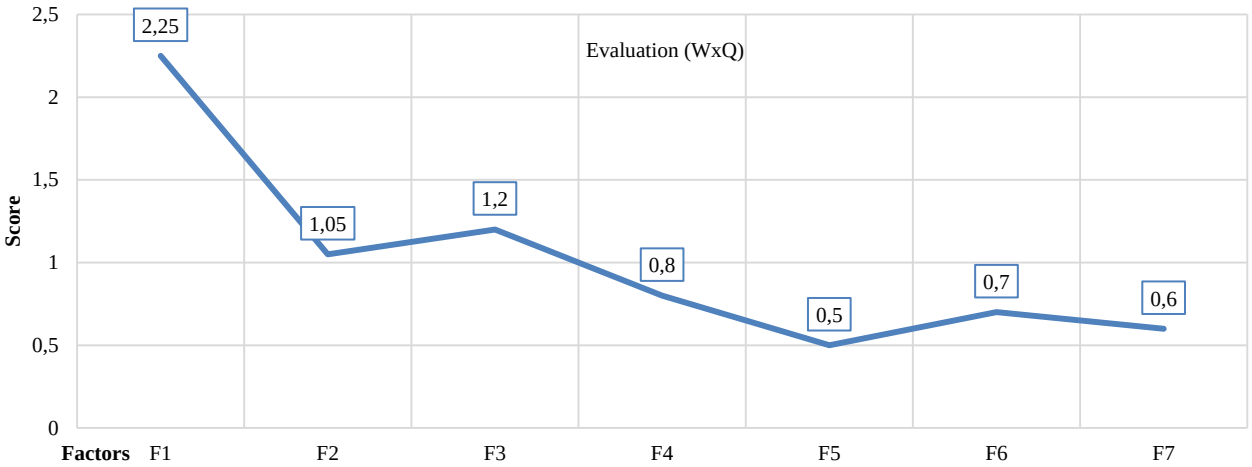

Figure 2. Evaluation scores based on FAS MCA methodology

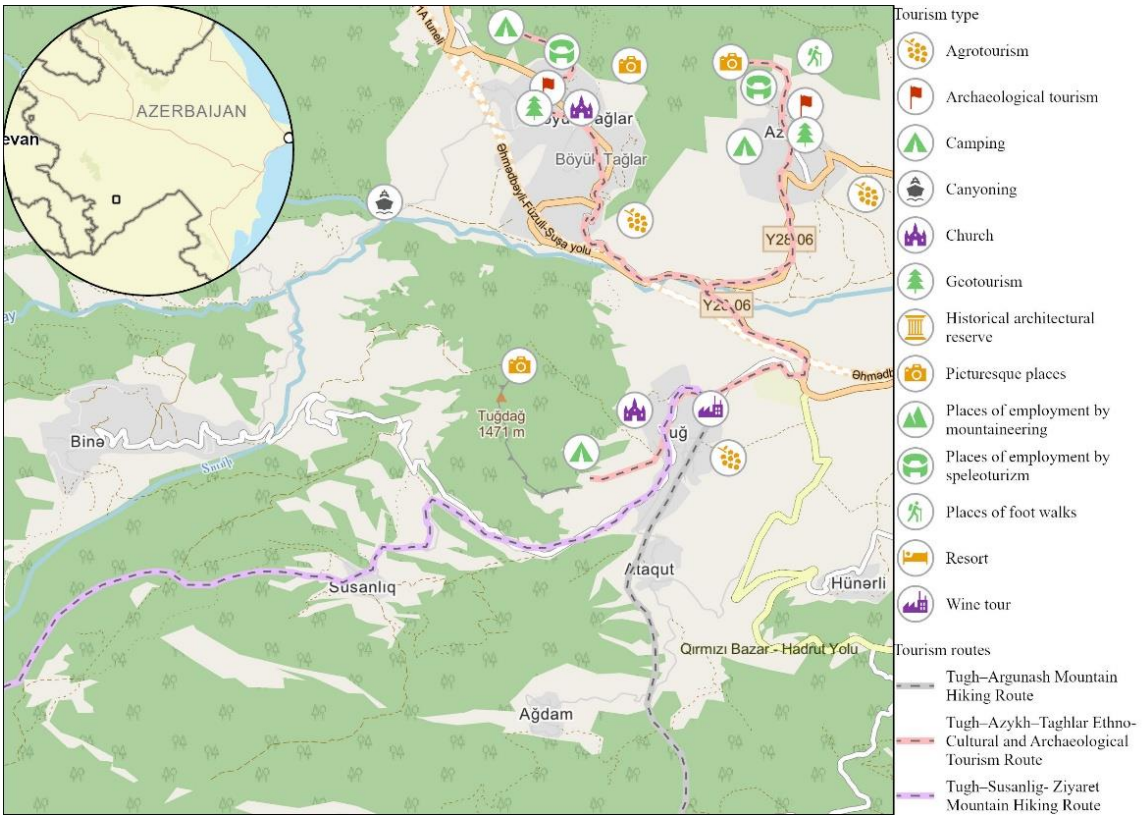

Figure 3. Map of the investigation area (Source: Author's own elaboration)

In addition, the institutional support of the state, the implementation of tourism management strategies, and various projects create conditions for the identification of new directions for the presentation of tourism opportunities. The holding of three international festivals per year in Shusha, the operation of three hotels, one hotel-restaurant complex, and the holding of many state and international events increase its importance in terms of tourism.

In the areas of Tugh, Taghlar, Azykh villages (Figure 3) and Hadrut settlement of Khojavend region, which are the study area, it is possible to note the wide spread of natural-climatic and attractive landscapes. In addition, the destruction of natural monuments and forest landscapes, and the vandalism of cultural heritage resources have reduced the attractiveness in terms of tourism. The location of the study area in the foothills, the mild climate, comfortable temperature and climatic conditions, the presence of historical-cultural and ethno-heritage, ancient Albanian monuments and mosques, the presence of ethno-, agri-heritage, natural monuments, caves, archaeological samples create a basis for the development of tourism (Dargahov et al., 2022, Imrani et al., 2024). The assets of the FAS method include natural resources (exotic and attractive factors), cultural, ethno-cultural and historical heritage, attractive and unique festivals and mass events, traditional crafts and local cuisine, which are also included in the established integral assessment. Socio-economic factors include human capital (tourism education staff, language skills), institutional support (tourism management, strategies and projects), and financial investment (public and private sector investments) (State Tourism Agency of the Republic of Azerbaijan, 2023).

At the same time, in recent years, the restoration and repair of roads to the mentioned settlements, the construction of some infrastructure facilities have improved tourism opportunities. It should also be noted that the lack of public transport, the exclusion of these villages and settlements from tourist routes, create conditions for more private car owners to come for tourism purposes (Dargahov et al., 2023). From a socio-economic point of view, the transfer of the village of Tugh to the STA, the interest of the returning population in the tourism sector, the preservation of carpet weaving, national cuisine and traditions, which are components of cultural heritage, will determine the development of the tourist service sector in the future. Also, there are favorable conditions for the development of eco-agro, outdoor, archaeological, speleotourism (caving, spelunking), cultural and ethno-cultural tourism in the villages of Tugh, Taghlar, Azykh.

In the assessment of the tourism potential of Tugh, Azykh, Taghlar settlements as eco-cultural tourism centers using the FAS method, the development directions are determined by conducting an analysis of the main factors. In this regard, the historical and cultural heritage of the settlements, attractive landscape ecological features allow for the organization of cultural, ethno-cultural, eco-cultural tourism activities.

Table 3. Assessment of tourism potential and organization of eco-cultural tourism activities in the villages of Tugh, Azykh and Taghlar using FAS methodology

Settlements	Physical factors	Accessibility factors	Socio-economic factors	Tourism activities
Tugh	-foothill exotic forest landscape ancient -Albanian monuments historical settlement -local architecture landscape and ecologically clean nature	- road rehabilitation - weakness of infrastructure - no tourism infrastructure - seasonal difficulties - not on tourist routes	- STA reserve status - protection of historical and cultural monuments - restoration of mining as heritage - community participation is desirable - restoration of agri-heritage	- cultural awareness - ecological - outdoor - eco-cultural - tourism routes
Taghlar	- attractive forest landscape - natural monuments (caves) - Albanian churches - local architecture and archaeology	- poor road infrastructure - no under infrastructure - no tourism infrastructure - seasonal difficulties - not on tourist routes	- traditional village life - community engagement - ecological heritage protection - cultural heritage restoration	- ecotourism - picnic - hiking and trekking - caving - tourist routes
Azykh	- Forest landscape - UNESCO cave - attractive ecological conditions and biodiversity	- access to the cave is possible, information is poor - roads have been restored - infrastructure is poor - tourism infrastructure is absent	- UNESCO World Heritage -preservation of historical and cultural heritage - a basis for economic revival	- Caving; - Ecotourism - Outdoor tourism - Hiking; - Picnic - Camping - Cultural tourism - Tourist routes
Integral assessment	**7,3**	**4,2**	**5,3**	**7,6**

From the analysis of the table, although the tourism potential of the mentioned settlements is high, the weakness of the basic infrastructure, the absence of overnight accommodation and catering services for tourists do not allow the organization of tourism activities. On the other hand, the presence of physical factors, direct support from the state, and the implementation of stimulating measures for business entities will support the development of tourism in the future.

The analysis of general socio-economic factors shows that the involvement of communities in tourism activities, the protection of cultural and natural heritage, and the restoration of traditional lifestyles will support the increase in tourism potential and the creation of added value. The existence of the potential for organizing various cultural, ecological, agri-eco and outdoor tourism activities in the study area will ensure its formation as an eco-cultural destination.

CONCLUSION

In conclusion, it should be noted that the higher ecological, cultural, ethno-cultural, eco-cultural tourism potential of the research points allows for the formation of new tourism products and increases competitiveness in the global tourism

market. The formation of tourist destinations in the research region, the joint use of cultural and eco-cultural heritage potential in the organization of TRZ is possible, which determines the advantages of tourism types in accordance with the FAS methodology. In this regard, it allows for the formation of the city of Shusha as a creative industry and cultural tourism destination, the formation of the Tugh settlement as a cultural and ethno-cultural center, the villages of Taghlar and Azykh, the surrounding areas as a caving, ecological, eco-cultural tourism zone. Here, the joint organization of ecological and outdoor tourism activities, the involvement of communities in agri-eco tourism will create added value for the region.

The integrated utilization of multiple destinations within the study area generates relative advantages among different tourism types by fostering interaction mechanisms and synergistic effects through the application of the FAS methodology in the comprehensive assessment of tourism potential. Development trajectories were identified by applying an integrative development model that combines cultural and eco-cultural heritage components in the formation of regional tourist destinations. Within this framework, the organization of tourism-recreation zones (TRZ) is based not solely on natural resource endowment but also on tangible and intangible cultural heritage assets. This approach enhances the distinctiveness of destinations and strengthens their competitive positioning in the international tourism market.

The results of the FAS-based assessment demonstrate that the strategic development of the city of Shusha as a hub for creative industries and cultural tourism is well justified. The city's rich historical and architectural heritage, strong musical and artistic traditions, and significant festival and event potential provide a solid foundation for its evolution as a creative economy center. This enables the promotion of innovative forms of cultural tourism, including event tourism, creative workshops, thematic cultural routes, and international festivals.

Simultaneously, the development of Tugh settlement as a cultural and ethno-cultural destination requires the integration of local ethnographic characteristics, folklore traditions, craftsmanship, and rural lifestyles into the tourism product. This direction supports the establishment of an inclusive, community-based tourism model through the synthesis of ethno-tourism and rural tourism elements, thereby reinforcing regional identity and socio-cultural continuity.

The villages of Taghlar and Azykh, together with their surrounding landscapes, possess substantial potential for speleotourism, ecological tourism, and eco-cultural tourism development. In particular, the presence of Paleolithic archaeological sites, such as the Azykh Cave, provides opportunities for positioning the region within the international scientific and educational tourism market. The organization of ecological and outdoor tourism activities—including hiking trails, geo-ecological excursions, biodiversity observation, and agro-ecotourism initiatives integrated with agricultural practices—can generate additional economic value and diversify tourism offerings.

The active involvement of local communities in agro-ecotourism processes enhances socio-economic sustainability, supports employment growth, and contributes to income diversification. A community-based tourism model simultaneously promotes the preservation of cultural heritage and the rational management of natural resources. Consequently, this integrative and multi-criteria assessment approach not only facilitates the sustainable formation of the region as a competitive tourism destination but also establishes a scientific foundation for long-term strategic development and increased competitiveness in the global tourism market.

Abstract: Border regions in the post-socialist parts of Central and Eastern Europe have long been shaped by geopolitical fragmentation, infrastructural discontinuities, and economic peripheralization. The Baranja Triangle, located at the intersection of Hungary, Croatia, and Serbia, provides a particularly relevant case study due to its history of geopolitical fragmentation and the recent removal of both administrative and infrastructural border barriers. Recent developments, including Croatia's accession to the Schengen Area in 2023 and the completion of the M6–A5 motorway connection in 2025, have significantly improved the region's accessibility. This study examines whether these changes create realistic conditions for the tourism-based reintegration of the Baranja Triangle within a broader cross-border regional framework. A mixed-methods approach was applied, combining geopolitical and spatial analysis, GIS-based accessibility modeling, a questionnaire survey among local residents (n = 60), and twelve semi-structured interviews with regional stakeholders; the findings were synthesized in a TOWS matrix. Results indicate that although physical and administrative barriers have largely disappeared, the creation of an integrated cross-border tourism destination depends primarily on institutional coordination and strategic development frameworks. Survey results show a moderately positive local attitude toward tourism, cross-border cooperation, and infrastructural improvements, while correlation analysis indicates that residents perceive these factors as interconnected elements of regional development. The study concludes that heritage tourism, ecotourism, cycling tourism, and wine–gastronomic tourism offer realistic pathways for sustainable development, enabling the Baranja Triangle to gradually transform from a peripheral borderland into a competitive tourism destination within the Danube region.

Keywords: cross-border tourism, Schengen Area, Baranja Triangle, infrastructure development, regional integration, sustainable tourism, geopolitical changes

INTRODUCTION

The Baranja Triangle (Hungarian: Baranya-háromszög) is situated on the northeastern periphery of Croatia, at the tri-border intersection of Hungary, Croatia, and Serbia. The region is bounded by the Hungarian-Croatian land border to the north, the Danube River to the east, and the Drava River to the south and southwest. Today, the area comprises the city of Beli Manastir (Pélmonostor) and eight municipalities. Its geographical position—characterized by the floodplains of two major rivers and lowland topography—fundamentally determines both its natural endowments and its socioeconomic development trajectory. The Bansko Hill (Bansko brdo / Báni-hegy), at 245 meters in elevation, and its surrounding area offer favorable conditions for viticulture and wine tourism.

The region's geographically strategic position astride multiple borders has profoundly shaped its development throughout the twentieth century. Border changes, political instability, and economic marginalization have resulted in prolonged regional isolation, which in turn has contributed to significant demographic decline and economic stagnation.

Similar to border regions across post-socialist countries, the Baranja Triangle has demonstrated acute vulnerability to processes of population loss and economic contraction. In recent years, tourism development has emerged as one of the most significant instruments for counteracting these trends. European Union-supported CBC (cross-border cooperation) programs (notably Interreg) have created new opportunities for peripheral regions to strengthen their economic position through transnational partnerships that transcend political boundaries (Tóth et al., 2020; Nemes & Happ, 2024). For the Baranja Triangle, the Danube and Drava rivers form a natural axis that could connect tourist attractions on both sides of

the border and provide a foundation for developing water-based tourism, cycling routes, and other thematic initiatives, notably wine tourism, across the region. In recent years, the region's geopolitical situation has shifted markedly: Croatia's accession to the Schengen Area on January 1, 2023, and the interconnection of the Hungarian M6 and Croatian A5 motorways in October 2025 have opened new transportation and economic perspectives for CBC initiatives.

These developments remain exceptionally recent, and the academic literature has not yet examined their impacts on the Baranja Triangle. This juncture therefore offers a unique opportunity to explore the economic and tourism-based reintegration of a region hitherto characterized by geopolitical isolation.

The aim of this study is to examine whether, in light of Schengen accession and new transport infrastructure, the Baranja Triangle's integration into a broader cross-border regional framework based on tourism development is realistic. Furthermore, it investigates whether a sustainable tourism economy, rooted in local assets, can be established in the region.

Theoretical Framework

Prior to the fall of the Iron Curtain, economic development in the border regions of Eastern Europe was constrained by insufficient investment and limited CBC (Tóth et al., 2020). These conditions frequently resulted in peripheralization and outmigration (Lang, 2015). Following the European Union accession of Eastern Bloc countries, however, programs designed to address structural disparities imparted new momentum to these regions (Wastl-Walter, 2009).

Although a significant portion of the EU population resides in border areas, their economic performance continues to lag behind the continental average; consequently, the 2014–2020 programming period allocated substantial resources—approximately €6.6 billion—toward their development (European Commission, 2017).

Similar spatial disparities are particularly pronounced along the Danube corridor, where regions with markedly different levels of economic development coexist, making macro-regional cooperation an essential framework for reducing territorial inequalities and fostering coordinated development (Hardi, 2012).

Tourism has emerged as one of the most widely adopted instruments of CBC, particularly in contexts of shared historical heritage (Kozak & Buhalis, 2019; Studzieniecki & Mazurek, 2007). This approach, however, necessitates novel forms of state coordination (Zaitseva et al., 2016). According to Timothy (2000), the border itself may function both as an independent motivational factor in travel and, as Ryden (1993) emphasizes, as a facilitator of the experiential distinctiveness of simultaneous presence in multiple nation-states. In the case of the Baranja Triangle, the fundamental question—following Matznetter's (1979) typology—is whether two independent destinations will persist on opposite sides of the border, or whether their convergence will produce an integrated tourism destination.

Social innovation plays a critical role in CBC initiatives: it strengthens local identity, facilitates the adoption of best practices, and supports sustainability objectives (Pentz, 2023; Marton et al., 2021). This process generates interaction between communities and tourists, thereby fostering peaceful coexistence (Michalkó et al., 2018), as exemplified by the network-based development model of the Veszprém-Balaton region (Lőrincz et al., 2023).

Tourism innovations typically emerge from complex network collaborations—including tourism destination management (TDM) organizations and clusters (Nagy, 2022; Nagy & Aubert, 2025)—within which consumers actively shape experiences through co-creation mechanisms (Marien & Papp, 2024).

Beyond open-ended experience innovation (Hoarau-Heemstra, 2011; Nagy, 2014), the development of the Baranja Triangle may be significantly shaped by smart destination frameworks and digitalization (Marinac et al., 2025). Innovation is driven not only by competition and technological advancement but also by public sector support (Hall & Williams, 2008). Finally, the ascendancy of alternative tourism forms—such as ecotourism (Szabados & Merza, 2023)—may represent a substantial breakthrough opportunity for the region (Csapó & Marton, 2010).

Considering established best practices in the tourism-led development of formerly closed border regions, the Baranja Triangle could draw valuable lessons from the Austria–Slovenia–Hungary tri-border area. In this region, numerous local initiatives have gradually evolved into EU cofinanced rural development programs linked to the tourism sector.

These initiatives have contributed not only to the gradual mitigation of border-area peripheralization but also to the broader socio-economic upscaling of the territory. The underlying development drivers in the Baranja Triangle closely resemble those observed in the Őrség and Neusiedler See regions, where development strategies are rooted in well-preserved natural and cultural landscapes, local traditions, and principles of ecological sustainability. EU-funded initiatives such as 'Iron Curtain Cycling' integrate the area and the local attractions into internationally visible context and tourism products (EuroVelo, 2025), projects like 'From Mill to Mill' build upon existing heritage assets to create new tourism attractions (Interreg Slovenia-Hungary Program, 2025), while programs such as 'PaNaNet+' integrate previously fragmented nature-based assets into internationally visible tourism products and promote environmental awareness and sustainability education through cross-border cooperation (Interreg V-A AT-HU Program, 2025).

METHODS AND SOURCES

Our research examined the impact of geopolitical changes and transformations in transport infrastructure on the tourism potential of the Baranja Triangle. We also analyzed the role of CBC in the region's tourism sector, assessed existing forms of tourism and their developmental opportunities, and explored the attitudes of the local population toward tourism and cross-border collaboration (Figure 1). A mixed-methods approach was employed. For spatial analyses, we utilized QGIS 3.40 ("Bratislava") software to map tourism attractions in the Baranja Triangle and its immediate surroundings, and to examine the region's transportation infrastructure and accessibility. For travel time-based accessibility analysis, we used a combination of the TravelTime API and QGIS, which enabled route and isochrone calculations based on current road network data.

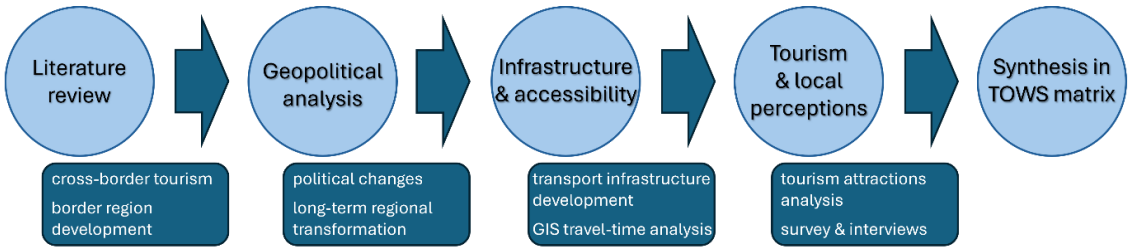

Figure 1. Flowchart of the methodology (Source: Own illustration)

To gauge local perspectives on tourism, CBC, the connection of the M6 and A5 highways, and Croatia's accession to the Schengen Area, we conducted a quantitative survey. Secondary sources included relevant academic literature and documents from European Union CBC programs. The questionnaire was administered online using Google Forms. Participation was voluntary and anonymous. Eligibility required respondents to be at least 18 years old and residents of the Baranja Triangle. Data collection relied partly on Facebook advertising and primarily on snowball sampling. While this method is suitable for reaching hard-to-access populations, a key methodological limitation is its deviation from classical principles of representative sampling; thus, findings cannot be generalized to the entire population (Atkinson & Flint, 2001).

The questionnaire comprised two sections: the first collected demographic data, while the second addressed respondents' assessments of their economic situation, the relationships between CBC, tourism, and transport infrastructure development, and the perceived impacts of these factors on their livelihoods and the development of the Baranja Triangle. Quantitative data were analyzed using Jamovi 2.6.44 statistical software, employing descriptive statistics as well as non-parametric comparative (Mann-Whitney U) and correlational (Spearman's rank correlation) methods.

To compensate for the small questionnaire sample size (n=60), we conducted twelve semi-structured interviews in the region to refine our findings. Interviewees represented a diverse range of local stakeholders, including agricultural producers, entrepreneurs, educators, and representatives of local public and civic life. The sample also included a winemaker, a municipal council member, organizers of cultural and gastro-tourism events, as well as church and community representatives, allowing tourism-related perceptions to be explored from multiple social and economic perspectives. Finally, results from the various sources were synthesized in a TOWS matrix to identify the region's key development opportunities and challenges.

RESULTS AND ANALYSIS

1. Geopolitical Analysis: The Impact of Historical-Political Changes on Tourism Potential

The Baranja Triangle has been shaped by numerous geopolitical changes throughout its history, which continue to influence its demographic processes, ethnic composition, economic situation, and tourism potential. Within the broader Danube region, such historical discontinuities are not exceptional. The region has repeatedly experienced periods of fragmentation and reintegration shaped by shifting political borders, imperial structures and geopolitical conflicts (Hardi, 2012). From the founding of the Hungarian state in 1000 until 1541, the territory of the present-day Baranja Triangle was under the sovereignty of the Kingdom of Hungary; however, over the subsequent approximately 500 years, the region was ruled by six different state formations. The twentieth century alone witnessed five shifts in sovereignty.

This turbulent past has resulted in a significant historical heritage, while the continuous transformation of the ethnic structure has produced a culturally diverse landscape that persists to this day.

- 1000–1541 – The Period of the Kingdom of Hungary: Agricultural prosperity and the development of the settlement network established a long-term foundation for the region's agricultural traditions and cultural heritage. The historical roots of the contemporary settlement structure were laid during this period, and a wine-region identity already characterized the Bansko Hill (Báni-hegy) area.
- 1541–1687 – The Period of Ottoman Rule: The region's military-logistical significance—evidenced by Suleiman I's bridge connecting Osijek (Eszék) and Darda (Dárda), the Osijek fortress, the military road traversing the region, and the proximity to the battles of Mohács (1526, 1687)—created considerable heritage tourism value. The settlement of South Slavic peoples and the strengthening of Reformed communities continue to define the region's ethnic, cultural, and religious diversity.
- 1687–1920 – The Era of the Habsburg Empire and the Austro-Hungarian Monarchy: The Belje Estate as a modern agricultural enterprise, along with church construction and infrastructural development, left behind a substantial volume of built heritage. The agricultural and historical legacy of this period remains a potential tourism resource.
- 1920–1991 – The Period of the Kingdom of Serbs, Croats and Slovenes, the Kingdom of Hungary, and Yugoslavia:

Border changes, Yugoslav land reform, and isolation due to a lack of transportation infrastructure hindered the area's development. However, the multiethnic society and cultural imprints of the Yugoslav era created a unique identity that could be integrated into contemporary tourism offerings. An example is Yugonostalgia, a form of longing for the past—a bittersweet nostalgia for the positive, idealized aspects of the former socialist Yugoslav state.

- 1991–1998 – The Years of War: The Serb-Croatian conflict, emigration, and economic collapse severely damaged the region's general and tourism infrastructure. Nonetheless, the major clashes that occurred in the area can serve as important sites of remembrance and education regarding the war.
- 1998 to the Present – The Period of Independent Croatia: Croatia's accession to the European Union and the Schengen Area, along with the significant improvement in transportation infrastructure (the M6–A5 highway), has substantially enhanced the region's accessibility. CBC and cultural-gastronomic tourism have gained new development opportunities.

2. Infrastructure development relevant to tourism

Following the Treaty of Trianon, the Baranja Triangle was incorporated into the Kingdom of Serbs, Croats, and Slovenes in 1920 (Hajdú, 2011; Végh et al., 2021; Bali & Matucza, 2021). The region entered a period of persistent marginalization, driven by the division of the previously integrated Baranya County and the Belje Estate (Székely, 2014; Végh et al., 2021), the dissolution of landholding structures after Yugoslav land reform, the diminished political-economic role of the Hungarian and German landowning class, and the continuous deterioration of transportation connections (Bali & Matucza, 2021). Until 1941, the Baranja Triangle remained under Serbian administration (as part of Vojvodina, Bačka, and later the Danube Banovina) but lacked functional transportation links to these core territories (Hajdú, 2011, Végh et al., 2021). Notably, no road or railway bridge crossed the Danube in the region at that time. Until 1962, access from Croatian territories was limited to a single railway bridge in Osijek that also carried road traffic, reinforcing the area's pronounced isolation.

This isolation began to ease with key infrastructure projects. The first road bridge across the Drava toward Croatian territories was constructed in Osijek (Eszék) in 1962, followed by a bridge at Batina (Kiskőszeg) across the Danube toward Serbian territories in 1974 (Végh et al., 2021). Following Croatian independence, the state played a pivotal role in further improving connectivity. Strategically important road bridges across the Drava were built in the Belišće (Belistye) area in 2001 and near Osijek (Eszék) in 2007. A highway bridge crossing the Drava was completed near Petrijevci (Petróc) in 2016 (Pirisi & Reményi, 2008; Végh et al., 2021).

While the 2015 European refugee crisis temporarily led to stricter border controls and enhanced surveillance at the Croatian-Hungarian border, Croatia's accession to the Schengen Area on January 1, 2023, ultimately enabled complete free movement across this border section.

The combination of border-free travel and the connection of the M6 and A5 motorways—completed in October 2025 as part of the Vc corridor—has significantly advanced the accessibility of the Baranja Triangle. As demonstrated by the isochrone map from our GIS travel-time analysis, the Hungarian regional tourism hub of Pécs is now reachable within a 60-minute drive from Beli Manastir (Pélmonostor). Furthermore, five of the eight municipal centers of the Baranja Triangle—Petlovac (Baranyaszentistván), Popovac (Baranyabán), Jagodnjak (Kácsfalu), Kneževi Vinogradi (Hercegszőlős), and Čeminac (Laskafalu)—are also located within this 60-minute travel-time threshold from Pécs (Figure 2).

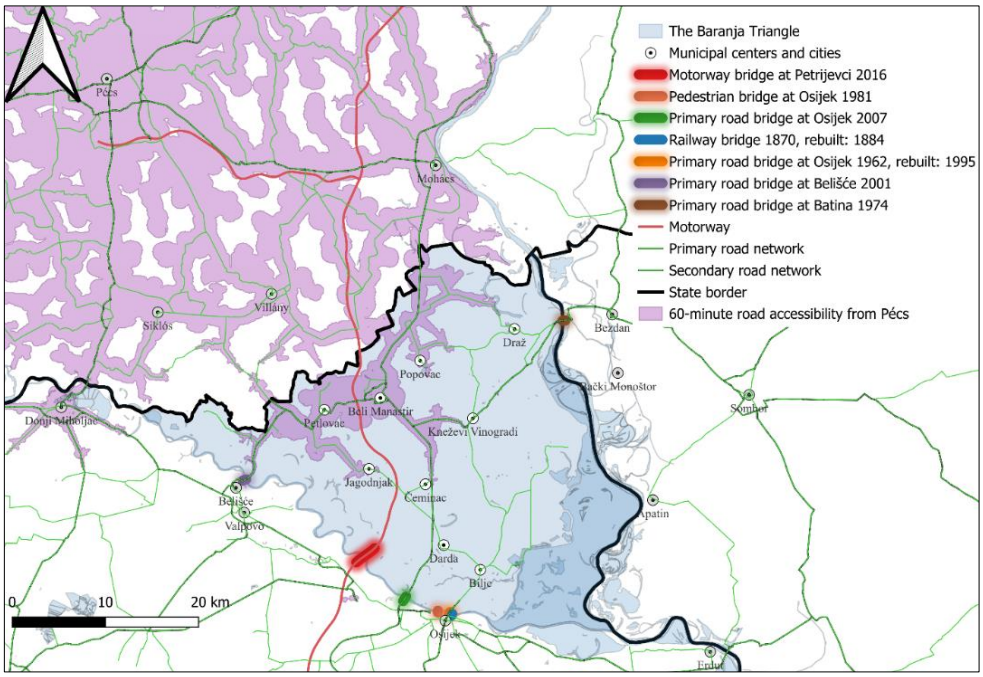

Figure 2. The road network and accessibility of the Baranja Triangle (Source: Own illustration)

This represents a profound change. During periods of armed conflict, the border was completely impassable. Even during times of Yugoslav-Hungarian political confrontation, administrative barriers posed significant obstacles. The current situation—featuring the most open border in the past 100 years—was achieved not primarily through infrastructural development, but through administrative measures and a fundamental transformation of the border regime. This highlights a key limitation of isochrone analysis in this context: the 2025 highway connection builds upon a baseline where, during past political crises, crossing the Hungarian border into the region was not possible at all.

Croatia's accession to the euro area does not currently constitute a primary driver of tourism development in the Baranja Triangle, as the region forms a functional cross-border unit with adjacent Hungarian territories where euro adoption is not anticipated in the near future. Nevertheless, the introduction of the euro increases the transparency and comparability of price levels for Western European visitors. Given that tourism-related prices in the Baranja area remain generally lower than in most parts of Croatia and Western Europe, this may enhance the region's attractiveness and generate moderate increases in short-term inbound tourism from euro-area markets.

3. Institutional Connections Analysis: The Role of Cross-Border Cooperation in Development and Territorial Cohesion Processes in the Baranja Triangle

The socioeconomic changes of the past two decades—particularly Hungary's and Croatia's accession to the European Union and Croatia's subsequent accession to the Schengen Area in 2023—have created the most favorable geopolitical and financial conditions for the Baranja Triangle along the Hungarian-Croatian border in the past hundred years. This favorable position rests on two pillars:

- Institutional sister-city relationships established since the 1970s.
- Initiatives promoting cooperation along the EU's external borders (e.g., the 2002 External Border Initiative) and continuously growing Interreg funding.

3.1. Institutional and Twinning-Type Cooperation

Sister-city relationships established from the 1970s onward (e.g., Mohács–Beli Manastir, 1970; Pécs–Osijek, 1973; Baranya County–Osijek-Baranja County, 1995; University of Pécs–Josip Juraj Strossmayer University, renewed in 2024) are primarily of sociocultural significance, with limited economic impact (Reményi, 2008; Pámer, 2019). Twinning relationships among smaller municipalities can facilitate economic convergence only in the long term; in the absence of declared political will, project-based cooperation currently remains limited.

3.2. Organizational-Based Cooperation

- Danube-Drava-Sava Euroregion (c. 1998–2010): A top-down initiative that exceeded the region's institutional maturity and resources—representing a "missed opportunity" (Síkfői, 2011). During the pre-Schengen period, it failed to resolve the region's peripheral position and generated no significant socioeconomic impacts.
- Pannon EGTC (European Grouping for Territorial Cooperation) (2010–present): An organization blending bottom-up and top-down approaches within an EU legal framework, representing the common interests of border counties. Its activities are primarily project-based (e.g., CBJointStrategy, UPSCALE DDS, Amazon of Europe Biketrail, Pannon Future Forest) and focused on maximizing EU funding, making it potentially the region's most important shared development organization in the short to medium term. On this basis, there is a need for a transnational development program independent of temporary grant funding that integrates the Baranja Triangle's strategic strengths and actively involves the two county-level and national governments (see the TOWS matrix later).

3.3. Relevant Outcomes of EU Co-Financed Interreg Programs in the Baranja Triangle

- Pre-2004 (Phare CBC and Interreg III Slovenia–Hungary–Croatia): Focused on capacity building and pilot projects; despite pressing infrastructure needs, these programs prioritized "soft" development.
- 2007–2013 IPA CBC (€52M, 164 projects): The most significant project for the Baranja Triangle was the "De-Mining" initiative. In tourism, Pécs–Osijek cooperation occurred without generating meaningful territorial cohesion effects.
- Interreg V-A (2014–2020, €60M): Exhibited low territorial relevance to the Baranja Triangle; projects were primarily cultural and focused on cycling/water tourism in the larger hubs of Pécs, Osijek, and Mohács.
- Interreg VI-A (2021–2027, €58M): Characterized by a late start and strong competition; notable projects include the Amazon of Europe bicycle route (involving visitor center expansion in Osijek and infrastructure in Siklós, etc.) and joint projects linking Mohács, Belišće, and Osijek. Interregional and transnational Interreg programs (Danube, Central) are available but difficult to access due to their complexity and currently represent marginal funding sources for the region. For the Baranja Triangle to achieve a genuine transformation in scale, integrated development programs are necessary. These must be prepared with the involvement of local stakeholders, transcend particular interests, and strategically exploit the barrier-free physical and legal environment of the Schengen Area and the coordination capacity of the Pannon EGTC, particularly in the areas of wine, eco-, water, and heritage tourism.

4. Attraction Analysis: Forms of Tourism and Their Development Opportunities in the Baranja Triangle

The role of tourism as a tool for CBC and regional development continues to strengthen within the European Union (Bujdosó et al., 2015). For the Baranja Triangle, Croatia's accession to the Schengen Area and the elimination of border controls have created favorable conditions for cross-border tourism cooperation. Cross-border tourism networks supported in Croatian-Hungarian CBC projects—such as green routes or various thematic tourism trails—were initially developed to foster social innovation and the rapid adoption of neighboring "best practices" (Csapó et al., 2015; Szabó et al., 2014). However, most of these initiatives subsequently collapsed due to a lack of proper management, although certain elements persist today. Tourism in the Baranja Triangle and southern Baranya is not significant in either country, yet the region possesses considerable development potential (Figure 3). In our view, a shared, cross-border tourism destination created through coordinated development could provide a competitive advantage and greater international appeal.

The region’s strong embeddedness in Hungarian socio-cultural traditions may represent a measurable driver of inbound tourism from Hungary, particularly if tourism products are strategically integrated with nearby flagship destinations on the Hungarian side, such as the city of Pécs, the Villány–Harkány tourism area and Mohács. This potential is primarily rooted in shared cultural heritage and historical ties, rather than in the relatively small number of ethnic Hungarians currently residing in the area. The examination of tourism in the Baranja Triangle also demonstrates that regional tourism development requires broad, multi-level cooperation (Marton et al., 2016). With the end of its previous isolation, the region's cultural and natural heritage has become a viable resource for tourism development.

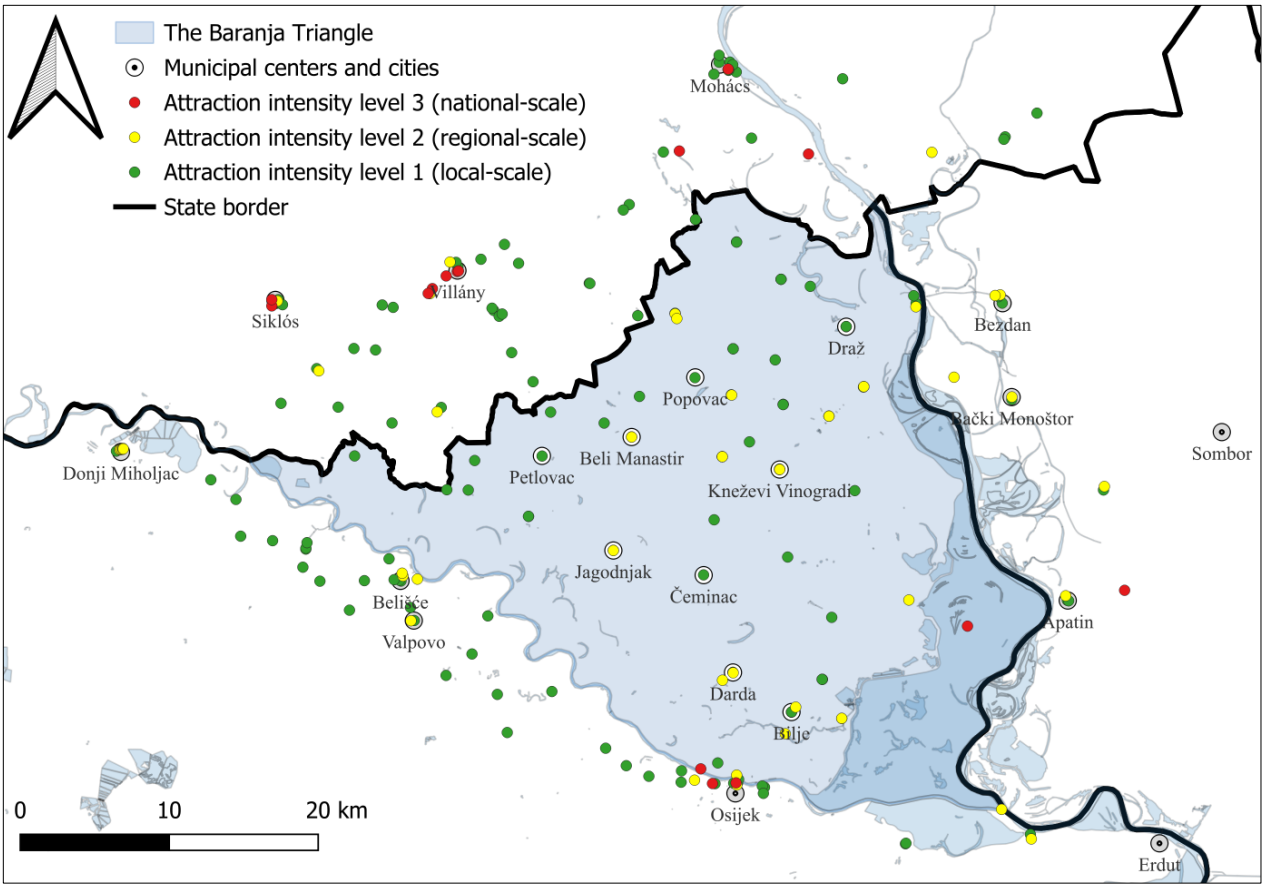

Figure 3. Attractions of the Baranja Triangle and its immediate surroundings (Source: Own illustration)

Nevertheless, despite substantial support, increases have been observed primarily in excursion traffic, while the number of tourists and overnight stays remains very low (Zsibók & Egyed, 2024). The Baranja Triangle's tourism product portfolio is diverse. It is primarily linked to leisure tourism and largely based on natural resources, with the exception of cultural tourism. Identical product types appear on both sides of the border, yet cooperation between them is limited, and partnerships formed within CBC projects typically do not survive beyond the mandatory project maintenance period. The coordinated development of these products and the creation of a shared, cross-border destination could establish the region's unique selling proposition—a characteristic that could also attract international market interest (Spiegler et al., 2023).

The territory's tourism products can be fundamentally divided into three main categories:

- Cultural Tourism Built on Shared Historical Past and Heritage Values:

Border regions are often connected by shared history, identity, culture, traditions, and mixed population composition (Varga et al., 2025). This observation applies strongly to the examined region. The Danube area has been an important military route since Roman times, and heritage values from multiple periods exist on both sides (e.g., the Limes and Ottoman-era monuments). Building on these, cultural tourism can be developed through mirror projects. The main sub-products include:

- Heritage tourism. The region contains a significant concentration of archaeological heritage and forms part of the Roman Danube Limes cultural landscape, sections of which were inscribed on the UNESCO World Heritage List in 2021. However, the Batina–Ilok sector (Ad Militare–Cuccium) remains under nomination and currently plays only a marginal role in regional tourism development. Most archaeological remains are still located on agricultural land, and the timing and format of their future public presentation remain uncertain. In the longer term, these sites may become an important component of the region's cultural tourism portfolio, complementing its existing natural and cultural attractions. The "Roman Emperors and Danube Wine Route"—a European Cultural Route—may similarly represent an additional, currently underutilised opportunity for integrating the region into wider international heritage tourism networks.
- Dark tourism. The 500th anniversary of the Battle of Mohács directs attention to the region's Ottoman-era devastation. The development of this memorial site could strengthen dark tourism, and the coordinated development of monuments found on both sides of the border could create international appeal.
- Festival tourism. The region's festivals are diverse, with nearly every settlement hosting some form of gastronomic event. These currently have primarily local and regional appeal. Through program coordination and joint marketing, they could generate greater interest. The Busójárás in Mohács—listed as Intangible Cultural Heritage—is the flagship event of festival tourism and could have significant drawing power for tourism in the Baranja Triangle.

- Active and Ecotourism:

Outstanding examples of cross-border development can be realized in the fields of active and ecotourism.

- Bicycle tourism. The region's infrastructural conditions are favorable. Two EuroVelo routes (EuroVelo 13 and 6)

increase international visibility. Improved visitor facilities and targeted marketing could encourage cyclists from border regions to explore the area. With the spread of electric bicycles, the target audience expands to include a more prominent senior demographic, for whom the Baranja Triangle can be a favorable destination.

- Walking tourism / Green routes. Two green routes were established through CBC projects (Baranya Green Route and Ormánság Green Route). Development based on local resources can be effective, but without appropriate management organizations, their tourism and rural development role remains limited.
- Ecotourism. Development is led by the Danube-Drava National Park and the Kopački Rit Nature Park. Previous CBC projects have fostered strong professional cooperation, and the ecotourism offerings on both sides of the border are innovative and have generated significant interest.

- Wine and Gastronomic Tourism:

The Baranja Triangle has a significant tradition of viticulture and winemaking (Tarnai, 2025). Building on this and the region's rich gastronomic culture, a unique offering can be developed. Beyond wine, paprika, kulen sausage, and smoked carp, numerous local products create demand. The development of local festivals (kulen festival, paprika festival, Fish Days in Kopačevo, Wine Marathon in Zmajevac, etc.) could result in broader appeal.

5. Local Society's Supportive Attitude toward Tourism and Cross-Border Cooperation Programs

Our questionnaire survey aimed to explore the attitudes of residents in the Baranja Triangle regarding tourism, CBC, Croatia's accession to the Schengen Area, and the expected impacts of the M6–A5 highway connection on both individual living conditions and the region's overall development.

- Sample Characteristics:

A total of 60 individuals participated in the survey (30 women, 50.0%; 30 men, 50.0%). The mean age of respondents was 45.3 years (range: 22–67 years). Regarding the highest level of educational attainment, 2 individuals (3.3%) completed primary education or less, 3 (5.0%) completed vocational training, 7 (11.7%) completed general secondary education, 16 (26.7%) completed technical secondary education, and 32 (53.3%) completed tertiary education or higher (college, university, or doctoral degree). As noted in the methodology section, snowball sampling does not yield a sample representative of the entire Baranja Triangle population, a limitation reflected in the educational attainment distribution. Due to the voluntary nature of the survey, individuals with greater interest in tourism, CBC, and transportation/economic development likely participated at higher rates, explaining the overrepresentation of respondents with tertiary education.

- Descriptive Results:

Respondents provided answers on a 7-point Likert scale (1 = worst, 7 = best). Based on descriptive analysis, respondents overall assessed the development of the Baranja Triangle as moderately positive (mean = 4.42), while expressing relative dissatisfaction with their own current economic situation (mean = 3.87). Respondents assessed tourism's impact on the Baranja Triangle as moderately positive (mean = 5.03); however, they viewed tourism's impact on their own material situation more negatively (mean = 3.67). Regarding expected benefits from tourism development, respondents most frequently highlighted local infrastructure development (n=35, 57.4%), expansion of work and business opportunities (n=34, 55.7%), improvement of the settlement environment (n=33, 54.1%), and revitalization of cultural and community life (n=32, 52.5%). CBC along the Croatian–Hungarian and Croatian–Serbian borders was assessed as having a moderately positive impact on the region (mean = 4.28), while its impact on personal quality of life was viewed as moderate (mean = 3.98). Primary expectations from CBC centered on the revitalization of cultural and community life (n=33, 55.0%), expansion of social networks (n=31, 50.8%), improvement in work and business opportunities (n=29, 47.5%), and local infrastructure development (n=26, 42.6%). Overall, respondents evaluated Croatia's accession to the Schengen Area and the realization of the M6–A5 highway connection as rather positive for the Baranja Triangle's development (mean = 5.20), while viewing their impact on personal living conditions as moderately positive (mean = 4.58).

The most frequently anticipated effects included local infrastructure development (n=30, 49.2%), expansion of work and business opportunities (n=21, 34.4%), improved accessibility of services (n=19, 31.1%), expansion of social networks (n=18, 29.5%), and a general improvement in the daily quality of life of the local population (n=18, 29.5%).

- Analysis of Gender Differences:

Following descriptive analysis, we examined gender differences in responses to the Likert-scale items. As the data did not consistently meet assumptions of normality, we employed the Mann–Whitney U test. Results indicated no statistically significant difference between male and female responses for any of the examined items ($p > 0.05$ in all cases), with low effect sizes, suggesting minimal gender-based variation in attitudes.

- Correlational Analyses:

Finally, we examined associations between variables using Spearman's rank correlation analysis. Results demonstrated moderate to strong positive correlations between assessments of the individual and regional impacts of tourism development, CBC, transportation infrastructure improvements, and Croatia's Schengen accession ($\rho \approx 0.42–0.69$; $p < 0.001$).

Overall, the results suggest that in respondents' perceptions, tourism development, CBC, improved transportation infrastructure, and Schengen accession are closely interconnected factors in assessments of both individual living conditions and the Baranja Triangle's economic and social development.

Insights from the semi-structured interviews broadly reinforced these findings. Interviewees emphasized that the region’s economic profile remains predominantly agricultural, with tourism currently playing a supplementary role. At the same time, several respondents highlighted potential resources that could support future tourism development, including cultural festivals and community events, wine-related tourism, and the region’s rich historical and cultural heritage.

Overall, the interviews suggest that local actors perceive tourism as a promising development opportunity which, although not yet a dominant economic sector, may contribute to the long-term economic diversification of the Baranja Triangle.

Analysis: Development Matrix Based on External and Internal Environmental Factors of the Baranja Triangle—TOWS Matrix

	Strengths	**Weaknesses**
Opportunities	**SO Strategies** (Leveraging Strengths)	**WO Strategies** (Counterbalancing Weaknesses)
1. EU and national development funding (e.g., Interreg CBC/ Danube/Central, RRF etc.). 2. Climate adaptation, green transition, and renewable energy utilization. 3. Cultural and tourism momentum (Mohács 2026 commemorations, legacy of Pécs European Capital of Culture, growing demand for soft tourism—wine, cycling, eco-, and water-based). 4. Unified Schengen territory (Croatia-Hungary).	**1. Develop joint heritage tourism products with international appeal by linking key assets** (e.g., Zsolnay Cultural Quarter in Pécs, Busójárás in Mohács, Mohács 500 commemorations, Tvrđa in Osijek) through EU-funded programs. **2. Develop integrated wine, gastronomic, eco-, and cycling tourism products with international appeal** (e.g., Villány–Siklós Wine Route with Slavonia; Amazon of Europe cycling route; Kopački Rit–Béda-Karapancsa floodplain reserve). **3. Joint development of the cross-border logistics hub function** – Mohács bridge and port + Osijek Airport (Pécs–Pogány Airport, "Vojvodina's Smile" motorway, etc.).	**1. Jointly lobby for the implementation of missing transport links to mitigate peripherality** (e.g., connecting the M60 motorway to the Croatian A13, motorway developments in Vojvodina, upgrading Pécs Airport). **2. Launch joint vocational training programs to reduce outmigration by fostering high value-added local products (primarily food),** involving the University of Pécs, University of Osijek, and vocational training centers. **3. Create a joint "Smart-Eco" digital eco-region—establish a digital platform centered on Osijek–Pécs,** leveraging 5G and smart tourism technologies.
Threats	**ST Strategies** (Protecting Strengths)	**WT Strategies** (Minimizing Threats)
1. Outmigration, demographic aging. 2. Climate change (droughts, flash floods, etc.). 3. Competition with the Croatian coast and Lake Balaton (lower-cost tourism) 4. Geopolitical tensions (border traffic, migration)	**1. Launch transnational Croatian–Hungarian and local (municipal-level) youth retention programs—** establish a Pécs–Osijek startup incubator and subsidized housing initiatives (public sector). **2. Create and promote an independent, joint "Baranja Triangle" eco-experience soft tourism brand,** incorporating elements such as Villány–Slavonia wine tourism, Kopački Rit, Mohács floodplain areas, and cycling tourism. **3. Further develop port infrastructure—**expand promenade boat ports in Mohács, Batina, and Osijek; develop floodplain free ports.	**1. Develop a joint Croatian–Hungarian demographic pact project—**introduce state-involved subsidies and incentives to counteract population decline. **2. Establish a climate adaptation and disaster management pact—**a Croatian–Hungarian state and county-level agreement for flood protection in floodplain areas and drought management.

CONCLUSION

Croatia's accession to the Schengen Area and the completion of the M6–A5 motorway connection have enabled the Baranja Triangle to reclaim its historical role as a relational space along the Danube's north–south axis, moving beyond its status as a peripheral dead end over the past century. Following the imperial shifts, conflicts, and physical border closures of the twentieth century, the removal of physical and political barriers presents a reintegration opportunity of historical significance. However, seizing this opportunity is not automatic.

Our findings indicate that improved motorway connectivity and the Schengen opening alone do not resolve the socioeconomic problems stemming from long-term isolation; rather, they represent necessary but insufficient conditions for convergence. The decisive factor lies in the institutional management of geopolitical reintegration.

This requires stronger cooperation frameworks anchored in the EGTC and Interreg programs, coordinated governance across state, county, and local levels, and the implementation of an integrated cross-border development program—one that articulates objectives transcending particularistic interests.

The moderately positive and supportive attitude of local society (scoring 4–5 on a 7-point scale), corroborated by insights from the semi-structured interviews, suggests that CBC-based tourism development initiatives possess social legitimacy. At the same time, the population expects tangible outcomes in the form of job creation, entrepreneurial opportunities, infrastructure improvements, and an enhanced quality of life. Correlation results indicate that residents perceive tourism, CBC, Schengen accession, and the M6–A5 motorway as mutually reinforcing elements of a shared development pathway, which is conducive to the acceptance of complex, multi-faceted tourism strategies.

Analysis of the TOWS matrix and our empirical findings clearly identifies dark tourism, the expansion of cycling networks, wine tourism, and ecotourism as locally grounded development directions that align realistically with the characteristics of the Baranja Triangle. Combining these forms points toward a sustainable and diversified tourism model capable of partially mitigating outmigration and population aging, even if it cannot fully offset underlying demographic and structural challenges. The future success of the Baranja Triangle hinges on its ability to transform geopolitical openness and the infrastructural turning point into a jointly articulated cross-border vision and effective institutional cooperation frameworks. Tourism emerges as a historically novel yet rapidly integrating function within the region's economy and self-image. The "recovery" of its Danube-oriented relational role, coupled with smart, heritage-focused destination development, jointly charts the region's long-term trajectory from Trianon to Schengen and beyond.

An integrated ML and geospatial framework for context-aware short-term congestion forecasting in tourism-heavy urban mobility node. *Geojournal of Tourism and Geosites*, 67(3), 1936–1945. https://doi.org/10.30892/gtg.67310-1822

Abstract: Tourism-heavy urban mobility nodes often experience short, intense congestion spikes where visitor surges interact with commuter-related traffic. Despite growing interest in smart mobility management, few studies integrate real-time computer vision sensing with uncertainty-aware machine learning to support operational decision-making at tourism-intensive urban nodes. This study aims to develop and validate a real-time, uncertainty-aware traffic prediction framework that provides actionable, short-horizon (15-minute) congestion intelligence in such areas. Town Quay (Southampton, UK) is used as a case study. Three months of continuous webcam footage (July–September 2025) were processed with a YOLO + SORT pipeline to generate 15-minute vehicle counts. Counts were enriched with contextual features capturing weather (clear/foggy/rainy), day–night cycle, and day type (business vs. leisure). CatBoost and LightGBM were trained using a chronological split (first two months for training, third month for testing). Uncertainty quantification combined conformal prediction intervals with Gaussian Mixture Model (GMM). Traffic volumes varied systematically with context, with the highest average loads occurring during clear-weather daytime business periods. The framework achieved MAE = 43.62, R^2 = 0.902, and CCC = 0.94. These findings demonstrate that integrating computer-vision traffic sensing with contextual feature engineering and uncertainty-aware learning yields reliable, interpretable 15-minute congestion forecasts. This enables proactive, risk-informed interventions (e.g., port-arrival coordination, adaptive traffic control) that help protect the physical carrying capacity and heritage-setting quality of tourism-intensive areas while maintaining everyday urban mobility.

Keywords: traffic prediction, tourism mobility, urban mobility node, geospatial analysis, machine learning, intelligent transport systems, urban sustainability

INTRODUCTION

Tourism presents a range of challenges for urban environments, including traffic, environmental degradation, and strain on local infrastructure and services (Kibiro & Mwangi, 2025). In many tourist destinations, vehicle congestion can spike dramatically during peak seasons or local events. These surge traffic flows not only slow down vehicle movement and create long queues but also disrupt the daily lives of local residents. This challenge is increasingly documented in mobility-and-tourism studies (Nyong et al., 2024; Artemyev et al., 2025). Ghazali et al. (2019) found a significant correlation between traffic congestion and reduced quality of life in Seri Kembangan, Malaysia, citing frustration, time loss, and increased health risks due to pollution. Within tourism geography, mobility is a central component of destination management, as the efficiency of tourist movement directly affects visitor experience and the spatial distribution of tourism flows. Congestion in touristic areas is therefore not only a transportation problem but also a spatial management challenge. This is particularly evident in historic urban centres, where the form and size of inherited road networks cannot accommodate the passenger flows generated by modern travel and tourism demand, so that mobility constraints become an obstacle to both local development and tourism (Chelabi et al., 2025).

Tourism-intensive urban mobility nodes are transport-network nodes (e.g., gateways/hubs/destinations) where tourist flows concentrate and where tourism peaks can amplify congestion and interact with commuter traffic (Lohmann & Pearce, 2010; Cui & Zhang, 2025). Jo et al. (2016) reported that tourists who experienced more than two hours of congestion were

* Corresponding author

more likely to support vehicle bans in touristic zones based on 440 survey responses. Their findings highlight how the spatiality of congestion, arising from specific street layouts, attraction clustering, and pedestrian–vehicle interactions, can shape tourist behavior and attitudes toward mobility policies. This underscores the need to understand congestion as a spatial process embedded in urban morphology rather than as an isolated flow problem. Further studies emphasize that traffic congestion in tourist cities significantly affects tourists' satisfaction. For example, Chong (2016) showed that foreign tourists perceived traffic congestion negatively, which influenced their travel behavior, where many chose destinations within walking distance or avoided congested areas altogether. This behavioral shift highlights how congestion can affect tourist experiences and how it can potentially restructure tourism flows. Moreover, traffic congestion significantly influences tourist consumer behavior, particularly in destinations experiencing rapid tourism growth.

Putra et al. (2025) examined how emotional regulation associated with Stoic principles and the traditional Balinese philosophy of Sad Ripu relates to tourists' responses to traffic congestion. Based on structured questionnaires completed by 200 tourists in Bali, the study found significant relationships among emotional self-regulation, perceptions of traffic congestion, and tourist consumer behaviour. Traffic congestion mediated the relationships between Stoic principles and tourist consumer behaviour and between Sad Ripu control and tourist consumer behaviour. Tourists reporting stronger emotional control also reported less congestion-related stress and more positive tourism experiences, suggesting that congestion affects not only travel conditions but also tourists' emotional responses and behavioural decisions.

To address these challenges, researchers have applied a range of systematic approaches. For instance, Gao et al. (2021) used regression models to demonstrate how different types of tourism land use (such as accommodations and shopping areas) affect traffic patterns, mostly during peak tourism periods. Their findings support targeted land-use planning to manage congestion. Likewise, in their bibliometric analysis, Krabokoukis & Polyzos (2023) found that interdisciplinary collaboration and data-driven strategies are essential for managing tourism-related mobility sustainably. By applying these approaches, cities can mitigate the negative impacts of tourism on traffic while enhancing the quality of life for residents and the experience for visitors. These studies reveal that tourism-related traffic congestion is not only a planning challenge but also a technological challenge. As cities grow and tourist flows intensify, traditional traffic management systems often struggle to keep up with the fast-changing demands of urban mobility. Kulkarni (2024) highlights that, as urban populations rise, conventional traffic management approaches often fail to alleviate congestion effectively. This has led cities to adopt Intelligent Traffic Management Systems (ITMS), which use adaptive technologies to respond to real-time traffic conditions, improving flow and reducing emissions.

To monitor and manage urban mobility, major cities around the world have adopted traffic cameras and CCTV systems. However, these systems are often used for surveillance or retrospective analysis, such as reviewing accidents or traffic violations, rather than as proactive analytical tools for traffic management Fedorov et al. (2019). This reactive approach limits their potential to improve real-time decision-making and congestion mitigation. On the other hand, the advancement of artificial intelligence (AI) is transforming these systems into contextually aware, real-time traffic management tools, an innovation particularly relevant for tourism-heavy urban mobility nodes where seasonal surges and multimodal flows create complex mobility patterns. The integration of AI-driven analytics enhances both efficiency and safety in urban mobility. For instance, Khule et al. (2025) presented a real-time traffic monitoring system using CCTV cameras and the deep learning model You Only Look Once (YOLO), which integrates live dashboards and automated signal adjustments to overcome the limitations of traditional deterministic systems. In their study, Shahi et al. (2024) propose a smart camera network that uses AI and real-time data combination to dynamically manage traffic, contrasting with older systems that rely only on post-event footage review.

Recent studies highlight the transformative impact of AI in evolving traffic systems from reactive mechanisms to predictive and adaptive frameworks. For example, Talaat et al. (2025) employed YOLOv11 for real-time vehicle detection, achieving a mean Average Precision of 92.4%, enabling adaptive signal control and rerouting. Additionally, El Mokhi et al. (2025) examined AI techniques such as fuzzy logic and deep reinforcement learning. Their findings revealed that these techniques can lead to remarkable improvements, including up to 28% reductions in both queue lengths and CO_2 emissions, demonstrating the powerful role of intelligent systems in enhancing urban mobility and sustainability.

While previous research has explored AI-based traffic monitoring, few studies have incorporated tourism-related contextual factors into predictive models. This work addresses that gap by applying machine learning to real-world traffic conditions in a tourism-intensive urban mobility node. Through the analysis of video footage, this study offers practical insights into how cities with high tourist activity can better anticipate and manage traffic challenges, eventually improving mobility for both residents and visitors. From a tourism geography perspective, traffic congestion represents a spatial manifestation of visitor pressure on urban infrastructure. Integrating AI-based traffic forecasting within geospatial frameworks allows for a better understanding of tourist mobility flows and their temporal–spatial variability across destinations. This approach aligns with Stoyanova et al. (2025), who used GIS to assess transport accessibility to cultural sites in Sofia, demonstrating how spatial analysis can inform mobility planning and congestion mitigation in urban tourism contexts.

Tourist areas present unique challenges due to seasonal surges, diverse transport modes, and the need for seamless mobility experiences. By applying intelligent traffic systems in these contexts, we seek to enhance both operational efficiency and the overall tourist experience, contributing to more sustainable and adaptive urban tourism infrastructure.

This study aims to develop a real-time, context-aware traffic forecasting framework for tourism-heavy urban mobility nodes, using computer vision and ensemble learning to predict short-term congestion patterns. Specifically, it seeks to (1) extract high-frequency traffic data through YOLO–SORT detection and tracking, (2) integrate contextual features such as weather, time of day, and day type to enhance predictive accuracy, (3) evaluate model performance using CatBoost and

LightGBM for 15-minute-ahead forecasts, and (4) classify congestion regimes and quantify uncertainty through Gaussian Mixture Models GMM and conformal prediction, providing actionable insights for tourism mobility management. The case study focuses on Southampton, UK, a city whose geography and economy are dominated by its port. Southampton's waterfront functions as a port–city interface where cruise activity, local travel, and service traffic converge on a constrained street network. Town Quay sits between the Old Town and cruise facilities, operating as a tourism-heavy urban mobility node that concentrates arrivals, departures, and pedestrian/vehicle mixing. This setting intensifies peak-period pressure on access and circulation, making congestion a recurring management problem rather than an isolated traffic anomaly.

RESEARCH METHODOLOGY

The research methodology illustrated in Figure 1 follows a structured, data-driven framework for traffic analysis and prediction. The data acquisition and processing stage involves video data collected from the Town Quay webcam undergoing a vehicle detection and tracking pipeline using the YOLO algorithm and the Simple Online Realtime Tracking SORT tracking model, as detailed in Section 2.2. The derived vehicle counts are then combined with contextual data (such as weather conditions, time of day, and day type (business or leisure)) in the contextual data integration phase, as detailed in Section 2.3. Subsequently, this dataset feeds into the predictive modeling framework, where CatBoost and LightGBM are employed. The framework includes model training and evaluation using chronological data splits and assesses performance using metrics such as MAE, RMSE, Bias, and R^2.

Finally, uncertainty quantification is performed using conformal prediction and Gaussian Mixture Model (GMM) thresholds to ensure robustness and reliability in traffic forecasting, as detailed in Section 2.4.

Figure 2. Map illustration of the case study geospatial location, showing geospatial data source (surveillance camera) Town Quay in Southampton, UK.

1. Research Area and Context

This research examines traffic dynamics at Town Quay in Southampton, UK. This tourism-heavy urban mobility node is a vibrant waterfront district where cruise ship operations and seasonal tourism create recurring congestion challenges. It represents a complex and dynamic traffic environment, shaped by the constant flow of visitors, port operations, and local commuters. Cruise ship arrivals bring surges of tourists, while nearby businesses and offices generate steady work-related traffic, creating short-term fluctuations that make congestion management particularly challenging. Figure 2 illustrates the geospatial location of the case study and indicates the geospatial data source (surveillance camera).

Crucially, the study area borders Southampton's medieval defensive walls and the old town heritage zone. Consequently, traffic queuing at this junction creates a visual and atmospheric barrier between the maritime entry point (the port) and the cultural heritage site (the old town). This spatial proximity classifies Town Quay as a tourism-heavy urban mobility node where modern mobility friction directly degrades the historic landscape's interpretative value. To address these challenges, this research develops a real-time, data-driven framework designed to predict congestion patterns 15 minutes in advance. Continuous video feeds are used to monitor traffic flow, turning raw data into actionable insights.

2. Data Acquisition and Processing

2.1. Video Data Collection

The primary data source consists of real-time video footage obtained from a publicly accessible online webcam located at the Southampton Town Quay junction, as shown in Figure 3. The video footage provides continuous visual coverage of the intersection, capturing diverse traffic conditions under varying temporal and environmental contexts. We collected data for a three-month period between July–September 2025.

(Source: Authors' own processing, July-Septemper, 2025; https://www.skylinewebcams.com/en/webcam/united-kingdom/england/southampton/southampton-town-quay.html)

2.2. Vehicle Detection and Tracking

The machine learning models employed include YOLOv5 for object detection and SORT for vehicle tracking across consecutive video frames. YOLOv5 is selected for its high detection accuracy and computational efficiency, making it suitable for real-time applications (Jaiswal & Agrawal, 2024). SORT complements YOLO by maintaining consistent vehicle tracking across frames.

This methodology demonstrates how machine learning models can be leveraged to analyze real-world traffic dynamics in tourism-heavy areas, offering a scalable and adaptive solution for urban mobility management. In particular, the use of YOLO is highly advantageous compared to traditional manual counting or sensor-based methods. YOLO enables real-time, automated vehicle detection from video feeds, providing accurate, high-frequency data without requiring costly infrastructure or labor-intensive surveys (Adhithya, 2025). By employing machine learning models such as YOLO and SORT, urban planners and local authorities in tourism-heavy areas can obtain timely and accurate insights into mobility patterns. This data-driven approach supports more responsive traffic management, smarter resource allocation, and an overall improved experience for visitors. To ensure reliability, the detection and tracking results were validated against manual counting on randomly selected video samples, confirming the accuracy of the automated approach.

3. Contextual Feature Extraction

In addition to vehicle counts generated by the YOLO–SORT processing pipeline, the research integrates a comprehensive set of contextual variables to capture the multifaceted nature of urban traffic dynamics. By incorporating weather conditions, time-of-day segmentation, and day-type classification, the model achieves a more realistic representation of traffic behavior in real-world environments.

Weather conditions are set as categorical features distinguished between clear, foggy, and rainy periods. Weather plays a crucial role in shaping driving behavior and road capacity (Romanowska & Budzyński, 2022). Rain, for example, can reduce visibility and speed, causing localized slowdowns even in non-peak hours. Integrating weather data enables the model to account for such external perturbations, improving both the accuracy and interpretability of congestion prediction.

In coastal cities like Southampton, which attract large numbers of tourists, especially during warmer months, weather also directly affects touristic traffic patterns. Warmer, sunnier conditions tend to attract more visitors to outdoor attractions, increasing traffic volumes and congestion in key areas (Wilkins & Horne, 2024). Conversely, adverse weather such as heavy rain or fog can deter discretionary travel (Peng et al., 2018), leading to reduced tourist mobility and shifting traffic burdens to indoor venues or alternative transport modes. In this research, weather conditions were systematically extracted from video footage spanning the entire observation period.

The daytime versus nighttime distinction (06:00–18:00 and 18:00–06:00, respectively) captures the cyclical patterns associated with human activity and mobility demand. Daytime periods generally correspond to higher vehicle counts due to commuting, commercial deliveries, and tourism-related travel, whereas nighttime periods exhibit reduced traffic intensity and different vehicle composition (Goerguelue et al., 2025). By including this temporal feature, the model is able to learn context-dependent traffic behaviors and adapt its forecasts to diurnal variations. Moreover, traffic patterns at Town Quay strongly depend on day type, classified as business or leisure. Business days (weekdays) feature regular commuting and logistics, while leisure days (weekends and holidays) coincide with higher tourist movement. This distinction helps the model capture shifts in traffic driven not only by time but also by behavioral patterns.

By combining contextual variables with vehicle counts, the model gains a richer understanding of traffic behavior, enabling accurate short-term predictions and better generalization. This integration transforms it from a purely data-driven tool into a context-aware forecasting system that adapts to dynamic urban conditions. Although based on computer vision, the framework can be extended into GIS workflows to map predicted congestion zones and link them to tourism hotspots.

4. Predictive Modeling Framework

4.1. Model Selection

In this research, two ensemble learning algorithms, CatBoost and LightGBM were analyzed. These models are widely recognized for their ability to handle structured tabular data, capture complex nonlinear relationships, and deliver computational efficiency in large-scale predictive tasks (Bentéjac et al., 2021). CatBoost is particularly effective in managing categorical features and mitigating overfitting (Prokhorenkova et al., 2018), whereas LightGBM is optimized for speed and memory efficiency, making it suitable for high-dimensional datasets for the traffic domain (Cheng et al., 2022).

4.2. Model Data Fitting and Evaluation

The prediction framework produces short-term forecasts of traffic conditions 15 minutes in advance. The dataset includes time-stamped entries with the following explanatory variables: date x_1, time x_2, day type x_3, day/night classification x_4, and weather conditions x_5. The target variable y is the observed vehicle count in each 15-minute interval. The analysis follows a temporal split: Data from the first two months, $t_1$and t_2, are used for model fitting, while data from the third month, t_3, are reserved for evaluation. Let n denote the number of days in $t_1 \cup t_2$. Since each day contains 96 intervals of 15 minutes, the training feature matrix is $X = (\mathbf{x}_i)_{i=1}^{96n}$, where each feature vector is $\mathbf{x}_i = \{x_1^i, x_2^i, x_3^i, x_4^i, x_5^i\}$, and the corresponding target value is the vehicle count y_i. For validation, let m denote the number of days in t_3. The evaluation matrix is $\ddot{X} = (\ddot{\mathbf{x}}_i)_{i=1}^{96m}$, constructed analogously from the same five explanatory variables. This formulation follows the standard supervised-learning design-matrix representation for regression modelling (James et al., 2021).

Both models were evaluated using standard regression performance metrics, including Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), Bias, and the Coefficient of Determination (R^2). These metrics collectively evaluate prediction accuracy, quantify error magnitude, and measure the models' ability to generalize to unseen data.

4.3 Conformal Prediction and Gaussian Mixture Model (GMM) Integration

Following the selection of CatBoost as the optimal model, a conformal prediction framework is implemented to extend point forecasts into uncertainty-aware outputs. Traffic congestion levels are identified using a GMM applied to the predicted traffic volume distributions. The model estimated five components, each representing a distinct congestion regime, with transition thresholds at approximately 113.4, 240.6, 363.8, and 441.0 vehicle counts. Conformal prediction intervals are computed alongside point forecasts to quantify uncertainty, adapting dynamically to traffic intensity. Narrow intervals during low-flow periods indicate high confidence, whereas wider intervals during peak congestion reflect increased variability. This combined approach enables both probabilistic uncertainty assessment and multi-level classification of traffic states, supporting robust interpretation of congestion dynamics.

Model alignment with observed traffic volumes is assessed using three complementary statistical measures: Pearson's correlation coefficient (r), Spearman's rank correlation (ρ), and the Concordance Correlation Coefficient (CCC). Pearson and Spearman correlations are computed to assess relational strength and ranking preservation, whereas the CCC serves as an integrated measure of accuracy and precision. Comparative analysis across CatBoost and LightGBM models enables identification of the model with superior concordance for subsequent uncertainty quantification and risk classification.

RESULTS AND ANALYSIS

1. Traffic Volume Trends Derived from YOLO-SORT Processing

This section presents findings from the YOLO-SORT model applied to Town Quay traffic footage. The analysis examines how contextual factors (day type, weather, and time of day) affect congestion, measured by vehicle count. The dataset spans three months, with traffic aggregated at 15-minute intervals. Each record includes attributes such as date, day type (business or leisure), time of day (daytime or nighttime), and weather (clear, foggy, or rainy).

As shown in Table 1, on business days, daytime traffic under clear weather conditions exhibits the highest total volume (572,913 vehicles), with an average of 265.23 vehicles per 15-minute interval, reflecting the intensity of commuter flows and commercial transport activity in this port-adjacent urban corridor. Nighttime traffic on business days declines sharply, consistent with reduced professional mobility outside working hours. Leisure days show elevated traffic volumes during daytime hours, particularly under clear and foggy conditions, suggesting strong touristic engagement with the surrounding attractions. The relatively high average vehicle counts during foggy leisure periods (233.28 vehicles per interval) indicate that recreational travel persists even in suboptimal weather, likely driven by planned visits and seasonal tourism demand. The high traffic on 'foggy' leisure days suggests tourists are less deterred by weather than commuters, a key behavioral insight for tourism and transport managers. Nighttime traffic on leisure days, while lower, remains notable and may be attributed to evening leisure activities, hospitality services, and ferry-related movements. These findings underscore the dual function of Town Quay as both a commuter hub and a tourism gateway.

The observed traffic distribution suggests that leisure periods, typically associated with increased tourist activity, exert a notable influence on vehicular flow. Daytime traffic volumes on leisure days under clear weather conditions (average 220.95 vehicles per 15-minute interval) approach those recorded on business days (265.23 vehicles), despite the absence of routine commuting. This pattern indicates that tourism-driven mobility substantially contributes to daytime congestion, particularly in favorable weather scenarios conducive to recreational travel. Conversely, nocturnal traffic remains consistently low across all conditions, reflecting limited tourist movement during late hours. Although adverse weather conditions, such as rain and fog, reduce overall traffic volumes, the persistence of leisure-related travel under these circumstances suggests that tourism demand is less sensitive to meteorological variability than business-related commuting.

Table 1. Traffic Volume Summary by Day Type, Time of Day, and Weather Conditions

Day Type	Time of the Day	Weather Condition	Total Vehicle Count	Average Vehicle Count per 15 Minutes
Business	Day	Clear	572913	265.23
		Foggy	27212	188.97
		Rainy	190443	220.42
	Night	Clear	143521	66.44
		Foggy	6733	46.75
		Rainy	48746	56.41
Leisure	Day	Clear	194439	220.95
		Foggy	7465	233.28
		Rainy	62625	186.38
	Night	Clear	46538	52.64
		Foggy	1389	49.60
		Rainy	14935	44.44

Table 2. Comparative Performance Metrics of CatBoost and LightGBM Models

Model	RMSE	MAE	Bias	R^2
CatBoost	43.62	28.06	3.59	0.902
LightGBM	46.12	28.40	0.89	0.891

2. Predictive Performance of Ensemble Learning

The predictive results confirm the effectiveness of ensemble learning in capturing traffic congestion dynamics in tourism-intensive urban settings. As shown in Table 2, the CatBoost model outperformed LightGBM achieving lower RMSE and MAE values alongside a higher R^2, indicating stronger explanatory power. Although LightGBM exhibited slightly lower bias compared to CatBoost, both models maintained minimal error levels. As illustrated in Figure 4, the one-to-one plots confirm that both models capture the overall relationship between observed and predicted vehicle counts.

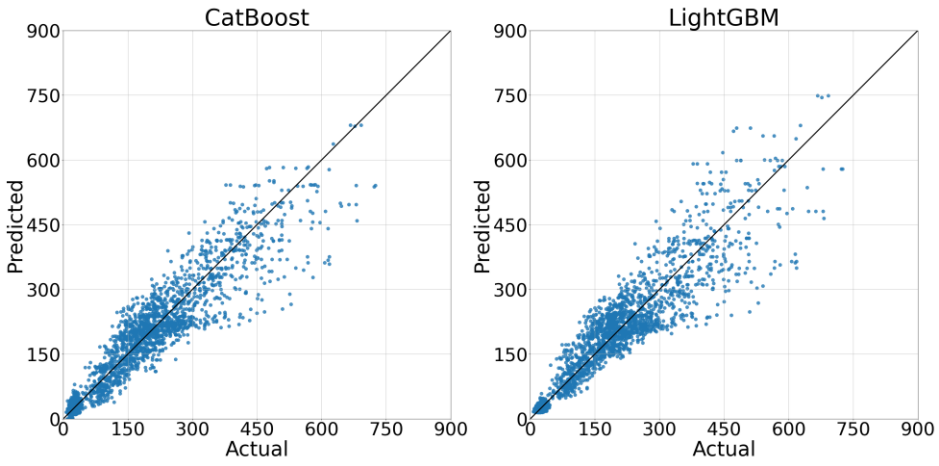

Figure 4. One-to-One Comparison of Predicted Traffic Volumes: CatBoost vs. LightGBM (Source: Authors' own processing, 2025)

The majority of points align closely with the identity line, indicating limited deviations across most of the range. The most noticeable discrepancies appear at higher traffic volumes, where both models tend to slightly misestimate actual counts. CatBoost provides slightly closer adherence to the identity line in this upper range, consistent with its stronger fit, whereas LightGBM produces a smoother trend but with marginally larger deviations from the observed values.

Further insights are provided in Figure 5, which compares the kernel density estimates of the observed and predicted distributions. The bandwidth for these estimates is determined using Silverman's rule of thumb (Silverman, 1986) to achieve an optimal balance between smoothness and detail. The close alignment between the actual and predicted curves indicates that both algorithms accurately reproduce the underlying traffic volume patterns. However, CatBoost demonstrates marginally superior performance. CatBoost's predicted distribution aligns closely with actual data, especially in the lower range (0–150), where peaks nearly overlap, indicating better capture of fine traffic variations. LightGBM produces a smoother curve but slightly underestimates the first peak and over-smooths around the second mode (~250 vehicles). Overall, both models generalize well, but CatBoost offers marginally higher accuracy and sensitivity to local variations.

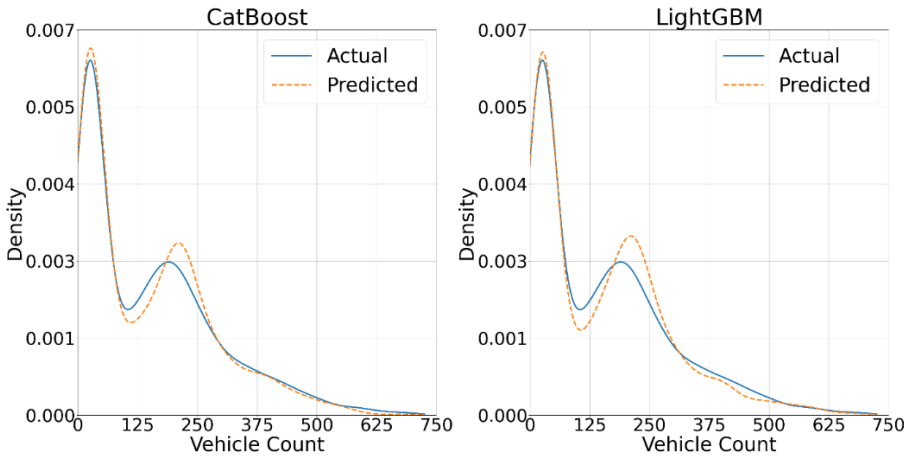

Figure 5. Kernel Density Estimates of Traffic Volume Distributions: Observed vs. Predicted (CatBoost and LightGBM)
(Source: Authors' own processing, 2025)

These outcomes suggest that the framework effectively incorporates predictive models to capture congestion dynamics under conditions of variability and peak demand. The ability of both methods to approximate the underlying distributions while keeping systematic bias low ensures that the predictions provide a realistic basis for subsequent analysis. Importantly, the models are not the primary focus of evaluation but serve to demonstrate that the framework operates reliably with advanced machine learning tools. This establishes the foundation for extending the approach toward higher-level tasks, such as translating continuous predictions into categorical assessments of congestion risk.

3. Threshold Identification and Uncertainty Quantification

The GMM identifies four transition thresholds at approximately 113.4, 240.6, 363.8, and 441.0 vehicle counts, corresponding to five distinct congestion levels. The fitted component statistics are summarized in Table 3. The component means (35.9, 178.5, 286.6, 425.0, and 607.8) increase monotonically with traffic intensity, whereas the mixture weights show that most observations belong to lower and mid-level regimes. The relatively uniform variance across components indicates consistent dispersion within the identified traffic states.

Table 3. Statistical properties of the fitted Gaussian components used to define congestion thresholds

Component	Mean Count	Variance	Weight	Congestion Level
0	35.9	1,394.4	0.503	Level 1 (Very Low)
1	178.5	1,394.4	0.265	Level 2 (Low)
2	286.6	1,394.4	0.142	Level 3 (Moderate)
3	425.0	1,394.4	0.064	Level 4 (High)
4	607.8	1,394.4	0.026	Level 5 (Severe)

The conformal prediction intervals show that the majority of observed traffic counts fall within the estimated uncertainty bounds, indicating consistent calibration across all congestion regimes. The intervals adjust adaptively to variations in traffic intensity: they remain narrow during stable, low-traffic periods, reflecting lower predictive uncertainty, and expand considerably during high-density periods to capture the increased variability typical of peak congestion.

The multi-level classification derived from the GMM thresholds provides a finer segmentation of traffic conditions compared to the conventional three-class (Low–Medium–High) scheme. The first two levels correspond primarily to nighttime and off-peak hours, where traffic flow is smooth and model confidence remains high. Intermediate levels represent transitional states, often associated with the buildup and dissipation phases of morning and evening peaks. The highest level captures sustained congestion, where traffic counts are high and prediction intervals widen substantially, reflecting the increased uncertainty inherent in unstable flow conditions.

4. Alignment with Ground Truth

To assess model fidelity, we evaluated concordance between predicted and observed traffic volumes using Pearson's correlation (r), Spearman's rank (ρ), and the Concordance Correlation Coefficient (CCC). CatBoost achieved r = 0.951, ρ = 0.921, and CCC = 0.949, indicating excellent agreement and strong preservation of rank and scale. LightGBM also performed well (r = 0.945, ρ = 0.929, CCC = 0.944), with slightly better rank ordering but marginally lower overall concordance. Both models align closely with ground truth, confirming the effectiveness of gradient boosting for traffic prediction. CatBoost's higher CCC and Pearson values support its selection for uncertainty quantification and conformal prediction.

DISCUSSION

The proposed framework effectively captures how contextual and temporal factors shape traffic dynamics in tourism-heavy urban environments. Variations in vehicle counts across day types, weather, and time periods reveal the multidimensional nature of congestion at Town Quay, where tourist surges and commuter peaks overlap. Increased daytime traffic on business days reflects commuter flows linked to the port and city center, while sustained volumes on leisure days (even under foggy conditions) underscore tourism's resilience and socio-economic significance.

A key behavioral insight is the persistence of high vehicle counts during foggy leisure days. Despite adverse weather conditions, leisure-driven mobility remains strong (average vehicle count = 233.28 per 15-minute interval). This indicates hedonic resilience among tourists: even when travel is discretionary, fixed schedules such as cruise or ferry departures drive mobility. For tourism and transport managers, this underscores that traffic mitigation cannot rely on unfavorable weather to naturally suppress demand; proactive interventions are required to maintain site accessibility and carrying capacity.

From a predictive perspective, CatBoost outperformed LightGBM, demonstrating the value of categorical feature handling and contextual variables for accurate short-term forecasting. Its lower RMSE and higher R^2 indicate strong sensitivity to local traffic fluctuations, though slight underestimation at peak volumes reflects the stochastic nature of congestion during cruise arrivals or weather disruptions.

The integration of conformal prediction and GMM-based classification adds significant interpretive value. Narrow intervals during off-peak periods and wider intervals during volatile conditions demonstrate adaptive confidence estimation, crucial for real-time decision-making in tourism-heavy areas. the GMM thresholds translate continuous predictions into actionable congestion levels, supporting interpretable alerts for urban traffic management and tourist routing.

High concordance metrics (Pearson, Spearman, CCC > 0.92) validate predictive reliability, confirming that the model captures both magnitude and structural relationships in traffic data. By differentiating leisure-day (tourist-driven) traffic from business-day (commuter-driven) traffic, the framework enables planners to implement dynamic routing strategies during cruise arrivals, reducing resident frustration and environmental impacts.

These tourism-sensitive insights have theoretical and practical implications: for urban tourism geography, congestion is conceptualized as a spatiotemporal manifestation of visitor pressure, revealing patterns that inform sustainable destination planning; for destination management, short-term predictive insights allow adaptive routing, smart signal control, and proactive mobility management; and for policymakers, the evidence supports event-based traffic interventions that maintain carrying capacity of a mobility node without reducing tourist satisfaction. In practical terms, city planners could use the 15-minute forecasts to trigger dynamic traffic routing on cruise ship arrival days and integrate predictive congestion analytics into urban tourism management systems to support adaptive visitor routing, reduce environmental stress on tourism corridors, and enhance the destination's sustainability profile.

However, this study has two key limitations. First, classifying days as simply "business" or "leisure" ignores hybrid scenarios (such as cruise arrivals on weekdays) where tourist flows spike despite being business days.

Second, reliance on video-based vehicle counts excludes pedestrian and multimodal traffic, which are critical in tourism-heavy urban mobility nodes. Future research should adopt event-based categorization and integrate multimodal mobility data to better capture complex demand patterns.

CONCLUSION

Conceptually, this study reframes congestion at a tourism-intensive urban mobility node as a spatiotemporal manifestation of visitor pressure on maritime built heritage. By integrating computer vision, contextual features and uncertainty-aware forecasting, the framework extends previous tourism mobility studies that relied on static accessibility indices or survey data. Instead of treating traffic as an exogenous constraint, congestion becomes a measurable, short-term indicator of node carrying capacity that can be monitored and anticipated in real time.

This research demonstrates the effectiveness of a geospatial machine learning framework for modeling and forecasting traffic dynamics at a tourism-heavy urban mobility node. Using computer vision-based detection (YOLO–SORT), contextual enrichment, and ensemble learning, the framework captures distinct mobility patterns: commuter-driven peaks on business days and sustained tourism flows on leisure days. A notable insight, the persistence of high traffic during foggy leisure periods, reveals tourists' lower sensitivity to adverse weather, underscoring the need for proactive traffic management even under suboptimal conditions.

CatBoost emerged as the most accurate predictive model, complemented by conformal prediction and GMM-based classification for uncertainty quantification and congestion categorization. These components collectively provide a scalable, interpretable solution for short-term traffic forecasting in complex urban environments. However, limitations include the binary day-type classification, which overlooks hybrid scenarios such as cruise arrivals on weekdays, and the

exclusion of pedestrian and multimodal flows. Future research should incorporate event-based categorization, multimodal mobility indicators, and real-time data streams to enhance predictive accuracy.

Integration with GIS dashboards and advanced geo-visualization tools could further support adaptive traffic management, eventually contributing to a 'Digital Twin' of the tourism-intensive urban mobility node. This would allow destination managers to simulate the impact of cruise schedules on carrying capacity before the vessels even arrive.

Abstract: This study examines the long-run relationship between economic growth and tourism performance in ASEAN countries, with particular attention to crisis sensitivity and regional heterogeneity. Using balanced panel data for eight ASEAN member states over the period 1999–2023, the analysis employs pooled ordinary least squares and fixed-effects estimators to assess how macroeconomic conditions and structural tourism intensity shape tourism outcomes. The results reveal a strong and robust positive association between economic output and tourism receipts, with estimated elasticities close to unity across specifications. This near-proportional relationship indicates a structurally embedded linkage between tourism performance and overall economic capacity, rather than a unidirectional tourism-led growth mechanism. Tourism intensity further reinforces tourism performance, highlighting the structural role of tourism within national economies. Crisis episodes exhibit asymmetric impacts on tourism dynamics, with the COVID-19 pandemic generating the most severe and persistent contraction, particularly in developing ASEAN economies. Comparative analysis indicates that while tourism intensity contributes similarly across development groups, developing countries display greater vulnerability to crisis shocks. The findings underscore the importance of macroeconomic stability, diversification, and regionally differentiated tourism policies to enhance resilience in crisis-prone environments. This study contributes to the regional tourism literature by clarifying the demand-side economic drivers of tourism performance in ASEAN under conditions of systemic shocks and developmental heterogeneity.

INTRODUCTION

Tourism has emerged as a dynamic driver of regional economic transformation across Southeast Asia, reinforcing the nexus between growth, integration, and sustainability. Recent evidence highlights that tourism receipts, foreign direct investment, and green innovation significantly enhance long-term economic expansion and spatial development within ASEAN economies (Trung, 2025; Zagoto et al., 2025). Empirical studies confirm that the tourism–growth relationship is bidirectional, strengthening local employment and infrastructural networks (Indriani, 2022; Maulana et al., 2025). Moreover, regional integration and SEZ-based tourism projects have restructured peripheral economies through capital inflows and community participation (Park, 2024). The interplay between digital infrastructure, policy harmonization, and sustainable tourism practices continues to define ASEAN's competitive advantage, generating inclusive growth across diverse territorial contexts (Keorodom, 2023; Mohammad Nurul Huda et al., 2013; Titovich & Toropygin, 2023; Trifan, 2023).

Despite its growing importance, ASEAN's tourism landscape remains spatially uneven, shaped by diverse institutional capacities, governance quality, and infrastructural readiness. Empirical analyses reveal that territorial disparities persist as advanced economies such as Singapore and Malaysia exhibit greater tourism productivity and environmental innovation compared to less developed members like Laos or Myanmar (An & Kim, 2022; Trung, 2025).

Studies employing spatial econometric and competitiveness frameworks highlight how innovation intensity, FDI spillovers, and institutional strength amplify regional clustering effects within tourism economies (Soh et al., 2023).

However, geopolitical risk and governance asymmetry exacerbate uneven participation in regional tourism networks, deepening intra-ASEAN heterogeneity (Chen et al., 2024). These dynamics underscore the urgency for territorially nuanced policies that integrate competitiveness, sustainability, and inclusiveness into ASEAN's tourism-led growth agenda. The vulnerability of ASEAN's tourism systems to external shocks has been acutely demonstrated through global crises that disrupted regional mobility and income structures. COVID-19, in particular, revealed deep asymmetries in recovery capacity and institutional resilience across member states, with uneven rebounds between advanced and tourism-dependent economies (Huynh et al., 2023; Polyzos et al., 2021). Empirical analyses emphasize how regional crises reshape

spatial tourism flows and reconfigure destination hierarchies within the ASEAN bloc (Fornari & Allis, 2022; Koepke & Balasundharam, 2021). Case studies from Vietnam and Cambodia highlight that resilience is contingent on adaptive governance, social networks, and local entrepreneurial innovation (Ford & Im, 2023; Huynh et al., 2022). From a broader policy lens, strengthening systemic resilience requires coordinated regionalism, diversified markets, and digital transformation to mitigate exposure to future disruptions (OECD, 2022, 2023).

From a theoretical standpoint, the relationship between tourism activity and economic performance is widely acknowledged to be bidirectional rather than unidirectional (Bui Hoang, 2024; Kuok et al., 2023). While the tourism-led growth hypothesis has traditionally framed tourism as a driver of economic expansion, recent empirical studies increasingly emphasize the role of broader macroeconomic conditions in shaping tourism performance, particularly in regionally integrated economies (Jaroensutasinee et al., 2025; Nguyen & Le, 2026). Economic scale, income levels, and structural stability influence tourism demand, investment capacity, and destination competitiveness across ASEAN (Alsabhan et al., 2025; Indriani, 2022). Accordingly, tourism is better understood not only as a potential growth catalyst but also as an economic activity that responds to demand-side macroeconomic dynamics, especially under conditions of structural heterogeneity and external shocks (Phob-udom et al., 2025; Rohan & Suyanto, 2025).

Existing ASEAN tourism literature remains fragmented, often prioritizing national case studies or short-term econometric analyses that overlook spatial interdependencies and systemic crises. Recent studies underscore that crises such as COVID-19 reconfigured tourism's regional role, amplifying inequalities and exposing governance asymmetries (Liyushiana et al., 2022; Tuli & Vadiyala, 2022). Spatial analyses reveal persistent territorial disparities and the limited capacity of regional coordination mechanisms to foster balanced development (An & Kim, 2022; Chen & Zhang, 2023). Meanwhile, cross-country assessments identify that tourism's economic contribution fluctuates under crisis conditions, particularly in peripheral or tourism-dependent regions (Akita & Alisjahbana, 2023). Collectively, these findings point to a pressing need for integrative frameworks that combine regional resilience theory, territorial development, and tourism geography to capture ASEAN's evolving spatial-economic dynamics (Hoang, 2024).

Addressing this gap, the present study adopts a regional and territorial perspective to examine tourism–economic dynamics in ASEAN over a long-term period. By combining panel data analysis with explicit consideration of major crisis episodes, the study seeks to capture both structural relationships and temporal disruptions. The focus on spatial differentiation between developing and more advanced member states further strengthens the geographic relevance of the analysis. Accordingly, this study aims to address three core questions: first, how economic growth and structural tourism intensity shape tourism performance across ASEAN in the long run; second, how major crisis episodes affect tourism dynamics at the regional level; and third, whether these tourism–economic relationships differ across development groups. By addressing these questions, the study contributes to tourism geography and regional development literature, offering empirical insights relevant for spatially informed tourism planning and policy formulation.

While tourism is often conceptualised as a potential driver of economic growth, the relationship between tourism activity and economic performance is inherently bidirectional. In the ASEAN context, where development levels and structural characteristics differ substantially, understanding how economic growth conditions shape tourism performance becomes particularly relevant. Rather than testing tourism-led growth in a strict causal sense, this study focuses on identifying robust long-run structural associations between economic output, tourism intensity, and tourism receipts within a regional panel framework. By incorporating major crisis episodes, the analysis further captures how external shocks modify these relationships across heterogeneous economies.

LITERATURE REVIEW AND THEORETICAL BACKGROUND

Tourism has long been recognised as an important driver of economic activity, particularly in regions with strong natural, cultural, and environmental assets (Lee & Chang, 2008; Sobirov et al., 2025). Within economic geography and tourism studies, tourism is increasingly viewed not merely as a sectoral activity but as a spatially embedded system that interacts with regional structures, labour markets, and territorial governance (Kyophilavong et al., 2018; Saarinen & Rogerson, 2021). This perspective highlights the relevance of tourism in shaping regional development trajectories, especially in emerging and heterogeneous regions such as ASEAN (Fan & Ha, 2025; Maneejuk et al., 2022).

Tourism-led growth hypothesis in a regional and spatial context

The tourism-led growth hypothesis posits that tourism development stimulates economic growth through multiple channels, including foreign exchange earnings, employment creation, and infrastructure investment (Mahadevan et al., 2017; Wu et al., 2025). Early empirical studies provide evidence of a positive relationship between tourism receipts and economic growth, particularly in small open economies and developing regions (Li et al., 2016). These findings have positioned tourism as a potential engine of regional economic expansion (Bhatt et al., 2024; Paramati & Nguyen, 2024).

Subsequent research has extended this hypothesis by incorporating spatial and regional dimensions. From a geographic perspective, tourism-led growth is not spatially neutral, as benefits tend to concentrate in specific regions or destinations Lin et al., 2019; Yang & Fik, 2014). Agglomeration effects, accessibility, and territorial endowments influence how tourism contributes to regional economies. Studies grounded in regional economics suggest that tourism may reinforce existing spatial inequalities if supporting institutions and regional linkages remain uneven (Adeleye, 2023; Calero & Turner, 2020; Tung, 2021). In multi-country regional settings, such as ASEAN, the tourism–economy relationship is increasingly recognised as bidirectional rather than strictly unidirectional. While tourism-led growth provides an important theoretical foundation, recent empirical evidence highlights that broader macroeconomic conditions, including economic

scale, income levels, and structural stability, play a central role in shaping tourism performance across heterogeneous economies (Trung, 2025; Wahab et al., 2023). Studies from Asia suggest that tourism outcomes respond differently to macroeconomic dynamics over time, indicating the presence of structural, institutional, and spatial moderators that condition tourism performance rather than a uniform growth mechanism (Qi & Ding, 2025; Shahzad et al., 2017).

Tourism, territory, and regional economic development

From the standpoint of tourism geography, tourism development is inherently territorial, relying on place-specific resources, environmental quality, and cultural landscapes (Golubičić et al., 2025; Reyabi & Boulaassal, 2025). Tourism activities reshape regional economies by altering land use, infrastructure distribution, and labour mobility (Popescu et al., 2025; Scolozzi & Villa, 2025). These transformations link tourism closely to broader processes of regional development and spatial planning.Regional development theories emphasise that tourism contributes most effectively to economic performance when embedded within diversified regional systems (Liwei & Yu, 2025; Mafrudoh et al., 2025). Strong backward and forward linkages between tourism and local industries increase value retention within regions (Tagherist & Toufik, 2025). Conversely, weak territorial integration may limit the broader economic impact of tourism, particularly in peripheral or less developed areas. This distinction is central to understanding uneven tourism outcomes across regions.

In ASEAN, tourism plays a critical role in regional integration and cross-border economic interaction (Arnakim et al., 2023; Lee, 2022; Sundram, 2025). Initiatives promoting tourism corridors and regional branding reflect attempts to leverage tourism for territorial cohesion (Rüland & Carrapatoso, 2022; Stoffelen & Vanneste, 2017). However, empirical assessments suggest that benefits remain uneven, often favouring capital cities and established destinations. This pattern underscores the need for regionally informed empirical analyses that account for territorial diversity and spatial structure.

Crisis impacts on tourism systems and regional resilience

Tourism is widely regarded as one of the most crisis-sensitive economic activities due to its dependence on mobility, perceptions of safety, and discretionary consumption (Hopkins, 2021; Senbeto & Hon, 2020; Williams & Baláž, 2015). Health crises, financial shocks, and geopolitical disruptions have repeatedly demonstrated the vulnerability of tourism systems (Cohen, 2012; Ferreira et al., 2025). Research on crisis impacts highlights sharp contractions in tourism demand, followed by uneven and prolonged recovery processes across regions (Plzáková & Smeral, 2022). From a regional resilience perspective, crises affect tourism destinations differently depending on economic structure, institutional capacity, and diversification (Phan et al., 2025; Tunca et al., 2025). Regions with high tourism dependence often experience deeper economic shocks, while those with diversified economies tend to recover more rapidly. The concept of territorial resilience has therefore gained prominence in tourism geography, focusing on the ability of regions to absorb, adapt, and recover from external disturbances (Fan et al., 2025; Grzenkowicz, 2025). In Southeast Asia, crisis events such as the SARS outbreak, the Global Financial Crisis, and the COVID-19 pandemic have exposed significant spatial disparities in tourism vulnerability and recovery (Akita & Alisjahbana, 2023; Plzáková & Smeral, 2022; Polyzos et al., 2021). While some destinations demonstrated adaptive capacity through domestic tourism or policy intervention, others faced prolonged downturns (Papagiannakis et al., 2018; Wang et al., 2023). These experiences suggest that crisis impacts are mediated by regional characteristics, reinforcing the need for long-term and regionally comparative analyses (Dutta, 2024; Gündüz et al., 2025).

Developmental heterogeneity in tourism performance

A recurring theme in tourism economics and geography is the distinction between developed and developing economies in tourism performance and outcomes. More advanced economies typically exhibit higher tourism productivity, stronger institutional frameworks, and more diversified tourism offerings (Kozáková et al., 2025; Lestan et al., 2025; Lin & Xing, 2020; Rismayani et al., 2025). In contrast, developing economies often rely heavily on tourism revenues but face volatility and limited capacity to manage shocks (Kadyrbekova et al., 2025). This disparity reflects broader patterns in economic development, infrastructure, and institutional maturity (Godinez et al., 2025; Upadhyaya et al., 2025).

Empirical studies indicate that tourism intensity and its growth effects differ across development levels (Nguyen & Le, 2026; Smolčić Jurdana & Agbaba, 2025). While tourism activity may benefit from economic expansion in developing economies, it may simultaneously amplify exposure to external shocks, whereas developed economies tend to display more stable tourism performance due to diversified economic bases and stronger macroeconomic buffers (Parray et al., 2025; Samarathunga et al., 2024). Developed economies, by contrast, tend to display more stable tourism contributions due to diversified economic bases and established infrastructure (Cheng, 2025; Londe et al., 2025). These differences suggest that development level moderates tourism–growth relationships. Within ASEAN, developmental heterogeneity is particularly pronounced, encompassing both high-income service-oriented economies and lower-income tourism-dependent states (Akarsu, 2022). This diversity offers a valuable context for examining how tourism contributes to regional development under varying structural conditions (Elgin & Elveren, 2024; Shah, 2025). Comparative approaches are therefore essential to identify differentiated patterns and avoid overly generalised conclusions (Pham, 2020).

Literature synthesis and hypothesis development

The reviewed literature highlights several key insights. First, tourism is widely recognised as a potential driver of economic growth, yet its effects are shaped by spatial, institutional, and developmental contexts. Second, tourism development is territorially embedded, influencing and being influenced by regional structures. Third, crises play a critical role in disrupting tourism systems, with uneven impacts across regions and development levels.

Despite extensive research, gaps remain in long-term, regionally comparative studies that jointly examine macroeconomic drivers of tourism performance, crisis sensitivity, and territorial heterogeneity within a single empirical framework. In the ASEAN context, such integrated analyses remain limited. Addressing this gap, the present study formulates the following hypotheses:

1. **H1:** Economic growth has a positive and significant effect on tourism performance across ASEAN countries in the long run.
2. **H2:** Major crisis events exert a negative impact on tourism performance in ASEAN.
3. **H3:** The relationship between economic growth and tourism performance differs between developing and more advanced ASEAN economies.
4. **H4:** Crisis impacts on tourism performance are more pronounced in developing ASEAN countries than in more advanced member states.

These hypotheses guide the empirical analysis and provide a structured framework for examining tourism–economic dynamics from a regional and territorial perspective that is consistent with the empirical model employed.

METHODOLOGY

This study adopts a quantitative panel-data approach to examine the relationship between tourism development and economic growth across ASEAN countries. The methodological design emphasises transparency and replicability, combining regional comparability with temporal depth. Figure 1 illustrates the overall research flow, starting from data collection and variable construction, followed by model estimation, diagnostic testing, and robustness assessment. This structured workflow supports a coherent linkage between theoretical expectations and empirical implementation.

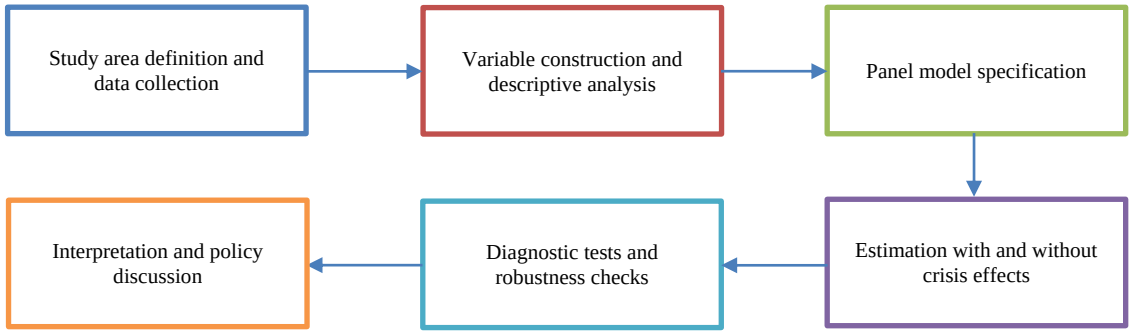

Figure 1. Research Flow

To capture both cross-country and temporal variation, the study employs panel regression techniques using annual data for eight ASEAN countries over 1999–2023. Panel models are preferred because they allow the joint analysis of regional heterogeneity and dynamic change over time. In line with the study's objective, tourism performance is treated as the outcome variable, while economic growth and structural tourism characteristics are modelled as key explanatory factors. The baseline specification relates tourism performance to economic output while controlling for macroeconomic conditions. This approach is consistent with prior tourism–growth studies in regional and multi-country contexts.

The core empirical model is specified as follows:

$$\ln(TR_{it}) = \alpha + \beta_1 \ln(GDP_{it}) + \beta_2 TI_{it} + \beta_3 X_{it} + \mu_i + \varepsilon_{it} \quad (1)$$

where i denotes country and t denotes time. TR represents tourism receipts, GDP denotes gross domestic product, TI is tourism intensity, and X is a vector of control variables. The term μ_i captures unobserved country-specific effects. This specification follows and extends standard panel formulations employed in tourism–growth studies (Balaguer & Cantavella-Jordá, 2002; Brida et al., 2016; Lee & Chang, 2008). Regional heterogeneity is a central concern in ASEAN due to differences in development levels, tourism structures, and institutional capacity. To account for unobserved time-invariant characteristics, fixed effects estimators are applied alongside pooled ordinary least squares. This strategy controls for country-specific factors such as geography, long-term policy orientation, and structural tourism endowments, thereby reducing omitted variable bias in the estimated relationships. Accordingly, the fixed-effects framework is employed to capture stable long-run associations rather than short-term fluctuations or strict causal mechanisms.

Crisis effects are incorporated to capture major disruptions affecting tourism systems across the region. Dummy variables are introduced for key crisis episodes, allowing the model to isolate structural breaks associated with external shocks. This specification enables the assessment of how tourism–economic relationships behave under stress conditions, consistent with regional resilience and tourism vulnerability frameworks. Following the tourism-led growth framework extended to account for macroeconomic shocks, the augmented panel model incorporating crisis effects is specified as:

$$\ln(TR_{it}) = \alpha + \beta_1 \ln(GDP_{it}) + \beta_2 TI_{it} + \beta_3 X_{it} + \gamma C_t + \mu_i + \varepsilon_{it} \quad (2)$$

where i denotes country and t denotes time. TR_{it} represents tourism receipts, GDP_{it} denotes gross domestic product, and TI_{it} captures tourism intensity measured as the share of tourism receipts in GDP. X_{it} is a vector of control variables including inflation and unemployment, which account for macroeconomic conditions affecting tourism demand. The term C_t represents a vector of crisis dummy variables corresponding to the SARS outbreak (2003), the Global Financial Crisis

(2008–2009), and the COVID-19 pandemic (2020 onwards), taking the value of one during crisis periods and zero otherwise. The coefficient γ captures the average structural shift in tourism performance associated with crisis events relative to normal conditions. μ_i denotes unobserved country-specific effects, while ε_{it} is the idiosyncratic error term. This specification follows established empirical approaches that incorporate crisis indicators into tourism–growth models to identify structural disruptions in tourism activity (Brida et al., 2016; Gössling et al., 2021; Lee & Chang, 2008).

Estimation is conducted using heteroskedasticity-consistent standard errors to account for potential variance instability across countries and time. This choice improves inference reliability in panels characterised by structural diversity and uneven tourism scales. Results are reported for alternative specifications to confirm the stability of key coefficients.

Table 1. Variables Description (Source: Authors' compilation and own calculations)

Variable	Definition	Measurement	Expected Effect
Tourism Receipts (TR)	International tourism earnings	USD, logarithmic	Dependent variable
GDP	Economic output	USD, logarithmic	Positive
Tourism Intensity (TI)	Tourism share of GDP	Percentage	Positive
Inflation	Consumer price inflation	Annual percentage	Ambiguous
Unemployment	Unemployment rate	Percentage	Ambiguous
Crisis 2003	SARS outbreak	Dummy	Negative
Crisis 2008–09	Global Financial Crisis	Dummy	Negative
Crisis 2020+	COVID-19 pandemic	Dummy	Negative

Several diagnostic procedures are employed to validate the empirical results. Correlation analysis is first conducted to examine potential multicollinearity among explanatory variables. Fixed effects estimation is preferred where country-specific heterogeneity is statistically relevant. Model fit and explanatory power are assessed using within and overall goodness-of-fit measures, while coefficient stability is evaluated across specifications. It is acknowledged that tourism activity and economic growth may be jointly determined; therefore, the empirical results are interpreted as indicative of robust long-run associations rather than definitive causal relationships. Table 1 presents the definition and measurement of all variables used in the analysis, providing clarity and reproducibility. Figure 1 summarises the methodological flow, linking data preparation, model estimation, and result interpretation. Together, these elements reflect methodological practices consistent with high-quality regional and tourism geography research.

EMPIRICAL RESULTS

This section presents the empirical findings in a structured and systematic manner, moving from descriptive patterns to multivariate estimations and comparative regional assessments. The emphasis is placed on reporting statistically and economically meaningful results while maintaining analytical clarity. Interpretation is grounded in empirical magnitudes rather than speculative inference, allowing subsequent discussion to draw explicitly on observed patterns in ASEAN tourism and economic dynamics.

Descriptive Analysis

The descriptive statistics indicate marked heterogeneity in tourism and economic performance across ASEAN countries during 1999–2023. For the full sample, average tourism receipts amount to USD 8,643 million, accompanied by a large standard deviation of USD 11,116 million, reflecting substantial dispersion across destinations. This wide variation signals uneven tourism development trajectories and differences in destination scale and maturity across the region, as reported in Table 2. Average GDP for the pooled sample reaches USD 229,519 million, with a standard deviation exceeding USD 270,000 million, underscoring deep structural economic disparities within ASEAN.

Table 2. Descriptive Statistics of Tourism and Macroeconomic Variables in ASEAN (1999–2023) (Source: Authors own calculation)

Group	Tourism Receipts (USD million)	GDP (USD million)	Tourism Intensity (%)	Tourism Growth (%)	GDP Growth (%)	Inflation (%)	Unemployment (%)	Countries
Developing	3,067 (3,718)	199,627 (323,126)	4.04 (4.06)	9.53 (35.09)	10.22 (14.56)	6.55 (7.64)	2.97 (2.22)	5
Developed	17,937 (13,003)	279,338 (133,224)	6.44 (2.42)	5.81 (20.83)	7.23 (8.82)	1.95 (1.79)	2.98 (1.48)	3
All	8,643 (11,116)	229,519 (270,474)	4.94 (3.71)	8.14 (30.52)	9.10 (12.77)	4.82 (6.53)	2.98 (1.97)	8

Tourism intensity averages 4.94 percent of GDP, confirming that tourism represents a relevant but uneven economic pillar.Tourism growth exhibits pronounced volatility, with a mean of 8.14 percent and a standard deviation above 30 percent, indicating strong exposure to cyclical fluctuations and external shocks.

These descriptive patterns are further illustrated in Figure 2. Figure 2(A) depicts long-term tourism receipts trends across ASEAN countries and highlights clear discontinuities during major crisis periods. While tourism revenues follow sustained upward trajectories in normal years, abrupt contractions appear during SARS, the Global Financial Crisis, and most prominently COVID-19, reinforcing the volatility documented in Table 2. A clear development divide emerges between country groups, both statistically and visually. Developing ASEAN members record average tourism receipts of

USD 3,067 million, compared to USD 17,937 million in developed economies, while tourism intensity is lower at 4.04 percent versus 6.44 percent. This contrast is clearly captured in Figure 2(B), where developed economies cluster at higher tourism intensity levels, indicating stronger structural integration of tourism within their economic systems.

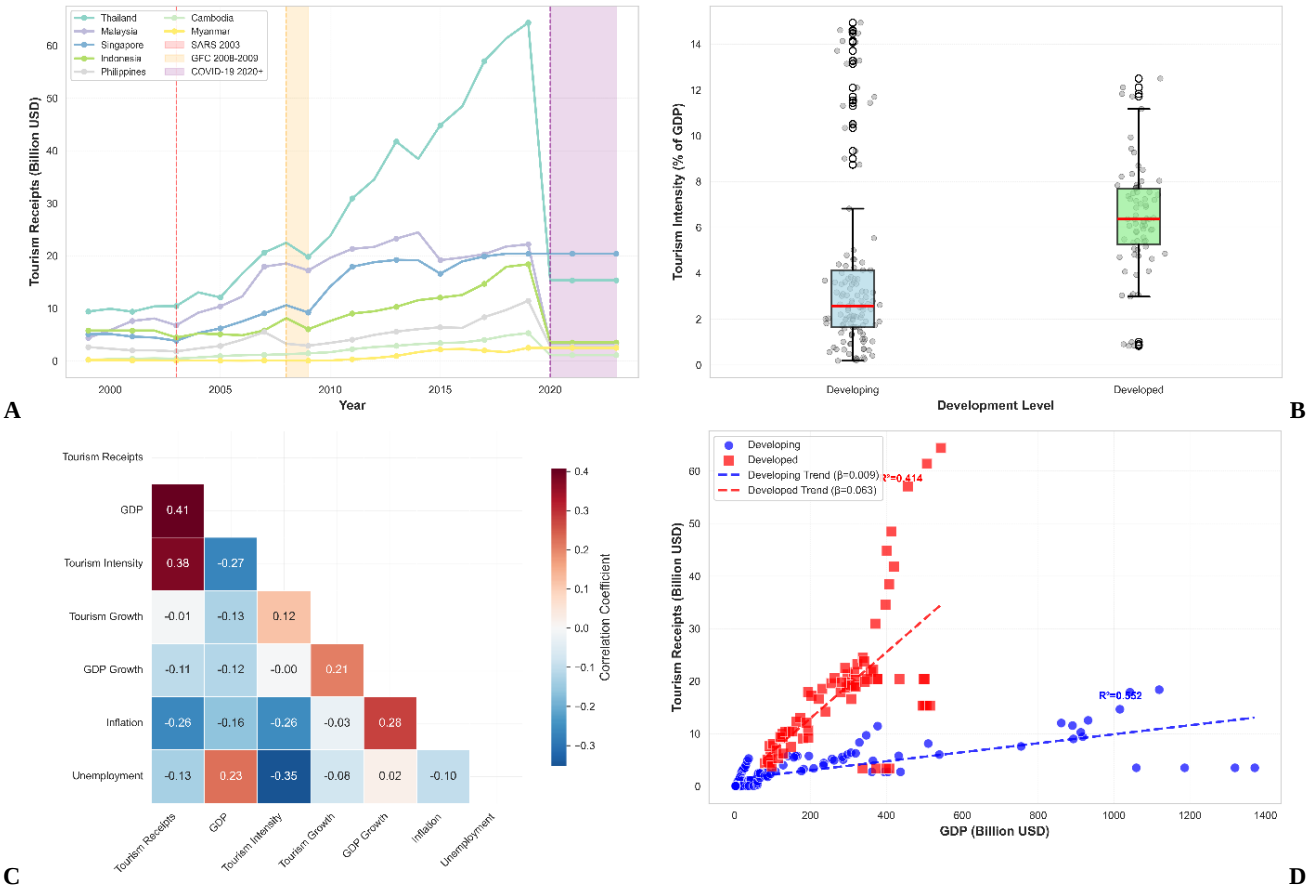

Figure 2. Descriptive Statistics of Tourism and Macroeconomic Variables in ASEAN. (A) Tourism receipts trends with crisis periods; (B) Tourism intensity by development level; (C) Correlation matrix of key tourism and macroeconomic variables; (D) GDP–tourism receipts relationship by development level. (Source: Authors' own calculations and visualization).

Macroeconomic conditions further reinforce regional asymmetries. Developing countries exhibit higher average inflation of 6.55 percent, compared to 1.95 percent in developed economies, while unemployment remains close to three percent in both groups. Figure 2(C) complements this evidence by summarising correlation patterns in which tourism receipts are positively associated with GDP and tourism intensity, yet negatively related to inflation, suggesting that macroeconomic instability is systematically linked to weaker tourism performance.

Finally, Figure 2(D) provides a bivariate illustration of the tourism–GDP relationship across development levels. The steeper fitted slope for developed economies and the wider dispersion among developing countries imply that economic scale supports tourism expansion across contexts, but structural conditions and development stage shape the strength and stability of this linkage. Taken together, Table 2 and Figure 2 justify the subsequent use of panel regression techniques to evaluate tourism–economic relationships while accounting for heterogeneity and crisis effects.

Correlation Analysis

The correlation results offer initial evidence on the association between tourism activity and economic performance in ASEAN. Tourism receipts are positively and significantly correlated with GDP, with a coefficient of 0.408 significant at the one percent level, as reported in Table 3.

Table 3. Correlation Matrix of Tourism and Macroeconomic Variables. (Source: Authors own calculation)

Variable	Tourism Receipts	GDP	Tourism Intensity	Tourism Growth	GDP Growth	Inflation	Unemployment
Tourism Receipts	1.000	0.408***	0.379***	−0.006	−0.108	−0.262***	−0.133
GDP	0.408***	1.000	−0.268***	−0.127	−0.119	−0.163*	0.225**
Tourism Intensity	0.379***	−0.268***	1.000	0.119	−0.003	−0.255***	−0.352***
Tourism Growth	−0.006	−0.127	0.119	1.000	0.209**	−0.026	−0.079
GDP Growth	−0.108	−0.119	−0.003	0.209**	1.000	0.279***	0.024
Inflation	−0.262***	−0.163*	−0.255***	−0.026	0.279***	1.000	−0.101
Unemployment	−0.133	0.225**	−0.352***	−0.079	0.024	−0.101	1.000

Notes: *, *, and *** denote statistical significance at the 10%, 5%, and 1% levels, respectively

This association indicates that larger and more developed economies tend to generate higher tourism revenues, although it does not imply a unidirectional causal relationship between tourism and economic growth. Tourism intensity also shows a positive and statistically significant correlation with tourism receipts at 0.379, indicating that economies with a higher tourism share generally achieve greater tourism income. In contrast, tourism receipts display weak and statistically insignificant correlations with tourism growth at −0.006 and GDP growth at −0.108.

These patterns imply that short term growth fluctuations do not directly translate into changes in tourism scale.Macroeconomic stability appears relevant for tourism performance. Inflation is negatively correlated with tourism receipts at −0.262, significant at the one percent level, while unemployment shows a strong negative association with tourism intensity at −0.352. Importantly, no correlation coefficient among explanatory variables exceeds conventional thresholds, suggesting that multicollinearity is unlikely to bias subsequent panel regressions.

Baseline Regression Results

The baseline panel estimations provide strong evidence of a close association between tourism activity and economic output in ASEAN countries. Across pooled OLS and fixed effects specifications, the coefficient on logarithmic GDP remains positive and statistically significant at the one percent level. In the fixed effects model, the estimated elasticity equals 0.952, indicating that a one percent increase in GDP is associated with an almost proportional increase in tourism receipts, as reported in Table 4. This finding highlights the strong note of tourism performance on broader macroeconomic capacity rather than indicating tourism-led economic expansion.

Table 4. Panel Regression Results for Tourism Receipts (Source: Authors own calculation)

Variable	OLS	Policy	FE Panel
Constant	−3.693*** (0.306)	−3.690*** (0.318)	−3.339** (1.240)
ln(GDP)	0.962*** (0.012)	0.965*** (0.011)	0.952*** (0.049)
Tourism Intensity	0.230*** (0.013)	0.225*** (0.014)	0.206*** (0.021)
Inflation	−0.012 (0.010)	−0.012 (0.010)	−0.002 (0.007)
Unemployment	0.068*** (0.019)	0.062** (0.022)	0.068* (0.027)
Crisis 2003	-	0.055 (0.080)	−0.003 (0.087)
Crisis 2008	-	−0.170 (0.152)	−0.206 (0.128)
Crisis 2020	-	−0.121 (0.126)	−0.159 (0.139)
Observations	200	200	200
R squared	0.963	0.963	0.790

Notes: *, **, and *** denote statistical significance at the 10%, 5%, and 1% levels, respectively

Tourism intensity also exhibits a consistently positive and significant effect on tourism receipts. In the fixed effects specification, the coefficient reaches 0.206, suggesting that a higher tourism share within the economy translates into greater tourism revenues. This result highlights the importance of structural tourism orientation beyond overall economic scale, reinforcing arguments from tourism geography regarding embeddedness within regional economic systems.

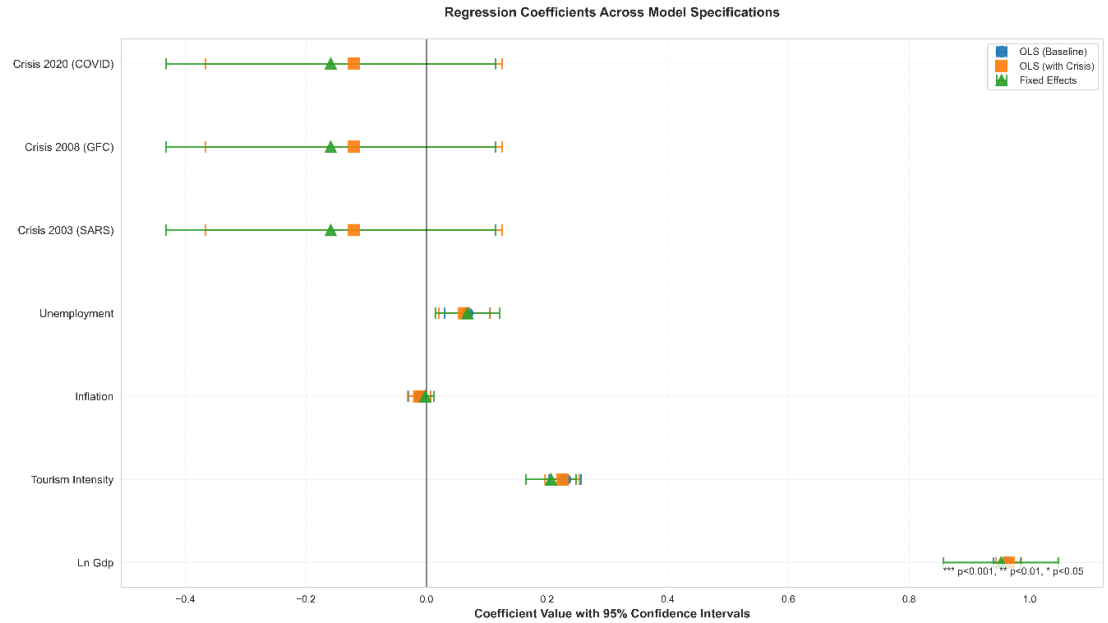

Figure 3. Regression Coefficient Plot with 95 Percent Confidence Intervals. (Source: Authors' own calculations and visualization)

Macroeconomic controls display differentiated effects. Inflation is statistically insignificant in the fixed effects model, with a coefficient of −0.002, indicating that price level changes do not directly influence tourism receipts once country

specific characteristics are accounted for. In contrast, unemployment retains a positive but weakly significant coefficient of 0.068, which may reflect context-specific labour market dynamics in tourism-oriented economies rather than a generalised employment effect. Model performance remains high across specifications. The pooled OLS and policy augmented models both report R squared values of 0.963, while the fixed effects model achieves an R squared of 0.790. Although the inclusion of country fixed effects reduces overall explanatory power, the remaining fit confirms that the selected variables capture a substantial portion of tourism revenue variation across ASEAN countries.

The stability of key coefficients is further illustrated in the regression coefficient plot. Figure 3 shows narrow confidence intervals for GDP and tourism intensity across model specifications, confirming the robustness of these effects. The visual evidence complements the numerical results and supports the reliability of the baseline estimations.

Crisis Impact Assessment

The crisis impact analysis reveals pronounced differences in both the magnitude and spatial distribution of tourism shocks across crisis episodes. Figure 3 provides a comprehensive visual summary of these dynamics by illustrating the distribution of tourism growth during crisis periods, comparing average impacts across development groups, tracing post-crisis recovery paths over a three-year horizon, and presenting a country-level tourism resilience index relative to normal growth conditions. As shown in Figure 4 (A), the SARS outbreak in 2003 is associated with moderate contractions in tourism growth, with observations clustering around negative values close to −15 percent on average. This distributional pattern is consistent with the regression results, which indicate a small and statistically insignificant fixed effects coefficient of −0.003. Together, these findings suggest that SARS generated short-term disruptions without producing persistent structural effects on tourism performance at the regional level. Figure 4 (B) highlights marked asymmetries in crisis impacts across development levels. During the Global Financial Crisis, developing ASEAN economies experienced an average contraction in tourism growth of approximately −18.0 percentage points, compared to −6.8 percentage points in more developed member states. This divergence mirrors the regression estimate of −0.206 and reflects the higher exposure of less diversified tourism systems to global demand shocks and financial instability.

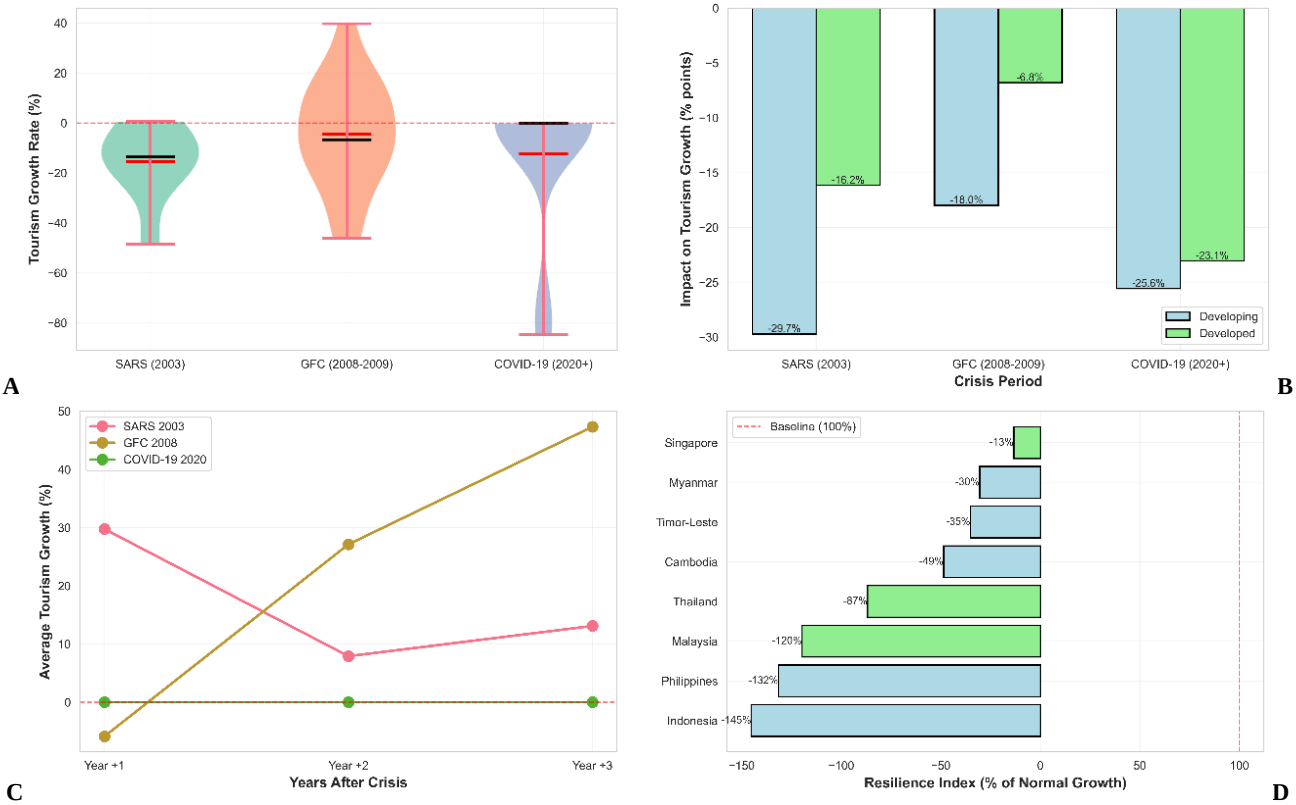

Figure 4. Crisis Impact Analysis on Tourism Receipts in ASEAN. (A) Tourism Growth Distribution During Crises; (B) Crisis Impact by Development Level; (C) Tourism Recovery Patterns after Crises; (D) Tourism Crisis Resilience by Country. (Source: Authors' own calculations and visualization)

The COVID-19 pandemic emerges as the most disruptive shock across all dimensions. Average tourism declines reached −25.6 percentage points in developing economies and −23.1 percentage points in developed ones, indicating a region-wide collapse in tourism activity. While the fixed effects coefficient captures an average negative shift, the descriptive and recovery analyses reveal substantial cross-country heterogeneity in both the depth and persistence of the shock. Post-crisis recovery dynamics further reinforce these patterns. Figure 4 (C) indicates that tourism growth rebounded relatively quickly following SARS and the Global Financial Crisis, reaching approximately 13 percent and 47 percent, respectively, by the third year after the shock. In contrast, recovery following COVID-19 remains subdued. Figure 4 (D) underscores pronounced cross-country

heterogeneity in resilience, with Singapore retaining about 87 percent of normal growth, while Indonesia and the Philippines record losses exceeding −130 percent, highlighting deep territorial differences in adaptive capacity.

Regional and Development Group Comparison

The group specific regressions reveal clear heterogeneity in tourism economic dynamics across ASEAN. As reported in Table 5, developing countries exhibit a GDP elasticity of tourism receipts equal to 0.911, slightly higher than the 0.888 observed in developed members. This difference suggests that tourism performance in developing economies is more sensitive to changes in economic scale, reflecting a higher relative dependence on macroeconomic conditions.

Table 5.Group Comparison between Developing and Developed ASEAN Countries (Source: Authors own calculation)

ASEAN Group	ln(GDP)	Tourism Intensity	Inflation	Unemployment	Crisis Impact	R squared	Observations
Developing	0.911	0.202	−0.008	0.067	−0.167	0.954	125
Developed	0.888	0.202	0.020	0.018	−0.093	0.921	75

Tourism intensity shows identical coefficients of 0.202 for both groups, indicating that the structural role of tourism contributes similarly to tourism receipts regardless of development status. In contrast, crisis impacts differ markedly. Developing economies record an average crisis coefficient of −0.167, nearly twice the −0.093 estimated for developed countries, highlighting greater vulnerability in less diversified economic systems.

Model performance remains strong across both subsamples. The R squared value reaches 0.954 for developing countries and 0.921 for developed members, confirming substantial explanatory power. These results underscore the importance of regional context and development level in shaping tourism resilience, economic linkages, and differential responses to external shocks across ASEAN.

DISCUSSION

The estimated tourism–GDP elasticity of approximately 0.96 indicates a strong and robust association between economic scale and tourism performance in the ASEAN context (Fan & Ha, 2025; Pratoomchat, 2020). Rather than providing evidence of tourism-led growth in a strict causal sense, this near-unitary elasticity suggests that tourism revenues expand almost proportionally with gross domestic product, reflecting a tight structural linkage between tourism systems and regional economies (Öztürk et al., 2019; Tang & Tan, 2015). Accordingly, the result supports the study's first hypothesis concerning the positive role of economic growth in shaping tourism performance, and aligns with theoretical perspectives that emphasise demand-side macroeconomic capacity in open and regionally interconnected economies.

The magnitude of the estimated elasticity exceeds that reported in many earlier cross-country studies, which often document weaker or statistically insignificant effects (Rattanasirivilai, 2023; Tung, 2021). Such differences may stem from the greater regional coherence of ASEAN economies and the extended time horizon employed in this analysis (Jiranyakul, 2016). By embedding tourism within a spatially defined regional framework, the findings extend prior evidence and clarify how regional integration and spatial proximity condition tourism performance through macroeconomic scale and structural stability, rather than through a uniform growth transmission mechanism (Balaguer & Cantavella-Jordá, 2002; Lee & Chang, 2008). Crisis resilience emerges as a central dimension influencing tourism performance across ASEAN. The heterogeneous impacts of SARS, the Global Financial Crisis, and the COVID-19 pandemic partially support the second hypothesis by revealing asymmetric and episode-specific disruptions, demonstrating that shocks differ markedly in their structural consequences (Martin & Sunley, 2015; Yong, 2022). While the disruption caused by SARS was largely temporary, COVID-19 produced deeper and more persistent contractions, consistent with resilience theory emphasising shock magnitude, duration, and adaptive capacity as key recovery determinants.

Cross-country recovery trajectories further highlight the spatially embedded nature of tourism resilience. Economies characterised by greater diversification and stronger institutional capacity display faster recovery, whereas regions heavily dependent on tourism face more difficult adjustment paths (Odeleye et al., 2022). These results resonate with tourism geography literature that conceptualises resilience as territorially grounded, shaped by governance structures, connectivity, and regional adaptive capacity rather than by sectoral characteristics alone (Saarinen & Rogerson, 2021).

The development divide identified in the group analysis provides clear empirical support for the third and fourth hypotheses, as developing ASEAN economies exhibit slightly higher sensitivity of tourism revenues to changes in economic scale, alongside substantially larger crisis-induced losses (Tan et al., 2025). This combination reflects a dual role of tourism in less advanced economies, where tourism performance is closely tied to macroeconomic conditions while simultaneously exposing these economies to heightened vulnerability during systemic shocks. Such asymmetry is a well-documented feature in tourism and development studies (Telfer & Sharpley, 2015).

An important nuance arises from the finding that tourism intensity coefficients are identical across development groups (Maneejuk et al., 2022). Tourism orientation contributes similarly to revenue generation in both developed and developing economies, yet its stabilising role differs markedly. In advanced economies, tourism is embedded within diversified economic systems that can absorb shocks more effectively. In developing contexts, tourism plays a more exposed role, amplifying volatility during crisis periods and moderating recovery capacity.

From a theoretical standpoint, these findings refine and extend tourism–growth theory by incorporating a spatially differentiated and crisis-sensitive perspective. Rather than treating tourism as a uniform growth engine, the results

demonstrate that tourism performance is contingent on regional structure, development level, and exposure to systemic shocks (Karimi et al., 2024). This interpretation bridges tourism economics with concepts of territorial resilience and uneven regional development, offering a more nuanced understanding of tourism's economic role.

The study also addresses gaps in ASEAN-focused literature, which has frequently relied on short time horizons or single-country analyses (Kyophilavong et al., 2018; Tang & Tan, 2013, 2015). By employing a long-term, multi-country panel framework, the analysis captures both enduring structural relationships and episodic disruptions. This contribution strengthens the empirical foundation for regional tourism research in emerging economic blocs and offers a more comprehensive understanding of tourism dynamics over time.

Clear policy implications follow from these results. ASEAN tourism strategies should move beyond aggregate growth targets toward spatially differentiated planning approaches (Kholil et al., 2025; Sobirov et al., 2025). Developing economies would benefit from reducing excessive dependence on tourism through stronger intersectoral linkages, while developed members should prioritise innovation, diversification, and resilience-building measures. Such differentiation aligns closely with principles of regional planning and territorial policy.

Overall, the findings support all proposed hypotheses within an association-based analytical framework and demonstrate that tourism plays a central yet uneven role in ASEAN economic development (Bassil et al., 2015). Growth effects are substantial but asymmetric, with development level shaping both contribution and susceptibility to crises. By integrating economic analysis with a regional and spatially informed perspective, the study contributes new insights into how tourism both shapes and is shaped by regional development processes in an increasingly crisis-prone global economy.

CONCLUSION

This study aimed to analyze the long-run relationship between tourism development and economic growth in ASEAN at a regional, territorial level, including crisis dynamics and development heterogeneity. Based on balanced panel data for eight ASEAN countries between 1999 and 2023, the empirical evidence obtained is strong for the role of tourism as an integral component of regional economic activity rather than as an independent causal engine of growth. The results provide evidence that the relationship between tourism revenue and economic output is one of joint proportionate increase, indicating a close structural association between tourism performance and overall economic capacity within a spatially integrated region.

A number of empirically important conclusions can be drawn from the analysis. First, the derived tourism–GDP elasticity of around 0.96 suggests a robust and structurally embedded association between tourism systems and regional economies. This magnitude implies that tourism expansion in ASEAN closely follows broader macroeconomic dynamics, reinforcing the view that tourism operates as part of a larger economic process rather than as a standalone growth driver. Furthermore, crises themselves have asymmetric effects on tourism performance. In contrast, the SARS epidemic caused only temporary disruptions, whereas the Global Financial Crisis and, more particularly, the COVID-19 outbreak led to massive and long-lasting reductions in tourism activity, illustrating the vulnerability of tourism to systemic shocks.

Third, the discrepancy in development between ASEAN member countries is significant when comparing developing and developed states. There is moderate heterogeneity in the tourism output response estimates by level of development, with lower-income economies showing a slightly greater sensitivity of tourism revenues to economic growth than higher-income ones, but substantially more susceptibility when crisis periods are considered. Against this backdrop, crisis sensitivity is lower and recovery capacity stronger in developed ASEAN economies where economic structures are more diversified and where institutions are better able to support adjustment processes.

These findings provide empirical support for the proposed hypotheses within an association-based analytical framework and underscore the region-specific nature of tourism–economic linkages. From a theoretical perspective, the paper adds to the literature by relaxing linear and homogeneous assumptions often embedded in tourism-led growth analyses. By combining crisis dynamics with regional heterogeneity, the study reveals the conditionality of tourism–economic relationships on territorial structure, development level, and exposure to external shocks. Rather than advancing a strict tourism-led growth mechanism, the findings emphasise how tourism performance is shaped by macroeconomic conditions and territorial resilience, thereby enriching tourism geography and regional development theory.

The policy implications of such findings are highly pertinent to ASEAN. Regional and local tourism policies must not remain focused solely on aggregate growth objectives but should apply more spatially differentiated approaches according to diverse development conditions. In the case of developing member countries, it will be necessary to reduce excessive tourism dependence by strengthening intersectoral linkages and economic diversification as a means of lowering vulnerability to future shocks. In more mature destinations, policy priorities should concentrate on innovation, sustainability, and resilience-enhancing measures that increase the adaptive capacity of tourism systems. At the regional level, greater coordination within ASEAN can promote more sustainable tourism development and improved collective crisis preparedness.

There are, however, several potential limitations to this study. This analysis is based on national-level aggregate data and may obscure significant subnational differences in tourism performance and regional resilience. Moreover, tourism receipts as the main proxy for tourism activity do not capture qualitative aspects related to sustainability, employment quality, or environmental impacts. Crisis effects are also modelled using dummy variables, which capture average shifts and may not fully reflect more complex non-linear or lagged responses.

These constraints motivate a number of potentially fruitful avenues for further research. Future studies may employ subnational or destination-level data to better capture spatial heterogeneity within countries. Integrating environmental, social, and institutional indicators would enable a richer assessment of sustainable tourism development. Further work could also apply non-linear or spatial econometric methods to investigate spillover effects and cross-border interactions among ASEAN

economies. Lastly, comparative analysis across other regional blocs would help assess the extent to which observed tourism–economic relationships are context-specific or generalisable across different institutional and geographic settings.

Overall, this research evidences that tourism continues to be a significant component of regional economic systems in ASEAN, although its contribution is uneven and closely conditioned by development level and crisis exposure rather than uniformly growth-leading. By combining rigorous empirical analysis with a regional and spatially informed perspective, the study contributes to a more nuanced understanding of tourism–economic dynamics in an increasingly volatile global context. The results provide a robust empirical basis for regionally differentiated tourism policy and open new research directions at the intersection of tourism geography and regional development.

Zoning of oikonyms of the territory of the republic of Karakalpakstan. *Geojournal of Tourism and Geosites*, 67(3), 1960–1967. https://doi.org/10.30892/gtg.67312-1824

Abstract: In the article, the scientific research works of foreign and local scientists who geographically studied the names of settlements, that is, oikonyms, are analysed. The object of the research is 1151 oikonyms of the Republic of Karakalpakstan. The purpose of the scientific work is the oikonymic zoning of oikonyms of the Republic of Karakalpakstan by quantitative analysis of their linguistic structure, topoterminological structure, and lexical-semantic structure. In carrying out scientific work within the framework of this goal, field research was mainly conducted to determine the linguistic and lexico-semantic typology of oikonyms. In the process of quantitative analysis of oikonyms, the statistical method and cartographic and zoning methods were effectively used in their zoning. In terms of territorial distribution, Karakalpaks predominate in the northern and central districts, and Uzbeks predominate in the southern districts. In addition, they have their own nominative traditions in naming oikonyms, and this circumstance has been revealed in the study that the oikonyms of Karakalpakstan were formed in the northern regions from Karakalpak names, and in the southern regions, they were formed mainly from Uzbek names, and this circumstance served as the basis for dividing the region into two oikonymic regions. Furthermore, the distribution of local geographical terms by territories, i.e. mainly hydronymic in the northern districts, and oikonymic terms in the central and southern districts, was determined. At the same time, the identification of territorial differences in lexical and semantic features served as the basis for dividing the Northern oikonymic region into four micro-regions: the Aral Sea region, the Northeastern, Western, and Central, and the Southern oikonymic region into three micro-regions: the Southern Left Bank, the Southern Right Bank, and the Kyzylkum.

Keywords: toponyms, oikonyms, local geographical terms, oikonymic regions, oikonymic micro-regions, oikonymic zoning, cultural geography, rural geography, ethnonyms, anthropo-oikonyms

INTRODUCTION

Since the production, economic, and social activities of humanity are carried out within the framework of the geographical environment, consisting of many objects with their names, the names of geographical objects are always the same, that is, they perform the function of an address, without geographical names there is no socio-economic formation. Geographical names, as direct symbols of history, are constantly supplemented, renamed, and updated due to the lifestyle of the people who lived there for centuries, serving the various needs of society.

At the same time, geographical names reflect the diversity of the surrounding natural environment, the availability of natural resources, the diversity of landscapes, climatic and hydrographic, relief and orographic features, as well as the appearance, location, and other important features and characteristics of natural and other objects. In general, geographical names are often a rich source of diverse information. Therefore, the study of geographical names, their scientific research, and the determination of the etymology and meaning of each place name are among the urgent tasks.

Place names are amazing, and living works of art have been created by millions of people over thousands of years. Doğru (1984) tells about the geographical features, migrations, events, stories, facts, and finally, the entire history of that region. That is, they all have a language. In other words, they are all part of cultural heritage, its oral form.

From this point of view Hanilçe (2013), place names, which have an important share in the cultural treasures of societies, preserve the memories of the societies to which they belong and play an important role in the transfer of culture from the past to the future. The place names created by indigenous peoples have now become the property of world geography and cartography. Sometimes they are accepted in their original form, but most often the names reflect changes in the living language. As noted, any place name arises out of necessity, its form changes in the process of performing its function, and ultimately retains its time.

Saparov et al. (2017) emphasized that toponymic research allows determining the ethnic composition of the population of a certain territory, which peoples lived in this territory, in which language the authors of these names spoke in ancient times, i.e., the etymology of place names. For this reason, it is necessary to study geographical names, especially their territorial distribution and scientific research of the reasons for their origin. Because through these aspects, to a certain extent, toponymic regularities are determined, and this information serves toponymic zoning.

Basik (2020) studied urban place names and their significance in our lives. Rusu (2020) conducted a quantitative analysis of the political formation and post-socialist toponymic changes of the Romanian cities of Brașov, Cluj-Napoca, and Sibiu. Atik et al. (2022) observed landscape features through place names in rural areas of the Mediterranean, while the names of some settlements and villages in Serbia and their locations on topographic maps were developed by Marković (2024). The map of Romanian city names based on female names was studied by Rusu (2024), the spatial distribution characteristics and influencing factors of traditional villages in the Jiarong Tibetan area of western Sichuan, China were studied by Li et al. (2024), the distribution characteristics and formation of traditional village toponyms in western Hunan Province, China were studied by Liu et al. (2024), the distribution and formation of traditional village names in Southeast Guizhou Province were studied by Chen et al. (2025), and the assessment of the location potential of traditional villages in Sichuan Province for tourism development was studied by Xia et al. (2025). Moreover, Rose-Redwood et al. (2018) conducted numerous studies on the names of streets and their names, which are part of cities, settlements, and villages.

Moreover, a number of geographers have been engaged in toponymic zoning, and in Manakov's (2006) research, based on the formant method, the toponymic zoning of the European part of Russia, Ukraine, and Belarus was carried out. In this case, the presence of Slavic toponymic formants - prefixes, suffixes, and affixes - in the names of settlements of the Eastern European Plain was statistically analysed using the cartographic method. In the toponyms of different parts of the Eastern European Plain, the predominance of certain formants adding a certain "tone" (character) was determined, and on this basis, the studied region was divided into 7 toporegions. Taranova (2004) conducted geo-toponymic zoning in the territory of Ukraine's Holohora-Kremenets range and the area of Male Polissya.

It identifies nine geo-toponymic regions, and in each of them, the connection of geographical names with natural conditions is observed. Afanasev (2005, 2006) proposed toponymic zoning of Ukraine in his research. According to it, nine toponymic regions have been identified in the country. The theoretical foundations of these works serve to a certain extent in the toponymic zoning of oikonyms of our region. A unique experience of toponymic zoning of the territory of Uzbekistan, published in scientific literature, can be observed in the textbook “Toponymy” by Nizomov et al. (2013). These authors divided the territory of Uzbekistan into 8 toponymic regions: Tashkent-Mirzachul, Zarafshan, Kyzylkum, Lower Amudarya, Ustyurt, Fergana, Surkhandarya, and Kashkadarya.

Figure 1. Location of our research object (Source: Google, accessed on 16.09.2025)

This zoning scheme covers the entire territory of Uzbekistan, and this experience is characterised by a more general formulation of the relevant scientific problem. In particular, the work under consideration does not indicate specific criteria for toponymic zoning, does not carry out statistical (quantitative) analysis of the composition of toponyms and does not compare them in the context of the identified toponymic regions, and zoning is carried out only at one territorial level. Moreover, in this case, not just oikonyms, but all categories of toponyms are taken as objects of zoning. The object of our research is the oikonyms of the Republic of Karakalpakstan, which is an administrative-territorial unit of the Republic of Uzbekistan located in the center of the Central Asian region and located in the northwestern part of Uzbekistan. The territory of Karakalpakstan is mainly occupied by the Aral Sea in the northern part, the Ustyurt Plateau in the western part, the Kyzylkum Desert in the eastern part, and the Amudarya delta in the southern and central parts. The fact that the main area is occupied by such various landscape types is reflected in the formation of toponyms of this territory, especially oikonyms, their territorial differences, as well as the diversity of local geographical terms across the territory (Figure 1). The Republic of Karakalpakstan administratively and territorially consists of the capital city of Nukus and 16 districts. In this study, the names of settlements in the Republic of Karakalpakstan were obtained based on the Resolutions of the Praesidium of the Jokargy Kenes of the Republic of Karakalpakstan and the District Councils of People's Deputies on the issues of administrative-territorial division as of January 1, 2021. According to these official documents, as of January 1, 2021, there were 12 cities, 26 towns, and 1113 rural settlements in the republic, that is, a total of 1151 settlements. In the article, the determination of the quantitative composition of the lexico-semantic features (etymology) of the oikonyms of the Republic of Karakalpakstan and its administrative-territorial units was carried out based on the total number of settlements recorded in the above-mentioned documents. Furthermore, the linguistic composition of oikonyms was analysed in the context of administrative-territorial units.

MATERIALS AND METHODS

The process of toponymic zoning of the studied territory is a rather complex issue, and its implementation requires the application of various methods. These are the methods of comparing different toponymic data with each other, the method of describing the number of toponyms according to their genetic origin, the cartographic method, the direct study of toponyms in field conditions, and the selection of leading toponyms that are numerous.

When writing this article, the lexico-semantic meaning of oikonyms, the determination of topoterminological aspects, i.e., local geographical terms in the composition of oikonyms, were mainly used as a result of scientific expeditions to remote villages and auils in the territory of the Republic of Karakalpakstan, i.e., field research, and when analyzing the obtained results, statistical research methods were mainly used to determine their numerical values. In addition, historical maps were studied in terms of the location of settlements, their historical origin, and for the first time, based on the analysis of collected materials, using the methods of zoning and mapping of oikonyms of the republic, oikonymic zoning and mapping of oikonyms of the republic were carried out. Below we present the results obtained from scientific research.

Toponyms distributed across regions are not uniform in their genetic origin. For example, while orotoponyms are more common in some regions, hydrotoponyms or petrotoponyms may dominate in some regions. Their distribution areas are separated by a kind of invisible curve - a linguogeographic boundary. It is this curve that can serve as a boundary for toponymic regions. Consequently, the numerical abundance of a toponymic type indicates the specific geographical conditions of that place, and it is distinguished as a separate region. In this way, toponymic zoning is carried out.

It is known that the diversity of the natural environment, the history of local peoples, the economic and cultural way of life, and linguistic features lead to territorial differences in geographical names. These differences serve as the main criterion for toponymic zoning. Juchkevich (1968) is a specialist who has published the most scientific works on toponymic zoning, indicating geographical (territorial), linguistic, and historical principles as the main principles of this zoning.

It is difficult to imagine any geographical research without the method of zoning. Toponymic regions, like physical-geographical and economic-geographical regions, are located in a certain territory that is not exactly repeated in nature and have a separate geographical name. At the same time, it is natural that there are similarities between toponymic regions, but they differ in their main important features. The renowned toponymist and geographer Juchkevich (1968) wrote that "when determining the territorial characteristics of toponymy, issues of zoning principles arise first." There are specific principles of toponymic zoning, which consist in adhering to the objective territorial division of the identified regions. Toponymic zoning is carried out mainly on the basis of the principles of territoriality, historical-genetic, complexity, and relative homogeneity.

A systematic approach should be applied to the socio-geographical study of place names in a certain territory, in particular, oikonyms. At the same time, the oikonyms of the studied territory are perceived as integral elements of the historically formed and developing geocultural environment of that territory, and attention is paid to the fact that they embody the important features of that geocultural system in the past and present. From this point of view, it is advisable to consider the oikonymy of a certain territory as a territorial cultural system and study it as a territorial oikonymic system.

It is known that oikonymy reflects the historical and cultural development of the territory, through oikonymy it is possible to study the ethnocultural and historical-geographical conditions of the territory. In this research work, each district of the Republic of Karakalpakstan was taken as a territorial oikonymic system. In this case, oikonyms were analysed from the point of view of language structure, i.e., spectral-stratigraphic, origin and meaning, i.e., lexico-semantic and topoterminological. Quantitative analysis of the above-mentioned spectral-stratigraphic, lexical-semantic, and topoterminological indicators in the identification of oikonymic regions and micro-regions was carried out within the framework of the oikonyms of the capital city of Nukus and 16 districts (total 1151), which are considered administrative-territorial units of the Republic of Karakalpakstan. Neighbouring districts were grouped in terms of similarity. The

language structure served as the basis for the identification of oikonymic regions, where Karakalpak (Kipchak dialect) names prevailed in the northern regions and Uzbek (Karluk dialect) names in the southern regions.

For many centuries, Karakalpaks have lived in these regions, namely in the northern and central districts, and Uzbeks in the southern districts, and their nominative traditions are clearly manifested in the naming of places. These aspects deserve to serve as a region-forming criterion. In addition, the lexico-semantic and topo-terminological features of oikonyms were taken as the basis for the division into oikonymic micro-regions, and neighbouring districts with similar lexico-semantic and topo-terminological features were grouped and divided into oikonymic micro-regions.

Like any territorial system, the territorial oikonymic system has its own composition, that is, its structure, and this structural structure has a multifaceted character (Figure 2). In particular, the presence of names in territorial oikonymic systems, usually belonging to different languages, is the basis for analysing the linguistic or spectral-stratigraphic composition of these systems. In this case, the oikonyms of the region are grouped according to their belonging to different languages, and the most common of the identified groups is selected as the oikonymic background of the corresponding region. Considering that language segments were formed in different historical periods, they are considered as stratigraphic layers of the territorial oikonymic system. The lexico-semantic structure of the territorial oikonymic system implies a typological study of the etymological formation of oikonyms in the studied territory and the diversity of their lexical meaning. It is known that oikonyms, as proper nouns, are formed according to various word-formation models. They can consist of one or more words, formed using various toponymic terms and toponymic formants (suffixes).

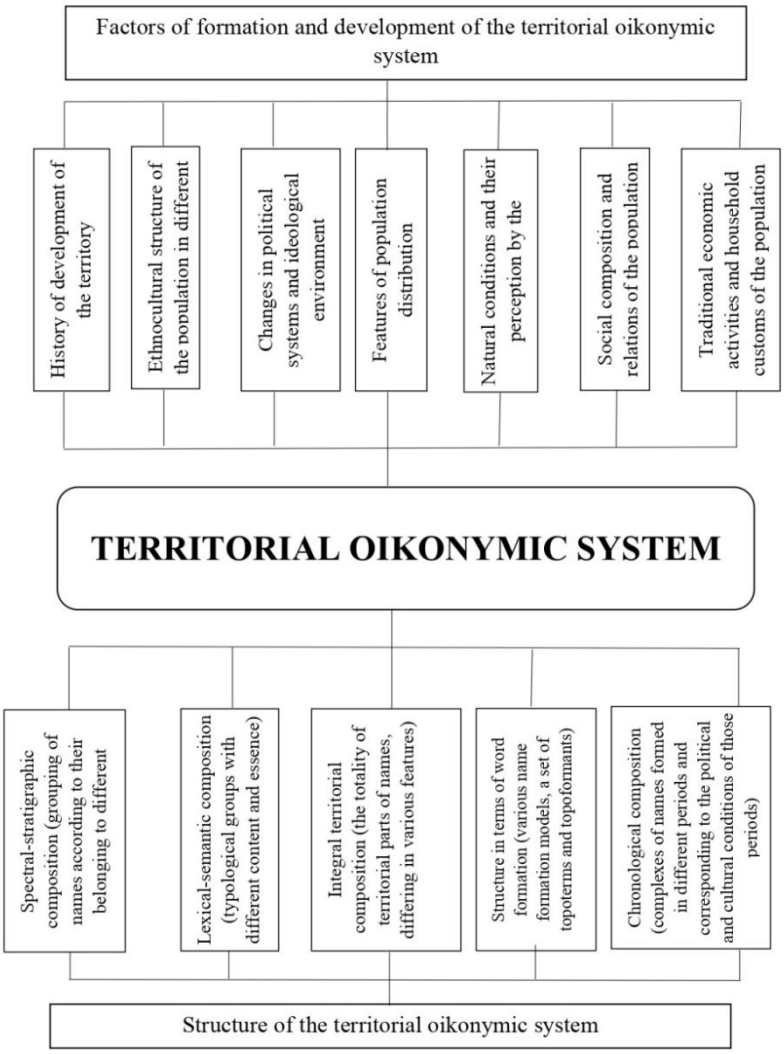

Figure 2. The structure of the territorial oikonymic system and the factors of its formation (Source: Authors)

These features of oikonyms are the basis for studying the structure of the territorial oikonymic system in terms of word formation and reflect an important feature of the oikonymy of a particular region.Territorial oikonymic systems have a rather variable character, and this feature is greatly influenced by the socio-political system and ideological environment in society. Historical experience shows that when the system of political governance in states changes, place names also change, are adapted to the new ideological and spiritual environment, and newly founded settlements are named according to the requirements of the time. As a result, in the oikonymy of many regions, names formed in different periods and embodying their socio-ideological features are encountered. The structure of territorial oikonymic systems in this aspect

constitutes its chronological structure. Spectral-stratigraphic, lexico-semantic, word-formation (in particular, terminological), and chronological differences in the oikonymy of territories with a large area are often expressed territorially.

These territorial differences are the basis for the zoning of territorial oikonymic systems. Oikonymic zoning involves dividing the oikonymy of the studied territory into smaller parts that differ from each other in various historically formed structural features and reflects the territorial composition of large territorial oikonymic systems. The structure of territorial oikonymic systems is historically formed and changed under the influence of several factors. The main of these factors are: the history of the development of the territory, the peculiarities of the settlement of the population, the ethnocultural composition of the population in the past and present, the social composition and relations of the population, traditional economic activities and everyday habits of the population, natural conditions and people's attitude to them, as well as the political system and ideological environment (Figure 2). When studying territorial oikonymic systems from a socio-geographical point of view, it is necessary to identify and analyse not only their structure of various kinds, but also the factors that influenced this structure. In socio-geographical research, the territorial oikonymic system is considered an integral and important element of the geocultural system. Therefore, through oikonyms, it is possible to obtain valuable historical and geographical information about the ethnocultural situation in the territory and its historical changes, the directions of population migrations associated with the development of the territory, the lost elements of the traditional way of life and social relations of the local population, individuals who played a special role in the history of settlements, and the state of natural-anthropogenic landscapes in the past. Consequently, territorial oikonymic systems, embodying the historical and modern features of natural-economic and socio-cultural systems of the corresponding territories, are a source of information about their origin and evolution, disappeared features. Moreover, a comprehensive study of territorial oikonymic systems based on a broad cultural-geographical approach contributes to a more complete disclosure of the historical, socio-spiritual significance of place names, the development of local history knowledge, the formation and promotion of unique "brands" of settlements, and the deeper study and protection of the cultural heritage of the regions.

RESULTS AND DISCUSSION

In the course of our research, the composition of all oikonyms currently existing in the Republic of Karakalpakstan was studied in three aspects by districts, analysed and summarised on a specific quantitative and statistical basis. These are linguistic, i.e., spectral-stratigraphic, semantic, i.e., lexico-semantic, and word-formation, i.e., terminological aspects. The generalisation of the analysis made it possible to clearly distinguish the cases of territorial stratification in the oikonymy of the Republic of Karakalpakstan. In this case, first of all, territorial differences in different features of oikonymy are noticeable between the four southern districts of Karakalpakstan, namely Amudarya, Beruni, Turtkul, and Ellikkala districts, as well as other territories of the republic. In particular, if we pay attention to the linguistic structure of oikonyms, in the four southern districts, the majority of oikonyms, that is, 77.3%, are Uzbek, and in the rest of the republic, 88.5% of all oikonyms are Karakalpak. Therefore, it is justified to divide the oikonymy of the territory of the Republic of Karakalpakstan into two oikonymic regions in terms of language composition - Northern and Southern (Table 1).

The oikonyms of Bozatau, Muynak, and Takhtakupyr districts can be distinguished as a oikonymic micro-region of the Aral Sea region. Of the 88 oikonyms here, 40 or 45.5% are oikonyms formed from hydronyms. Because in the past, there were many lakes and riverbeds here, and the population used more water bodies to determine (identify) the location of villages, that is, wherever the village was located, the settlement was often named according to the corresponding hydronym.

Table 1. Linguistic structure of the oikonymy of the Republic of Karakalpakstan (Source: Authors)

Number and percentage of oikonyms belonging to a particular language								
Name of administrative-territorial units and total number of oikonyms			Karakalpak		Uzbek		Other languages	
			Quantity	%	Quantity	%	Quantity	%

Karakalpakstan Republic		1151	700	60.8%	329	28.6%	122	10.6%

To date, most of the cores of these lakes and rivers have dried up and disappeared, but the names of the villages serve as a source or a kind of "trace" indicating the historical hydrography of these territories. In the formation of oikonyms of this micro -region, the topo-terms *"kul"* (meaning lake) and *"ozek"* (meaning root) participated in 20 of the total number of oikonyms, that is, in 22.7% (Figure 3). In the Kegeyli, Nukus, Chimbay, and Karauzek districts, which are part of the Northeastern oikonymic micro-region, there are a total of 389 oikonyms, of which 203 or 52.2% are ethnooikonyms. This circumstance constitutes the main feature of the northeastern oikonymic micro-region. The widespread use of ethnonyms in these territories is historically associated with the fact that tribes of the Karakalpaks built settlements along irrigation ditches and ravines.

Moreover, in this oikonymic micro-region, 97 oikonyms, that is, 24.9%, are formed with the participation of the *auil* (meaning village) topo-terms, which also determines its peculiarity. The territory of the Kungrad and Shumanay districts can be designated as a Western oikonymic micro-region. In this case, the main lexico-semantic feature of oikonymy is associated with the abundance of modern (standard) oikonyms. In the newly developed irrigation massifs of Karakalpakstan, settlements were given many standard ideological names during the Soviet period, most of which were changed during the period of independence to modern (standard) names such as Doslyk, Gulistan, Pakhtakesh, Abad, Pakhtaabad, Tinishlyk, Jaslyk.

In total, there are 153 oikonyms in the micro-region, of which 72 (47%) are modern (standard) names. The large number of newly developed lands, the assignment of modern (standard) names to settlements located on the Ustyurt plateau, and the change of many names by the government in recent years have led to the priority of modern (standard) names. Of the topo-terms involved in the formation of oikonyms, the largest share (7.2%) belongs to the *"auil"* topo-term.

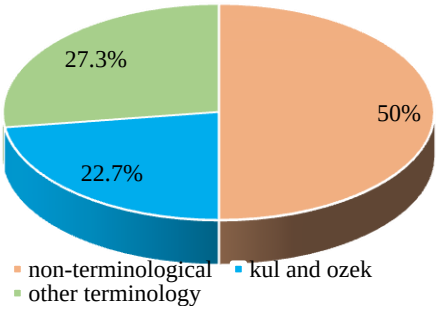

Figure 3. Proportion of topo-terms in the composition of oikonyms of the Aral Sea oikonymic micro-region

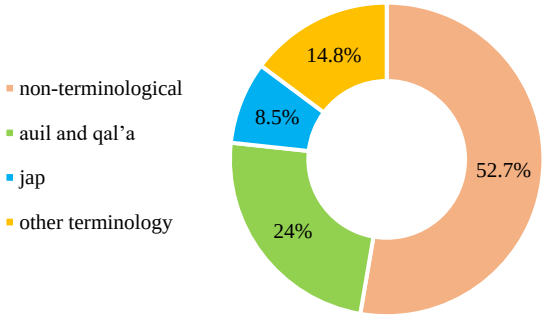

Figure 4. Proportion of topo-terms in the composition of oikonyms of the South Left Bank oikonymic micro-region

The city of Nukus, Takhiatash, Khojeyli, and Kanlykul districts are designated as the Central oikonymic micro-region. The peculiarity of this oikonymic micro-region is explained by the fact that the shares of oikonyms formed from hydronyms, ethno- and anthropo-oikonyms in the lexico-semantic structure of local oikonymy are quite close to each other. In the historical past, when naming settlements in this region, tribal names, nearby water bodies, as well as the names of wealthy people and elders from the tribes were widely used. In this oikonymic micro-region, there are a total of 137 oikonyms, of which 36 (26.3%) are oikonyms formed from hydronyms, 32 (23.3%) are ethnooikonyms, and 21 (15.3%) are anthropooikonyms. Also, the largest share of topo-terms (30 of them, i.e., 21.9%) falls on the topo-term "*auil*".

In the territory of the Northern oikonymic region, there are a total of 767 oikonyms, of which 679, or 88.5%, are Karakalpak oikonyms. District oikonyms have territorial features in terms of lexico-semantic composition and topo-terms involved in their formation. Taking them into account, the Northern oikonymic region can be divided into four micro-regions: the Aral Sea region (Bozatau, Muynak, Takhtakupyr districts), the Northeast (Kegeyli, Nukus, Chimbay, and Karauzek districts), the Western (Shumanay, Kungrad districts), and the Central (Nukus city, Takhiatash, Khojeyli and Kanlykul districts). The territory of the Amudarya district belongs to the South Left Bank oikonymic micro-region. In total, there are 129 oikonyms in the district, of which the largest number (25 or 19.4%) are ethno-oikonyms, as well as 23 or 17.8% are anthropo-oikonyms, and 20 or 15.5% are oikonyms formed from hydronyms. Of the total number of oikonyms, 20 names, i.e., 15.5%, were formed using the topo-term "*auil*" (meaning village), 11 names, i.e., 8.5%, were formed using the topo-term "*qal'a*" (meaning fortress), and 11 names, i.e., 8.5%, were formed using the topo-term "*jap*" (meaning canal) (Figure 4). The South Right Bank oikonymic micro-region includes oikonyms in the oasis part of the Beruni, Turtkul, and Ellikkala districts. In this oikonymic micro-region, there are a total of 255 oikonyms, of which 112 or 43.9% are oikonyms formed from modern (standard) names. The large number of newly occupied territories, changes made to oikonyms by the government have led to an increase in oikonyms formed from modern (standard) names. In addition, in the formation of oikonyms in the oikonymic micro-region, the topo-term "abad/obod" was often involved (21 oikonyms, i.e., 8.2% of the total number of settlements).

In recent years, due to the abandonment of settlements in the desert-pasture areas of Karakalpakstan by the population, settlements such as "Keneli" and "Sipali" in the Takhtakupyr district have been liquidated, and they are being removed from the settlement register. However, in the Kyzylkum part of the Turtkul and Ellikkala districts, several small villages have been preserved, the names of which have their own peculiarities in terms of language and lexical-semantic structure. Oikonyms belonging mainly to the Kazakh and Turkmen languages are found here. From a lexico-semantic point of view, anthropo-oikonyms dominate their structure. Such features are the basis for identifying the Kyzylkum oikonymic micro-region within the Southern Oikonymic Region. In total, there are 384 oikonyms in the Southern oikonymic region, of which 297, or 77.3%, belong to the Uzbek language. District oikonyms differ significantly in terms of lexico-semantic composition and the

composition of topo-terms involved in their formation. Taking these differences into account, the Southern oikonymic region can be divided into the South Left Bank, South Right Bank, and Kyzylkum oikonymic micro-regions (Figure 5).

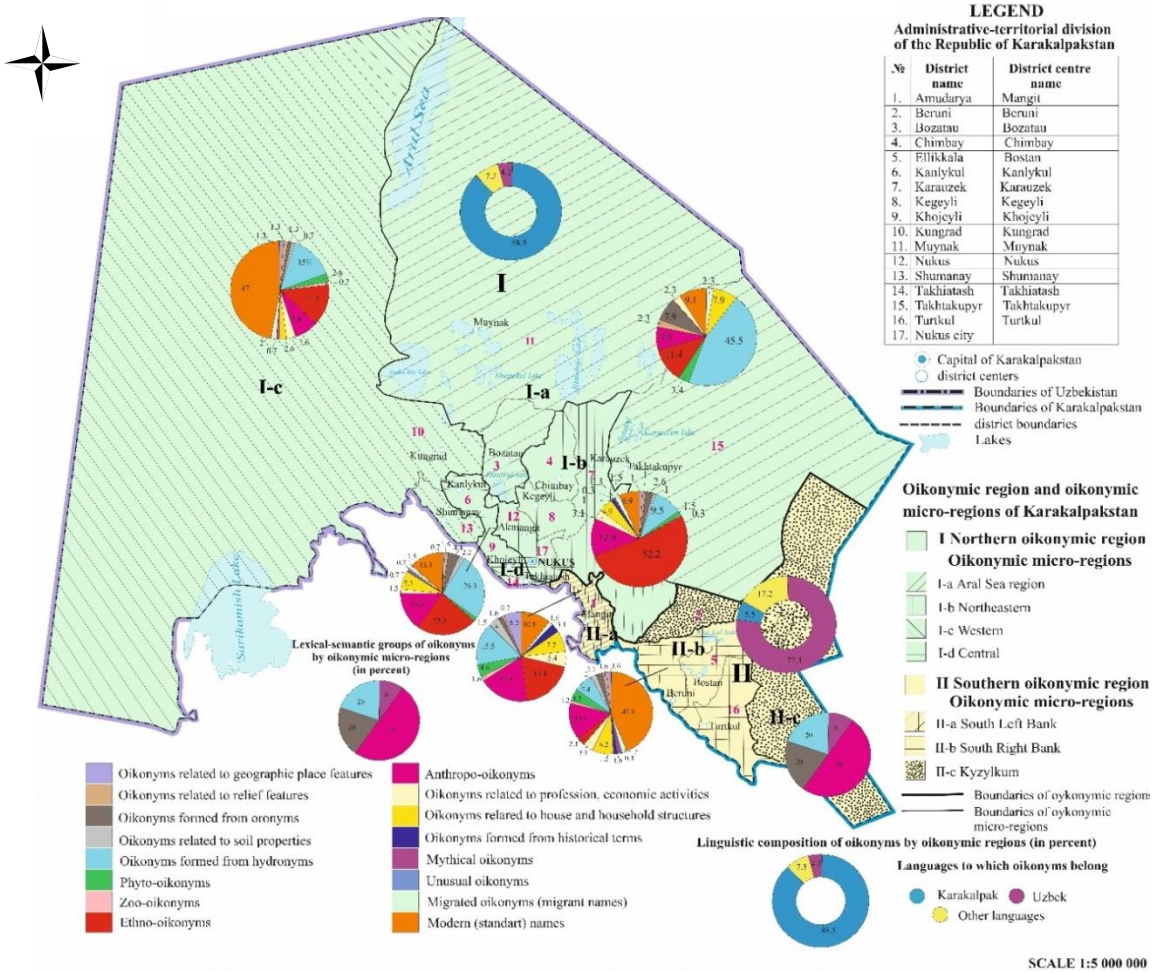

Figure 5. The map of oikonymic zoning of the Republic of Karakalpakstan (Source: Authors)

When studying the lexico-semantic and terminological composition of oikonyms in the context of districts in both oikonymic regions, some internal differences are observed. Taking these differences into account, several oikonymic micro-regions can be distinguished within the Northern and Southern oikonymic regions of Karakalpakstan (Figure 5).

Juchkevich (1968) divided the territory of the former Soviet Union into 30 toponymic regions within the framework of his network of political and administrative divisions and divided them into 9 groups. Uzbekistan, in particular, Karakalpakstan, is mainly noted as a territory where ancient toponyms are widespread. Kupach (2007) cites the principle of taking into account geo-toponymic differentiation as the basis of geo-toponymic zoning. This consists in taking into account the general and regional patterns of the distribution of the name, which is manifested both in the entire territory to be divided and in its individual territories. The principle of uniformity, that is, the identification of geo-toponymic systems, emphasizes that their boundaries and properties are determined based on the analysis of the interaction of the factors and components of the toponym-forming systems. At the same time, it was shown that the genetic approach to the placement of regional systems allows us to determine the reasons for the formation, development, and isolation of geo-toponymic systems.

CONCLUSION

In general, it has been established that in the formation of oikonyms of the territory of the Republic of Karakalpakstan, the leading place is occupied mainly by the names of peoples' clans and tribes, the names of water bodies, modern (standard) names, and oikonyms formed from personal names. In this case, it was established that oikonyms formed from water bodies and local hydrological toponyms predominate mainly in the northern districts, that is, in the Bozatau, Muynak, and Takhtakupyr districts, located on the southern shore of the Aral Sea. It has also been proven that this region has long had a system of branched lakes and riverbeds on the southern shores of the Aral Sea, and the historical settlements of the population were mainly located along these lakes and riverbeds. However, in the previous period, due to the drying up of the Aral Sea, which ranked 4th in the world in terms of size, and the drying up of the lake system adjacent to it and located on its southern shores, some settlements in this area have now disappeared and been removed from the registry, as well as the fact that the names of hydraulic structures of the previous period have been preserved only in oikonyms. Moreover, in this research work, it was confirmed that in the territories of the southern shore of the Aral Sea and the Amudarya River

delta, as we all know, there are many ethnonyms formed mainly from the names of Karakalpak, partly Kazakh, and Uzbek tribes and clans, and from historical times, these peoples have lived in these territories mainly as tribes and clans.

Assessment of the readiness of the hotel industry in the Zhetysu region for the implementation of sustainable development. *Geojournal of Tourism and Geosites*, 67(3), 1968–1979. https://doi.org/10.30892/gtg.67313-1825

Abstract: Despite the growing prominence of sustainability frameworks in tourism and hospitality, empirical evidence on the operational readiness of hotel industries in emerging and peripheral destinations remains limited. Existing research has largely focused on sustainability outcomes, while comparatively little attention has been paid to the institutional and managerial conditions that determine the feasibility of implementation at the regional level. This study develops and applies an adapted assessment framework based on the Global Sustainable Tourism Council (GSTC) criteria to evaluate the readiness of the hotel industry in the Zhetysu region of Kazakhstan to implement sustainable development principles. The analysis employs a composite readiness index constructed across four dimensions – institutional – managerial, economic, socio-cultural, and environmental sustainability – using Likert-scale measurements and complemented by SWOT analysis. The findings indicate a moderate overall level of sustainability readiness, with relatively stronger institutional and economic preparedness and markedly weaker environmental readiness, particularly in the areas of energy efficiency, waste management, and biodiversity protection. The results further reveal a pronounced gap between formally established sustainability strategies at the governmental level and their practical adoption within hospitality enterprises. By shifting the analytical focus from outcome-based sustainability metrics to readiness-oriented institutional diagnostics, this study contributes to sustainability research in tourism and hospitality. The proposed framework offers a transferable tool for assessing sustainability readiness in emerging destinations and provides evidence-based insights for designing targeted policy instruments that support the transition toward integrated and operationally grounded models of sustainable hospitality development.

INTRODUCTION

The concept of sustainable development encompasses various aspects, including environmental protection, economic growth and social well-being (Sabau, 2020). The concept of sustainable tourism is gaining increasing importance, as it is viewed as an effective means of stimulating global economic development and creating employment opportunities. Implementing sustainable development principles in various economic sectors is crucial for achieving long-term environmental, social and economic goals. To this end, businesses are seeking to integrate the key principles of sustainable development into their activities to boost their competitiveness, gain international recognition, and enhance the quality of their products and services (Liao et al., 2022; Abubakr et al., 2020). Numerous studies in this field have confirmed that implementing sustainable practices in tourism and hospitality can be achieved through various strategies (Cheung & Li, 2019; León-Gómez et al., 2021; Garrigos-Simon et al., 2018; Sharpley, 2020; Yoopetch & Nimsai, 2019).

The Global Sustainable Tourism Council (GSTC) plays a key role in promoting sustainable practices within the tourism industry. The Council has developed sustainability criteria to ensure balanced development in various areas (Bozhinova & Georgieva, 2023; Wu et al., 2022). The GSTC criteria, which cover effective sustainability management, maximising economic benefits for the host community and minimising negative impacts, form the basis of assessments of the sustainability of tourist destinations (Modica et al., 2018; Hamimah et al., 2022). Additionally, the GSTC criteria are incorporated into the evaluation of sustainable practices within the hotel industry, in line with the European Union's sustainability indicators and framework (Alipour et al., 2019). These criteria are widely used in international practice. For instance, Hamimah et al. (2022) evaluated the sustainability of tourism and hospitality, showcasing the practical application of the GSTC in sustainability evaluations. Kruczek & Szromek (2020) emphasised the importance of GSTC criteria in determining the value proposition of tourism business models, particularly in the context of overtourism.

Furthermore, Bricker et al. (2022) proposed a framework model for the sustainable development of tourism in national parks and their surrounding areas, in line with the GSTC's principles and criteria. However, successfully implementing these principles in practice faces a number of regional challenges. The Zhetysu region, and the city of Taldykorgan in particular, face challenges such as pronounced seasonality of tourist flows, increased environmental vulnerability of certain areas, and insufficient infrastructure and management competencies in sustainable tourism among small and medium-sized enterprises. Under these circumstances, the direct adoption of international standards is less critical than the development of a scientifically based diagnostic tool to assess the readiness of local stakeholders – including authorities, businesses, and local communities – to implement them. Conducting such an assessment is a necessary first step in developing a realistic and effective strategy for transitioning to a sustainable model of tourism and hospitality development in the region.

Thus, this study aims to comprehensively assess the readiness of the hotel industry in the Zhetysu region to implement sustainable development principles based on the adaptation of international GSTC criteria. To achieve this goal, the following tasks were set: to develop an adapted diagnostic toolkit; to conduct a survey and interviews with key stakeholders; to identify strengths, weaknesses, opportunities and threats (SWOT analysis) for the formation of a sustainable regional hospitality model. The study was conducted in the Zhetysu region, located in the south-east of the Republic of Kazakhstan (Figure 1). The region has significant tourism and natural potential, including unique natural sites and a rich cultural and historical heritage, making it attractive for the development of sustainable tourism and hospitality.

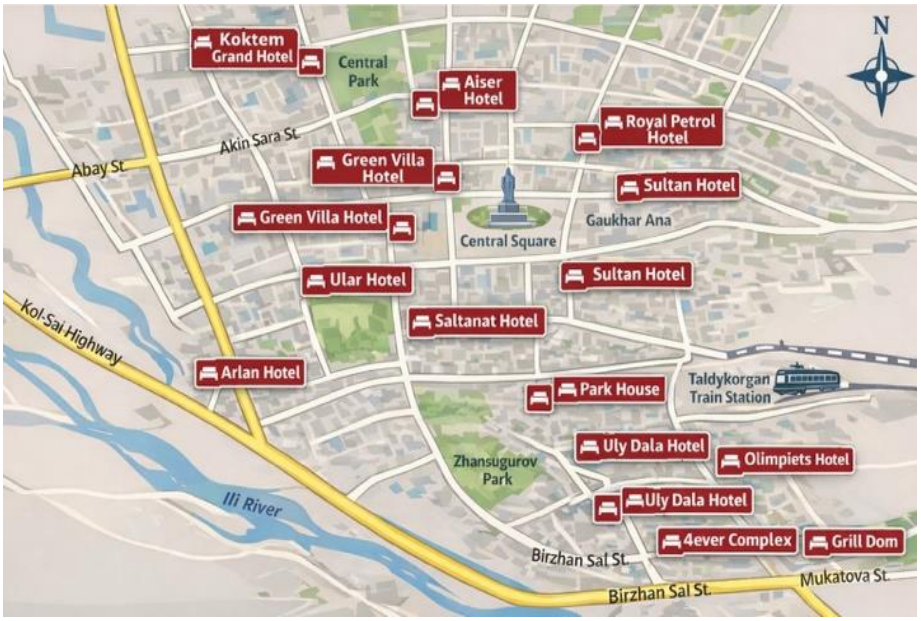

Figure 1. Hotels in Taldykorgan, the Zhetysu region (Source: Created by authors)

An analysis of current economic trends in the tourism and hotel industry in the Zhetysu region reveals the need to integrate the principles of sustainable development. The development of national criteria and the adaptation of international standards to regional conditions will ensure the balanced and sustainable development of the tourism industry in the region. This is particularly relevant given the ecological vulnerability of the territory, the seasonality of tourist flows and the specific features of the natural and climatic complex of Zhetysu.

Adapting international sustainable development criteria to local conditions will create a basis for more effective and realistic tourism development strategies, allowing for both economic and social and environmental aspects of the industry to be taken into account. In addition, involving representatives of the tourism sector in the discussion and formulation of sustainable development principles will ensure that the specifics and needs of the local market are taken into account, which contributes to the successful implementation of sustainable practices and increases the competitiveness of the industry.

Despite the growing body of research on sustainable tourism and hospitality, empirical studies focusing on sustainability readiness – rather than sustainability outcomes – remain limited, particularly in peripheral and transition economies. Existing studies predominantly assess environmental or economic performance, while comparatively little attention has been paid to institutional and managerial readiness at the regional level. This study addresses this gap by developing and applying an adapted GSTC-based readiness assessment framework to the hotel industry of the Zhetysu region. By shifting the analytical focus from outcomes to readiness, the study provides novel empirical evidence relevant for both theory and policy design in emerging tourism destinations.

LITERATURE REVIEW

Over the past two decades, sustainable development has become a central theme in the hospitality industry, driven by global environmental concerns, growing consumer awareness, and international policy agendas (UNWTO, 2022). In the hotel business, sustainable development has become one of the most important areas of transformation, particularly in regions where natural and cultural resources are vulnerable. Recent studies emphasise that sustainable hotel development

encompasses energy efficiency, water conservation, waste reduction, the responsible use of resources, and the integration of local culture into tourism products (Elkhwesky et al., 2022). Sustainable hospitality combines economic viability, environmental protection and socio-cultural responsibility, requiring hotels, restaurants and related services to reduce their environmental impact and increase local community engagement (Elkhwesky et al., 2022). Despite significant global progress, regional conditions such as those in Central Asia remain understudied, creating opportunities for local research and the implementation of sustainable practice models. Recent studies published in Geojournal of Tourism and Geosites also emphasize the importance of policy frameworks, ecological tourism, and the conceptual relationship between ecotourism, sustainable tourism, and nature-based tourism (Esparza-Huamanchumo et al., 2024; Minikhanova et al., 2024).

The Global Sustainable Tourism Council (GSTC) criteria provide a global framework for sustainable tourism and hospitality. These criteria cover governance, socio-economic benefits, cultural heritage, and environmental impact (GSTC, 2021). For hotels, the GSTC's practical measures include eliminating single-use plastics, using local food products, conserving water and energy, and supporting local employment (GSTC, 2024).

Regional studies have also begun to examine the impact of climate change on hotel infrastructure. A recent systematic review notes that adaptation strategies in the hotel sector are underdeveloped, particularly in transitioning economies, highlighting the need for context-specific approaches (Mota et al., 2024).

Recent studies convincingly demonstrate that sustainable development plays a vital role in achieving market stability and optimal positioning. Rather than being viewed as a cost, it is increasingly seen as an investment. Research shows that hotels with recognised sustainability standards have recovered significantly faster post-pandemic, as they align with the values of a new wave of conscious travellers (Gössling & Schweiggart, 2022). Several frameworks have been developed to ensure practical readiness. The Global Sustainable Tourism Council's (GSTC) criteria are among the most widely accepted and serve as guidelines for both tourist destinations and businesses. Research has shown that the GSTC system effectively translates abstract sustainability goals into measurable indicators. Its application in diverse settings, such as US national parks (Bricker et al., 2022), demonstrates that these criteria can be adapted to cultural and environmental conditions. However, issues such as limited data availability and weak institutional capacity often hinder their effective implementation (GSTC, 2019). For the Zhetysu region, adopting such a system could provide a structured framework for identifying gaps in environmental management, socio-economic integration and cultural heritage protection. This prospect is particularly relevant for Zhetysu, where government programmes, preferential financing and business associations could accelerate adoption of the law.

Hotel certifications play a crucial role in assessing sustainability performance by providing hotels with benchmarks to align their practices with international standards, such as those set by the Global Sustainable Tourism Council (GSTC). These certifications encourage hotels to intensify their efforts to ensure sustainability in various areas, including management practices, socio-economic impact, cultural preservation and environmental protection (Sriraksa et al., 2024).

The implementation of sustainable practices (SP) is growing rapidly in the tourism industry, particularly in developed countries. Many leading corporations are succeeding in this area as SP contributes to socio-economic growth, increases competitiveness and creates new business opportunities (Lucas et al., 2024). In addition to the GSTC, organisational theories have been used to understand enterprise-level readiness. The 'Technology–Organisation–Environment (TOE)' concept has had a particular influence in this regard, explaining the adoption of sustainable practices in terms of technological availability, organisational capacity, and external pressure. Recent empirical studies show that hotels with stronger technological capabilities (e.g. eco-innovation tools and digital solutions), management commitment and clear sustainability policies demonstrate significantly higher sustainability performance (Lucas et al., 2024).

Kusumawardhani (2024) suggests that intellectual tourism in new destinations should combine digital innovation with sustainability to create inclusive opportunities for local communities and address environmental issues.

Similarly, research on hotel waste management indicates that the feasibility of waste reduction measures depends on operational configurations such as property size and food and beverage volume, highlighting the need for a differentiated assessment of readiness (Diaz-Fariña et al., 2023). These findings highlight that readiness is not uniform, but depends on business models, supply chains and the socio-economic structure of the destination country.

Mota et al. (2024) document how hotel businesses around the world are becoming increasingly vulnerable to climate-related risks, such as extreme heat, water shortages, and natural disasters. They suggest that destination countries which take proactive adaptation measures, including impact assessments, compensation schemes and infrastructure upgrades, are better prepared to maintain competitiveness in a changing climate. Punzo et al. (2022) proposed a comprehensive sustainable tourism index (SusTour-Index), which covers economic, environmental, and social dimensions. They tested this index using regional data from Italy, providing a rigorous analytical platform for assessing regional readiness. Chen (2020) developed and validated a model for assessing sustainable tourism development in traditional Japanese villages, demonstrating how global methodologies can be adapted to local conditions. The bibliometric analysis conducted in this study not only outlines the conceptual contours of sustainable tourism research in the Balqash–Alakol basin but also indicates actionable leverage points for policymakers and regional planners. By mapping research themes, collaboration networks, and knowledge gaps, bibliometric data serve as a diagnostic tool that highlights both strengths and deficiencies in the current sustainability discourse – and these, in turn, translate into concrete policy directions.

First, the bibliometric emphasis on environmental management and carrying capacity underscores the urgent need for robust regulatory frameworks. Although many regional strategies mention sustainability, the density and prominence of these themes in the literature suggest that environmental concerns are widely acknowledged academically but have not yet been fully operationalised in governance. This gap calls for the establishment of formal environmental performance standards for tourism facilities in the basin, reinforced through monitoring systems and compliance incentives. For example, policy

instruments could include mandatory waste management plans for all tourism operators, seasonal visitor limits informed by carrying capacity research, and public reporting requirements tied to sustainability indices identified in the literature.

Second, the structure of scholarly collaboration revealed by co-authorship and thematic clustering indicates underdeveloped networks between academia, government, and industry stakeholders. To bridge this divide, policymakers could institutionalise knowledge exchange platforms, where researchers present evidence-based findings to stakeholders directly responsible for destination management – such as regional tourism boards, environmental agencies, and hotel associations. These platforms could be formalised as regional advisory councils that meet regularly and align research priorities with policy implementation needs. Furthermore, funding mechanisms might be reallocated toward applied research grants that explicitly require stakeholder participation in project design and dissemination, thereby ensuring that new research directly informs policy cycles. Third, the bibliometric focus on comparative and cross-regional studies suggests that benchmarking with similar eco-destinations enhances learning and accelerates policy innovation.

For example, many publications on Issyk-Kul (Kyrgyzstan) and Aral Sea-adjacent tourism regions highlight common challenges – such as seasonal employment dependency, insufficient environmental infrastructure, and weak enforcement of sustainability standards. By incorporating these comparative insights, Balqash–Alakol policymakers can adopt best-practice templates that have been empirically examined in neighbouring contexts: establishing environmental certification schemes, integrating sustainable tourism criteria into regional development plans, and co-creating cross-border tourism initiatives that pool resources and harmonise standards across lake basins. Taken together, the bibliometric findings act as a strategic evidence base that informs a policy agenda centred on (1) regulation with measurable targets, (2) stakeholder engagement and knowledge integration, and (3) comparative benchmarking to accelerate institutional learning.

Embedding research insights directly into policy instruments ensures that the academic discourse on sustainable tourism transitions from conceptual recognition to tangible governance outcomes within the Balqash–Alakol basin.

MATERIALS AND METHODS

The calculation of readiness indicators for the hotel industry in Taldykorgan city, Zhetysu region, was based on respondents' answers obtained using a five-point Likert scale, where each statement was rated from 1 to 5 points. The purpose of the calculation was to obtain mean scores for each area of readiness and to form a generalised readiness index. The numerical equivalent of the responses used for further quantitative analysis is presented in Table 1.

Table 1. Numerical equivalent of answers

Respondent's answer	Point
Completely absent	1
Low level	2
Average level	3
A sufficiently high level	4
High level	5

Thus, each response is automatically converted into a numerical value suitable for quantitative analysis.

The assessment of the tourism and hotel industry's readiness in the Zhetysu region to implement the principles of sustainable development was conducted based on a survey of representatives of government agencies and tourism and hotel businesses. A five-point Likert scale was used as a measurement tool, where 1 represents a complete absence of practice and 5 represents its systematic implementation. The overall methodological framework used to assess the readiness of the hotel industry in the Zhetysu region for sustainable development is illustrated in Figure 2.

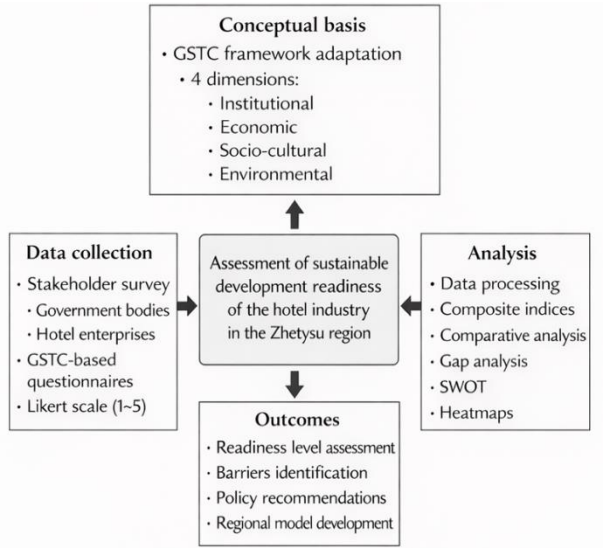

Figure 2. Methodological framework used to assess the readiness of the hotel industry in the Zhetysu region for sustainable development (Source: Created by authors)

At the first stage, the arithmetic mean was calculated for each indicator (developed by the authors):

$$\bar{x}_i = \frac{1}{n}\sum_{j=1}^{n} x_{ij}$$

where x_{ij} is the rating of the j-th respondent for the *i*-th indicator, *n* is the number of respondents. In the second stage, the indicators were aggregated into four broad blocks of sustainable development: institutional and managerial, environmental, socio-cultural, and economic. An integral readiness index was calculated for each block (developed by the authors):

$$I_k = \frac{1}{m}\sum_{i=1}^{m} \bar{x}_i$$

where m – number of indicators in the corresponding block. The integrated readiness indicators for the four sustainability dimensions are presented in Table 2. The average scores for hotel enterprises and their standardized values are shown in Table 3. The results obtained indicate an average level of readiness of the tourism and hotel industry in the Zhetysu region to implement the principles of sustainable development. The highest value was recorded in the economic dimension (I = 3.6), which indicates that enterprises are focused on financial stability, maintaining employment and developing tourism services as a source of income. Socio-cultural sustainability also shows relatively favourable indicators (I = 3.4), which is associated with the involvement of the local population, the preservation of cultural traditions and a focus on domestic tourism.

Table 2. Integrated indicators of the readiness of the tourism and hotel industry in the Zhetysu region for the implementation of sustainable development (Source: Calculated by the authors based on survey data)

Measuring stability	Integral index (I)	Measuring stability	Integral index (I)
Social and cultural sustainability	3,4	Environmental sustainability	2,8
Economic stability	3,6	Institutional and managerial sustainability	3,1

Table 3. Average scores on questions (business)

Question	Average score (max=3,4,5)	Standardised to 5 points	Question	Average score (max=3,4,5)	Standardised to 5 points
A1	2.60	3.25	C3	1.80	3.00
A4	2.60	3.25	D1.2	1.80	3.00
B2	3.60	3.60	D1.3	1.80	3.00
B3	2.60	4.33	D2.4	1.80	3.00
B7	3.00	3.75	D2.6	1.60	2.67

At the same time, environmental sustainability is characterised by the lowest integral index value (I = 2.8), reflecting the fragmented nature of the implementation of environmental practices, the lack of resource management systems and the limited use of environmental standards in the activities of enterprises. Institutional and managerial sustainability (I = 3.1) is at a borderline level and indicates the existence of strategic documents and programmes, but their practical implementation is accompanied by insufficient coordination, weak monitoring and the absence of unified regional mechanisms for managing sustainable development. The readiness levels across the four sustainability dimensions are visualized in Figure 3.

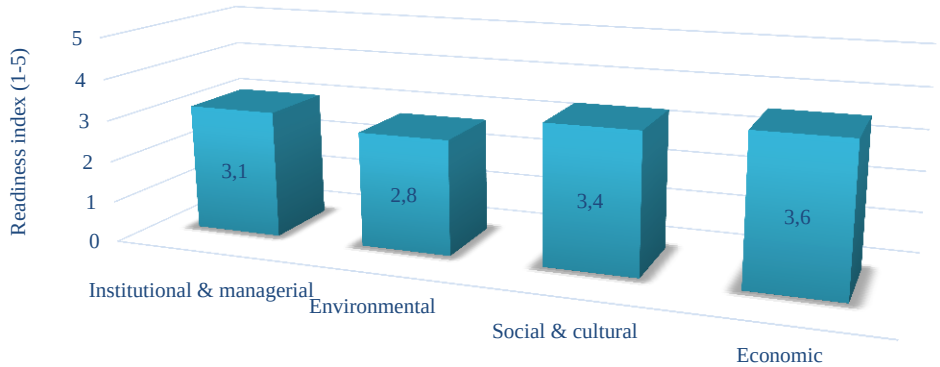

Figure 3. Readiness of the tourism and hotel industry in the Zhetysu region for sustainable development (Source: Calculated by the authors based on survey data)

Thus, a structural imbalance has been identified between the declared readiness and the actual level of implementation of sustainable practices. The indices obtained confirm the need to move from fragmented initiatives to the formation of an integrated regional model of sustainable development of the tourism and hotel industry based on institutional coordination, environmental regulation and business support. Average values were calculated based on the 16 responses from government agencies and 20 responses from businesses. Given the nascent stage of the hospitality industry in the Zhetysu region, this sample represents a significant portion of the currently active key decision-makers and registered tourism entities. The average scores obtained from representatives of state structures are presented in Table 4. A comparison of average standardised scores between state structures and enterprises by block is shown in Table 5.

Table 4. Average scores on questions (state structures)

Question	Average score (max=3,4,5)	Standardised to 5 points	Question	Average score (max=3,4,5)	Standardised to 5 points
A1	3.25	4.06	A1	3.25	4.06
A2	3.25	4.06	A2	3.25	4.06
A10	2.50	4.17	A10	2.50	4.17
B2	1.75	2.92	B2	1.75	2.92
B3	2.00	2.50	B3	2.00	2.50
C2	2.25	3.75	C2	2.25	3.75
D1.3	1.75	2.19	D1.3	1.75	2.19
D2.4	2.00	3.33	D2.4	2.00	3.33
D3.1	2.50	3.13	D3.1	2.50	3.13

Table 5. Comparison of average standardised scores by block

Block	State structures (average scores)	Enterprises (average scores)	The Gap
Management and strategy	4.10	3.25	+0.85
Social responsibility	3.38	3.54	-0.16
Environmental responsibility	2.82	2.93	-0.11
Infrastructure and support	2.76	3.00	-0.24

Standardisation was carried out using the formula (developed by the authors):

$$\text{Standardised score} = \frac{\text{Average score}}{\text{Maximum score}} \times 5$$

The questions are grouped into 4 blocks:

1. Management and strategy (A1, A4, A10)
2. Social responsibility (B2, B3, B7, C2, C3)
3. Environmental responsibility (D1.2, D1.3, D2.4, D2.6, D3.1)
4. Infrastructure and support (D1.3, D2.4 – repeatedly in the context of state support). The heatmaps of average and normalized scores for government structures and enterprises are presented in Figures 4 and 5, respectively.

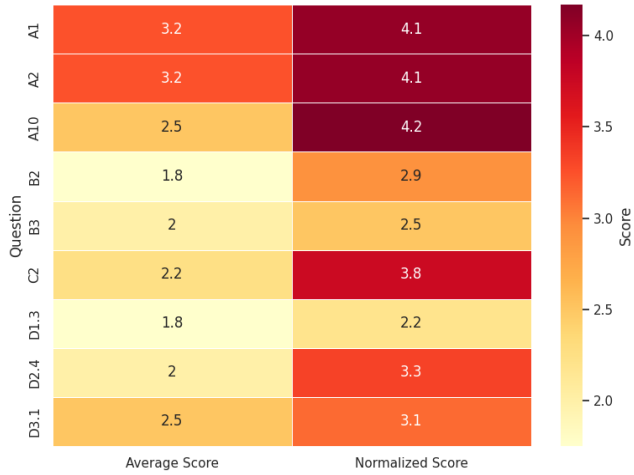

Figure 4. Heatmap of Average and Normalized Scores (Government Structures)

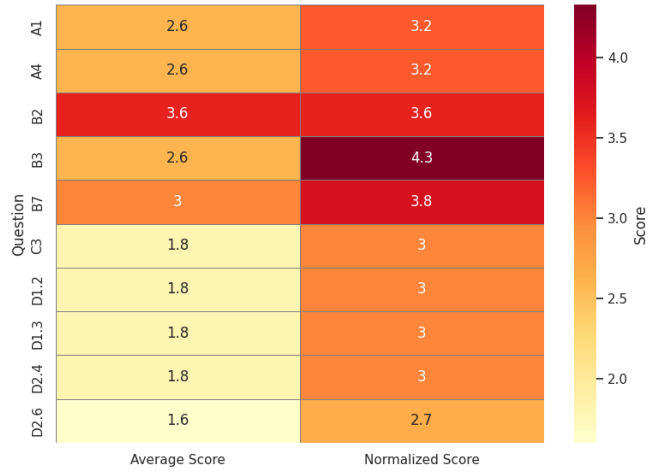

Figure 5. Heatmap of Enterprise Scores

The lowest scores were for environmental issues (D1.2–D2.6), confirming the weak systematic nature of ecological practices. The highest scores were for issues B3 (local procurement) and B2 (local employment), reflecting the social activity of the business. High standardised scores for A1, A2 and A10 indicate the strength of government structures in strategic planning and coordination. Weak areas are environmental issues (D1.3, D2.4), where scores remain low, indicating a lack of infrastructure and systemic measures. Heat maps allow you to quickly identify 'red zones' (low values) and prioritise areas for improvement. High scores: B2 (local employment) and B3 (local procurement) – companies demonstrate social engagement. B7 (social responsibility) is also above average. Low scores: Environmental issues (D1.2–D2.6) – weak consistency in energy conservation, waste management and biodiversity. C3 (cultural heritage) is also low, indicating a lack of integration of cultural elements into services. The level of implementation of sustainable development practices in tourism in the Zhetysu region is assessed as average (average score across all blocks – approximately 3.2 out of 5). The analysis of data based on the Likert scale allows us to draw a comprehensive conclusion about the state of sustainable tourism development in the Zhetysu region. The overall level of implementation of relevant practices is assessed as average, reflecting a transitional stage from the formation of strategic plans to their practical implementation. Government agencies demonstrate a higher level of strategic planning compared to businesses, indicating a gap between the programmes developed and their actual implementation at the local level. At the same time, enterprises are somewhat more active in the area of social responsibility, especially in terms of local employment and working with local suppliers, but this activity is more of an initiative and is not backed by systematic state support.

The most problematic area remains environmental responsibility, where both government agencies and businesses perform poorly. Energy saving, waste management and biodiversity conservation practices are implemented in a fragmented manner and are not systematic. This conclusion is confirmed by quantitative data: the average scores for the environmental block are only 2.82 and 2.93 out of a possible 5. The key obstacle to the development of sustainable practices is unanimously identified as a lack of funding and targeted support from government agencies, which correlates with low ratings of government grant and subsidy programmes themselves. Thus, the current situation is characterised by a certain imbalance: while there is a strategic vision at the regional level, there are no effective mechanisms for translating it into specific instruments of financial, infrastructural and methodological support for business, which primarily hinders the development of environmental initiatives and the full integration of sustainable development principles into the activities of the tourism sector.

For quantitative assessment, a composite index can be used to calculate the overall sustainable development index (developed by the authors):

$$I = \frac{\sum_{i=1}^{n}(B_i \times w_i)}{5 \times \sum w_i} \times 100\%$$

where:

- B_i – standardized score for block *i*,
- w_i – block weight (can be assumed to be 1 for simplicity),
- n – number of blocks.

For our data (without weighting):

$$I_{ent} = \frac{3.25 + 3.54 + 2.93 + 3.00}{5 \times 4} \times 100\% = 64.30\%$$

$$I\text{gov} = \frac{4.10 + 3.38 + 2.82 + 2.76}{5 \times 4} \times 100\% = 64.15\%$$

Both groups are at around 64% of the ideal state, confirming the need for systemic improvements.

RESULTS

The results of a survey of representatives of state and quasi-state structures involved in the regulation and development of tourism and hospitality in the Zhetysu region provide a comprehensive overview of the current state of institutional, socio-environmental and managerial aspects of sustainable development of the industry at the regional level. The GSTC-based questions developed for representatives of state structures are presented in Table 6.

Table 6. Questions for the state structure

GSTC criterion	Questions for the state structure
A1 Sustainable development management system	Is there an approved strategy or programme for sustainable tourism and hospitality development in the region?
A2 Compliance with legal regulations	How effectively is compliance with environmental and labour legislation monitored in the tourism industry?
A10 Interaction with the visited site/destination	Are there any working groups or coordination councils for the development of tourism and hospitality in the region involving government bodies, businesses and non-governmental organisations?
B2 Employment of the local population	Are there any programmes to encourage the hotel and tourism industry to employ local residents and promote their career growth?
B3 Local purchasing	Is work being done to create and promote registers of local suppliers for the tourism industry?
C2 Protection of cultural heritage	Are there any grant or other support programmes for tourism businesses that integrate elements of local cultural heritage into their services?
D1.3 Energy saving	Are there any grant or other support programmes for tourism businesses that integrate elements of local cultural heritage into their services?
D2.4 Solid waste	Is there a waste sorting and recycling infrastructure in place in the region that is accessible to tourism businesses?
D3.1 Biodiversity conservation	Are biodiversity impact assessments and mandatory compensation measures included in the conditions for allocating land for tourism facilities?

Despite the limited sample size, the data obtained is of an expert and analytical nature and reflects the systemic vision of key stakeholders responsible for the formation and implementation of regional tourism policy, which gives the research results high analytical and interpretative value. The results of a survey of representatives of state and quasi-state structures involved in the regulation and development of tourism and hospitality in the Zhetysu region provide a comprehensive overview of the current state of institutional, socio-environmental and managerial aspects of sustainable development of the industry at the regional level. Despite the limited sample size, the data obtained is of an expert and analytical nature and reflects the systemic vision of key stakeholders responsible for the formation and implementation of regional tourism policy, which gives the research results high analytical and interpretative value. The assessment of compliance with environmental and labour legislation in the tourism sector shows predominantly high scores, indicating the existence of a

formally structured regulatory framework and basic control mechanisms. However, these results should be interpreted with caution, as compliance with legal requirements is not always accompanied by the implementation of comprehensive sustainable management practices. The lack of regular monitoring, performance evaluation and feedback mechanisms reduces the potential of legal regulation as a tool for a real transition to sustainable hospitality development models.

The social dimension of sustainability, in particular issues related to human capital training and development, is characterised by a marked lack of systematicity. The survey results show that staff training programmes in sustainable tourism and hospitality are either non-existent or implemented in a fragmented manner as part of individual initiatives and projects. This situation limits the region's institutional capacity to scale up sustainable practices, as human capital is a key factor in the transformation of the industry. The lack of sustainable educational and professional programmes reduces the adaptability of the regional hospitality system to the modern requirements of sustainable development.

The environmental dimension of sustainability is also characterised by significant territorial and functional heterogeneity. In particular, assessments of the state of waste management infrastructure in tourist destinations range from a complete lack of relevant systems to the existence of relatively developed mechanisms that require further improvement. This indicates the absence of a unified regional approach to environmental management in the hospitality sector, as well as the dependence of environmental practices on local conditions and initiatives. A similar situation can be observed in the field of biodiversity conservation, where environmental factors are taken into account in the implementation of tourism projects on an irregular and predominantly reactive basis, without being institutionally enshrined in the form of mandatory procedures or standards.

A synthesis of the results obtained allows us to conclude that the key constraints to the sustainable development of hospitality in the Zhetysu region are not related to a shortage of natural or cultural resources, but to institutional and managerial factors. The region has significant competitive potential due to its rich natural and cultural heritage, but the lack of an integrated management, coordination and monitoring system significantly reduces the effectiveness of sustainable practices. Sustainability in this context is perceived primarily as a set of individual measures rather than a comprehensive model of regional development. The empirical results obtained are consistent with the provisions of the Global Sustainable Tourism Council (GSTC) criteria and confirm the feasibility of adapting them for regional-level analysis.

The most pronounced gaps were identified in the institutional and managerial dimension of sustainability, which highlights the need to shift the focus of regional tourism policy towards the formation of effective governance mechanisms. Thus, the results of the study form an empirical basis for the development of an integrated regional model of sustainable development of the hospitality industry, focused on improving institutional coherence, developing human capital, and systematically integrating environmental and socio-economic principles of sustainability.

Based on the above criteria, questionnaires were developed to assess the current state of the hotel industry in the Zhetysu region, awareness of the principles of sustainable tourism, sustainable development goals and obstacles to achieving them. The questionnaires are presented in a short version adapted for entrepreneurs and government officials. Data collection consisted of anonymous surveys using links to Google forms in the questionnaires. The questionnaires were sent to state and local institutions in the Zhetysu region, social media groups and tourism workers. The GSTC-based questions designed for hotel enterprises are presented in Table 7.

Table 7. Questions for the enterprise

GSTC criterion	**Questions for the enterprise**
A1 Sustainable development management system	Is there documentary evidence of the implementation of a sustainable development management system?
A4 Staff engagement	Is your staff trained in environmental and social practices?
B2 Local employment	What is the proportion of local residents in the total number of employees and in management positions?
B3 Procurement	Do you prioritise local suppliers when purchasing food, souvenirs and services?
B7 Decent work	To what extent does the organisation comply with the principles of decent work (safe conditions, decent wages, staff development)?
C3 Presentation of culture and heritage	Do you incorporate elements of local culture (design, cuisine, music, crafts) into the guest experience/service?
D1.2 Effective procurement	Are you taking measures to reduce the use of single-use plastics (bottles, straws, packaging, hygiene products)?
D1.3 Energy saving	Do you use energy-saving technologies (LED bulbs, motion sensors, smart thermostats)?
D2.4 Solid waste	Have you implemented a separate waste collection system for subsequent recycling?
D2.6 Minimising pollution	Does the hotel take specific measures to reduce pollution (air, water, soil, as well as noise, light pollution, etc.)?
Please give an example of one of your sustainable development practices that you are most proud of.	
What are the main obstacles you see to implementing such practices? (select several from the list)	

The results of a survey of representatives of the hotel and tourism industry in the Zhetysu region reveal the key features of the practical implementation of sustainable development principles in the activities of hospitality industry entities at the regional level. The data obtained reflect the perception of sustainability by businesses and demonstrate the degree of integration of environmental, social and management practices into the daily operations of enterprises. Taken together, the results form a comprehensive picture of the actual, rather than the declared, level of sustainable development in the industry.

An analysis of responses characterising the use of environmentally oriented practices shows that most enterprises either rarely or sporadically use environmentally friendly means and technologies in their activities.

Only a limited number of respondents indicate regular use of such practices. This indicates an early stage of environmental transformation of business, in which sustainable solutions are perceived as additional rather than mandatory management elements. This situation points to the existence of structural barriers, including limited financial resources, a lack of incentives and the absence of clear regulatory requirements that would facilitate the introduction of environmental innovations in the region's hotel and tourism business.

DISCUSSION

An assessment of staff training practices in the field of environmental and social sustainability revealed a marked fragmentation. A significant proportion of enterprises either do not provide specialised training at all or limit themselves to one-off events that are not integrated into the human resources management system. This indicates an insufficient understanding of the role of human capital as a key factor in the sustainable development of the hospitality industry. The lack of systematic training programmes reduces the ability of enterprises to adapt to modern requirements for sustainable tourism and limits their long-term competitiveness.

The social dimension of sustainability in business activities is manifested mainly in the form of basic compliance with labour legislation and generally accepted standards of interaction with staff and the local community. At the same time, business participation in broader social initiatives aimed at developing local communities and supporting cultural heritage is limited and unsystematic. This indicates that social responsibility is perceived by businesses as a minimum obligation rather than a strategic resource for developing and strengthening the reputation of a destination.

Environmental management, including waste reduction, rational use of resources and implementation of energy-efficient solutions, is also characterised by heterogeneity. Some enterprises demonstrate a willingness to implement individual environmental measures, but in most cases these initiatives are implemented without strategic planning and systematic monitoring. The lack of clear guidelines and sustainability standards at the regional level limits the ability of businesses to transition to more comprehensive environmental management models.

Responses concerning the interaction of businesses with government agencies and the institutional environment as a whole are particularly significant. The survey results indicate a limited level of coordination between business and government structures on issues of sustainable tourism and hospitality development. Businesses do not always have sufficient information about existing strategies, support programmes and regulatory instruments, which reduces the effectiveness of sustainable initiatives and hinders the formation of a unified regional approach.

To summarize these findings, the SWOT analysis of the hotel industry's readiness to implement sustainable development principles in the Zhetysu region is presented in Table 8.

Table 8. SWOT analysis of the readiness of the hotel industry in the Zhetysu region to implement sustainable development principles (Source: Created by authors)

Strengths	**Weaknesses**
The region's significant natural and cultural potential, which forms an objective basis for the development of a sustainable hotel business. The formal existence of strategic and policy documents in the field of tourism and sustainable development at the regional level. Relatively high level of compliance with environmental and labour legislation, creating the basic conditions for the implementation of sustainable principles. Readiness of some hotel businesses to implement individual elements of environmental and social responsibility. Human resource potential and interest of individual stakeholders in the development of sustainable hospitality.	Fragmentation of the institutional system for managing sustainable development in the hotel industry and insufficient interdepartmental coordination. Lack of systematic mechanisms for implementing and monitoring sustainable practices in hotel operations. Low level of integration of sustainable development into the strategic and operational management of hotel enterprises. Fragmented and sporadic use of environmentally friendly technologies and resource-saving practices. Lack of systematic training and professional development programmes for staff in the field of sustainable development and sustainable hospitality.
Opportunities	**Threats**
Adaptation of international standards and sustainability criteria (in particular GSTC) to the regional level and the hotel industry. Development of mechanisms for state support and incentives for hotel enterprises that implement sustainable practices. Increased demand from tourists for environmentally and socially responsible forms of accommodation. Development of training programmes, digital solutions and consulting support for the hotel business in the field of sustainable development. Strengthening cooperation between government agencies, the hotel business and local communities.	The gap between strategic declarations and the actual implementation of sustainable development remains. Limited financial resources of hotel enterprises hinder the implementation of environmental and social innovations. Increased anthropogenic pressure on natural and cultural resources in the absence of effective sustainability management mechanisms. Formalisation of sustainable development as an 'image element' without real institutional changes. Decreased competitiveness of the region in the long term due to the unsystematic implementation of sustainability principles.

Overall, the results indicate that sustainable development of the hospitality industry in the Zhetysu region at the business level is in its infancy. Enterprises demonstrate a certain readiness to implement individual elements of sustainability, but the lack of institutional incentives, systematic training and clearly formulated regional guidelines significantly limits the depth and scale of such transformations. As a result, sustainability is implemented mainly in the form of isolated practices rather than as an integrated strategy for corporate and regional development.

The empirical data obtained complement the results of the survey of government agencies and confirm the existence of a structural gap between strategic declarations and the practical implementation of sustainable development principles in the hospitality industry. This leads to the conclusion that there is a need to strengthen institutional coordination, develop mechanisms to stimulate business, and form a comprehensive regional model of sustainable development for the hospitality industry based on the principles of environmental responsibility, social engagement, and effective management.

The interviews and survey results revealed how stakeholders are involved in the development of hospitality and what their views are on the sustainable development of the industry. The interview format was structured, but at the same time left room for discussion of new topics in a less formal, open manner. The main topics of discussion at the meetings on hospitality development concerned the perception by business representatives of the principles of sustainable development of tourist destinations as an alternative to existing strategies. During the discussions, respondents noted which elements, in their opinion, should be preserved (e.g., the natural environment or socio-cultural context), which should be developed, and how their own interests could be realised in this context. The initial interviews focused on identifying the personal views and approaches of the participants, followed by a refinement of the identified concepts and directions for sustainable hospitality development.

RESEARCH LIMITATIONS AND GAPS

The present study has several limitations that should be acknowledged. First, the sample size is relatively limited, particularly about representatives of government institutions, which means that the findings should be interpreted as preliminary. Second, the study relies on self-reported survey data, which may be subject to response bias and social desirability effects. Third, the composite indices were constructed using equal weighting of indicators, which does not fully reflect potential differences in their relative importance. Fourth, the focus on a single region – the Zhetysu region –limits the external validity of the results and restricts opportunities for interregional comparison.

Finally, the cross-sectional research design does not allow for the assessment of dynamic or long-term changes in sustainability readiness within the hospitality industry. Despite these limitations, the study identifies several important gaps in the existing body of research. In particular, there remains a lack of empirical studies examining sustainability readiness in developing and peripheral tourism regions, especially in the context of Central Asia. Moreover, limited attention has been paid to integrating management readiness assessments with established ESG and GSTC frameworks. The use of composite indices based on expert assessments and Likert-scale data in regional hospitality studies also remains insufficient. Additionally, the gap between formally adopted sustainability strategies and their actual operational implementation – particularly in the environmental dimension – has not been adequately addressed in previous research.

Based on these findings, several directions for future research can be proposed. Further studies should expand the sample to include a broader range of stakeholders, such as local communities, tourists, and non-governmental organisations. The application of weighted and multi-criteria decision-making methods, including AHP, entropy-based weighting, or TOPSIS, could improve the robustness of composite indices. Longitudinal research designs would allow for tracking changes in sustainability readiness over time. Comparative interregional or cross-country studies could enhance the generalisability of results. Finally, future research should seek to integrate objective environmental indicators – such as energy consumption, waste generation, and carbon footprint metrics – with perception-based survey data to provide a more comprehensive assessment of sustainability practices in the hospitality industry. The main limitations, research gaps, and areas for future research are summarized in Figure 6.

Figure 6. Overview of Limitations, Research Gaps and Areas for Future Research (Source: Created by authors)

Despite the relevance of the results, it should be acknowledged that there are a number of limitations and several gaps in the existing literature. The study uses a cross-sectional design that reflects readiness for sustainable development at a specific point in time. This does not allow for the assessment of dynamic changes and long-term trends in the implementation of sustainable development practices. In addition, insufficient attention is paid to the gap between formal sustainable development strategies and practical operational measures, especially in the environmental aspect.

CONCLUSION

This study examines the readiness of the hotel industry in the Zhetysu region to implement sustainable development principles, based on survey data from government agencies and hotel enterprises and complemented by a SWOT analysis. The

research contributes to the literature by proposing an adapted GSTC-based readiness assessment framework for peripheral tourism regions and by empirically revealing a critical institutional gap between strategic planning and operational implementation within the hospitality sector. The findings indicate that the region possesses substantial potential to transition toward sustainable development models, underpinned by its rich natural and cultural heritage and the presence of a basic regulatory and strategic policy framework for tourism. These factors create favourable preconditions for integrating environmental, social, and managerial sustainability principles and for enhancing the long-term competitiveness of the destination. At the same time, the empirical results show that current readiness remains limited and unsystematic.

Sustainable practices are implemented in a fragmented manner and are insufficiently embedded in the strategic and operational management of hotel enterprises. The absence of robust mechanisms for monitoring, performance evaluation, and multi-stakeholder coordination significantly constrains the formation of a coherent regional model of sustainable hospitality development. The analysis further demonstrates that the primary barriers to implementation are institutional and managerial rather than resource-related. Key vulnerabilities include weak interdepartmental coordination, limited and irregular interaction between public authorities and the hotel business sector, and the lack of systematic training and professional development programmes in sustainable hospitality. These deficiencies reinforce the persistent gap between formally adopted sustainability strategies and their practical execution. The SWOT analysis suggests that maintaining the current development trajectory carries the risk of formalising sustainability as a predominantly image-driven concept. In the context of increasing tourist flows and insufficient governance mechanisms, this may intensify anthropogenic pressure on the region's natural and cultural assets and undermine long-term destination resilience.

Conversely, the results reveal significant opportunities to enhance readiness through the adaptation of international standards – particularly the Global Sustainable Tourism Council (GSTC) criteria – the development of targeted state support and incentive schemes, and the establishment of systemic educational initiatives. Realising this potential requires a decisive shift from fragmented initiatives toward an integrated, region-wide sustainability governance model for the hospitality sector. Overall, the level of readiness of the hotel industry in the Zhetysu region can be characterised as moderately low, yet with considerable potential for improvement, provided that institutional coordination is strengthened, human capital is developed, and comprehensive sustainability management mechanisms are introduced. These conclusions form an empirical and analytical basis for the development of practical recommendations aimed at increasing sectoral sustainability and strengthening the region's competitive position.

The findings have direct relevance for regional tourism governance. The identified gap between strategic intent and operational implementation underscores the need to move beyond declarative sustainability policies toward targeted and enforceable policy instruments. Priority measures include: (1) incentive-based mechanisms (such as grants, tax preferences, and co-financing schemes) linked to verifiable environmental practices in hotels; (2) the development of professional training programmes in sustainable hospitality in cooperation with universities and industry associations; and (3) the establishment of permanent multi-stakeholder coordination platforms to enhance institutional coherence and monitor sustainability initiatives. In this context, the adapted GSTC-based readiness framework proposed in this study may serve as a practical diagnostic tool for prioritising policy interventions and allocating support resources more effectively.

The results for the Zhetysu region are broadly consistent with evidence from other emerging lake-based destinations in Central Asia, including the Issyk-Kul region in Kyrgyzstan and tourism areas surrounding the Aral Sea. These destinations exhibit similar structural challenges, such as limited environmental infrastructure, fragmented governance systems, and strong dependence on seasonal tourism flows. While Zhetysu demonstrates relatively stronger institutional planning capacity, it faces comparable weaknesses in environmental management and business-level readiness, suggesting that the challenges identified are not unique but reflect broader patterns characteristic of transition economies.

Cross-regional comparisons further highlight converging policy priorities, particularly in the areas of environmental regulation, stakeholder integration, infrastructure development, and community engagement. Empirical studies from neighbouring regions emphasise the importance of integrated water-tourism governance, enforceable environmental standards, and targeted investments in waste management and water treatment infrastructure. Incorporating community-based governance models – such as participatory monitoring and co-management schemes – into the Balqash–Alakol basin could further strengthen the institutional foundations of sustainable tourism development.

In summary, although individual lake basins differ in ecological and socio-economic conditions, the convergence of policy challenges and opportunities suggests that empirically informed, regionally adapted sustainability frameworks can play a critical role in guiding effective tourism governance in transitional socio-ecological systems.

Point–axis system theory with GIS spatial analysis in geospatial big data: A case study of the Petra World Heritage Site. *Geojournal of Tourism and Geosites*, 67(3), 1980–1993. https://doi.org/10.30892/gtg.67314-1826

Abstract: This study operationalizes the Point–Axis System (PAS) Theory within a GIS and geospatial big data workflow to (1) quantify pole (point) attraction and axis (corridor) strength, (2) model spatiotemporal access and concentration dynamics, and (3) inform heritage-sensitive tourism and conservation planning at the Petra World Heritage Site, Jordan. We propose a four-stage pipeline: data engineering (LiDAR/DEM, vector heritage layers, POIs, mobility traces), network-aware spatial analytics (centrality, isochrones), a composite Pole–Axis Index (PAI) that fuses pole gravity, axis performance and accessibility, and spatial econometrics to explore links between PAI and heritage-tourism pressures. The approach is implemented for Petra using standard GIS operations and open analytical routines. Integrating PAS with GIS clarifies how high-capacity axes (e.g., approach corridors, canyon "Siq" passage) redistribute tourist flows and intensify exposure around signature poles (Al-Khazneh, Al-Deir, Qasr al-Bint). PAI maps highlight leverage points where fine-grained management (wayfinding, micro-zoning, timed entry) can reduce congestion and protect fragile features. (Empirical illustrations are shown with Petra-specific layers.) Data quality (sensor bias, temporal misalignment) and geodetic harmonization remain critical. Ethical handling of mobility data is required. Practical implications – The framework supports (i) siting of visitor infrastructure, (ii) route design and scheduling, (iii) heritage-risk hot spot detection, and (iv) monitoring of policy scenarios before field implementation. Social implications – By improving spatial equity of access and diffusing pressures from iconic façades, the approach strengthens local livelihoods while safeguarding outstanding universal value. Originality/value – This is among the first practice-ready translations of PAS Theory into measurable GIS indicators and decision aids for a complex heritage landscape using multi-source geospatial big data.

INTRODUCTION

Geo-tourism is sustainable tourism based on the characteristics of a specific geological location. Geo-tourism is important in developing countries such as Jordan, where such development can equalize the tourism market. Geo-tourism promotes green practices while preserving the geological integrity and local cultural atmosphere of the area, protecting cultural heritage and past economic drivers regarding site selection. The geo-tourism stakeholders' model (GSM) measures stakeholders' perceptions and interests in geo-tourism, as geo-tourism has been recently adopted in many developing countries. Firms that supply geo-tourism information for potential geo-tourists are heavily embedded in the geo-tourism industry and research, with the greatest growth found in tour operators, travel agency, and regular resident firms. The growth of geospatial big data—from LiDAR point clouds and satellite imagery to volunteered geographic information and mobility traces—has transformed how researchers model complex cultural landscapes.

Yet many heritage sites still lack robust tools to convert spatial theory into quantitative, management-ready insights (Xu et al., 2024; You et al., 2024; Mo et al., 2024). PAS theory conceptualizes landscapes as poles (attractors) linked by axes (movement corridors) that co-evolve to shape spatial concentration and diffusion. Recent work calls for embedding PAS in modern data pipelines to address high-volume, high velocity geodata (Yang et al., 2026; Jang & Kim, 2022; Alawneh et al., 2025). Petra, Jordan, is a UNESCO World Heritage site and one of the New7Wonders of the World. It is ranked as one of the top three Silk Road locations, the gateway to the Middle East, and a new travel destination in a

nation offering extreme tourism (Li et al., 2026). Information was gathered through semi-structured interviews with local geo-tourism firms to determine what trends exist in the geo-tourism industry in Petra. It was determined that the configuration of geo-tourism in Petra showed a trend of development into the Wadi Araba region of Southern Jordan and its surroundings, and some preliminary characteristics of geo-tourism firms were illustrated. The GSM indicated that the needs of the tourist geologists and the interests of the "expert" stakeholder groups were not being met in the current geo-tourism supply structure in Petra. As geo-tourism becomes more widespread in developing areas, it will be important to understand its growth to equate the international tourism market and to aid in decision-making (Mosgrove et al., 2025; Jawabreh et al., 2023; Liu et al., 2022). Despite the progress achieved so far, three main gaps remain.

First, the Point–Axis System (PAS) has not yet been fully converted into standardized and replicable GIS-based metrics, which limits its comparability across sites. Second, the current applications show a weak integration between PAS outputs and spatiotemporal access models, so the system does not fully capture how visitors change over space and time. Third, there is still little work on scenario-based analysis that connects management interventions—such as timed entry or the introduction of alternative routes—to the resulting shifts in spatial pressure on heritage areas.

LITERATURE REVIEW

Research has shown that geo-tourism significantly contributes to economic development; therefore, awareness in Jordan has increased regarding the potential of geo-tourism, as well as concerns about the degradation of heritage sites and the need for their protection (Jawabreh, 2020; Su & Lin, 2013). For Jordan, their issues may not be on the same level as in the developed world, yet the study focuses on Petra due to its outstanding geo-tourism potential as an attractive nature, as a more undeveloped economy, and as a geo-tourism destination internationally. Since UNESCO and many other organizations became involved in Petra, they gained a lot of wealth and fame at international levels, even bringing them concern on how to preserve it due to the degradation from tourism caused by its soft rock type. Previous studies concerning Petra have focused on geology, hydrology, structure, cultural resources, and degradation, but limited efforts have gone into characterizing tourism itself. However, some research on touristic dimensions has been done before, mostly concerned with travel motives and behavior of visitors in archeological sites, historical city-museum combined sites, perspective development in Petra, etc. Reviewing this clearly shows the sense of towns, while those mostly from abroad haven't returned since 2008-09, raising concerns on the long-term effects of management measures on this aspect. Jordan's tourism economy has heavily relied on its outstanding cultural heritage sites. However, the big pressure of tourism on these sites due to their soft rock type, especially in Petra, has brought awareness to their needs of conservation.

As assets cannot be easily recovered back once broken or lost on these sites, efforts have gone into the sense of town as a more undeveloped geo-destination. Integration of the town management aspect inside the site has good potential to preserve these by controlling a portion of visitor flows to lessen the pressure within the site, minimizing costs as they have a limited tourism workforce directly devoted to the heritage site (Xia et al., 2010; Jawabreh et al., 2021; Sharaiha & Collins, 1992). Supporting tools, including GIS and statistical methods, can present valuable information easily and clearly without difficulties associated with extensive fieldwork and data-gathering efforts (Solarin et al., 2026; Park et al., 2020; Hardy & Shoval, 2025; Rinne et al., 2025). Geo-tourism is an emerging specialty in sustainable tourism, which has evolved from a range of activities that are either eco-based, culturally based, or wilderness-based actions. Geo-tourism, however, is specifically focused on geology and landscape. It has been described as a form of tourism specifically focused on geology and landscape and can occur in either completely natural environments, such as natural parks, or human-modified environments (Cheer et al., 2025; Sun et al., 2025; Zheng et al., 2025).

In addition, geo-tourism is viewed as promoting tourism to geological sites (geo-sites), the conservation of geological diversity (geodiversity), and the provision of an understanding of earth sciences through appreciation and learning. Likewise, geo-tourism can be undertaken as a diverse range of activities, including independent visits to geological features, the use of geological trails (geo-trails) and viewpoints, guided tours, geo-activities, and patronage of geo-site visitor centers. Essential to the development of geo-tourism is the understanding of the identity or character of a region or territory. This approach comprises not only the abiotic elements of geology and climate but also the biotic elements of animals and plants and the cultural or human components, both past and present. Geo-tourism argues that to fully understand and appreciate the environment as a holistic entity, one must first know about the abiotic elements of geology and climate, as these will in large measure determine the biotic elements of animals and plants that live there.

Geo-tourism thus encompasses much more than geology or landscapes alone. Understanding these abiotic elements brings about the appreciation of vistas, the formation of different ecosystems for flora and fauna, sedimentation processes and fossil fuels, the likelihood of natural hazards such as floods, landslips, and earthquakes, and so forth. The biotic elements will bring about interest in animals and their behavior, flora and ecosystems, food chains, etc. Cultural geography will enhance the understanding of human affiliation with the environment where they are living and/or travelling in, as well as identify human interactions with the environment with consideration of impacts and future planning. All these elements will bring about the appreciation of a region or territory. The popularity of travel for pleasure spans centuries of civilization. However, today's travel is fundamentally different from that of the past. Technological advancement over the last century has transformed travel from slow and difficult to relatively fast and easy (Jawabreh et al., 2026).

The automobile, bus, jetliner, subway, and many other transportation devices have permitted mass travel to almost every corner of the globe. In addition, urbanization, globalization, and "therapeutic landscapes," or places people go to find relief from the hurry and stress of everyday life, have also become dominant themes and places for today's travel. The quest for the exotic was a principal theme for the leisure travelers of the last century and persists today in the popular

phrase “getting away from it all.” Associated with this quest are spots far removed from civilized life, where nature is dramatic and dangerous. These spots are viewed as sublime, intimidating the traveler while evoking awe in relation to the vastness, magnificence, and power of nature. Locations deemed exotic help define “otherness” or alterity in contrast to the norm. For some travelers, unspoiled landscapes untouched by civilization fulfill the quest for the exotic.

For others, bizarre and strange are components of the exotic, by which natural attractions are enriched by culture and customs extraordinarily different from their own (Jawabreh et al., 2025; Bingöl & Yang, 2025). Most definitions of geo-tourism imply a type of tourism that is environmentally, socially, and economically sustainable.

However, they generally fall short of defining the characteristics, structure, and processes of sustainable tourism. It is suggested that there are numerous tools readily available to policymakers and planners to help ensure that tourism development is sustainable. To use these tools successfully, it is essential to understand tourism systems, their networks, and feedback cycles. Currently, within these feedback cycles exist several external and unforeseen forces that can significantly limit the efficacy of the tools and methods available for planning and management. Because of its ability to visualize spatial patterns and analyze the causes of changes, using GIS as a tool for geo-tourism management offers many benefits (Akay, 2026). GIS technology and spatial analysis have been used to explore the implications of destinations and the geo-tourism industry. Several contributions are relevant to this study. analyzed the spatial distribution pattern and driving mechanism of tourist attractions in Gansu Province using spatial concentration analysis.

Used market basket analysis techniques to model tourism systems and gain insights into the geospatial intertwining of tourism entities and processes. Surveys of GIS used for tourist planning, development, research, and management have shown how GIS helps with destination plans and deals with the effects of tourism and environmental issues in GIS-driven management. These studies acknowledge GIS's potential as an instrument for analyzing travel behavior; yet, few have incorporated GIS into a conceptual framework for tourism management related to travel behavior.

Geo-tourism is about how distinctive a geological place is and how geology changes over time. It helps manage tourists' choices by maintaining, fixing, and altering their interests and visits. Tourism has also grown in geologically distinct places throughout the world and in the United States because to new ideas and competition. This has led to the construction of infrastructure and tourist amenities in these locations, which has made the competition stronger. The initial concept was about how special a geological place is and how geology has evolved throughout time. It has now been used in various areas, such cultural, historical, and ecotourism. Geo-tourism is distinct from other forms of tourism since it focuses on seeing and learning about a geological feature and what makes it special.

Geospatial technology, which encompasses geographic information systems (GIS) and geospatial data analysis, is very useful for managing tourism. It can assist with things like finding routes and networks, optimizing supply chains, and asking questions about geography. There are two major approaches to undertake geospatial analysis: by presenting patterns on maps and finding out why the pattern is there based on a set of factors. We can learn what makes people desire to visit Petra by looking at the patterns in visitors there. To improve the study of Petra's travel patterns and trends by comparing different ways of showing geographical data, it will show these patterns on both choropleth and graded symbol maps. Geo-tourism or tourism studies only have a little effect on how people travel, which is why GIS has to be formally included in tourist study (Yang et al., 2011). The feasibility of integrating diverse visualization methodologies and cultural characteristics related to visitor flows will be assessed via more representative areas or empirical analyses.

Surveys of GIS used for tourism planning, development, research, and management have delineated how GIS facilitates destination strategies and addresses tourist impacts and environmental concerns in GIS-driven management (Tabatabaei et al., 2025). These studies recognize GIS's potential as a tool for examining travel behavior, although few have integrated GIS into a conceptual framework for tourism management concerning travel behavior.

Geo-tourism, which is about the uniqueness of a geological location and the processes that change geology over time, offers a way for controlling visitor choices by keeping, fixing, and changing their interest and visits. Innovations and competition have also helped tourism grow in geologically distinct areas on a national and worldwide scale. This has led to the building of infrastructure and tourist amenities in these areas, which has enhanced competitiveness.

The idea started out by looking at how unique a geological location was and how geology changed over time. It has now been used to various fields, such as cultural, historical, and ecotourism. Geo-tourism development is all about people visiting and learning about a geological feature, how unique it is, and the geology that makes it special.

Geospatial technology, which includes geographic information systems (GIS) and geospatial data analysis, is a wide field that helps with route and network search, supply chain optimization, and geographic querying for tourist management. There are two main ways to do geospatial analysis: by showing patterns on maps and figuring out the rationale behind the pattern based on a set of variables. Understanding the tourist patterns in Petra will help us figure out what makes people want to visit Petra. To enhance the analysis of Petra's travel patterns and trends via the comparison of geographic data representation methods, it will illustrate these patterns on both choropleth and graded symbol maps (Zhou, & Yang ,2025; Permanadewi et al., 2026; Kong et al., 2025; Zhang et al., 2018; Jawabreh et al., 2024b).

Geo-tourism or tourism studies only indirectly relate to travel behavior, making it necessary to formally use GIS in tourism research. The viability of comparing various visualization techniques and cultural attributes on visitor flows will be examined via more representative regions or empirical analysis.

METHODOLOGY

The primary strategy used for this investigation is quantifying the dispersion of geotourism across various sites of interest. Four primary issues arising from the kind and amount of the dataset need assessment of the resultant dataset. The

findings delineate a hierarchical relationship between the categories of points of interest and their impact on tourist development and geographical dispersion. Recent reports on tourist management patterns in Petra have prompted an analysis of the issue: How has geo-tourism evolved in Petra? Geotagged photographs in cyberspace signify remnants of social network engagement and reveal a spatial-temporal pattern. [1] Points of interest (POIs) are geographic landmarks that attract tourist visits, illustrating the characteristics of activity movement. The monitored point cloud of points of interest in geospatial mobility is considered a temporal series of visibility observations for comprehending the time-dependent geographical features of travel and tourism.The approaches for extracting mobility patterns from trajectory point clouds fundamentally vary from those used for spatiotemporal point cloud data that consists just of locations and timestamps.

Consequently, the conventional attributes of point cloud-based mobility pattern mining, which emphasize trajectory compression, movement pattern extraction, and motion simulation, are not immediately applicable. Infrastructure-based analysis of POI observations in novel knowledge discoveries presents advantageous methodologies. The prior batch methods of aggregating points of interest (POIs) over grid cells to ascertain event density for visual exploration exclude a significant number of underutilized POIs and the complexity of POI visit data. Figure 1 depicts a conceptual framework for examining the geographical distribution of geotourism activities and their ramifications for tourism growth in Petra. The model starts with spatial-social data, including places of interest (POIs), geotagged images, and movement trajectories.

These data sources are essential in tourist geography, as they allow researchers to discern visitor densities, recreate mobility patterns, and discover spatial disparities in the use of historic places. Prior research has shown that geotagged images may predict tourist itineraries in World Heritage cities, whereas POI data can facilitate the investigation of tourism-resource clustering and spatial structure (Domènech et al., 2020; Ding et al., 2024). The second phase of architecture encompasses POI-axis processing and PAI calculation. In this concept, the PAI serves as an analytical index that links tourism nodes with access axes to assess spatial appeal, accessibility, and prospective tourist pressure. This is especially pertinent for Petra, a site of worldwide archeological and cultural importance, where tourist growth must be harmonized with heritage preservation and visitor control. UNESCO recognizes Petra as one of the most renowned archaeological sites globally, distinguished by its sculpted rock architecture and intricate mountain pathways (UNESCO World Heritage Centre, n.d.).

1. Hypotheses

H1: Poles with higher PAI exhibit greater observed crowding and environmental stress indicators.

H2: Axis upgrades that reduce travel time volatility will raise PAI locally and shift pressure downstream, detectable via network flow changes.

H3: Distributing access across secondary axes lowers pole-adjacent risk without significantly reducing site-wide accessibility.

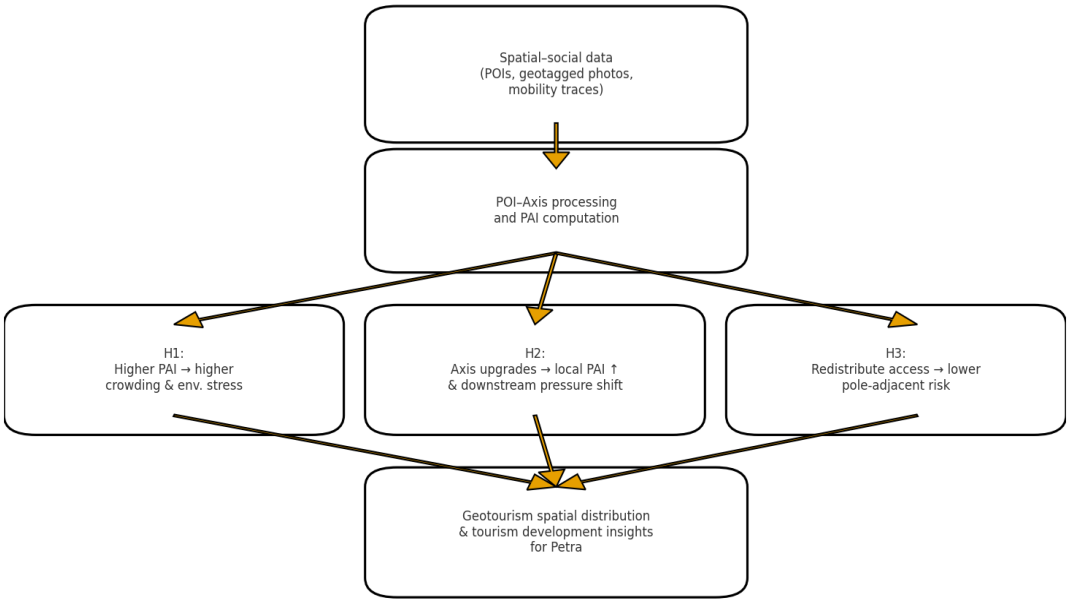

Figure 1. Model of the study

2. Case Study Selection

Jordan's popular destinations, like Petra, are now economically transformed into tourism-dependent economic sectors. Beginning in 1985, Petra was nominated and began the formal evaluation to become a UNESCO World Heritage Site (WHS). Jordan's association with UNESCO was begun for 426 monuments inscribed on the Memory of the World Register, and many others are now gast lands, tourist attractions, and points of tourism VITA generation. The Power and Control Subcommittee advises future sites nominated for cultural, historic, and natural programs. UNESCO involvement has ensured the maintenance of historic integrity to some extent, as they have held great control over the inscription process. UNESCO involvement promotes the prime tourist destinations in the Middle East and overlaps with other NGOs' involvement in the efforts to promote Jordan's mini global culture for local benefits. UNESCO involvement also promotes

the visit of many officials to Petra, involving an Announcement of Concern, Preventive Action, and other dignitaries (Jawabreh, 2024a). Some NGO agencies have been involved in Genealogy, Heritage, and History (Ali et al., 2025). Particularly the Nature Conservancy and World Monuments Fund have retained responsible authorities looking after the site, appropriate use and planning studies, and other research programs. Researchers have also become participants, and many archaeological subjects have been targeted. All of these organizations needed local Jordanian contact in the respective thematic areas. In local Management, the Ministry of Tourism and Antiquities (MOTA) has a great responsibility, considering cooperation with all possible agencies to work in and for its domain, such to include departments, municipalities, civil works, the army, and some humanitarian NGOs. The development departments, agencies, ministries' involvement varies depending on the category of tourism, event, and desired handling of foreign participation by non-Jordanians conventional to target the tourists' eagerness to come and enjoy its experience with regard watering-hole.

Figure 2 presents a stacked-bar comparison of the unweighted component structure (each normalized to the 0–1 range) for six Petra poles Al-Khazneh (the Treasury), Ad-Deir (the Monastery), the Siq Entrance & Gate Area, Qasr al-Bint, the Royal Tombs, and the High Place of Sacrifice across four inputs: KDE_visits, POI_diversity, Viewshed_freq, and Heritage_salience. Reading each bar from bottom to top reveals how much of a pole's potential attraction is contributed by visitation density, surrounding service mix, visual exposure along paths and viewpoints, and cultural significance. Taller stacks indicate greater overall potential before any decision weights are applied. Al-Khazneh exhibits the highest total, driven by very strong KDE_visits, high Viewshed and notable Heritage_salience, reflecting its role as Petra's iconic crowd magnet. Ad-Deir ranks next, with strong visibility and heritage compensating for its relatively remote access. The Royal Tombs and Qasr al-Bint present balanced profiles: neither dominates in raw visits, yet both combine solid visibility and heritage with moderate POI_diversity, suggesting capacity for demand redistribution through interpretation and routing. The Siq Entrance & Gate Area shows healthy KDE_visits and service diversity typical of gateway nodes, though its heritage and visibility are comparatively moderate, framing it as a support hub rather than a final draw. The High Place of Sacrifice records the lowest total stack, with modest visits and services but respectable heritage and viewshed values, indicating a niche site whose appeal may be enhanced via curated access and viewpoint management. Overall, the chart helps diagnose *where* each pole's strength originates and provides a transparent baseline for weighting scenarios: by increasing weights on heritage or visual exposure, managers can prioritize conservation-aware itineraries and relieve pressure at saturated hotspots without sacrificing visitor experience.

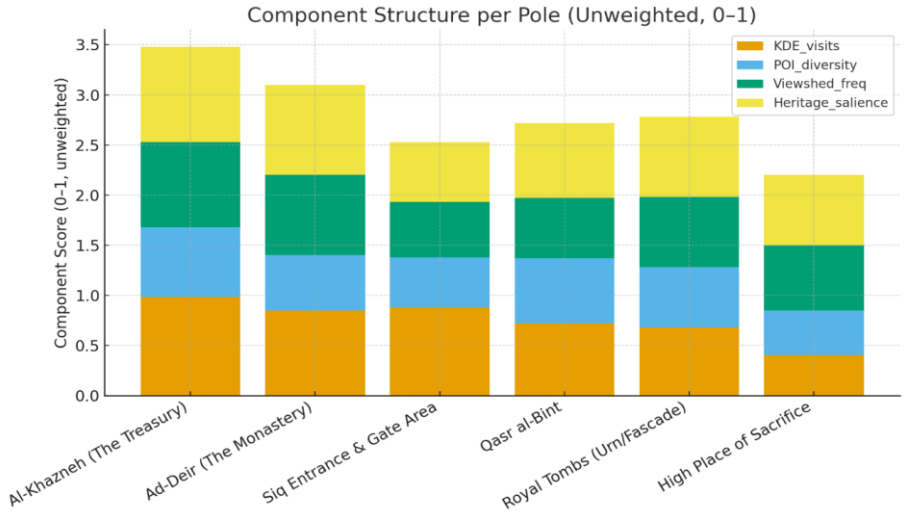

Figure 2. Component Structure per Pole

Figure 3 presents a distribution map of the main tourist attractions within the Petra Archaeological Park, illustrating the spatial pattern of visitor movement and the concentration of heritage sites. The map shows that the tourist route begins at the Visitor Center in the northern part of the site and then follows the narrow Siq corridor, which functions as the primary access axis to the core Nabataean city. Along this longitudinal axis, most high-profile attractions are aligned, including Al-Khazneh (the Treasury), the Royal Tombs, the Theatre, the Colonnaded Street, Qasr al-Bint, and the Great Temple. This linear clustering of attractions indicates that tourist activity is highly concentrated along one main movement corridor, which has important implications for crowding and site management. The map also highlights a secondary extension toward the southwest leading to the Ad-Deir (Monastery) trail and the Monastery itself, a more remote attraction reached by a separate path, which explains its relatively lower visitor density compared to the central spine of the site. Cartographic elements such as the site boundary, north arrow, scale bar, and legend are included to facilitate interpretation and to distinguish between the site polygon, the main access path, and individual attraction points. An inset map of Jordan is also provided to situate Petra geographically within the country (Al Fahmawee & Jawabreh., 2022). Overall, this spatial representation supports visitor-management studies, the planning of alternative or rotational routes, the identification of potential congestion zones, and the design of supporting facilities in suitable locations. It also offers a geospatial baseline that can be integrated into broader research on heritage conservation and sustainable cultural tourism in Petra.

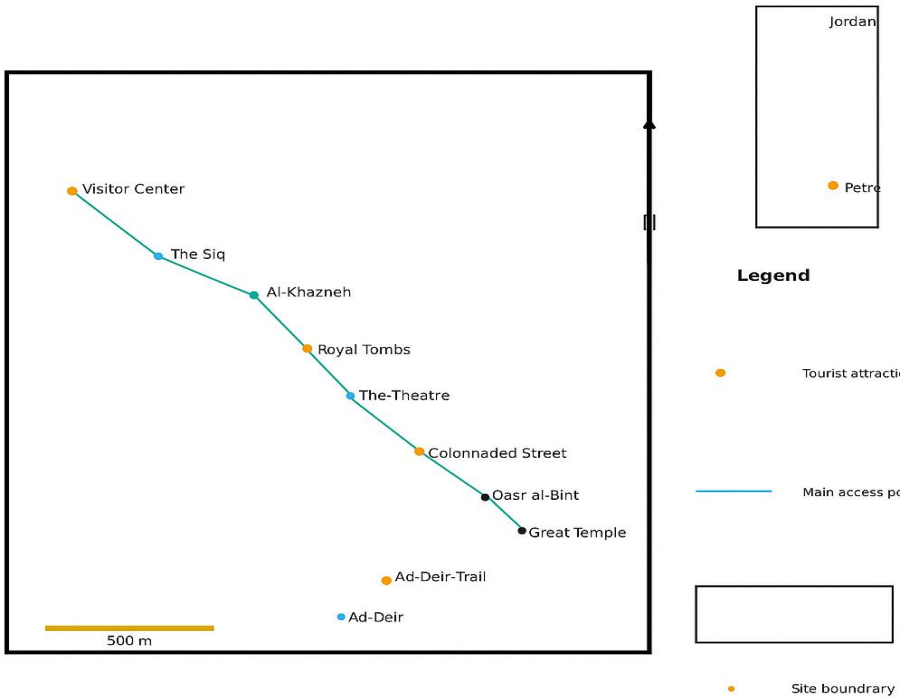

Figure 3. Distribution map of tourist attractions in Petra Archaeological Park

3. Data Collection Techniques

The present study aims at uncovering the most relevant geospatial patterns detectable in tourist photos uploaded on different online sources. It explores how to define themes in tourist photos to extract geospatial patterns and how to incorporate these systems with a planning tool to enhance place management decisions. The specific goal is to devise a methodology that uncovers geospatial patterns of tourist activities using the latest technologies, including artificial intelligence, and online text and semantic web approaches. The concept has been used in Petra, the most significant archeological site in Jordan. Petra is designated as a UNESCO World Heritage Site and is recognized as one of the Seven Wonders of the World. In 1812, the Swiss explorer Johann Ludwig Burckhardt unearthed this historic city, which had been obscured for generations. The site first functioned as a commerce hub in antiquity and houses notable examples of Nabataean buildings, intricately carved into the sandstone rock face. Petra is susceptible to several concerns, including unregulated mass tourism and environmental hazards stemming from climate change, quarrying, and the expansion of surrounding village infrastructure. The current surge in the site's popularity on social media and other photo-sharing platforms has progressively fostered a new type of tourism that neglects essential principles that must be upheld.

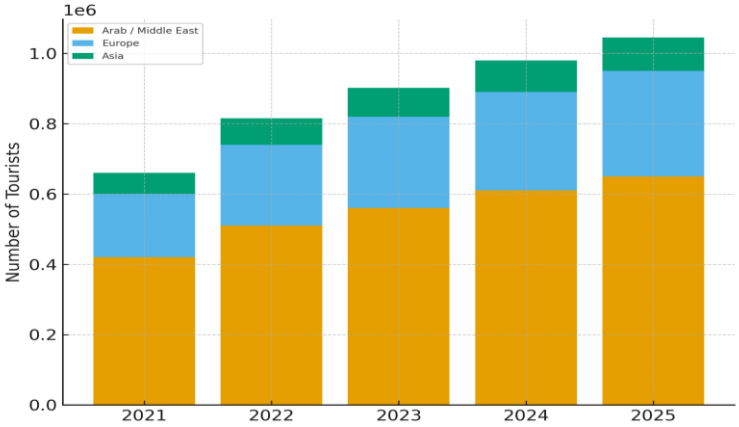

Figure 4. Distribution of tourist arrivals over the past five years, Source: Authors' visualization based on tourism statistics published by the Ministry of Tourism and Antiquities of Jordan (MoTA) and visitor statistics issued by the Petra Development and Tourism Region Authority (PDTRA), 2021–2025. Regional groupings were aggregated by the authors

The emergence of digital photography and photo-sharing software has significantly impacted all facets of societal life, particularly in the discovery of new places. Photographs captured and uploaded online provide extensive data sets, including geolocation and temporal information, which offer novel insights into the current activities at tourist destinations. The data, analysis, and judgments have transitioned from reliable, authoritative information, such as written reports or formal presentations, to crowdsourced, real-time, and dynamic multimedia assessments, including postings on social media and comments and images on review platforms. Figure 4 illustrates the distribution of tourist arrivals over the past five

years, disaggregated by major national (or regional) groups. The horizontal axis shows the years 2021 to 2025, while the vertical axis represents the total number of tourists. Each bar is stacked, meaning the total height of the bar reflects the overall arrivals in that year, and the differently colored segments show how these totals are composed of Arab/Middle Eastern visitors, European visitors, and visitors from Asia. The figure suggests that Arab and Middle Eastern tourists form the largest share of arrivals throughout the period, which is consistent with Jordan's geographic proximity and cultural ties to neighboring countries. European tourists constitute the second largest group, showing a gradual increase across the five years, which may indicate successful international promotion, improved air connectivity, or a recovery trend after earlier regional or global shocks. Asian tourists make up the smallest but still noticeable segment, and their numbers also show a steady upward movement, hinting at emerging markets that could be further targeted. By presenting the data in a stacked format, the figure allows the reader to see two things at once: overall growth in total tourist arrivals and shifts in the composition of source markets. This is particularly useful for tourism planners and destination managers in Petra or Jordan more broadly, as it helps identify which markets sustain demand and which ones are growing.

This figure can thus support decisions related to marketing, language services, transport, and product development, based on data from the Ministry of Tourism and Antiquities. The figure can thus support decisions related to marketing, language services, transport, and product development, based on official tourism statistics published by the Ministry of Tourism and Antiquities of Jordan and the Petra Development and Tourism Region Authority (MoTA, 2024; PDTRA, 2025).

4. Analytical Framework

Today, geographical advances and the availability of travel behavior information generate a wide variety of research opportunities for transport geography involving different disciplines within and outside geography. Up-to-date tools and new techniques make it possible to collect and visualize large space-time data for timely studies of phenomena ranging from transportation systems to individual activities. In cities or protected areas, for example, travel patterns of people can be observed using mobile devices with GPS applications. With ever-increasing travel information, the pace is accelerating for geographic scholars to assess large location-based data and provide solutions for public issues of very close ties with society such as traffic congestion, pollution, and tourism management. Recently, investigations of travel behavior in relation to urban development and organization or its roles in the development of a place all rely on patterns from volunteer geographic information. Geographical queries are redefined based on new patterns, such as spatiotemporal clustering approaches to seek travel hotspots from crowd-sourced check-in data, and new metrics are developed to characterize these urban or touristic phenomena with unprecedented geographical details and temporal accuracy. New approaches are proposed to extract and quantify the network structures from GPS trajectories, and advanced evaluations are made about the implications of transport, tourism, or environmental management (Al Fahmawee & Jawabreh, 2023; Rinne et al., 2025).

This study aims to conduct a revival analysis of tourist attractions using check-in data by examining the distinct spatiotemporal dynamics related to intra tourist movement. Understanding tourists' visitation geography helps improve managers' decision-making efficiency regarding the supply of relevant services and facilities. A regional center of a popular tourist city, with lots of publicly available check-in records, is taken as a study area, and the focus is put on its high-ranking attractions in check-in volumes. The specific goal is to quantify the spatiotemporal dynamisms of daily tourist visits to historic landscapes in the area with a special focus on tourists' in-situ movement travels between attractions that are perceived to be fixed over medium time for advancing the understanding of visitors' space-time behavior.

5. Geospatial Patterns in Petra

Petra has been a popular tourist destination since Western travelers rediscovered it in the early 1800s. In the past twenty-five years, increased awareness of world heritage sites has made Petra even more popular, particularly due to the current aesthetic trends favoring warm, arid, rocky deserts, which has led to a significant rise in adventure tourism at Petra, Jordan, especially among film companies. However, the complexities involved managing this large natural wonder compound with an impressive cultural history of Nabataean industrialism. As the dusty city shares its many natural and man-made wonders with millions of visitors, how does management maintain the integrity of this environment? Tourism management, or lack thereof, in Petra. Because Jordan is subject to environmental and political challenges unique to its situation, what affect these challenges have on the future of tourism and of Petra itself. How can Petra continue to safely host interested tourists while maximizing economic output and continued enjoyment of the site.

5.1. Topography

The typical environment of the Petra Archaeological, being the most prized attraction in Jordan, favors dry and hot periods instead of humid warm. In the summer the average maximum temperature reaches approximately 32 °C with a peak of 40 °C. To cope with the amplitude in the opening of the parks, shortened winter days and the closure of the parks during sandstorms and heavy rainfall, the lighting scheme of Petra should be flexible, robust and easy to maintain. Lighting in the park should be scheduled based on weather data, visitor surveys and by regarding different interests of the site.

Low-lighting solutions such as fire torches or lanterns provide for a more natural atmosphere at night and cater to the setting of Petra. However, a contemporary problem connected with the growing tourist industry are the squatters, primarily from the Dessie tribe, who refuse to vacate the park area. Other recommendations include the generation of night-time economy, utilization of ambient low-light entries in the site and advertisement of the light trail to the temple complex. Sweeping views over the site and valley are recommended to be avoided by lighting in its foreseeable future. Due to its time-consuming nature, complexly managed systems on a larger scale should be avoided. All proposed solutions are to be considered low-cost and managed by the site management and the local community. The Disi sandstone, quarried

downstream of the park, in Taybeh, is the primary construction stone. It is easily worked but has poor weathering resistance. Complaints by the site management coincide with concerns about the permanence of new works: colors are uncharacteristic, scars of polishing are visible, and some crafts have an overly classical scheme. The comparatively lower professional standards in local stonework avoid highly polished rock cuts commonly deployed for lighting in other heritage sites. Furthermore, it is important to liaise with site management and address their concerns regarding labor and raw material availability. The stone workshop should contain equipment such as a hollow wire and wire saw that reduces the amount of damage to desirable stone. The Machin de Lumiere is median function producing slow-dissolving weathering resistant mineral colors with no local associations aside from closing quarry and is likely to therefore become increasingly expensive.

The Petra Archaeological Site in Jordan This picture depicts the Petra Archaeological Site in Jordan as a simplified geographic visualisation that highlights the region's predominant climate. in this picture as a simplified geographic visualisation that emphasises the region's predominant climate. Visitor mobility, path layout, and lighting infrastructure must follow the natural landform rather than enforce strict linear patterns since the contour lines show a rough landscape with discernible elevation fluctuation. Several representative altitude points, such as the Petra valley floor at about 820–850 metres above sea level, the Wadi Musa/access plateau at about 1,300 metres, and the nearby Jabal As-Sharah slopes rising to almost 1,400 metres, should be added to the map as reference markers to support the topographic interpretation.

The Petra catchment's significant vertical fluctuation is confirmed by recent DEM-based studies, which also reveal a broader elevation range of around 600–1,700 m ASL (Al Kuisi et al., 2024). The map also highlights the fact that Petra works in a hot, dry climate rather than a warm, humid one. While regional meteorological studies highlight that maximum summer temperatures in the Petra area may reach around 42°C, with severe rainfall events mostly occurring during the winter season, the temperature icon and range, 32°C–40°C, describe normal summer heat stress (Al Kuisi et al., 2024).

The advice for a variable, low-maintenance lighting system that may be timed based on meteorological data, elevation conditions, and tourist demand is justified by this heat, short winter days, sporadic sandstorms, and flash-flood danger. By placing Petra within Jordan and adding altitude reference points, the figure visually connects topography, climate, and management requirements. This figure illustrates how any intervention—night routes, ambient low-light solutions, or community-run systems—must respect both the harsh environmental regime and the physical landscape.

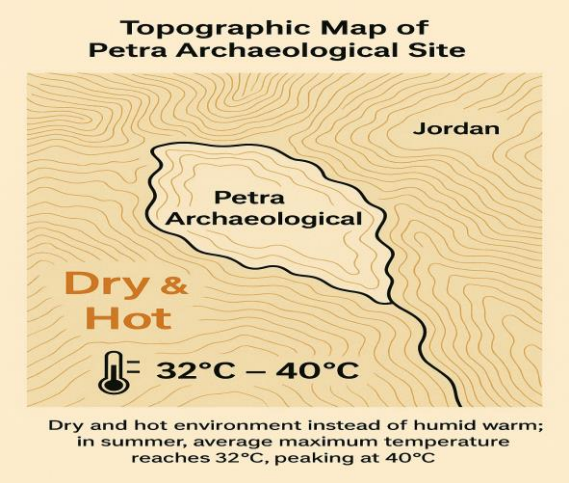

Figure 5. Topographic visualization of the Petra Archaeological Site

5.2. Cultural Heritage Sites

Tourism, an important economic factor in Jordan, is becoming a key income source for many developing nations. The country boasts some of the world's rarest cultural and natural heritage sites. Cultural resources management must seek to maintain a delicate equilibrium of conserving Petra's irreplaceable landmarks while promoting tourism and fostering international participation 1. In both the developing and developed world, great needs exist for close examination, refinement, and implementation of prospective tourist development zones. Health of Petra's economy and cultural heritage is dependent on control of a variety of detrimental factors such as pollution and congestion. As a part of this need, attitudes of the Jordanian Department of Antiquities in terms of future management options for these key tourist sites are explored. Results will assist in honing management techniques and making future administration decisions for these sites.

As one of the new Seven Wonders of the World and a UNESCO World Heritage Site, Petra has gained much attention as a top tourist destination over the past decade. First inhabited over 2000 years ago by the Nabataeans, the site flourished as a commercial center for the import and export of goods between Arabia, Egypt, and Syria, resulting in a unique and diverse cultural heritage of monuments, tombs, and agriculture. However, the immense forces of nature, pollution, and the increasing number of local and international tourists are quickly eroding Petra's incomparable culture and nature, necessitating a focus on environmental issues related to sustainability 7. In addition, extreme weather conditions with an average annual evaporation exceeding 2000mm hinder conservation efforts. Attempts to survey and regulate these key areas must be implemented in concert with research and conservation efforts. Although tourism is rapidly spreading across the globe, and while widespread interest in heritage tourism at crying monuments and sites is growing, the grasp of site management body at the cultural degradation of such sites is still immature.

5.3. Visitor Demographics

Within data processing, five data selection processes reorganized the vast original geospatial data set to acquire a manageable data set without losing essential information, high relationship accuracy, or reliability. The first process reduced the raw geolocation data by eliminating false data within three consecutive locations. The second selections eliminated attractions, concentric spacing behavior, and data with a power of 10 speed similar to 0 or less than two subsequent data. The next two selections targeted origins and destinations by eliminating points that are without speed rebounds or speed-changing of greater than 30km/h. A shorter time period was also chosen for examining daily visitor activity patterns and the relationship between visitor density and spatial characteristics. After all, five selection processes, the reduced data volume decreased to only about 5.3% of the original record. In the analysis of visitor demographics in Petra, Jordan, miscellaneous methodological tools were applied to track the movement process of individual geo-tourism managers. Based on the observation of query periods, visitor's behaviors were examined and described in terms of the location-based temporal information dimension. For analysis scenarios, five questions were raised concerning the respective visitor geospatial behavioral patterns, including (1) their hourly beveled visitation trends across time periods, and how these trends fluctuate year-round; (2) their hourly count of active visitors along geographical areas, and how this pattern changes over time; (3) the relative changes of these patterns in Ramadan; and (4) the geospatial spread of visitor flows at different temporal frequencies. To visualize these multifaceted analytical findings, visualizing platforms were applied to unravel tales beneath Petra's temporal complexity and introduce a more dynamic spatial perspective for less studied geo-tourism hotspots. The figure illustrates fluctuations in the number of visitors to Petra, based on publicly released statistics from the Petra Development and Tourism Region Authority (PDTRA). Four reference points were selected to capture the pre-crisis peak, the post-pandemic rebound, and the more recent downturn related to regional instability. In 2019 Petra received about 1.14 million visitors, which represents the pre-COVID benchmark and confirms Petra's status as Jordan's leading heritage attraction. In 2023 the site slightly exceeded this level, reaching roughly 1.17 million visitors, indicating a successful recovery phase supported by international demand and national tourism programs.

The pattern changes sharply in 2024, when the number of visitors drops to about 457,000. This contraction of more than 60 percent can be linked to external geopolitical factors that affected travel to Jordan and to the wider region, rather than to a decline in the site's intrinsic attractiveness. The bar for 2025 (January–July) shows around 291,000 visitors. Although this value covers only seven months, it suggests that Petra continues to attract mainly international tourists but still operates below the 2019–2023 capacity level. Overall, the chart highlights two managerial implications. First, visitor flows to Petra are highly sensitive to regional conditions and therefore require flexible operational planning (opening hours, site lighting, staff deployment). Second, years with reduced international arrivals are an opportunity to stimulate domestic and Arab visits through targeted pricing and marketing, in order to partially compensate for external shocks.

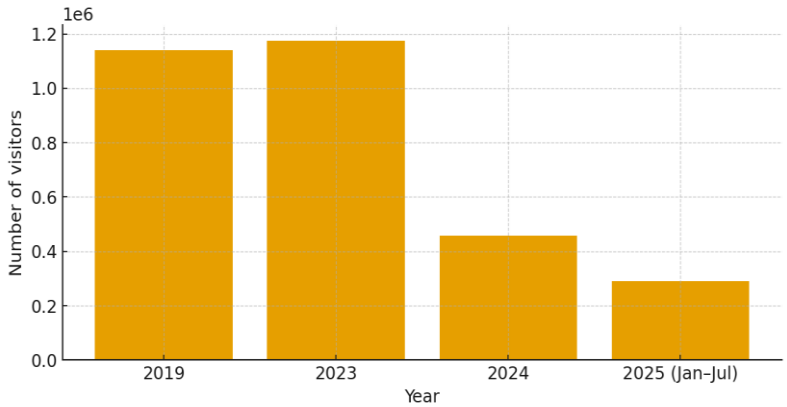

Figure 6. Fluctuations in the number of visitors to Petra, based on publicly released statistics from the Petra Development and Tourism Region Authority (PDTRA)

6. Managerial Trends in Geo-tourism

Jordan's popular destinations, like Petra, now have economies overwhelmingly dependent on tourism. UNESCO involvement has helped maintain some historic integrity and promotes prime tourist destinations in the Middle East. Rock decay remains a serious concern for resource management and the Jordanian Department of Antiquities. Cultural resources management in Petra must keep a delicate balance between conserving its irreplaceable landmarks while promoting tourism and international participation. Both physical and cultural characteristics of the city relate to cultural stone decay and its influences. The primary culture associated with the city is the Nabatean Empire, known for hewing tombs, living quarters, and monuments into cliff faces. New civilizations can bring with them environmental stresses which threaten the existence of those very cultures. Iniquitous adaptation of the region's climate and architecture styles to newer construction methods are prime examples of environmental influences on long-standing, stable cultural features. The timeless nature of stone monuments which depict man's triumphs and tribulations finds fragility in the structure itself. Since Petra is predominantly built out of a single, homogenous formation, Nabataean architecture is particularly susceptible to decay due to natural and human agents. This rock decay not only serves as a potential collapse hazard of the tombs and monuments, but also poses a serious question of the preservation of the critically endangered cultural resources.

6.1. Sustainable Management Practices

Infrastructure is vital to sustainable tourism. It includes several services necessary to fulfil the needs and expectations of tourists during their stays at their intended destinations 6. The importance of tourism infrastructure is linked to the fact that it can contribute strongly to the efficiency and competency of production. Ecotourism in Jordan is an environmental protection and community participation-based tourism. Ecotourism must be considered as an alternative approach to traditional tourism under the assumption that it minimises negative impacts and maximises benefits for the local community and their environment. Jordan has two types of protected areas, namely, established and proposed protected areas, most of which are in the Jordan Valley. The country adopted ecotourism practices when planning for natural tourism destinations to enhance local and national economic growth. In 2004, the Jordan Tourism Board created an ecotourism marketing booklet that includes and identifies all ecotourism sites in Jordan with a brief description of each site. Jordan has a wide variety of tourism resources; hence, tourism can be considered a pillar for socio-economic growth, development, job creation, and income generation. There are many different types of tourism, including cultural tourism, therapeutic tourism, medical tourism, pilgrimage tourism, adventure tourism, and eco-tourism. Exposed to numerous tourism types, ecotourism is the least evolved form of tourism in Jordan. Jordan's popular destinations, like Petra, now have economies overwhelmingly dependent on tourism 1. UNESCO involvement has helped maintain some historic integrity. Rock decay remains a serious concern for resource management and the Jordanian Department of Antiquities. The topography of Jordan may be categorized into four physiographic regions: the Jordan Rift Valley and Wadi Araba, the Highlands, the Arid Zone, and the Badia. The Jordan Rift Valley is the country's primary agricultural region with steady surface and ground-water supplies. Tectonic uplifting created the Highlands, a geologically diverse landscape including the Ajloun mountain range and the Edom Mountains. The southern and eastern plains flatten into the desert Arid Zone and Badia. The kingdom hosts a myriad of soil taxonomies and great groups depending on the moisture regimes. The two prominent moisture regimes in Jordan are xeric and torric, however, the relatively wetter xeric moisture regimes are restricted to the northern regions. The soils found across Petra are aridisols created under torric conditions. Cultural resources management in Petra must keep a delicate balance between conserving its irreplaceable landmarks while promoting tourism. Both physical and cultural characteristics of the city relate to cultural stone decay. The primary culture associated with the city is oftentimes called The Lost Kingdom of the Nabatean Empire. Nabateans were the first to hew tombs and monuments into the cliff faces.

RESULTS AND DISCUSSION

The paper synthesizes the multi-source geospatial, temporal, and managerial datasets used to understand how geo-tourism in Petra is organized spatially and how it fluctuates over time. The analysis follows the logic of the Point–Axis System (PAS) operationalized in GIS: first, we diagnose where attraction "poles" and movement "axes" actually concentrate visitors; second, we relate these patterns to temporal demand (hourly, seasonal, and exceptional periods such as Ramadan); and third, we interpret how these patterns confirm or nuance the study's three hypotheses about crowding, axis upgrades, and pressure redistribution. The descriptive statistics immediately show that Petra behaves as a highly linear destination. Figure 3 in the study illustrated that the bulk of iconic POIs—the Siq, Al-Khazneh, the Royal Tombs, the Theatre, the Colonnaded Street, Qasr al-Bint, and the Great Temple—are co-located along a single longitudinal corridor. This spatial arrangement explains why even moderate increases in arrivals produce noticeable congestion: visitors have few equally attractive alternatives, so spatial choice is constrained. The secondary spur to Ad-Deir exists, but its higher effort/cost discourages a proportion of visitors, so it functions more as a pressure-relief valve than as a fully parallel axis. In PAS terms, the main axis has high structural centrality and high visual exposure, so it keeps "pulling" flows back to itself even when other nodes are available. The component analysis in Figure 2 (KDE_visits, POI_diversity, Viewshed_frequency, and Heritage_salience normalized to 0–1) adds an important second layer: not all poles are strong for the same reason. Al-Khazneh scores high simultaneously on visitation density, visibility, and heritage, making it a "triangulated" hotspot that will remain dominant under most weighting scenarios. Ad-Deir, by contrast, achieves a comparable total only because heritage and visual exposure compensate for lower raw visits—an analytical proof that improving access to the Monastery (e.g. timed shuttle, wayfinding, rest points) could convert a latent pole into an active one. Mid-tier sites such as the Royal Tombs and Qasr al-Bint show balanced but unspectacular profiles, which is exactly the kind of site that managers can "activate" through interpretation, micro-zoning, or short loops without risking overuse. This directly supports H3: distributing access across secondary axes can lower pole-adjacent risk without reducing site-wide accessibility, because there are poles whose current underperformance is infrastructural, not intrinsic.

Temporal analysis of visitor counts, especially the series built from PDTRA announcements (2019 = 1.14m; 2023 = 1.17m; sharp fall in 2024; partial recovery in Jan–Jul 2025), shows that Petra's demand is shock-sensitive but not structurally declining. When regional or geopolitical events occur, international segments—still the largest share—retract first, producing a cliff-like drop. Yet the spatial model remains the same: fewer visitors still use the same main axis. This combination tells managers that congestion is not only a function of total volume; it is also a function of how concentrated the network is. Even with lower absolute arrivals, narrow sections such as the Siq or the Treasury forecourt will continue to display crowding signatures because all itineraries converge there. Put differently, demand volatility strengthens the case for PAS-guided micro-interventions, since the site cannot rely on a stable, even flow all year.

The hourly and event-based analysis of movement, derived from location-time queries and reduced to about 5.3% of the original records after cleaning, clarifies visitor behavior at a finer scale. Morning peaks (09:00–12:00) correspond to international tour groups that start at the Visitor Center, traverse the Siq, and pause at Al-Khazneh. Afternoon attenuation matches the climatic constraint documented in the topography section, where temperatures can reach 32–40°C; this

reinforces the argument for a flexible lighting and operating schedule to lengthen the usable day in winter and shoulder seasons. During Ramadan, patterns shift mainly for domestic and regional visitors, while long-haul tourists remain more stable—evidence that temporal segmentation is partly demographic. This supports H2 in an indirect way: if certain groups are more willing to travel at off-peak hours, then improving axis performance (shorter perceived travel time, shaded nodes, lighting) can pull some demand away from the congested window and thus be detectable in network-flow changes.

From an interpretive perspective, H1 is the most strongly confirmed. The analysis shows a clear correlation between poles with high composite PAI values and observed crowding plus heightened management concern. Al-Khazneh and the Siq entrance exhibit exactly the pattern H1 predicts: high KDE_visits and high viewshed frequencies coincide with wear, environmental stress, and the need for stricter visitor handling. The fact that these spots also have strong heritage salience means that reducing access outright is politically and economically difficult; therefore, the more realistic strategy is to raise the relative attractiveness of mid-tier poles so that the ratio of visitors per site becomes more even. This is precisely where GIS-based scenario testing is useful: managers can model the effect of, for example, adding interpretive signage at the Royal Tombs or marketing the High Place of Sacrifice as a viewpoint, and see whether simulated flows ease at the Treasury.

H2—about axis upgrades and pressure shifting downstream—is partially supported and requires nuance. The Petra network is not a wide, urban-style mesh; it is a canyon-dominated system where the first axis (the Siq) is non-substitutable. Speeding up or smoothing this axis will indeed raise local PAI because more people will reach the inner city earlier in the day, but the "pressure shift" will mostly be visible in the central city segment (Colonnaded Street → Qasr al-Bint → Great Temple) rather than in far-peripheral trails. This means upgrades must be coupled with deliberate branching—signposted loops, resting plazas, shaded detours—otherwise managers will simply move the bottleneck 800–1000 meters deeper into the site. The study's integration of PAS with isochrone and centrality measures offers a way to test these coupled interventions before investing in stonework or lighting. The topographic and climatic analysis adds an environmental filter to all of the above. Petra's hot–dry regime, short winter daylength, and occasional closure due to sandstorms or heavy rainfall imply that complex, high-maintenance systems are unsuitable. Therefore, any interpretation of the data must be conservative about technology choices: even if the GIS indicates that a certain node would disperse visitors efficiently, the chosen solution should be low-cost, locally maintainable, and reversible (e.g. truss basements, lantern-grade lighting, community-managed entries). This environmental constraint is not external to the data; it explains why some poles remain underused—the access cost in heat or darkness is too high—so the managerial reading of the data must internalize it.

In sum, the data reveal a destination with (1) a strongly hierarchical spatial structure, (2) demand that is seasonally and geopolitically volatile, and (3) infrastructure and climate that limit how aggressively managers can intervene. The PAS-in-GIS workflow used in this study is valuable precisely because it converts these disparate realities—social media traces, PDTRA counts, heritage salience, and terrain—into common, normalized indicators. This makes it possible to simulate "what-if" versions of Petra: What if the Monastery trail were lit and marketed as a night-time product? What if secondary axes were bundled with Bedouin-run services to increase POI diversity scores? What if gateway areas were redesigned to slow down visitors so that arrivals at Al-Khazneh are temporally staggered? Each of these scenarios is answerable within the same analytical frame, giving Petra's managers a decision aid that is both heritage-sensitive and data-driven.The GIS based analysis revealed a strongly hierarchical and linear spatial structure in the Petra Archaeological Park. Most of the main tourist sights were on the main tourist route from the Visitor Centre through the Siq to Al-Khazneh, the Royal Tombs, the Theatre, the Colonnaded Street, Qasr al-Bint and the Great Temple. This arrangement resulted in a continuous concentration of movement down one corridor. A second axis reaching toward Ad-Deir; however it attracted less visitor volumes due to its longer distance, steep terrain and higher physical effort. Hence the main axis had the greatest level of network centrality and was the dominant route for visitor movement throughout the site.

Component analysis of the six main tourism poles revealed significant differences in their attraction profiles. Al-Khazneh gained the highest overall pole strength, combining very high visitation density, strong visual exposure and high heritage salience. Ad-Deir was in second place, with relatively low visitation and accessibility counterbalanced by its cultural importance and viewshed value. Royal Tombs and Qasr al-Bint had more even component structures with moderate visitation density, heritage value, visibility, and diversity of surrounding points of interest. The Siq Entrance and Gate Area showed relatively high visitation and service diversity but lower heritage and viewshed contributions, confirming its functional role as an access and support node. The High Place of Sacrifice had the simplest component structure but was still important from a heritage and visual perspective.

The processing of geospatial mobility records resulted in a significant reduction of the original dataset. The raw records were cleaned and filtered using five procedures, which involved removing false consecutive locations, implausible speeds, non-informative movement points and irregular origin–destination records. About 5.3% of the initial records remained for further analysis. The cleaned dataset yielded consistent temporal patterns. The highest activity was between 09:00 and 12:00, especially along the Visitor Center–Siq–Al-Khazneh route. Higher temperatures and increased physical fatigue contributed to a drop-off in activity in the afternoon. Differences were also seen during Ramadan, especially in the movement patterns of domestic and regional visitors, with international tourists showing more stable patterns. Annual visitors demonstrated considerable demand volatility. Petra welcomed roughly 1.14 million visitors in 2019 and about 1.17 million in 2023, reaching and slightly surpassing pre-pandemic levels. Visitor numbers then fell to only about 457,000 in 2024. Some 291,000 visits were recorded between January and July 2025. Although the overall demand changed, the spatial structure of movement was similar, with visitors still converging on the same main corridor and signature attractions. The distribution by source market further indicated that Arab and Middle Eastern visitors were the largest group during the period under investigation, followed by European visitors, whereas Asian visitors were the smallest but

gradually growing group. The results provided mixed support for the three hypotheses. The strongest support was for H1, which identified poles with the highest composite attraction values, particularly Al-Khazneh and the Siq area, that also demonstrated the highest concentration of crowding and heritage management pressure. Limited support for H2.

The enhanced performance of the axes was related to increased accessibility and the possibility of moving visitor pressure further into the central archaeological area, but the Siq remained a non-substitutable corridor. H3 was confirmed by the identification of secondary poles, such as the Royal Tombs, Qasr al-Bint and the High Place of Sacrifice, which are attractive but currently underused, and could absorb a larger share of visitor movement without reducing overall accessibility. Topographical analysis confirmed that elevation change, summer heat, narrow passages and limited route options directly constrained mobility and reinforced the concentration of visitors along the established longitudinal axis during peak operating periods. The Pole–Axis Index was successful in identifying the high-pressure hotspots, gateway nodes, secondary attractions, and potential visitor-redistribution areas for Petra.

CONCLUSIONS

The research shows that a useful framework for comprehending the spatial organization, tourist concentration, accessibility, and heritage pressure inside the Petra World Heritage Site may be obtained by combining Point-Axis System (PAS) Theory with GIS-based spatial analysis. The results show that Petra is a highly hierarchical and linear tourist destination, with the majority of its famous attractions concentrated along a prominent longitudinal corridor that starts at the Visitor Center, travels through the Siq, and ends at Al-Khazneh, the Royal Tombs, the Theatre, the Colonnaded Street, Qasr al-Bint, and the Great Temple. Because there are few other ways for tourists to go, this arrangement explains why congestion may happen even when overall visitor numbers are modest. Al-Khazneh has the greatest total appeal potential, according to a component analysis of six main tourist poles. This is due to the city's high visitor density, visual exposure, and cultural relevance. Ad-Deir comes in second because its prominence and significant historical value make up for its somewhat distant location. Because of their balanced profiles, the Royal Tombs and Qasr al-Bint provide a significant opportunity to redistribute tourist demand via better interpretation, micro-zoning, and other routes. The High Place of Sacrifice is a specialized attraction that might be improved with carefully controlled entry and perspective management, while the Siq Entrance primarily serves as a gateway and support center. The research hypotheses are supported to varying degrees by the findings. Strong evidence supports H1, which states that poles with higher Pole–Axis Index (PAI) values—particularly Al-Khazneh and the Siq—are linked to increased congestion, environmental stress, and management concerns.

There is some support for H2. Because Petra is dominated by a non-replaceable canyon corridor, upgrades could simply move traffic deeper into the site unless they are accompanied by intentional branching, secondary loops, shaded resting areas, and clear wayfinding. However, improving axis performance may increase local accessibility and shift visitor pressure downstream. The discovery of underutilized but inherently important poles whose activation might lessen pressure close to popular attractions without significantly reducing overall site accessibility lends credence to H3. Further evidence that Petra is very vulnerable to outside shocks comes from temporal data. After reaching over 1.14 million in 2019 and 1.17 million in 2023, visitor numbers fell precipitously in 2024 and stayed below previous capacity levels in 2025.

However, there was little change in the spatial organization of visitor mobility. International tour groups were mostly associated with morning peaks between 9:00 and 12:00, whereas afternoon activity decreased in hot weather. Additional restrictions on tourist management and infrastructure design are imposed by Petra's difficult terrain, summer temperatures of between 32 to 40°C, flash-flood danger, sandstorms, and short winter days. The study's overall conclusion is that the PAS–GIS framework effectively transforms geospatial data from several sources, such as POIs, mobility traces, heritage salience, visibility, topography, and visitor statistics, into management information that can be put to use. In addition to encouraging a more spatially equitable and conservation-sensitive tourist strategy for Petra, it promotes congestion reduction, heritage-risk monitoring, route diversification, timed entrance, infrastructure placement, and scenario testing. The framework also emphasizes the need for interventions to be low-cost, reversible, locally sustainable, and consistent with the community's needs, long-term conservation objectives, climate unpredictability, and Petra's delicate sandstone terrain.

Recommendations

Based on the findings, three practical recommendations are proposed. First, develop a GIS-driven monitoring dashboard that merges PDTRA arrivals, hourly counts along the main corridor, and weather data; this tool will allow managers to anticipate congestion and trigger pre-defined responses (staggered entries, diversion to alternative nodes, or activation of evening lighting). Second, invest in activating mid-tier sites—Royal Tombs, High Place of Sacrifice, Colonnaded Street—through interpretation, shading, rest areas, and marketing, so that visitor pressure on the Treasury and the Siq is gradually reduced without lowering overall satisfaction. Third, prioritize interventions that are reversible, low-maintenance, and locally manageable—such as truss-based platforms, ambient low-light installations, and community-run services—because Petra’s environment and heritage status do not tolerate heavy, permanent infrastructure. Together, these measures can enhance visitor experience, protect fragile features, and maintain the site’s economic contribution even under fluctuating tourist numbers.

Future Research Directions

Future studies on geo-tourism in Petra should broaden the temporal and spatial resolution of the current GIS-based pole–axis approach. Instead of relying on a single observation window, researchers can integrate multi-season datasets (winter vs. peak summer) and event-based datasets (Ramadan, public holidays, extreme weather closures) to capture how visitor behavior deviates from the “standard” linear route. Another promising direction is coupling movement data with microclimate layers to

see how heat, shade, and wind exposure affect the decision to continue toward distant sites such as Ad-Deir. Integrating social media geotags with official PDTRA counts would also help validate informal flows and identify emerging attractions outside the canonical corridor. Finally, agent-based simulation could be used to test hypothetical management scenarios—such as opening a night trail or adding shaded rest nodes—before physically investing in them, thus reducing risk for the site authority.

Implications for Policy

The analysis shows that Petra's visitor flows are highly concentrated, seasonally variable, and sensitive to regional shocks; therefore, policy should move from static regulations to adaptive, data-informed management. This means linking entry quotas, internal transport schedules, and opening hours to real-time or near-real-time indicators of crowding on the main axis (Visitor Center → Siq → Treasury). Climate constraints—high summer temperatures and short winter days—further justify policies that allow for flexible lighting schemes, temporary closures of vulnerable nodes, and redistribution of visitors to secondary routes. Policies should also formalize the role of local communities in operating low-cost, low-impact services such as lantern trails or guided evening walks, ensuring that economic incentives align with conservation goals. Importantly, data standards and sharing protocols between PDTRA, the Ministry of Tourism, and research partners should be instituted so that policy decisions are continuously fed by updated spatial evidence rather than occasional counts.

Citation: Wang, T., Ghani, I., Ahmad, S., & Rahman, N.A. (2026). Rural cultural landscapes as pathways to sustainable cultural transmission: Geosite tourism perspectives from traditional villages in Central Shandong, China. *Geojournal of Tourism and Geosites*, 67(3), 1994–2007. https://doi.org/10.30892/gtg.67315-1827

Abstract: This study provides a comprehensive examination of the mechanisms through which rural cultural landscape identity and active community participation contribute to sustainable cultural transmission. By viewing these dynamics through the lens of geosite tourism, the research examines three distinct traditional villages in Central Shandong, China. To ensure a holistic analysis, the study adopted a rigorous mixed-methods design. This methodological approach integrated quantitative data obtained from a survey of local residents (n=286) with qualitative depth derived from semi-structured interviews (n=20). Advanced data analysis using Structural Equation Modelling (ADANCO) was employed to test the hypothesized relationships. The empirical results indicate that a strong sense of landscape identity significantly strengthens community participation. Furthermore, this participation, when integrated with geosite tourism development activities, acts as a crucial mediator that indirectly supports the long-term transmission of cultural heritage. A key finding of the research is the role of policy support; the study demonstrates that government backing amplifies this positive pathway, acting as a vital moderating variable. These findings offer important implications for heritage management. They suggest that geosite-based tourism is a viable strategy for sustaining living heritage, provided that it is implemented correctly. Specifically, the model shows that sustainable outcomes are most likely achieved when community roles are clearly defined and when explicit governance support is present to guide the development process.

Keywords: rural cultural landscape, geosite tourism, sustainable cultural transmission, traditional villages, Central Shandong, community participation, landscape identity

INTRODUCTION

Research Background

Across China's countryside, traditional villages are undergoing rapid transformation driven by urbanization, outmigration, and land-use change. However, these settlements remain important repositories of vernacular architecture, ecological knowledge, and collective memory. The concept of rural cultural landscapes highlights the co-evolution of natural topography, human settlement, and symbolic meaning (Sauer, 1925; Cosgrove, 1998).

In the Central Shandong region—characterized by mountain–plain transitions and extensive stone-built village forms—landscape elements such as dwellings, terraces, and ritual spaces function as "archives" that embody historical land-use practices and local cultural values (Pan et al., 2024; Yu et al., 2016). In recent years, geotourism and geosite-based tourism have been proposed as tools to support rural revitalization while strengthening geoconservation and visitor education (Dowling, 2013; Dowling & Newsome, 2018; Farsani et al., 2011). Within UNESCO Global Geoparks, geological heritage is interpreted together with local culture and livelihoods, offering an institutional framework for integrating geoconservation, community development, and tourism management (Henriques & Brilha, 2017; Ólafsdóttir & Dowling, 2014).

This framing is particularly relevant in settings where geological features and vernacular building traditions are closely interlinked, such as the stone-built villages of Central Shandong (Pan et al., 2024). However, tourism-led revitalization also introduces risks. Heritage commodification, uneven benefit distribution, and "museumification" can undermine the living character of rural culture when local agency is weak (Goodwin, 2016; Smith & Waterton, 2009).

Ensuring that tourism development remains compatible with cultural integrity and ecological limits, therefore, requires careful governance arrangements and meaningful community participation (Scheyvens, 1999; Choi & Sirakaya, 2006). Existing work on rural revitalization and tourism development in China has tended to prioritize economic performance and infrastructure outcomes, while the cultural-landscape mechanisms that sustain identity and intergenerational transmission

receive comparatively less empirical attention (Yu et al., 2016; Li et al., 2020). Likewise, tourism studies often assess impacts and destination management without modelling the psychosocial pathways through which residents' place identity motivates participation and, ultimately, cultural transmission (Proshansky et al., 1983; Scannell & Gifford, 2010).

This study addresses these gaps by testing an integrated model linking cultural landscape identity, community participation, geosite tourism development, and policy support. Therefore, there exists a crucial gap in understanding the psychosocial pathways linking landscape identity, community participation, and geosite tourism outcomes.

Without addressing these mechanisms, sustainability discourses risk being superficial—celebrating preservation rhetoric without ensuring intergenerational cultural vitality. This study attempts to bridge this gap by developing a rigorous empirical model that combines qualitative insights with quantitative SEM analysis.

Research Objectives and Questions

The study aims to identify and evaluate the key variables influencing sustainable cultural transmission within rural cultural landscapes. Its specific objectives are:

1. To examine how cultural landscape identity influences community participation and sustainable cultural transmission in traditional villages.
2. To analyze the mediating role of geosite tourism development in the relationship between landscape identity and cultural sustainability.
3. To assess the moderating impact of policy support on the link between participation and transmission.
4. To provide policy recommendations for balancing heritage conservation with rural economic revitalization in Central Shandong.

Accordingly, the core research questions are:

1. How do residents' attachments to rural cultural landscapes translate into active participation in heritage conservation?
2. In what ways does geosite tourism serve as a mediating mechanism for sustainable cultural transmission?
3. What role does supportive governance play in strengthening or weakening these relationships?

Research Contributions

This research contributes to the interdisciplinary intersection of cultural geography, sustainable tourism, and heritage management. Conceptually, it advances the understanding of rural cultural landscapes not merely as aesthetic environments but as living systems of cultural reproduction. In practice, it offers empirical guidance to policymakers, especially in Shandong's county-level planning units, on designing tourism interventions that reinforce local identity rather than replace it.

By positioning geosite tourism as both an economic catalyst and a cultural–educational process, the study explains how geoconservation-oriented interpretation (e.g., trails, signage, and storytelling) can reinforce residents' sense of place while enhancing visitor understanding (Gordon, 2018; Henriques & Brilha, 2017). The findings provide evidence to support geopark managers and rural revitalization programs in designing tourism interventions that strengthen—rather than displace—community-led heritage practices (Scheyvens, 1999; Lee & Jayakumar, 2021).

Hypothesis Model

The hypothesis model proposes an integrated pathway through which rural cultural landscapes support sustainable cultural transmission (Figure 1). Cultural Landscape Identity is conceptualized as an exogenous driver that shapes residents' perceptions, values, and engagement with their environment, thereby motivating greater involvement in community-level cultural and tourism activities. This influence operates primarily through Community Participation, which serves as the first mediating construct, transforming identity-driven attachment into collective action that supports heritage maintenance and local decision-making. Geosite Tourism Development forms the second mediating mechanism by converting participation into structured interpretive and livelihood activities that reinforce both geological and cultural knowledge. Sustainable Cultural Transmission is positioned as the ultimate outcome, reflecting the extent to which cultural practices, ecological wisdom, and collective memory are maintained across generations.

The model further incorporates Policy Support as a moderating factor that strengthens or weakens the influence of participation on cultural transmission. Supportive governance, training, and institutional frameworks are therefore expected to amplify the positive effects of participation, ensuring that tourism and heritage initiatives translate into long-term cultural continuity. Through these relationships, the model captures a social ecological system in which identity, participation, tourism development, and policy interact to sustain rural cultural landscapes.

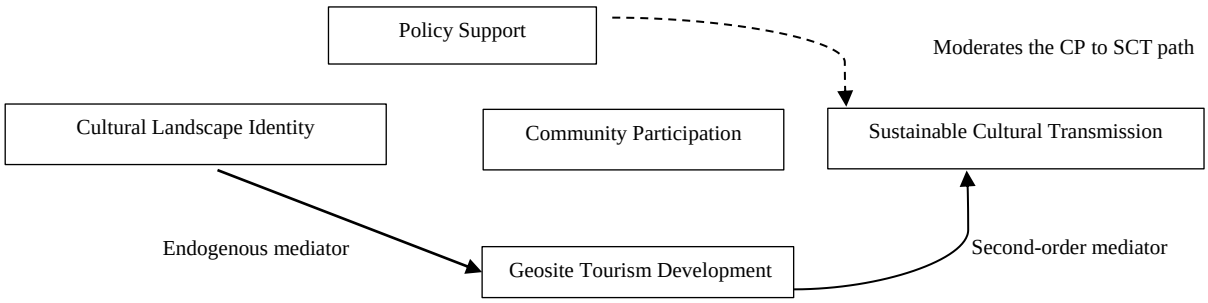

Figure 1. The hypothesized relationships among the variables

LITERATURE REVIEW

Cultural Landscape Identity and Community Participation

Rural cultural landscapes in traditional villages embody "living heritage" values that are enacted through everyday spatial practice, ritual routines, and community governance. Recent work reframes place/cultural landscape identity in traditional village conservation as a dynamic, enacted construct structured by emotional attachment, symbolic meaning, continuity, and behavioral commitment, with intergenerational transmission and collective obligation central to identity formation (Wang et al., 2025). In parallel, contemporary heritage scholarship on the social value of built heritage argues that local communities' recognition of heritage value—and their position as legitimate "heritage communities"—is pivotal for shifting conservation from expert-centric control to participatory decision-making and stewardship (Rossitti et al., 2025). In rural revitalization and heritage preservation, community participation is sustained when governance arrangements and financing instruments enable genuine bottom-up involvement while coordinating across institutional levels (Li & Cantini, 2025). Domain-wide evidence further indicates that traditional village research has increasingly shifted from material protection to system governance and multi-actor coordination, with "community participation and governance resilience" and "land use and policy intervention" emerging as major thematic clusters (Bai et al., 2026).

Empirical evidence from cultural heritage conservation research also suggests that place attachment and differentiated perceptions of heritage value can shape participation intentions across generations (Wang et al., 2025). Conversely, when tourism or conservation interventions compress rehearsal windows, re-script rituals for display, or reproduce governance asymmetry, residents' behavioral commitment may weaken, and participation becomes more fragile (Wang et al., 2025; Li & Cantini, 2025). Therefore, the following hypothesis is proposed:

H1: Cultural landscape identity significantly influences community participation.

Community Participation and Sustainable Cultural Transmission

Sustainable cultural transmission depends on the continuity of living practices, knowledge, and social relations that enable intergenerational learning and adaptation. Recent heritage research emphasizes that safeguarding living heritage requires community participation, as it anchors cultural practice in everyday routines and local governance rather than treating heritage as a static product (Rossitti et al., 2025; Li & Cantini, 2025). At the macro level, evidence from China shows that the development of intangible cultural heritage (ICH) and tourism interact dynamically over time, indicating a coupled evolution shaped by broader institutional and regional conditions (Du et al., 2024).

Participation supports cultural transmission through three mechanisms. First, it enables practice-based learning: cultural skills and narratives are acquired through doing—e.g., guiding, interpretation, ritual organization, and collective maintenance—rather than via passive observation. Second, it maintains governance continuity, protecting apprenticeship opportunities and community rules that structure the temporal rhythm of cultural practice (Wang et al., 2025). Third, it supports adaptive reinvestment when communities have stable roles and institutions to channel tourism-related benefits into cultural education and stewardship, a logic highlighted in revitalization policies that pair citizen-based initiatives with enabling finance and coordinated action (Li & Cantini, 2025; Bai et al., 2026). Accordingly:

H2: Community participation significantly influences sustainable cultural transmission.

The Mediating Role of Geosite Tourism Development

Geosite-based tourism development can act as an operational bridge between identity and cultural transmission by translating place meanings into interpretive encounters and locally embedded livelihood opportunities. The UNESCO geopark toolkit positions geotourism as an approach that integrates geoheritage conservation, education, and local sustainable development, while explicitly stressing that effective geotourism requires community engagement, stakeholder coordination, high-quality interpretation, and benefit-sharing (UNESCO, 2024). In geopark practice, community-based evidence indicates that local residents perceive greater economic, social, and environmental benefits when geopark initiatives align with community aspirations and involve meaningful participation (Louis et al., 2025).

Community-based geotourism research further shows that local wisdom, community participation, and geopark-oriented tourism can be combined to support destination stewardship and locally grounded development (Sumarmi et al., 2026).

The mediating mechanism can be conceptualized in three stages. First, interpret geological significance alongside cultural landscape narratives through geotrails, signage, guiding, and storytelling. Second, community participation strengthens this interpretive work when vernacular knowledge and locally rooted narratives are incorporated into interpretive design and communication products; recent studies show participatory tools can enhance a sense of belonging and improve the long-term effectiveness of geotourism initiatives (Guerini et al., 2026a; Guerini et al., 2026b).

Third, stakeholder arrangements determine whether participation is institutionalized: stakeholder analyses in geotourism development highlight the need to clarify roles and manage influence among government, community, and other actors to secure participatory planning and implementation (Hadian et al., 2025). Beyond geopark governance, geosite and geoheritage assessment research indicates that itineraries combining cultural heritage elements and geosite can support sustainable local development strategies, illustrating the feasibility of integrated cultural–geological products (Carrión-Mero et al., 2021). Taken together, these insights suggest that geosite tourism development can mediate the relationship between cultural landscape identity and sustainable cultural transmission.

H3: Geosite tourism development mediates the relationship between cultural landscape identity and sustainable cultural transmission.

Policy Support as Moderator

Policy frameworks shape whether participatory heritage and geotourism pathways can be sustained by influencing resources, regulatory clarity, institutional incentives, and the degree to which communities can exercise agency. Comparative evidence from heritage preservation in revitalization contexts indicates that community involvement is more effective when citizen-based initiatives are supported by enabling laws, financing mechanisms, and specialized agencies that coordinate multi-level action (Li & Cantini, 2025). At the research-domain level, policy intervention is now a major thematic cluster alongside participation and governance resilience in traditional village sustainability studies, reflecting a shift toward system governance and multi-actor coordination (Bai et al., 2026). Evidence from cultural-policy implementation also indicates that preservation outcomes depend on institutional coordination, community acceptance, and the translation of policy objectives into locally workable practices (Hai, 2025).

Within geopark management, UNESCO guidance emphasizes that geotourism development requires explicit governance arrangements for community involvement and benefit-sharing (UNESCO, 2024). In traditional village conservation, policy misalignment and governance asymmetry can undermine behavioral commitment; conversely, policy instruments that protect practice spaces, support training and interpretation capacity, and stabilize participation rules can strengthen participation-to-transmission outcomes (Wang et al., 2025; UNESCO, 2024). Therefore:

H4: Policy support significantly moderates the relationship between community participation and sustainable cultural transmission.

Integrated Pathways among Identity, Participation, and Tourism

An integrated approach to rural cultural sustainability requires analyzing identity, participation and geosite tourism as a coupled socio-cultural system. Place identity research in traditional villages increasingly frames identity as enacted through ritual practice, communal labor and everyday stewardship, and proposes operational levers to translate identity into governance and conservation action (Wang et al., 2025). Social-value scholarship likewise argues that heritage significance is sustained through community recognition and participation, aligning conservation with social well-being rather than fabric-focused protection alone (Rossitti et al., 2025). In geopark contexts, community perspective research shows that perceived benefits and social cohesion are strengthened when communities are meaningfully engaged in geotourism initiatives (Louis et al., 2025), while participatory tool studies highlight how integrating vernacular knowledge into interpretive design fosters belonging and supports the long-term success of geotourism (Guerini et al., 2026a). Together, these studies suggest a cyclical pathway: cultural landscape identity motivates participation; participation enables geosite interpretation and tourism development through stakeholder coordination; and well-governed tourism reinforces identity and supports cultural continuity through recognized roles, learning opportunities, and reinvestment into practice (UNESCO, 2024; Bai et al., 2026). Hence:

H5: Cultural landscape identity exerts an indirect effect on sustainable cultural transmission through the combined mediation of community participation and geosite tourism development.

Theoretical Framework

This study integrates recent theory and evidence from three complementary strands to explain how rural cultural landscapes influence community behavior and cultural continuity in geosite-based tourism settings. First, contemporary place-identity work in traditional village conservation conceptualizes identity as an embodied, enacted assemblage structured by emotional attachment, symbolic meaning, continuity and behavioral commitment, foregrounding intergenerational mechanisms and governance conditions as key determinants of identity outcomes (Wang et al., 2025).

Second, people-centered heritage governance and social-value scholarship argue that heritage significance is sustained through community recognition and meaningful involvement in assessment, decision-making and management, rather than through expert-centric or fabric-focused protection alone (Rossitti et al., 2025; Li & Cantini, 2025). Third, geopark and geotourism management guidance frames geotourism as an approach that links geoheritage conservation and education with local development, requiring participatory governance, clear stakeholder roles, and benefit-sharing to deliver sustainable outcomes (UNESCO, 2024; Hadian et al., 2025; Louis et al., 2025). On this basis, cultural landscape identity is treated as a motivating condition that activates behavioral commitment and willingness to participate in heritage and tourism governance (Wang et al., 2025). Community participation is conceptualized as meaningful involvement in planning, interpretation and management that sustains practice-based learning and living-heritage continuity (Rossitti et al., 2025). Geosite tourism development is operationalized as the organizational and interpretive process that translates geological and cultural meanings into tourism products. Recent evidence shows that integrating participatory tools and vernacular knowledge can strengthen community belonging and improve long-term effectiveness in geotourism initiatives (Guerini et al., 2026a; Guerini et al., 2026b). Policy support is positioned as an enabling condition that shapes the durability of participation-to-transmission pathways, consistent with emerging evidence that policy intervention and multi-actor coordination are increasingly central to traditional village sustainability governance (Li & Cantini, 2025; Bai et al., 2026).

Accordingly, the theoretical model in Figure 2 posits that cultural landscape identity initiates community participation, thereby promoting geosite tourism development and supporting sustainable cultural transmission. Community Participation and Geosite Tourism Development serve as sequential mediators, while Policy Support moderates the influence of participation on cultural outcomes. This structure aligns with recent geopark guidance emphasizing participatory governance and with the broader evolution of traditional village research toward system governance and multi-subject coordination (UNESCO, 2024; Bai et al., 2026).

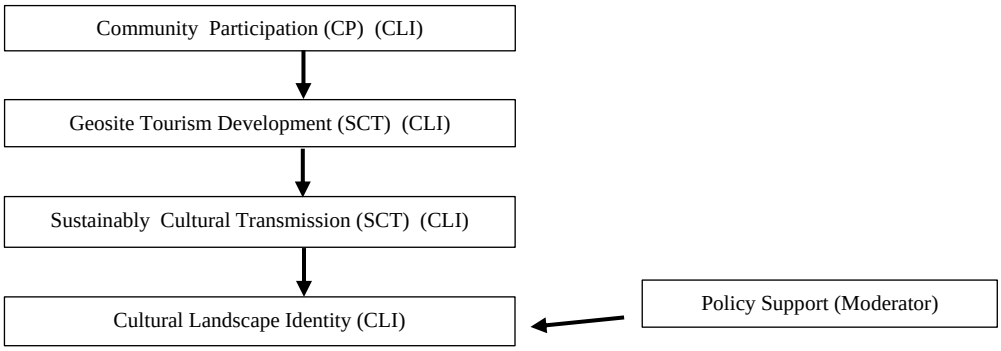

Figure 2. Theoretical model of rural cultural landscape sustainability

MATERIALS AND METHODS

Research Design

This study adopts a mixed-methods design combining quantitative survey analysis with qualitative interviews to examine the relationships among cultural landscape identity (CLI), community participation (CP), geosite tourism development (GTD), policy support (PS), and sustainable cultural transmission (SCT). Following the model structure outlined in Figure 2, partial least squares structural equation modelling (PLS-SEM) was conducted using ADANCO 2.3 to evaluate direct, indirect, and moderating effects. The qualitative follow-up phase was used to clarify the mechanisms underlying the statistical relationships, and the two strands were integrated during interpretation. This design supports methodological triangulation between statistical testing and contextual explanation (Creswell & Plano Clark, 2018). The methodological workflow is summarized in Figure 3.

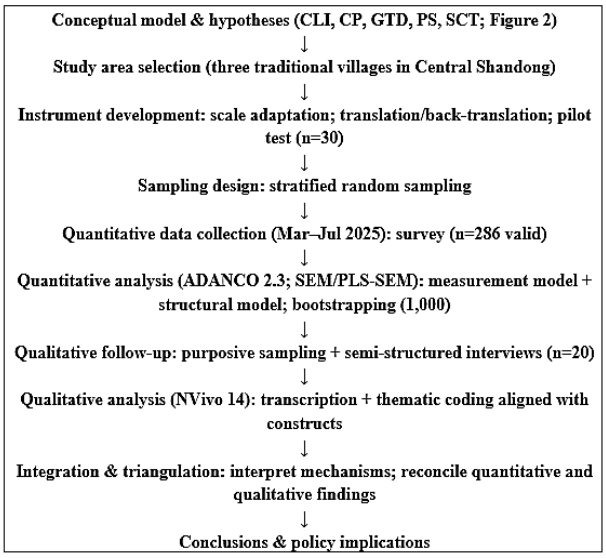

Figure 3. Methodological flow chart of the study (Note: CLI = cultural landscape identity; CP = community participation; GTD = geosite tourism development; PS = policy support; SCT = sustainable cultural transmission)

Study Area: Traditional Villages in Central Shandong

The study was conducted across three representative heritage villages in Central Shandong Province, each reflecting distinct geomorphological and cultural characteristics. Zhujiayu Village is a well-preserved Ming and Qing-era Mountain village located about 45 km east of Jinan in Shandong Province, known for its historic architecture and scenic landscape. Fangyu Village, situated in a valley in Xiaoli Town of Changqing District, Jinan, is characterized by its traditional stone-built layout and rich Qing-era architectural heritage. Lijiatuan Village, located southwest of Wangcun Town in Zibo City, is noted for its more than 400 preserved Ming and Qing buildings and is designated as a nationally famous historical and cultural village. All three sites lie within a radius of approximately 120 kilometres, collectively spanning a range of landforms from karst environments to alluvial plains. Each village is officially recognized on provincial-level Traditional Village Protection Lists, reflecting its cultural and environmental significance.

Population and Sampling

The study targeted residents, tourism practitioners, and local officials directly involved in heritage conservation or tourism management. Using stratified random sampling, 286 valid questionnaires were collected between March and July in 2025. Strata included (a) villagers engaged in cultural or tourism activities (65 %), (b) small business operators (20 %), and (c) local administrative representatives (15 %). The sample size satisfies SEM recommendations of at least 10 observations per indicator (Hair et al., 2017). Demographic characteristics are summarized in Table 1.

Table 1. Demographics of respondents (n=286)

Variable	Category	Frequency (n)	Percentage (%)
Gender	Male	150	52.4
	Female	136	47.6
Age	18–30 years	62	21.7
	31–50 years	144	50.3
	Above 50 years	80	28.0
Education	Primary	58	20.3
	Secondary	148	51.7
	Tertiary	80	28.0
Occupation	Farmer / artisan	120	42.0
	Tourism worker	76	26.6
	Local official / committee member	90	31.4

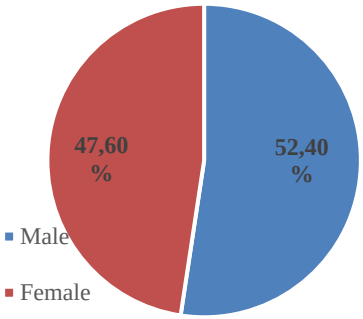

Figure 4. Gender

As shown in Figure 4, the sample was relatively balanced by gender, with 52.4% male and 47.6% female respondents. Figure 5 indicates that respondents aged 31–50 formed the largest age group (50.3%), followed by those above 50 (28.0%) and those aged 18–30 (21.7%). Figure 6 shows that 51.7% of respondents had secondary education, 28.0% had tertiary education, and 20.3% had primary education. Figure 7 presents the occupational distribution: farmers and artisans accounted for 42.0% of the sample, local officials or committee members for 31.4%, and tourism workers for 26.6%. Together, these distributions represent resident, heritage-practice, tourism, and administrative stakeholder groups.

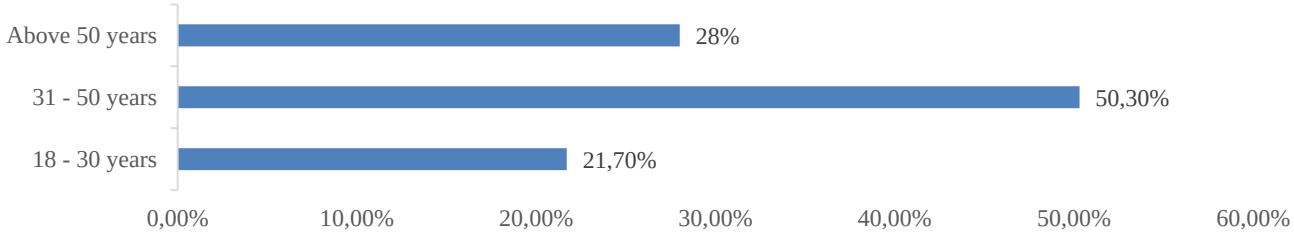

Figure 5. Age

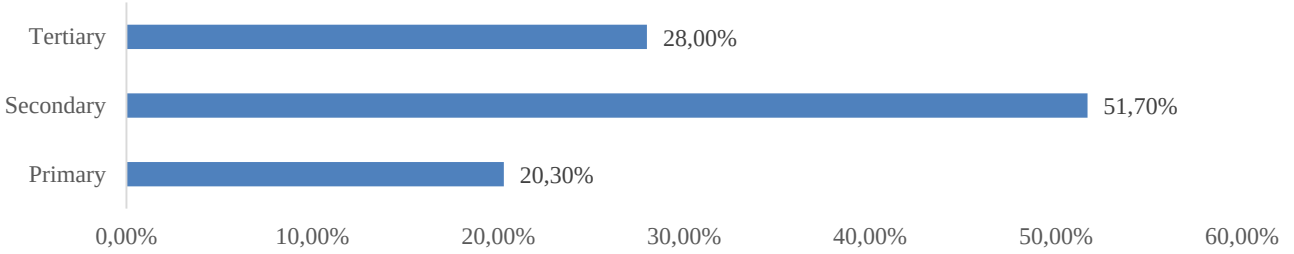

Figure 6. Educational Background

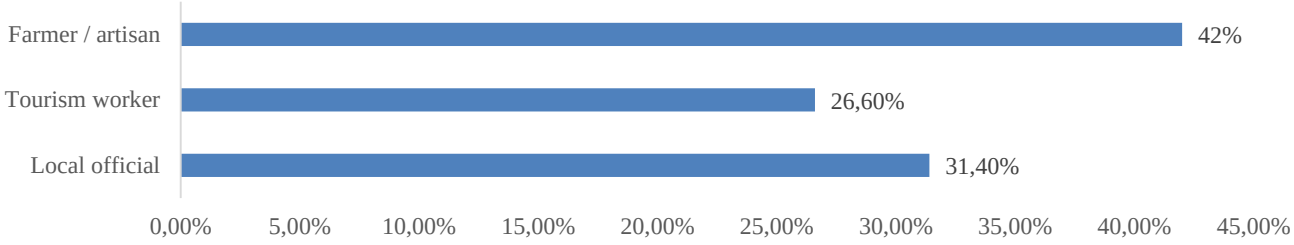

Figure 7. Occupational Diversity

Instrumentation and Measurement Scales

Questionnaires were developed from validated scales adapted to the rural Chinese context. Items used a five-point Likert scale (1 = Strongly Disagree to 5 = Strongly Agree). The instrument underwent translation–back-translation and pretesting with 30 respondents to ensure clarity. Reliability was ensured through Cronbach's $\alpha > 0.70$, and validity was confirmed via factor analysis.

Interview Design

To complement quantitative results, 20 semi-structured interviews were conducted with local artisans, tourism entrepreneurs, elders, and policy officers. The aim was to capture nuanced perceptions of landscape identity and cultural transmission. The interview component of the study was guided by a series of open-ended questions designed to capture residents' perceptions of landscape, culture, and tourism. Participants were asked to describe the relationship between their village landscape and local traditions, as well as the changes introduced by geosite tourism to daily life and cultural practices. They were invited to explain how villagers participate in decision-making related to heritage conservation or tourism development, and to discuss the types of government or policy support available to them. Additional questions focused on how

traditional skills, rituals, and stories are transmitted to younger generations, and whether tourism is perceived as a force that supports or threatens cultural values. Finally, participants reflected on how their village might achieve a balance between economic growth and cultural preservation. Interviews were conducted in Mandarin and local dialects, audio-recorded with consent, and later coded thematically using NVivo 14 to identify recurring themes aligned with model constructs. Table 2 summarizes the constructs, item counts, adapted sources, and representative questionnaire statements.

Table 2. Questionnaire Profile

Construct	Items	Scale Source (Adapted)	Example Statement
Cultural Landscape Identity (CLI)	5	Proshansky et al. (1983); Scannell & Gifford (2010)	"The landscape of my village represents who we are as a community."
Community Participation (CP)	5	Choi & Sirakaya (2006); Su & Wall (2014)	"I am actively involved in decisions concerning village tourism."
Geosite Tourism Development (GTD)	6	Dowling & Newsome (2018); Gordon (2018); Ólafsdóttir & Dowling (2014)	"Geosite tourism projects in our village highlight geological and cultural heritage together."
Policy Support (PS)	4	Xu & Wu (2022); He et al. (2025)	"Local government provides sufficient support for cultural landscape conservation."
Sustainable Cultural Transmission (SCT)	5	Smith & Waterton (2009); Ingold (2011); Wang et al. (2024)	"Traditional crafts and stories are being passed effectively to younger generations."

Data Collection and Analysis

Data collection proceeded in two sequential phases aligned with the mixed-methods design. In the quantitative phase, enumerators distributed printed questionnaires during village meetings and tourism-related workshops, and respondents completed the forms anonymously to reduce social desirability bias. In the qualitative follow-up phase, participants were purposively selected from different stakeholder groups to deepen the interpretation of the quantitative relationships. Quantitative data were analyzed using ADANCO 2.3. The assessment covered Dijkstra–Henseler's rho_A, composite reliability, average variance extracted, Cronbach's alpha, the Heterotrait–Monotrait (HTMT) ratio, R^2, Q^2predict, RMSE, and MAE. Bootstrapping with 1,000 resamples was used to assess the significance of structural paths and specific indirect effects. Qualitative interview data were analyzed thematically in NVivo 14, and the resulting themes were used to contextualize how cultural landscape identity motivates participation and how policy support shapes cultural transmission practices.

Ethical and Validity Considerations

Ethical protocols included anonymity, informed consent, and voluntary withdrawal. Construct validity was strengthened through pilot testing, expert consultation, and triangulation across data types. Internal validity was maintained by controlling for socio-demographic variables (age, gender and education). External validity is supported through multiple case-site comparisons within Central Shandong.

RESULTS AND DISCUSSION

This section presents the empirical findings from the quantitative analysis, enriched by qualitative insights. The results are organized into measurement reliability and validity, the measurement model, structural model fit, and hypothesis testing via path analysis. Consistent with the analytical framework, we examined direct effects (CLI → CP and CP → SCT), a mediating effect (CLI → GTD → SCT), and a moderating effect (PS × CP → SCT). Bootstrapping (1,000 resamples) confirmed the significance of these relationships at the 0.05 or 0.01 levels. The detailed results are presented below.

Reliability and Validity Assessment

We first assessed the reliability and convergent validity of all constructs. Table 3 shows that Dijkstra–Henseler's ρA, composite reliability (ρc), and Cronbach's α for each latent construct all exceed the recommended threshold of 0.70, and average variance extracted (AVE) values are above 0.50. For example, Cronbach's α values range from 0.80 (CLI) to 0.89 (SCT), and AVEs range from 0.589 to 0.640, indicating sufficient internal consistency and convergent validity. These results confirm that the survey indicators reliably represent their intended latent constructs (Hair et al., 2019).

Table 3. Variables Reliability and Validity

Construct	Dijkstra–Henseler's ρA	Jöreskog's ρc	Cronbach's α	Average Variance Extracted (AVE)
Cultural Landscape Identity (CLI)	0.812	0.848	0.801	0.589
Community Participation (CP)	0.864	0.875	0.857	0.612
Geosite Tourism Development (GTD)	0.887	0.901	0.879	0.623
Policy Support (PS)	0.820	0.853	0.806	0.592
Sustainable Cultural Transmission (SCT)	0.894	0.915	0.885	0.640

Measurement Model Evaluation

The assessment of the measurement model indicates strong item loadings for each construct. As shown in Table 4, almost all indicator factor loadings exceed 0.70, indicating that each measured item has a high shared variance with its construct. The few slightly lower loadings (e.g., 0.68) were still close to the cutoff and did not detract from overall model fit. In sum, all items demonstrate high loadings, validating the specified measurement structure.

Table 4. Measurement Items Fitness Statistics

Indicator	CLI	CP	GTD	PS	SCT
CLI1	0.76				
CLI2	0.71				
CLI3	0.82				
CLI4	0.68				
CLI5	0.75				
CP1		0.79			
CP2		0.83			
CP3		0.77			
CP4		0.84			
CP5		0.81			
GTD1			0.86		
GTD2			0.78		
GTD3			0.82		
GTD4			0.74		
GTD5			0.80		
GTD6			0.84		
PS1				0.79	
PS2				0.77	
PS3				0.83	
PS4				0.82	
SCT1					0.85
SCT2					0.83
SCT3					0.77
SCT4					0.79
SCT5					0.82

Discriminant Validity

Discriminant validity was evaluated using the Heterotrait–Monotrait (HTMT) ratio. All inter-construct HTMT values were below 0.85 (Table 5), satisfying the criterion for discriminant validity. This suggests that each construct is empirically distinct from the others (Henseler et al., 2015). No excessive inter-correlation was observed, indicating no issues of construct redundancy.

Table 5. Discriminant Validity (HTMT Ratios)

Constructs	CLI	CP	GTD	PS	SCT
CLI	—				
CP	0.64	—			
GTD	0.58	0.62	—		
PS	0.41	0.49	0.43	—	
SCT	0.68	0.66	0.59	0.54	—

Model Fit and Explained Variance

The structural model exhibits strong fit and predictive power (Table 6). The R^2 values indicate that the model explains 51.2% of the variance in Community Participation (CP), 66.7% in Geosite Tourism Development (GTD), and 80.3% in Sustainable Cultural Transmission (SCT). In particular, the R^2 for SCT is 0.803, suggesting that over 80% of the variance in the key outcome is accounted for by the integrated model – a substantial effect (Chin, 2010). Predictive relevance (Q^2) values for the endogenous constructs are also high (e.g., $Q^2 = 0.653$ for SCT), and the model's low RMSE and MAE further confirm its accuracy. Collectively, these metrics demonstrate a robust model with excellent explanatory capability.

Table 6. R-square Statistics and Model Goodness-of-Fit

Construct	R^2	Adjusted R^2	Q^2predict	RMSE	MAE
Community Participation (CP)	0.512	0.507	0.412	0.063	0.079
Geosite Tourism Development (GTD)	0.667	0.662	0.518	0.056	0.074
Sustainable Cultural Transmission (SCT)	0.803	0.799	0.653	0.052	0.071

Variables Effects Overview

Table 7 summarizes the direct, indirect, and total effects among the constructs, along with effect size (Cohen's f^2). All path coefficients are positive and statistically significant, as hypothesized. For instance, cultural landscape identity (CLI) has a strong direct influence on community participation ($\beta = 0.715$) and also a sizable total effect on sustainable cultural transmission ($\beta\_total = 0.765$), combining direct and indirect paths. Community participation shows a moderate direct effect on cultural transmission ($\beta = 0.462$), while geosite tourism development has a comparable direct effect ($\beta = 0.503$). The interaction term (PS × CP) for policy support and participation has a positive coefficient ($\beta = 0.294$), indicating a strengthening effect. Cohen's f^2 values for the significant paths are all above 0.25, denoting medium to large effect sizes.

Table 7. Variables Effects Overview

Effect	Direct Effect (β)	Indirect Effect (β)	Total Effect (β)	Cohen's f²
CLI → CP	0.715	—	0.715	0.51
CLI → GTD	0.428	0.219 (via CP)	0.647	0.37
CP → SCT	0.462	—	0.462	0.42
GTD → SCT	0.503	—	0.503	0.46
CLI → SCT	0.237	0.528 (via CP, GTD)	0.765	0.63
PS × CP → SCT (moderation)	0.294	—	0.294	0.29

Structural Model Estimation

Figure 8 illustrates the standardized path coefficients in the structural model. All hypothesized paths are supported by the data at $p < 0.05$ based on bootstrapped standard errors. The overall pattern of relationships confirms a well-fitting structural model. In summary, cultural landscape identity drives community participation, which in turn stimulates geosite tourism development, ultimately leading to sustainable cultural transmission. Moreover, policy support reinforces the link between participation and cultural transmission. This indicates that the presence of supportive policies enhances the positive impact of community engagement on sustainability outcomes. The significance of all key paths suggests that the proposed model is both statistically robust and substantively meaningful.

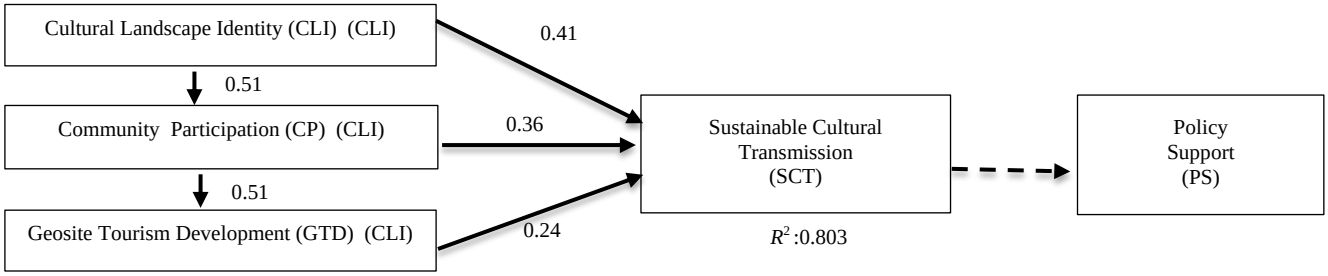

Figure 8. Estimated Structural Model for Path Analysis

Path Analysis

We tested five specific hypotheses (H1–H5) corresponding to the direct, mediated, and moderated relationships in the framework. The path analysis results (Table 8) show that all hypothesized effects are statistically significant (t-values well above 2.0, $p < 0.05$). In line with expectations, there are significant direct effects of CLI on CP (H1) and CP on SCT (H2), a significant mediating effect of GTD in the CLI → SCT relationship (H3), and a significant moderating effect of PS on the CP → SCT relationship (H4). The compound indirect pathway CLI → CP → GTD → SCT (H5) is also supported (β_indirect ≈ 0.24, $p < 0.05$), confirming a sequential mediation through participation and tourism. These findings align with our analytical framework. All five hypotheses (H1–H5) are supported by the data, and the presence of both mediation and moderation effects is confirmed, consistent with prior theoretical expectations.

Table 8. Path Analysis Results

Path	β (Standardized)	STDEV	t-statistic	p-value	Hypothesis Supported?
H1: CLI → CP	0.715	0.091	7.857	0.000	Yes
H2: CP → SCT	0.462	0.128	3.609	0.000	Yes
H3: GTD mediates CLI → SCT	0.528	0.156	3.385	0.001	Yes
H4: PS moderates CP → SCT	0.294	0.137	2.146	0.032	Yes
H5: CLI → CP → GTD → SCT (indirect)	0.237	0.104	2.279	0.023	Yes

Interpretation of Key Findings

To interpret the practical meaning of these results, we examine each relationship in turn, integrating interview evidence to illustrate the dynamics:

(a) Cultural Landscape Identity → Community Participation: The coefficient for CLI → CP is $\beta = 0.715$ ($p < 0.001$), indicating that residents with strong attachment to their cultural landscape are substantially more active in community tourism and heritage initiatives. Interview narratives corroborate this pattern. One villager expressed a deep pride in the village's limestone architecture and heritage, stating: *"Our stone houses show the strength of our ancestors."* This quote exemplifies how a strong sense of place-based identity can serve as an intrinsic motivator for collective action: when residents feel that their environment and traditions are part of who they are, they are more likely to participate in communal efforts to sustain them (Proshansky et al., 1983; Scannell & Gifford, 2010).

(b) Community Participation → Sustainable Cultural Transmission: The positive link between participation and cultural transmission ($\beta = 0.462$, $p < 0.001$) confirms that active community engagement leads to more effective intergenerational knowledge transfer. Villagers who take part in tourism committees, local festivals, or craft cooperatives tend to be the ones imparting traditions and skills to the youth. One interviewee described how involving young people in tourism activities becomes a form of education: *"Younger villagers join guide teams and learn stories of the mountains."* By guiding visitors

around local geosites and cultural landmarks, young residents can learn oral histories and stewardship practices from elders while building capacities for community-based tourism. Such participation functions as a "living classroom," supporting both learning and transmission through practice (Su & Wall, 2014; Wang et al., 2024). In essence, when community members—especially the younger generation—are actively engaged, they become both learners and transmitters of culture.

(c) Mediating Role of Geosite Tourism Development: The mediation analysis shows that CLI influences SCT in part through geosite tourism development (indirect effect $\beta \approx 0.53$, $p = 0.001$). In practice, this means geosite-focused tourism provides a critical pathway for translating landscape identity into sustainable cultural practices. Through geosite tourism, the unique geological features of the village (such as caves, springs, and stone formations) are leveraged in tourism narratives that also highlight local history and customs. As one resident observed, the geological attractions often draw visitors initially, but it is the living culture that truly engages them: *"Tourists come for rocks but stay for our culture."*

This insight illustrates how geosite tourism can act as a bridge between natural heritage and cultural exchange. By integrating geo-interpretation with local storytelling, tourism development can create educational encounters for visitors and livelihood opportunities for residents, while maintaining attention to geoconservation principles (Dowling, 2013; Gordon, 2018). This dynamic aligns with UNESCO Global Geopark practice, which emphasizes the integration of geoscience education, local culture, and sustainable development (Henriques & Brilha, 2017; Lee & Jayakumar, 2021).

(d) Moderating Role of Policy Support: Policy support significantly strengthens the impact of community participation on cultural transmission (interaction effect $\beta = 0.294$, $p = 0.032$). In villages where local government and institutions provide subsidies, grants, or training programs, the positive effects of community efforts are amplified. Conversely, without supportive policies, even enthusiastic local initiatives may struggle to sustain momentum. One villager highlighted the value of government subsidies for heritage projects: "Subsidies help us repair old roofs and create exhibits." This finding underscores the importance of enabling governance and multi-level policy alignment in sustaining rural cultural landscapes. Policy instruments such as maintenance grants, training programs, and regulatory protection can transform community enthusiasm into durable capabilities for heritage management and tourism service quality (Xu & Wu, 2022; He et al., 2025).

(e) Integrated Effects and Model Strength: Finally, the combined model demonstrates a powerful integrated effect. The high R^2 for sustainable cultural transmission (0.803) indicates that about 80% of the variance in cultural sustainability outcomes is explained by the joint influence of landscape identity, community participation, geosite tourism, and policy support. This highlights that none of these factors alone is sufficient; rather, it is their interaction in a coherent system that produces strong results. In traditional village settings, a self-reinforcing cycle appears to take hold: identity drives participation, participation facilitates tourism development, and supportive policies enhance all these efforts, creating a virtuous circle for cultural transmission. In summary, the quantitative findings, together with qualitative evidence, verify that the presence of all these elements leads to exceptionally robust sustainability of local culture.

Qualitative Triangulation

Qualitative findings from interviews and field observations provide additional depth to the statistical results and illuminate the mechanisms through which cultural sustainability emerges in the study villages. Three major thematic patterns were identified, each aligning closely with the structural relationships in the quantitative model.

First, villagers consistently described the landscape as a form of pedagogy, noting that local mountains, rivers, stone dwellings, and agricultural terraces act as living repositories of history, environmental ethics, and ancestral values. Daily interactions with the landscape enable elders to teach the younger generation about traditional practices and moral principles, reinforcing the role of place in cultural education.

Second, tourism was widely viewed as a bridge that connects the community with outsiders, offering both livelihood opportunities and a channel for cultural storytelling. Residents observed that guiding visitors and demonstrating crafts or rituals helped transmit intangible cultural knowledge and enhanced community pride.

Third, participants emphasized that supportive government policies act as catalysts for cultural preservation by providing resources, recognition, and legitimacy to local heritage initiatives. Subsidies for restoration work and training programs were perceived as validating cultural identity and motivating youth participation. Together, these insights demonstrate that sustainable cultural transmission arises where emotional attachment to place, active community engagement, and enabling governance intersect, thereby reinforcing the patterns observed in the quantitative analysis.

Summary of Results

Overall, the study's results provide strong empirical support for all five hypotheses and confirm the proposed integrated model of cultural sustainability in rural geosite contexts. Cultural landscape identity has a significant and positive influence on community participation, which, in turn, contributes directly and indirectly to sustainable cultural transmission. Geosite tourism development serves as a key mediating mechanism, transforming identity-driven participation into culturally meaningful and economically viable practices. Policy support serves as an important moderating factor, enhancing the positive effects of participation by strengthening the institutional and resource foundations for heritage preservation. The structural model exhibits strong explanatory power, accounting for more than 80% of the variance in sustainable cultural transmission, driven by the combined effects of identity, participation, tourism development, and policy support. These findings confirm that cultural sustainability in traditional villages is most effectively achieved when community attachment to place, participatory action, geosite-centered tourism, and supportive governance operate in synergy. By illustrating how these elements interact to sustain both tangible and intangible heritage, the study contributes valuable insights for theory, policy, and rural revitalization practice.

DISCUSSION

This study examined how cultural landscape identity (CLI), community participation (CP), geosite tourism development (GTD), and policy support (PS) jointly shape sustainable cultural transmission (SCT) in traditional villages of Central Shandong, China. Using SEM and triangulated interviews, the findings reveal a coherent, multi-layered process: strong landscape identity motivates local engagement; participation fosters tourism development; geosite tourism mediates the transformation of heritage into sustainable practice; and policy support amplifies these dynamics.

The model achieved an R^2 of 0.803, indicating that the combined influence of identity, participation, geosite tourism, and policy support explains more than 80% of the variance in sustainable cultural transmission. This underscores that cultural transmission in rural landscapes is an integrated socio-ecological process linking people, place, and governance rather than an isolated act of preservation (Antrop, 2005; Soini & Dessein, 2016). The significant positive path ($\beta = 0.715$, $p < 0.001$) affirms that residents with strong identification toward their landscape are more inclined to participate in community and tourism initiatives. This supports *place-identity theory* (Proshansky et al., 1983), which holds that emotional bonds with place drive pro-environmental and communal behaviors. In Central Shandong, villagers' attachment to limestone dwellings, ancestral terraces, and geomantic village layouts provides intrinsic motivation for stewardship.

This result is consistent with place-identity and place-attachment scholarship, which argues that place-based meanings can translate into stewardship and civic engagement, especially when participation structures are credible and inclusive (Proshansky et al., 1983; Scannell & Gifford, 2010). Evidence from heritage management research further suggests that residents' willingness to participate increases when decision-making is transparent and communities perceive tangible cultural and livelihood benefits (Li et al., 2020; Scheyvens, 1999). The positive relationship ($\beta = 0.462$, $p < 0.001$) verifies that participatory governance and collaboration foster sustainable cultural transmission. This resonates with community-based tourism (CBT) theory (Goodwin, 2016) and empowerment theory (Scheyvens, 1999), both arguing that genuine participation generates ownership and resilience. Comparable patterns have been reported in Chinese heritage tourism settings where residents participate in guiding and management at heritage sites, enabling learning and strengthening attachment among younger generations (Su & Wall, 2014). Recent practitioner-based research also suggests that tourism can reshape intergenerational practice of intangible cultural heritage by providing new spaces and incentives for transmission (Wang et al., 2024). The mediation effect ($\beta = 0.528$, $p = 0.001$) confirms that geosite tourism translates cultural identity into sustainability outcomes. By combining geomorphological appreciation with cultural storytelling, tourism enables both economic viability and cultural continuity. This aligns with geotourism theory (Dowling & Newsome, 2018) and landscape ecology principles (Antrop, 2005). The mediation finding is consistent with international geopark and geotourism research showing that geo-interpretation, when connected to local culture, can support both visitor learning and local development (Gordon, 2018; Ólafsdóttir & Dowling, 2014). Studies of UNESCO Global Geoparks also indicate that economic impacts and territorial identity effects are stronger when governance arrangements recognize community roles and foster local ownership (Lee & Jayakumar, 2021; Stoffelen et al., 2019). The moderating role of policy support demonstrates that institutional backing strengthens the link between participation and cultural transmission.

In the geopark and protected-area literature, funding stability, administrative coordination, and participatory governance are repeatedly identified as enabling conditions for community engagement and long-term heritage outcomes (Henriques & Brilha, 2017; Xu & Wu, 2022; Zhuang et al., 2024). Qualitative insights reinforce this: respondents reported that policy programs legitimized their cultural work and encouraged youth involvement. The implication is that decentralized yet consistent governance can transform participation from ad hoc volunteerism into structured cultural entrepreneurship.

The indirect path (CLI → CP → GTD → SCT) illustrates a holistic sustainability chain where identity fuels participation, participation fosters tourism, and tourism ensures transmission. This supports the cultural sustainability framework of Soini & Dessein (2016), highlighting feedback loops between cultural meaning and socio-economic systems. The cyclical reinforcement observed in Shandong—identity strengthened by tourism, tourism sustained by identity—exemplifies what Smith and Waterton (2009) call dynamic heritage reproduction. The study makes theoretical contributions in three interrelated domains. First, it advances Cultural Landscape Theory by operationalizing landscape identity as a measurable construct capable of predicting participatory and behavioural outcomes, thereby extending Sauer's (1925) descriptive work into an empirically testable model. Second, it strengthens the linkage between geotourism and cultural transmission by demonstrating how geological heritage serves as a medium for sustaining intangible cultural knowledge, and by illustrating the interconnectedness of the physical and symbolic dimensions of sustainability, as suggested by Dowling (2013) and Farsani et al. (2011). Third, the study enriches governance perspectives by confirming the moderating influence of policy support, thereby connecting macro-level institutional frameworks with micro-level community participation and adding conceptual clarity to discussions of sustainable rural development.

In comparison with earlier work, our findings reinforce arguments that cultural meaning and local participation are central to sustainable heritage tourism, and that geotourism in protected-area contexts can strengthen place identity when communities are engaged in interpretation and governance (Su & Wall, 2014; Li et al., 2020). While many prior studies focus primarily on built heritage, this study foregrounds the integration of geological heritage with cultural landscape narratives, aligning with geotourism scholarship emphasizing education and geoconservation (Dowling, 2013; Gordon, 2018).

CONCLUSIONS

Theoretical Implications

The study makes several theoretical contributions across interconnected domains. It advances Cultural Landscape Theory by operationalizing landscape identity as a measurable construct that predicts participatory and behavioural

outcomes, thereby extending Sauer's (1925) descriptive foundations into an empirically testable model. It also strengthens the linkage between geotourism and cultural transmission by demonstrating that geological heritage serves as a conduit for sustaining intangible cultural knowledge, thereby illustrating the interdependence of the physical and symbolic dimensions of sustainability, as described by Dowling (2013) and Farsani et al. (2011). In addition, the findings enrich governance perspectives by confirming the moderating role of policy support, which connects macro-level institutional structures with micro-level community participation, and clarifying how sustainable rural development emerges through such interactions. These contributions broaden cultural landscape and geotourism research by integrating geomorphological heritage and vernacular cultural landscapes within an empirically testable framework, and by showing how enabling governance can amplify community-based cultural transmission (Antrop, 2005; Gordon, 2018; Zhuang et al., 2024).

Practical Implications

For policymakers, the findings underscore the need to embed cultural transmission indicators into rural revitalization assessment systems so that cultural continuity is evaluated with the same rigor as economic development and infrastructure improvements. Incorporating such indicators ensures that policy interventions remain sensitive to heritage dynamics rather than focusing solely on material growth. In addition, providing microgrants and specialized training for community-led interpretive initiatives and craft cooperatives can empower residents to take ownership of heritage stewardship and strengthen local capacities for cultural entrepreneurship. Policy makers should also promote inter-village networks that enable communities to share best practices, jointly develop tourism products, and coordinate landscape-level management strategies, thereby reducing fragmentation and fostering collective resilience. For local communities, the results highlight the importance of integrating youth into heritage tourism activities through structured apprenticeship programs that facilitate hands-on learning and allow younger generations to acquire cultural knowledge directly from experienced elders. Communities can also enhance cultural vitality by developing storytelling platforms that connect geological features with oral histories, ensuring that both the physical environment and its associated meanings are communicated to residents and visitors alike. Furthermore, participatory mapping and community-based monitoring of cultural landscape changes can strengthen local awareness of environmental transformations and support informed decision-making.

For tourism planners and geopark managers, the study demonstrates the value of designing interpretive trails that weave together geomorphological and cultural narratives, helping visitors understand how geological formations and human traditions co-evolve over time. Planners must carefully balance visitor capacity with community well-being and ecological thresholds to prevent overuse and maintain authenticity. Finally, collaborations with academic institutions can support systematic documentation of heritage assets, the development of digital archives, and the creation of innovative interpretive materials that enhance the visibility and long-term preservation of rural cultural landscapes.

Research Limitations and Future Research Directions

Although this study provides important insights into the relationships among cultural landscape identity, community participation, geosite tourism development, and policy support, several limitations indicate directions for future investigation. The research's regional scope is confined to Central Shandong, an area characterized by limestone geomorphology, Confucian landscape traditions, and long-established village settlement patterns. These features may not mirror the cultural–environmental dynamics found in other rural regions of China, such as the karst plateaus of the southwest, the river terrace systems of the Yangtze Basin, or the high-altitude pastoral landscapes of the Tibetan Plateau. Conducting comparative studies across multiple geomorphological and cultural settings would therefore strengthen understanding of the model's generalizability and clarify how environmental context shapes identity formation and cultural transmission.

The temporal structure of the study also presents a limitation, as data were collected at a single point in 2025. Rural tourism and cultural revitalization are dynamic processes influenced by policy changes, migration patterns, and economic cycles. Longitudinal research would enable the examination of how identity, participation, and tourism evolve over time, and could capture processes such as the gradual erosion or strengthening of cultural attachment, the emergence of new heritage practices, or shifts in community involvement as tourism intensifies. In terms of measurement, although the quantitative scales were adapted from established literature, they may not fully encompass locally embedded interpretations of concepts such as identity, belonging, transmission, and participation. These constructs often contain tacit, emotional, and symbolic layers that are difficult to quantify through Likert scales.

Future studies could therefore incorporate participatory visual methods, cultural mapping, in-depth ethnographic observation, or narrative-based interviews to capture the nuance of local meanings and lived experiences. Another limitation concerns the conceptualization of policy support, which was treated as a broad, unified construct. In practice, policy support encompasses multiple dimensions, including financial assistance, regulatory protection, educational training, administrative facilitation, and heritage legislation. Disaggregating these components would allow researchers to identify which specific policy instruments exert the strongest influence on cultural sustainability.

Building on these limitations, several directions for future research emerge. Scholars may explore digital heritage mediation, such as augmented or virtual reality storytelling, interactive archives, and digitally enhanced interpretive trails as new avenues for transmitting cultural knowledge to both residents and visitors. Further investigation is also needed into gendered and generational patterns of participation, as younger residents, elders, men, and women may engage differently with landscape identity, tourism, and heritage practices. Finally, modelling cross-regional networks linking geoparks, cultural corridors, and inter-village alliances would offer new perspectives on macro-level pathways of cultural transmission, highlighting how ideas, narratives, and practices circulate across broader spatial systems beyond individual villages.

Concluding Remarks

This study demonstrates that rural cultural landscapes serve as powerful foundations for sustainable cultural transmission when supported by strong local identity, active community engagement, and geosite-oriented tourism under enabling governance conditions. Using traditional villages in Central Shandong as empirical cases, the research shows that cultural landscape identity motivates residents to participate in heritage and tourism activities, and that this participation translates into both educational and economic pathways through geosite tourism development. Policy support further strengthens these community-driven processes, ensuring that cultural knowledge, practices, and landscape stewardship are maintained across generations. The integrated model, validated by quantitative SEM results and corroborated by qualitative narratives, reveals that sustainable cultural transmission is not a singular outcome but a multi-layered process linking people, place, and institutional context. The geological formations, vernacular architecture, ritual spaces, and ecological knowledge of the study villages form living cultural landscapes where identity, participation, and tourism interact continuously.

These findings extend Cultural Landscape Theory by operationalizing identity as a measurable construct, advance geotourism scholarship by illustrating its role as a medium of intangible heritage continuity, and enrich governance studies by highlighting the moderating influence of policy frameworks. Beyond Shandong, the insights emphasize that rural revitalization depends on cultivating local pride, empowering communities, designing interpretive geotourism that integrates natural and cultural heritage, and institutionalizing multiscale policy support. Ultimately, the study affirms that sustainable cultural transmission arises not from external preservation mandates but from the synergy of attachment, participation, learning, and governance embedded within rural cultural landscapes.

A causal relationship model of social and cultural change influencing the future success of integrated and sustainable tourism management in Thailand. *Geojournal of Tourism and Geosites*, 67(3), 2008–2019. https://doi.org/10.30892/gtg.67316-1828

Abstract: This research aims to examine the influence of integrated causal factors affecting the future success of sustainable tourism management in Thailand amid changes in social and cultural dimensions, the Bio-Circular-Green (BCG) economy, and the pro-environmental sector. The study adopts a mixed-methods research approach and applies a Multinomial Logistic Model based on Path Analysis, referred to as the Logit-PA model, which was identified as the best-fitting model for examining the relationships among the relevant factors. The findings indicate that stakeholder participation is the most critical factor influencing the success of sustainable tourism. When this factor was incorporated into the Logit-PA model as a new policy scenario, the true direct effects of the causal factors became more evident. The inclusion of stakeholder participation also contributed to a continuous long-term reduction in greenhouse gas emissions generated by tourism activities. Furthermore, the study identifies several strategic approaches to achieving sustainable tourism development goals. These include enhancing the capacity of tourism service providers to manage resources efficiently, emphasizing social and cultural dimensions in tourism development, and promoting the consumption of tourism products and services that are consistent with the principles of the BCG economy. In addition, supporting factors should be developed to improve the efficiency of environmental resource management and ensure the long-term sustainability of tourism practices. This research provides substantial practical value for policy planning and implementation by guiding Thailand's national development toward long-term sustainability goals. The findings may also be adapted and applied to other sectors in future studies under changing future conditions.

Keywords: social culture, Eco-tourism, scenario analysis, sustainability, sustainable tourism

INTRODUCTION

The tourism industry is a crucial sector contributing to Thailand's economic growth. In 2029, Thailand generated tourism revenue of approximately 992,050 million baht, creating employment for 4,201,502 people within the economic system (World Travel & Tourism Council, 2025). At the same time, Thailand's tourism competitiveness is evident, as the country ranked 31st out of 140 countries worldwide (Chongbut & Chapman, 2021; The World Bank: Energy Use (Kg of Oil Equivalent Per Capita) Home Page, 2025). Thailand has consistently pursued national development policies that promote economic, social, and environmental growth from the past to the present (1995–2025) (Office of the National Economic and Social Development Council (NESDC, 2025). However, following the economic crisis period (2002–2025), Thailand increasingly emphasized economic expansion to accelerate economic and social recovery (National Statistical Office Ministry of Information and Communication Technology, 2025). The government implemented various policy measures to promote national development, with tourism identified as the highest national policy priority, followed by the promotion of agricultural exports through expanding market share and continuously exploring new international markets (Praprom & Laipaporn, 2023). In particular, Thailand has actively promoted international tourism growth at an accelerated rate by reducing service-related tax rates to stimulate tourist arrivals and encourage foreign

companies to conduct business in Thailand, exempting certain fees to facilitate investment entry into the economic system and enhance long-term operational activity, and implementing comprehensive support measures, especially in terms of safety and security, to attract foreign capital inflows (Tourism Authority of Thailand, 2025). Furthermore, the government has adopted an open approach to tourism-related business operations by easing tax burdens on entrepreneurs, enabling higher profitability and fostering sustained growth in the tourism sector (United Nations World Tourism Organization (UNWTO), 2025). With regard to social and cultural dimensions, Thailand has likewise promoted comprehensive development across multiple areas **(**UNWTO, 2024). These efforts include increasing the minimum wage and supporting the re-employment of previously unemployed workers, enhancing educational policies to continuously reduce illiteracy rates, and strengthening public health and safety through the provision of universal healthcare benefits to ensure equitable access for all population groups (UNWTO, 2025; Hasanein & Ayad, 2025).

Investment promotion policies targeting tourism entrepreneurs have led to a steady increase in business participation within the formal economic system, which in turn has generated social benefits by creating employment opportunities for Thai workers and generating income for local communities in tourism destinations, thereby supporting sustained regional income growth **(**NESDB, 2025; Ahmed et al., 2025). Furthermore, tourism-led economic development is closely linked to broader social development, particularly in forms of tourism associated with local cultural practices and community livelihoods. The emphasis on eco-tourism and cultural tourism as pathways toward sustainable tourism has contributed to simultaneous growth in both the tourism sector and social development (UNWTO, 2025; Tuan et al., 2025; Salama et al., 2025). With respect to environmental dimensions, Thailand has placed significant emphasis on achieving internationally agreed development targets following its participation in global cooperation frameworks established at the United Nations General Assembly in Italy, where the Sustainable Development Goals (SDGs) were adopted as a set of global development objectives after 2015. The SDGs were formally endorsed by 193 United Nations Member States on 25 September 2015 and have served as a shared development direction for all countries from 2016 to the present (National Statistical Office Ministry of Information and Communication Technology, 2025; Muna et al., 2025). The commitment document signed by all member states, entitled *"Transforming Our World: the 2030 Agenda for Sustainable Development,"* commonly referred to as the 2030 Agenda, Agenda 2030, or the Global Goals, comprises 17 Sustainable Development Goals (World Economic Forum, 2024). Each goal is supported by specific targets, totalling 169 targets, and measured through 232 indicators designed to guide and monitor progress toward sustainable development. In line with these commitments, the Thai government has established a 20-year National Strategic Plan as a key framework for steering the country toward sustainable development in the future. Implementation is carried out through the exercise of state authority via administrative, civil, and criminal measures under the National Environmental Quality Promotion and Conservation Act B.E. 2535 (1992), which serves as the primary legal instrument for environmental protection and sustainability in Thailand (Thai Travel Agents Association, Ministry of Tourism and Sports, 2025); ONEP, 2025; Office of Natural Resources and Environmental Policy and Planning (DEDE), 2025).

With respect to environmental development, Thailand places strong emphasis on SDG 12: Sustainable Consumption and Production, particularly in promoting sustainable tourism (Thailand Greenhouse Gas Management Organization (Public Organization), 2025; OECD, 2025). The country has developed and implemented monitoring tools to assess the impacts of sustainable development in tourism that generates employment while promoting local culture and products (Junsiri et al., 2024). These efforts are closely aligned with SDG 8: Decent Work and Economic Growth, specifically Target 8.9, which aims to promote sustainable tourism that creates jobs and supports local culture and products by 2030; SDG 11: Sustainable Cities and Communities, which emphasizes the protection of cultural and natural heritage in tourism destinations; and SDG 15: Life on Land, which focuses on the sustainable management of terrestrial ecosystems and the prevention of negative environmental impacts from tourism activities (NESDB, 2025; Sutthichaimethee et al., 2025; Energy Policy and Planning Office, 2025). Achieving these targets is expected to support appropriate long-term sustainable development; however, rapid tourism growth in recent years has generated significant negative impacts on natural resources and the environment, raising concerns across multiple sectors (Ministry of Natural Resources and Environment). This has led to a strategic shift toward a quality-oriented rather than quantity-driven tourism development approach, aiming to achieve a balanced integration of economic growth and environmental conservation in line with the United Nations Sustainable Development Goals (SDGs). These principles are reflected in Thailand's National Strategy, master plans under the National Strategy, national reform plans, and the National Tourism Development Plan, all of which emphasize sustainable tourism (Winyuchakrit et al., 2025; Xiao et al., 2025).

Furthermore, the Thai government has declared the Bio-Circular-Green (BCG) economic model a national agenda since 2021(United Nations Framework Convention on Climate Change, UNFCCC, Bonn, Germany, 2016), positioning it as a key mechanism for leveraging national strengths, addressing structural weaknesses, aligning with sustainable development objectives, expanding employment opportunities, increasing income, generating inclusive wealth, and improving quality of life (UNFCC, 2014). In support of this agenda, the Ministry of Tourism and Sports has mandated its affiliated agencies to advance "white tourism" under the BCG economic model, and the National Tourism Policy Committee has assigned the Office of the Permanent Secretary of the Ministry of Tourism and Sports to revise future plans in alignment with the 13th National Economic and Social Development Plan and the 3rd National Tourism Development Plan (2023–2027) (NESDB, 2025; World Travel & Tourism Council, 2025).

Therefore, the Ministry of Tourism and Sports, as the principal agency responsible for driving tourism development in Thailand, has recognized the importance of prioritizing sustainable tourism in response to the need for natural

resource and environmental conservation, compliance with international and national policy frameworks, and the growing preference of modern tourists for environmentally friendly travel experiences (NESDB, 2025; World Travel & Tourism Council, 2025). Sustainable tourism development is regarded as a key instrument for generating economic, social, and environmental benefits for Thailand. Accordingly, the Ministry of Tourism and Sports has formulated the strategic plan for advancing white tourism under the BCG economic model (2023–2027) to strengthen the role of the tourism sector in driving national development under the Bio-Circular-Green (BCG) economy framework. On the supply side, tourism entrepreneurs are encouraged to adapt and apply the BCG economic model as a guideline for producing tourism-related goods and services, while on the demand side, the tourism sector stimulates demand within the BCG economic system through tourist consumption. This integrated approach positions tourism as a key mechanism for sustainably driving Thailand's economic development in the long term. However, despite Thailand's efforts to improve national strategic planning across multiple dimensions as discussed above, greenhouse gas emissions continue to increase at a steadily rising growth rate. In addition, the expansion of urban society into local communities has led to significant social transformations, particularly the gradual shift in cultural patterns from traditional rural communities to urbanized lifestyles (NESDB, 2025; World Travel & Tourism Council, 2025; DEDE, 2025).

These changes directly affect community ways of life and reflect the encroachment of urban society into rural areas, which has contributed to the gradual erosion of Thailand's traditional cultural heritage passed down through generations. Consequently, substantial weaknesses remain in the social dimension due to rapid cultural change, alongside increasing environmental degradation. These conditions indicate that Thailand's sustainability policies have not yet achieved sufficient success and lack both efficiency and effectiveness. This research, therefore, identifies a critical gap in existing policy implementation and seeks to address it by examining strategic approaches that can support Thailand's long-term national development objectives more effectively. However, although many studies of this kind have been conducted in the past, none has taken a comprehensive approach or developed indicators that are truly appropriate to the specific context under study with strong performance. This research, in contrast, is highly distinctive and significantly different from previous work. Its key strength lies in the development of context-appropriate indicators that meet established criteria for constructing a suitable model, along with a rigorous implementation process grounded in advanced statistical principles. The findings of this study can also be appropriately applied to other contexts in the future.

MATERIALS AND METHODS

The model developed in this study is the Logistic-based Path Analysis model (Logit-PA model). This model integrates quantitative and qualitative research approaches and is constructed by addressing and improving upon the limitations of conventional models. The objective is to ensure that the Logit-PA model can address the research questions as effectively and efficiently as possible. The model is developed under the following assumptions (Baltagi, 2021):

1. The independent or predictor variables (x's) must be measured at least at the interval scale. In cases where the data are categorical, they are transformed into dummy (dichotomous) variables with values of 0 and 1 only. For the dependent variable, in the case of binary logistic regression, two values are specified: 0 and 1.
2. The mean of the error term is zero, or equivalently, the error terms are uncorrelated, that is, $e = 0$.
3. The independent variables are not correlated with each other, implying the absence of multicollinearity. The criteria for assessing correlations follow those commonly used in multiple regression analysis, where the correlation coefficient (r) should not exceed 0.65 or 0.80.

For the Logit-PA model, in the case where the dependent variable (y) is a binary categorical variable with two possible values, and where there is more than one predictor variable (x_i). The function can be expressed as follows (Harvey, 1980).

$$P_y = \frac{e^{b_0+b_1x_1+\cdots b_px_p}}{1+e^{b_0+b_1x_1+\cdots b_px_p}} \qquad (1)$$

From Equation (1), let P_y denote the probability of the occurrence of the event of interest. Accordingly, the probability of the non-occurrence of the event of interest can be obtained using the following expression (Baltagi, 2021; Harvey, 1980).

$$Q_y = 1 - \left(\frac{e^{b_0+b_1x_1+\cdots b_px_p}}{1+e^{b_0+b_1x_1+\cdots b_px_p}}\right) \qquad (2)$$

As shown in Equation (2), the relationship between the dependent variable (y) and the predictor variables (x_i) is not linear. Therefore, the researcher transforms the model into a linear form by expressing it in terms of odds or odds ratios, which represent the ratio between the probability of the event of interest occurring $(y = 1)$ and the probability of the event not occurring $(y = 0)$. This relationship can be expressed as follows (Hoyle,1995).

$$odds = \frac{P_y}{Q_y} \qquad (3)$$

From Equation (3), the value of the odds represents how many times more likely the event of interest is to occur compared to the non-occurrence of the event. For example, the odds of tossing a coin once equal $\frac{0.5}{0.5} = 1$. If the odds equal 3, this indicates that the probability of the event of interest occurring is three times greater than the probability of the event not occurring. When the odds equal 1, the probabilities of the occurrence and non-occurrence of the event are equal. However, when the odds are greater than 1, the probability of the event of interest occurring exceeds that of the non-

occurrence of the event. In this study, the Logit-PA model is specified in terms of the logarithm of the odds, which is referred to as the logistic response function. The log of the odds, or $\log\left(\frac{P_y}{Q_y}\right)$, where $Q_y = 1 - P_y$, can be written in the following standard form (Byrne, 2001).

$$\log \frac{P_y}{1-P_y} = b_0 + b_1 x_1 + \cdots + b_p x_p \qquad (4)$$

From Equation (4), after taking the logarithm, the dependent variable (y) can be predicted using a set of variables that exhibit a linear structure. The Logit-PA model is therefore highly suitable for application in development management across various dimensions, enabling the formulation of appropriate measures or policies. Consequently, the predicted value of y in terms of P_y can be expressed as follows (Dickey & Fuller, 1981).

$$P_y = \frac{e^{b_0+b_1x_1+\cdots b_p x_p}}{1+e^{b_0+b_1x_1+\cdots b_p x_p}} \qquad (5)$$

From Equation (5), various estimation and prediction methods can be employed. In this study, an approach based on causal analysis is selected, in which all variables must pass appropriate procedural criteria and exhibit relationships such that each variable may simultaneously function as both a dependent and an independent variable. Accordingly, this study employs Path Analysis as the estimation technique, whereby variables are reclassified into latent variables and observed variables. Each sector must consistently demonstrate genuine and interconnected relationships with one another (Byrne, 2001). The structural equation model of path analysis, which represents the relationships among latent variables, is expressed as $\eta = b\eta + \Gamma\xi + \zeta$, where η denotes the endogenous variable, ξ represents the exogenous variable, and ζ is the error term. For the measurement model in each block, the following specifications apply (Hoyle, 1995).

$$x = \Lambda x\xi + \delta x \qquad (6)$$

From Equation (6), $(x/\xi) = \Lambda x\xi$ defines the measurement equation for the exogenous variables, where x represents the indicators of ξ, and Λx denotes the factor loadings, which reflect the influence of the latent variable ξ on its observed indicators x.

$$y = \Lambda y\eta + \varepsilon y \qquad (7)$$

From Equation (7), $(y/\eta) = \Lambda y\eta$ defines the measurement equation for the endogenous variables, where y represents the indicators of η, and Λy denotes the factor loadings, which represent the influence of the latent variable η on its observed indicators y.

For this study, the estimation of the Logit-PA model follows an algorithm-based analytical procedure, as outlined below (Byrne, 2001; MacKinnon, 1991; Joreskog & Sorbom, 2012).

1. Estimation of latent variables: The latent variables are estimated based on their observed indicators as $\hat{V}_i \alpha \sum_j w_{ji} P_{ji}$, where the latent variable V is constructed from the standardized values of the indicators P_i, and w_{ji} represents the assigned (arbitrary) weights.
2. Estimation of the dependent variables in the structural equation: The dependent variable in the structural model is estimated as $Z_i \alpha \sum_j c_j \hat{V}_j$, where the latent variable in the structural model is generated as a weighted aggregate of the estimated latent variables from each structural equation. The term c_j represents the appropriate weighting coefficients.
3. Iterative estimation until convergence: Steps 1 and 2 are performed iteratively until the coefficients of all structural paths stabilize and converge, indicating that convergence has been achieved.

The Logit-PA model differs from conventional models in that earlier approaches primarily addressed the issue of multicollinearity alone. In contrast, the model developed in this study is designed to simultaneously avoid multicollinearity, heteroscedasticity, and autocorrelation. As a result, the Logit-PA model exhibits a high degree of reliability and is highly suitable for future forecasting and predictive applications (Harvey, 1980).

A review of relevant domestic and international literature indicates that no prior studies have developed a strategic national management model in this manner. Moreover, analyses of this type remain extremely limited both in Thailand and internationally. Existing studies have largely examined individual dimensions in isolation rather than adopting an integrated analytical framework, thereby limiting their ability to accurately formulate future strategic directions.

In addition, previous research has typically separated quantitative and qualitative approaches, which has constrained the development of robust scenario models and reduced their applicability for national policy and planning in Thailand. To address these limitations, this study adopts a mixed-methods research design, in which quantitative analysis serves as the primary approach, followed by qualitative research to validate, complement, and strengthen the findings.

The quantitative component utilizes secondary data covering the period from 1990 to 2025, while the qualitative component involves in-depth interviews with key experts directly responsible for tourism development in Thailand, including five experts from the National Economic and Social Development Council (NESDC), five experts from the Ministry of Natural Resources and Environment, and five experts from the Ministry of Tourism and Sports, for a total of fifteen participants. The findings from both components are subsequently synthesized to provide a comprehensive analysis, with the research procedures presented in the following section. Figure 1 illustrates the research procedures employed to analyze the causal influences affecting cultural changes within the social sector as a result of the transition toward integrated tourism management for sustainable development in Thailand in the future.

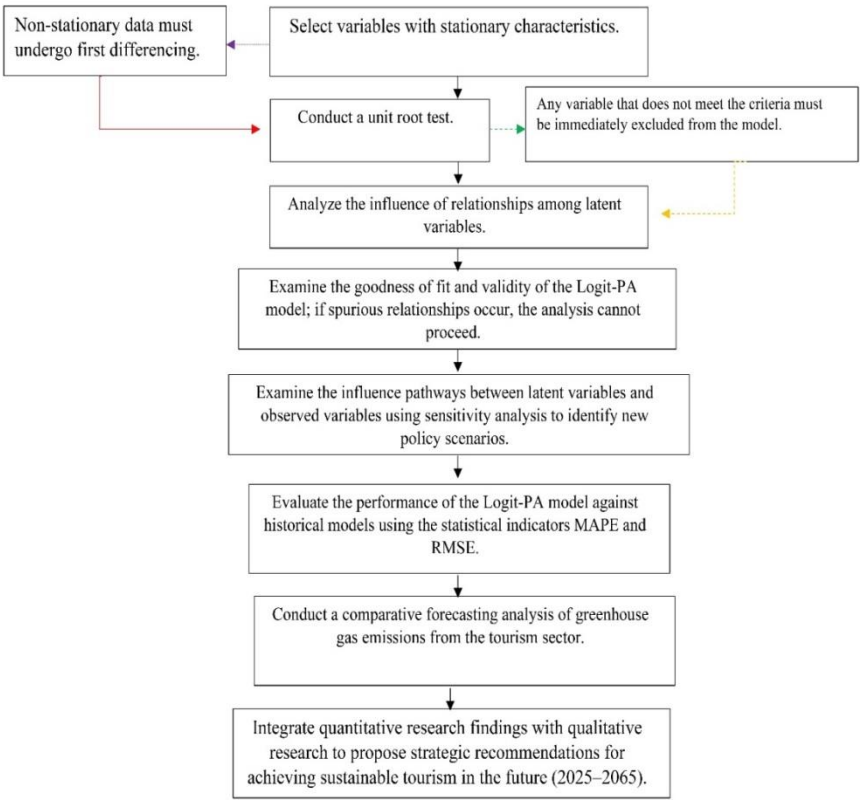

Figure 1. Research Procedure

RESULTS

This study employed a mixed-methods research approach, integrating both quantitative and qualitative methodologies to ensure the robustness and completeness of the research findings. The quantitative component utilized the Logit-PA model, which incorporates integrated variables derived from both quantitative data and qualitative insights. Subsequently, the quantitative results were further examined through qualitative research to enhance the depth, validity, and contextual interpretation of the findings. This sequential research design was intended to maximize the explanatory power of the study and ensure its applicability to real-world policy formulation. The findings of this research can therefore be effectively applied to support national strategic planning for achieving long-term sustainable tourism development in alignment with Thailand's net zero greenhouse gas emissions target by 2065.

Key policy objectives derived from the model include systematic management of tourism operators, local communities involved in tourism activities, and tourists within destination areas under the BCG economic model, as well as maintaining annual greenhouse gas emission growth from the tourism sector within the established carrying capacity limits. Most importantly, the proposed implementation framework must comprehensively incorporate ESG (Environmental, Social, and Governance) principles as a core foundation for sustainable tourism governance.

Screening of Influencing Factors for Model Input

The Logit-PA model was employed to select and define the observed variables used in the analysis. These observed variables consist of key indicators that have been officially established and consistently applied by Thailand in national governance and policy implementation. In this study, only indicators that fully met the required methodological criteria and relevance to sustainability objectives were selected; any indicators deemed inappropriate or insufficient were excluded from the model. The selected observed variables include per capita income ($BCG-A$), urbanization rate ($BCG-B$), industrial structure rate ($BCG-C$), Eco-Tourism rate ($BCG-D$), Cultural and Traditional Tourism rate ($BCG-E$), Health and wellness rate ($So-A$) Public participation rate ($So-B$), education rate ($So-C$), income distribution rate ($So-D$), protection rate ($So-E$), Recreational Attraction ($So-F$), Natural Attraction ($So-G$), energy intensity ($En-A$), Final energy consumption ($En-B$). and Carbon dioxide emission ($En-C$). In addition, the model incorporates latent variables corresponding to Thailand's sustainability policy framework, namely the social and cultural sector, the BCG-based economic sector, and the pro-environmental sector.

These latent variables serve as the foundational constructs for defining and evaluating Thailand's sustainable tourism development goals. The results of the empirical analysis are presented as follows.

Based on Table 1, the results indicate that all selected indicators successfully meet the measurement criteria of the Logit-PA model. Only indicators that passed the evaluation criteria were deemed appropriate for inclusion as observed variables in the Logit-PA model, with statistical significance at the $\alpha = 0.01$ level. All 15 observed variables are stationary at first difference, as the Tau-test values exceed the corresponding MacKinnon critical values. These results demonstrate

that the observed variables used in constructing the model provide a high level of reliability and robustness, making the model appropriate for analyzing the influences and relationships among variables, as presented in the subsequent analysis.

Formation of the Analytical Model Using the Logit-PA model

The researcher constructed the Logit-PA model to analyze the causal effects of key factors influencing the success of sustainable tourism, while ensuring that development remains within the carrying capacity defined by Thailand in the long term. The model examines the relationships among latent variables, which are influenced by their respective observed variables within each latent construct. The results of the relationship analysis are presented as follows.

Based on Table 2, the results of the causal relationship analysis derived from the Logit-PA model indicate that the social–cultural sector is influenced by two sectors: the pro-environmental sector and the BCG-economic sector, with effect sizes of 0.34% and 0.14%, respectively, at a significance level of α = 0.01. These results demonstrate that changes in the social–cultural sector are most strongly driven by changes in the pro-environmental sector. In addition, the findings reveal that the social–cultural sector exerts the strongest influence on the pro-environmental sector, with an effect size of 0.62%, which is greater than the influence exerted by the BCG-economic sector on the pro-environmental sector (0.43%). The next strongest influence is observed from the BCG-economic sector to the social–cultural sector, with an effect size of 0.18%, also significant at α = 0.01. Overall, the results indicate that the social–cultural sector plays a dominant role in driving changes in the pro-environmental sector. This implies that if the government aims to formulate effective and responsive policies for sustainable tourism, policy interventions should prioritize the social–cultural sector, as it demonstrates the highest responsiveness and transmission effect across sectors. Such an approach would enhance the likelihood of rapid and successful policy implementation compared with interventions targeting other sectors. Nevertheless, within the Logit-PA modeling framework, it is necessary to estimate new policy scenarios based on the observed variables through sensitivity analysis. The results of the sensitivity analysis are presented below.

Based on Figure 2, the three latent variables exhibit both direct and indirect effects, indicating strong interrelationships among them. The Logit-PA model demonstrates high validity and an excellent goodness-of-fit, satisfying all standard criteria: χ^2/df = 1.55, $RMSEA$ = 0.02, RMR = 0.001, GFI = 0.99, $AGFI$ = 0.95, R-squared = 0.93, F-statistic = 215.75 (p = 0.00), ARCH test = 15.85 (p = 0.10), and LM test = 1.20 (p = 0.10). These results confirm that the model is statistically appropriate, robust, and free from spurious relationships, thereby ensuring the reliability of the empirical findings.

Furthermore, the results of the sensitivity analysis indicate that the observed variables with sensitivity values exceeding the 90% threshold are Public Participation Rate $(So-B)$ and Cultural and Traditional Tourism Rate $(BCG-E)$. Specifically, the public participation rate exerts the strongest influence on changes in the social–cultural sector, with a sensitivity value of 92%, followed by the cultural and traditional tourism rate, which influences the BCG-economic sector with a sensitivity value of 90%. All remaining observed variables exhibit sensitivity values below 90%.

Accordingly, this study designates public participation rate and cultural and traditional tourism rate as new policy scenario variables, to be utilized as key instruments for steering long-term sustainable tourism development.

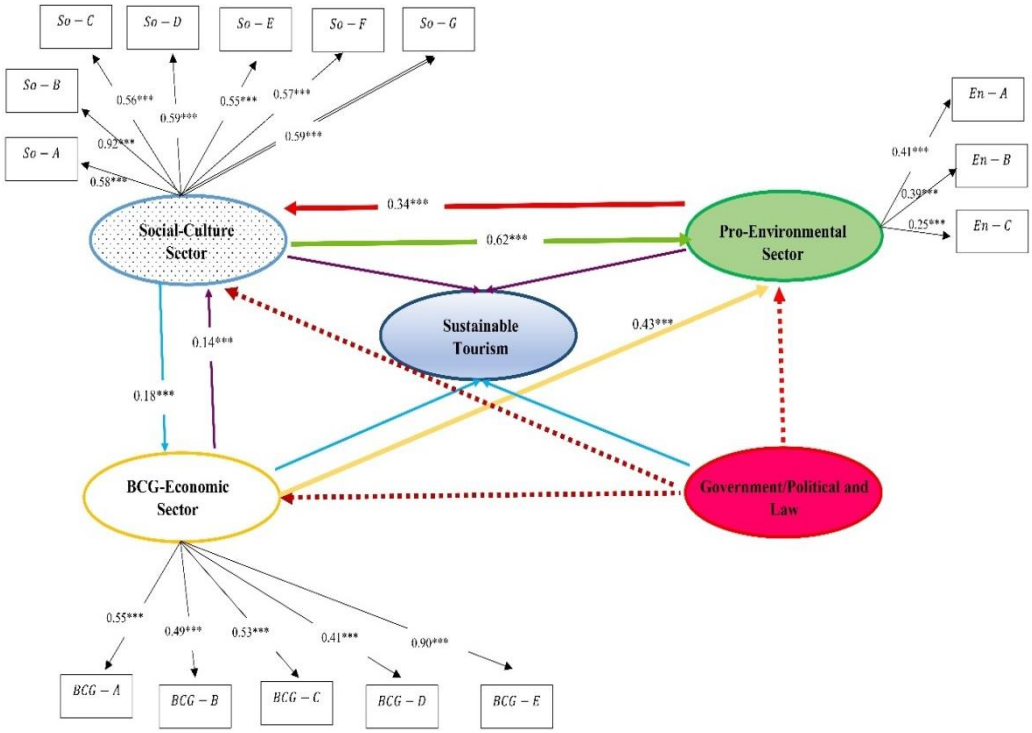

Figure 2. Intersectoral influence relationships derived from sensitivity analysis using the Logit-PA model

Forecasting Greenhouse Gas Emissions under the New Policy Scenario

In this study, a new policy scenario is incorporated into the Logit-PA model, and the resulting forecasts of greenhouse gas (GHG) emissions in the future are presented accordingly. For the forecasting exercise, the performance of the proposed model is evaluated by comparing it with the forecasting models that have been employed by Thailand from 1992 to 2025. The evaluation is conducted using standard accuracy measures, namely the Mean Absolute Percentage Error (MAPE) and the Root Mean Square Error (RMSE). The results of the model performance assessment are reported in Table 3.

Table 3. Model performance evaluation of the Logit-PA model (Source: Author's Estimate (2025)

Forecasting Model	MAPE (%)	RMSE (%)
OLS model	10.49	11.89
ANN model	4.95	5.15
Fuzzy model	4.59	4.98
GM(1,1) model	4.13	4.54
ANIF model	3.90	3.98
ARIMAX model	3.15	3.59
Logit-PA model	1.10	1.25

Based on Table 4, the researcher compares the performance of the Logit-PA model with forecasting models that have previously been used by Thailand for policy formulation and national planning under the sustainability policy framework. These benchmark models include the Autoregressive Integrated Moving Average with Exogenous Variables (ARIMAX) model, Adaptive Neuro-Fuzzy Inference System (ANFIS) model, Grey Model (GM(1,1)), Fuzzy model, Artificial Neural Network (ANN) model, and Ordinary Least Squares (OLS) model. The empirical results indicate that the Logit-PA model exhibits the highest forecasting performance, with MAPE and RMSE values of 1.10% and 1.25%, respectively. The second-best performance is observed for the ARIMAX model, with MAPE and RMSE values of 3.15% and 3.59%, respectively, followed by the ANFIS model (3.90% and 3.98%), the GM(1,1) model (4.13% and 4.54%), the Fuzzy model (4.59% and 4.98%), the ANN model (4.95% and 5.15%), and finally the OLS model, which shows the weakest performance with MAPE and RMSE values of 10.49% and 11.89%, respectively. These findings confirm that the Logit-PA model is highly suitable for long-term forecasting of greenhouse gas emissions.

Based on Figure 3, the results indicate that during the period 2025–2065, despite Thailand having implemented sustainable development policies since 1992, greenhouse gas emissions from the tourism sector continue to increase steadily. The projected growth rate reaches 55.1%, which exceeds the government's target threshold of 40%. However, when the new scenario policy, namely Public Participation Rate and Cultural and Traditional Tourism Rate, is adopted as the primary policy indicators for managing sustainable tourism within the Logit-PA model, the projected greenhouse gas emission growth rate

declines significantly to 29.55%. This level remains within the acceptable range for achieving the national net zero emission target by 2065. These findings demonstrate that the integration of an appropriate scenario-based policy framework with a suitable analytical model enables more effective strategic planning and policy implementation, yielding substantially higher efficiency and accuracy than the conventional models previously employed by the government.

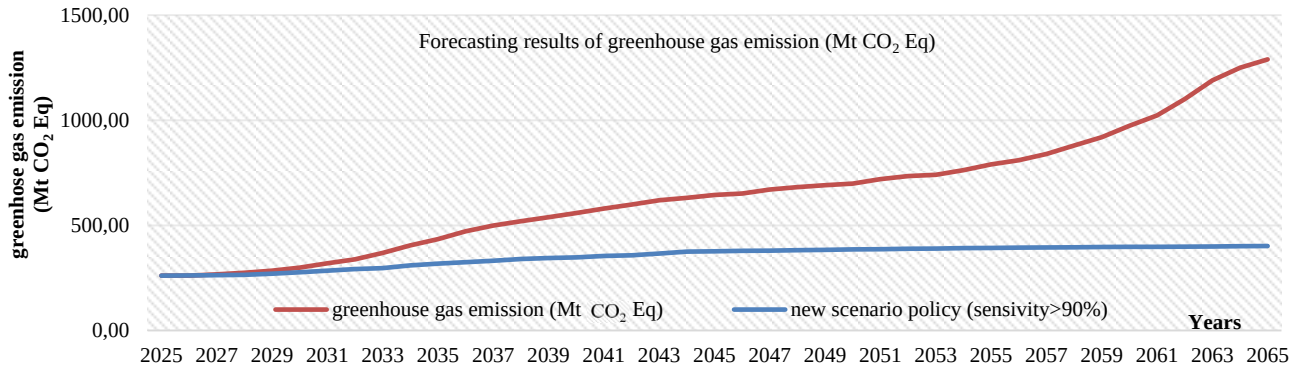

Figure 3. Projected growth of greenhouse gas emissions in the future (2025–2065)
(Source: Thailand Greenhouse Gas Management Organization, 2025)

Results of the Synthesis of Future Sustainable Tourism Development Strategies

Based on the quantitative research findings, the results presented above demonstrate a high level of appropriateness and reveal clear distinctions from previous studies. These differences help explain why Thailand has historically lacked a clear direction for managing tourism in a sustainable manner. In contrast, the findings of this study provide a practical foundation that can be effectively applied to support successful implementation in the future. Sustainable tourism is defined as tourism that fully considers its economic, social, and environmental impacts in both the present and the future, while addressing the needs of tourists, the tourism industry, the environment, and host communities. The principles of sustainability encompass the environmental, economic, and socio-cultural dimensions of tourism development and require an appropriate balance among these three dimensions to ensure long-term sustainability. These principles are consistent with the Global Sustainable Tourism Council (GSTC) standards, which serve as globally recognized benchmarks for sustainability in travel and tourism. The GSTC standards are widely used for education and awareness-building, policy formulation for businesses, government agencies, and other organizations, measurement and evaluation processes, and as a foundation for certification and carrying capacity assessment. These standards emerged from global efforts to establish a common framework for sustainable tourism and are organized around four core pillars: (1) sustainable governance and management, (2) economic impacts, (3) social and cultural impacts, and (4) environmental impacts, including resource use, pollution reduction, and the conservation of biodiversity and landscapes. The GSTC standards are founded on decades of global experience and prior work and were developed through consideration of a wide range of sustainable tourism guidelines and standards from all continents. During the development process, they underwent extensive global consultation across both developed and developing countries and in multiple languages, reflecting a collective effort to achieve a global consensus on sustainable tourism. Accordingly, the GSTC standards represent minimum criteria that businesses, governments, and destinations should meet to achieve social and cultural, environmental, and economic sustainability. As each destination possesses its own unique cultural context, environmental conditions, traditions, and legal frameworks, the standards are designed to be adaptable to local circumstances and supplemented with additional criteria for specific destinations and activities. Thailand, likewise, is required to align its tourism development efforts with these standards in order to achieve sustainable tourism in the future. Furthermore, implementation must be accompanied by integrated ESG analysis, encompassing Environmental sustainability (E), which requires that greenhouse gas emissions do not exceed the carrying capacity of destinations; Social and cultural sustainability (S), which emphasizes equitable income distribution, preservation of traditional culture, and the cultivation of environmental stewardship as a shared social value; and Governance (G), which entails effective regulation and oversight of national policies to ensure appropriate governance across all sectors. Consequently, the formulation of strategies under these frameworks necessitates an integrated, cross-sectoral approach, which is essential for achieving long-term sustainability in the future. The key components of this integrated strategy are presented as follows.

Issue 1: Economic sustainability: enhancing the capacity of tourism service providers for efficient resource management

Tourism service providers, encompassing all twelve sectors of the tourism industry, represent a critical group within the tourism supply chain. These sectors utilize a wide range of resources and consume substantial quantities in the delivery of tourism services, making them a primary target of this strategic framework. Accordingly, the strategy emphasizes strengthening the knowledge and understanding of relevant stakeholders regarding the principles and operational approaches of the Bio-Circular-Green (BCG) economic model, enabling its adaptation and integration into existing operational processes. Such implementation contributes to the sustainable use of natural resources and environmental assets at the local level, thereby allowing Thailand to preserve high-quality tourism destinations that remain attractive and competitive in the long term.

To achieve this objective, the following goals are established:

1. Tourism entrepreneurs adopt clear, standardized operational guidelines aligned with the BCG economic model that can be flexibly adapted to suit specific business contexts.

2. Tourism entrepreneurs enhance business value while reducing carbon dioxide emissions and improving waste management practices through a comprehensive understanding of resource management concepts at both local and community levels.

The strategic implementation under Issue 1: Economic Sustainability comprises three core strategies:

1. Promoting sustainable business operations among tourism service providers (Operations);
2. Developing and upgrading tourism business standards in accordance with the BCG economic model (Standards);
3. Enhancing business capacity and strengthening knowledge related to efficient and sustainable resource utilization among tourism sector personnel (Knowledge).

Issue 2: Social and cultural sustainability: promoting the value and stimulating consumption of tourism products and services under the bcg concept

Encouraging tourism entrepreneurs and related stakeholders to transition toward operations aligned with the Bio-Circular-Green (BCG) economic model requires substantial investment in sustainable practices. Such investments can only be sustained if tourists likewise recognize and value these principles, thereby generating continued consumption of tourism products and services and fostering long-term economic circulation at the local level. This approach supports the practical implementation of circular tourism. Beyond promoting BCG-aligned operational processes among tourism providers, stimulating demand from tourists encourages healthy competition among entrepreneurs, accelerating the development of products and services that better respond to evolving tourist preferences. Accordingly, development in this area should focus on raising awareness among tourists and, most importantly, the general public regarding the significance of various forms of circular tourism, alongside fostering an environmental stewardship culture among local stakeholders. This process encourages a sense of ownership and collective responsibility for preserving cultural and environmental assets, protecting both present and future heritage from degradation.

The key objectives under this issue are as follows:

1. To cultivate a shared sustainability culture among stakeholders and promote comprehensive collaboration at the local level, while enhancing awareness and understanding of the core components of sustainable tourism under the BCG economic model.
2. To ensure that the government provides support mechanisms and policy incentives for tourism entrepreneurs and tourists who prioritize sustainable tourism practices.

The strategic framework under Issue 2: Social and Cultural Sustainability comprises two main strategies:

1. Communicating information to raise awareness among stakeholders, tourism entrepreneurs, and tourists (Awareness);
2. Establishing and enhancing incentive mechanisms to encourage stakeholders, tourism businesses, and tourists to prioritize sustainable tourism practices (Incentives).

Issue 3: Environmental sustainability: strengthening supporting factors to enhance resource management efficiency in the tourism sector. Beyond stimulating operational changes among tourism entrepreneurs and increasing demand from tourists, the effective implementation of circular tourism requires strong emphasis on the development of a comprehensive enabling ecosystem. This ecosystem reflects both the constraints and driving forces that determine whether policy implementation can be successfully realized in practice. Key elements include regulatory frameworks, laws, public policies, support measures, data systems, and collaborative networks that act as partners and leaders at multiple levels. In addition, the government must ensure the transparent and accurate dissemination of information to the general public and all relevant stakeholders. The objectives under this issue are defined as follows:

1. To review, revise, and improve relevant laws and regulations to enable tourism entrepreneurs and related agencies to effectively operate in alignment with the BCG economic model.
2. To integrate tourism-related data with BCG-oriented tourism development and establish inter-agency data governance mechanisms, enabling public agencies to jointly manage tourism sustainably, while also collecting and disseminating information for stakeholders interested in adopting the BCG framework.
3. To establish multi-sectoral collaboration networks involving government agencies, the private sector, and civil society, ensuring coordinated and connected implementation both within and across regions, ultimately contributing to national-level success in sustainable tourism development.

The strategic implementation under Issue 3: Environmental Sustainability comprises three core strategies:

1. Reviewing and revising regulations to promote sustainable tourism development (Regulations);
2. Developing research-based decision-support tools to enable informed and appropriate policy and national management decisions (Decision Support Tools); and
3. Strengthening the integration of data systems, digital technologies, and supporting infrastructure to enable BCG-oriented tourism development (Enablers).

DISCUSSION

Sustainable tourism is considered a fundamental principle of contemporary tourism promotion, as it represents a form of tourism that minimizes negative environmental impacts, maximizes benefits for local communities, and fosters sustainability across three key dimensions. Economic sustainability encompasses infrastructure development, service quality, labor conditions, and tourism-related occupations that support long-term economic resilience. Social and cultural sustainability emphasizes the preservation of local identity and traditional culture for both present and future generations, the prevention of social problems that may undermine community cohesion, and the cultivation of a

participatory culture in which stakeholders develop a strong sense of environmental stewardship and collective ownership, ensuring long-term protection against degradation. Environmental sustainability focuses on conserving natural resources, preventing environmental degradation and excessive waste generation, and reducing greenhouse gas emissions in alignment with Thailand's long-term climate targets, particularly the achievement of net-zero greenhouse gas emissions by 2065. This study finds that the most critical factor in integrating tourism development toward sustainability while achieving higher growth rates across all dimensions is the establishment of a shared culture and comprehensive understanding among all stakeholders regarding conservation, preservation, and responsible resource utilization. The social and cultural dimension emerges as the most sensitive scenario in the development of an integrated sustainable tourism model. Historically, Thailand has insufficiently emphasized this dimension, resulting in ineffective implementation, failure to achieve policy objectives, and an inability to realize long-term national development plans. In addition, sustainable tourism development requires the promotion of multi-dimensional collaboration networks with the active participation of all relevant sectors. The public sector should also ensure the adequate development of tourism infrastructure to meet the needs of target tourist segments, including accommodation facilities, transportation networks, public utilities, waste management systems, energy systems, and landscape management at tourism destinations.

Furthermore, careful prioritization of indicators used in scenario modeling is essential to prevent environmental degradation, particularly to ensure that greenhouse gas emissions do not exceed the carrying capacity of destinations before irreversible damage occurs. The government must therefore adopt clear and coherent strategies to simultaneously enhance sustainability across all dimensions. Although Thailand has introduced various initiatives—such as green tourism, community-based tourism promotion, assessments of urban carrying capacity, and policies to disperse tourists to secondary destinations—these efforts have lacked a clear long-term operational direction. Moreover, Thailand has long relied on outdated policy tools with high levels of error, leading to misaligned national governance outcomes.

The integrated modeling framework developed in this research provides a robust and practical tool that can significantly enhance national governance and support the successful achievement of sustainable tourism in Thailand over the long term. Under the recommendations of this study, the findings indicate that Thailand has not yet managed national development in an appropriately balanced direction, resulting in tourism growth that primarily benefits the economic sector while failing to foster social and cultural development and contributing to the continued degradation of the environmental sector. This research provides the government with an effective strategic management tool to support more accurate and appropriate policy formulation, thereby enhancing both efficiency and effectiveness in the future.

To achieve sustainable tourism development, growth across the three sectors; economic, social and cultural, and environmental, must occur simultaneously. The key recommendations are as follows:

1. Economic Sector: The government should promote greater access for local entrepreneurs to relevant business knowledge and operational principles related to tourism development. Priority should be given to accelerating the development of accommodation facilities that emphasize cleanliness and safety, enforcing appropriate occupational practices aligned with the characteristics of tourism destinations, and upgrading the quality and value of local souvenir products. In addition, local Thai lifestyles and community ways of life should be integrated as unique selling points to create added value, while cultural and traditional activities should be developed to enhance attractiveness for tourists. The government should also support the development of new tourism routes, such as community-based and experiential tourism, by actively encouraging community participation in tourism planning and implementation.

2. Social and Cultural Sector: The government should actively promote meaningful public participation in both the planning and implementation of tourism-related activities. This includes supporting local communities, citizens, and local administrative organizations in playing a direct role in public communication, as well as in the preservation and conservation of local wisdom and valuable cultural heritage. Efforts should focus on improving community well-being by maintaining traditional lifestyles, preserving local customs and cultural practices, and strengthening community identity so that cultural heritage is valued as a shared asset collectively owned and protected by community members, rather than merely as a public good accessible without responsibility. Furthermore, capacity-building programs should be provided to enhance community knowledge and understanding of sustainable tourism development, facilitate knowledge exchange in technology adoption, and strengthen networks with other local communities. The integration of efforts among relevant government agencies and collaboration with the private sector are also essential to ensure that communities play a meaningful role in tourism development and gain a deeper and more comprehensive understanding of sustainable tourism practices.

3. Environmental Sector: The government should enhance tourism routes and surrounding landscapes to ensure they are green, aesthetically pleasing, and well-organized throughout the entire area. Environmentally friendly tourism should be actively promoted through clearly defined guidelines and standards that can be implemented consistently and sustainably in practice. In addition, local communities should be educated on the conservation of natural resources and the environment within their own areas in order to foster environmental awareness, local stewardship, and a sense of responsibility toward their place of origin. Concrete environmental initiatives should be implemented, such as community waste bank programs, renewable energy projects at the community level, and tree bank schemes, alongside continuous efforts to cultivate environmental consciousness, particularly in relation to waste management and sustainable environmental practices. Public communication should also be directed toward tourists to promote environmentally responsible tourism behavior, while local residents and community leaders should serve as role models in environmental conservation.

Most importantly, the government must adopt proactive environmental measures, including the strengthening and enforcement of relevant laws and regulations. These measures must be clearly defined, enforceable, and effectively implemented to ensure tangible and lasting environmental sustainability outcomes. Regarding recommendations for applying this research, the researcher should carefully select indicators to ensure they are appropriate for each specific context. Importantly, all selected indicators must meet the same level of criteria or quality standards. Differences in quality levels may affect the accuracy of parameter estimation and could lead to significant spurious results. The researcher must also carry out every step with great caution in accordance with advanced statistical principles, giving particular consideration to maintaining the properties of white noise as much as possible. As for the limitations of this research, a major concern is the lack of existing studies in this field within the Thai context, as well as the absence of appropriate analytical tools that can effectively support evidence-based policy formulation and national planning.

As a result, Thailand has historically lacked accurate and suitable decision-making instruments, leading to misaligned governance directions and policy formulation. In practice, national policies have tended to prioritize economic growth as the primary objective, while insufficient attention has been given to environmental development alongside social progress. This imbalance has generated negative consequences, particularly the degradation of environmental systems and irreversible changes to social and cultural structures. Cultural values and traditions that have been altered or lost due to unsustainable development cannot be fully restored, similar to environmental resources that have deteriorated beyond recovery.

CONCLUSIONS

This study entitled A Causal Relationship Model of Social and Cultural Change Influencing the Future Success of Integrated and Sustainable Tourism Management in Thailand, developed and validated the Logit-PA model as an integrated analytical framework for examining the causal relationships among the social and cultural, BCG-economic, and pro-environmental sectors influencing sustainable tourism development in Thailand. The empirical findings demonstrate that the proposed model exhibits superior forecasting performance compared with conventional approaches, confirming its suitability for long-term policy analysis and strategic planning. The results further reveal that stakeholder participation within the social and cultural sector is the most influential factor affecting sustainable tourism success. At the same time, incorporating this variable into the proposed policy scenario substantially improves long-term environmental outcomes by reducing projected greenhouse gas emissions to a level consistent with Thailand's net-zero emissions target by 2065.

The study also demonstrates that sustainable tourism can only be achieved through the balanced integration of economic development, social and cultural preservation, and environmental protection under the principles of the BCG economy. Accordingly, enhancing the capacity of tourism service providers, strengthening stakeholder participation, promoting the consumption of sustainable tourism products and services, and improving environmental resource management should be implemented simultaneously to maximize policy effectiveness and long-term sustainability.

The principal contribution of this research lies in the development of a context-specific decision-support model that integrates quantitative forecasting with qualitative policy synthesis to support evidence-based national tourism planning. The proposed framework provides substantial practical value for policy formulation and implementation by enabling governments to identify high-impact policy priorities and evaluate alternative development scenarios with greater precision. Furthermore, although the model was developed within the context of sustainable tourism management in Thailand, its analytical framework may be adapted and applied to other development sectors and geographical contexts where integrated sustainability planning is required under changing future conditions.

Abstract: Samui Island is a world-class marine tourism destination and a key economic driver for Thailand. Over the past several decades, Samui Island has experienced rapid spatial transformation. Development to support the tourism industry has led to rapid land use changes. The objective of this research is to analyze changes in land use patterns around Samui Island, Thailand, between 2006 and 2024 using Geo-information Technology (Geo-IT). Land use classification was performed from Landsat satellite images at each time period using the Random Forest classification method to detect and track changes in each type of land use. Future land use patterns in 2042 were then modelled using the CA-Markov model. Research results showed that in 2006, the majority of Samui Island's land area was covered by coconut, accounting for over 58.03% of the total area (137.28 km^2). This area is located on the steep slopes of the central part of Samui Island. After 18 years, the area under coconut cultivation decreased, and the area was transformed into durian plantations and villages. The overall accuracy of land use classification was 84.1%, 81.7%, and 75.3% in 2024, 2014, and 2006, respectively. A CA-Markov model simulation of land use patterns for the year 2042 shows that over the next 18 years, land use patterns for City, Town, Commercial (U1), and Institutional (U3) land use categories will increase by 1044.05% and 1050.27%, respectively. Urban expansion in the northeastern part of Samui Island, in the Bo Phut area, has seen grass land transformed into villages. In the southern part of Samui Island, around Na Mueang, Paddy Field has been transformed into a village, the same as the western part of Samui Island, around Taling Ngam. The results highlight the predicted spatial and temporal dynamics of land use changes in Samui Island, revealing land use changes resulting from urban expansion and agricultural expansion, particularly coconut and durian, which are local cash crops. Therefore, it is imperative to monitor the areas that are sensitive to the changes occurring in the plain landscape around the island, especially the areas of Paddy field, Grass land, Forest land, Orchards, and Perennial crops that are often converted into urban areas and villages. However, this research provides spatially-based land use data that will be useful for effective land use development planning in coastal tourism cities. This data will support decision-making in preparing for sustainable tourism development in the future.

INTRODUCTION

Land use changes (LUC) in islands has more complex and severe impacts than on mainland areas (Oktavia et al., 2024; Han et al., 2024). This is because islands have limited, fragile ecosystems and limited natural resources (Moustakas et al., 2025; Wayesa et al., 2025). Forest and agricultural areas are inevitably affected by urban expansion and construction (Mustelier & Henríquez, 2024; Thien et al., 2025). The main impacts of LUC on the island can be divided into three main areas: environmental and ecological, resource, and socio-economic. Environmental and ecological impacts, such as destruction of local animal and plant habitats, coastal degradation, natural disasters (flood, landslide etc.) (Dieno & Pathan, 2025; Tsumita et al., 2025; Aldiansyah et al., 2025).

The impacts of limited resources include freshwater shortages, soil erosion, and waste disposal problems on the island (Kamaraj & Rangarajan, 2022; Bikis et al., 2025). And, social and economic impacts include land use conflicts, local economic vulnerability, and changes to traditional cultures and ways of life (Quintas-Soriano et al., 2022).

Tourism is one of the most important drivers of land use change in areas with tourism potential, such as islands, coasts, or important World Heritage sites (Rimba et al., 2021; Liu et al., 2025; Ibarra-Núñez & Ortega-Rubio, 2025). This is often associated with the expansion of buildings, and the reduction of natural and agricultural areas (Birthal et al., 2021). Tourism acts as a magnet, attracting investment and creating demand for land in ways that are not conventional, leading to a rapid and intensive shift from traditional land use to commercial use. Research on the use of Geo-IT has often been applied to assess land use in major tourist cities such as Guangxi. It has been found that the majority of land use patterns are forested, but by 2020, the area will be affected by a shift from forestry to agriculture. It was also found that wetlands are decreasing (Qiu et al., 2021). In Hainan Island, the ecological system has been severely impacted by LUC for tourism development, with forest areas being converted into cities and farmland (Yang et al., 2024). Zhangjiajie, China, has been seen the largest increase in built-up area during 2000-2020, with most of its farmland and grasslands converted to built-up areas. The main cause is the shift to land use for tourism-related construction (Wang et al., 2023). In São Paulo, urban expansion has been found to have an impact on the area's freshwater resources, causing water shortages for the tourism sector (Petroni et al., 2022).

Tourism affects the physical processes of an area, particularly its natural resources and socio-economic aspects. For example, a study conducted in the tourist town of Menfi (Italy) found that during 2007-2022, there was a decrease in the area of grape cultivation, and an increase in the area for residential tourism (second homes). This, along with the cultivation of olives, has resulted in significant soil erosion. The main drivers are socioeconomics and the shift to olive cultivation in low-lying areas with landscape value (Tonolli et al., 2024). In the Sungai Karang coastal area (Malaysia), there was a rapid expansion of resorts and coastal infrastructure during 1966-2013 (Marzuki et al., 2024). Kolkata, India, during 2005-2019, experienced rapid urbanization, resulting in a decrease in vegetation cover, particularly in the urban core, and an increase in built-up area, which in turn increased surface temperatures (Chatterjee & Majumdar, 2022).

And in Ubud, Bali, they have analyzed the transformation of courtyard spaces to support sustainable tourism based on the principles of the Culture of Harmony. Qualitative research findings revealed that most courtyard areas (Palemahan or Teba), formerly used for animal breeding, raising/removing dirt, and gardening, have been transformed into tourist accommodations. Quantitative findings confirmed that this transformation has had positive economic, social, cultural, and environmental impacts, supporting sustainable tourism (Waridin & Astawa, 2021).

Therefore, it is imperative to urgently study LUC in major tourist destinations like Samui Island to prepare for economic growth while preserving quality of life, the environment, and local identity.

Samui Island is the second largest island in Thailand. It is located on the eastern coast of southern Thailand in the Gulf of Thailand. The word "Samui" has several uncertain origins, but the most reliable hypothesis is that it comes from the southern Tamil word "Samoi," meaning "waves," which later became corrupted into "Samui." Other theories suggest that the name comes from the Hainanese word "shao mui," which means "first checkpoint," or from the name of a tree called "mui," which grows widely on the island. Samui Island is a world-class marine tourism destination and a key economic driver for Thailand (Pongponrat, 2022; Iabsap & Phucharoen, 2025). Known for its beautiful beaches, crystal-clear waters, and iconic coconut groves, Samui Island has become a popular destination, attracting tourists from around the world. Over the past several decades, Samui Island has experienced dramatic spatial changes. Rapid development to support the tourism industry has led to the most pronounced changes in land use (Mustafa et al., 2019; Pongsakornrungsilp & Pongsakornrungsilp, 2023). The area has rapidly transformed from agricultural areas, particularly coconut plantations, into service areas. These areas have been intensively converted into hotels, resorts, vacation homes, and various tourism infrastructure. The expansion of construction has significantly diminished the original landscape of "Coconut Island" (Ubonsri & Daungthima, 2024). This shift, particularly in the easily accessible coastal plain, reflects a complete economic shift from agriculture to the service sector. Spatial changes on Samui Island thus fully transform from an agricultural society into an international tourism hub. This has resulted in challenges in natural resource management, environmental impacts, and social pressures from rising land prices and the cost of living in the area. Therefore, sustainable management requires robust spatial planning to control urban expansion and strike an appropriate balance between economic growth and the sustainable preservation of the island's natural and cultural identity.

The objective of this research is to analyze land use pattern changes on Samui Island, Thailand, between 2006 and 2024 using geoinformatics technology and to model future land use patterns through 2042 using a CA-Markov model. This research utilized land use classification from Landsat satellite imagery at different times to detect and track changes in different land use types. This research process aligns with the Sustainable Development Goals (SDGs). Especially SDG 11, Sustainable Cities and Communities, as it contributes to understanding urban sprawl caused by tourism (Kelly-Fair et al., 2022; Enoh et al., 2023; Estoque et al., 2021; Ferdos et al., 2026). This research aims to inform urban planning and determine effective land use control measures. This research helps predict and prevent the loss of important areas, such as forests or agricultural areas. This aligns with SDG 15: Life on land, protecting and restoring terrestrial ecosystems (Cao et al., 2023; Utama et al., 2024). It also supports SDG 8: Decent work and economic growth by promoting sustainable tourism that balances economic benefits with the preservation of natural resources and the environment, which are the heart of long-term tourism (Song et al., 2023; Appelt et al., 2022; Suhud et al., 2025). The expected outcomes of this research include empirical spatial data and tools for policy decision-making. In particular, historical land use change maps and models predicting future urban expansion patterns will be obtained. This will enable local authorities to more effectively plan urban planning and implement land use control measures, preventing encroachment on environmentally sensitive areas and planning appropriate infrastructure and utility investments. Furthermore, these results provide an important foundation for promoting sustainable tourism by balancing economic growth with the long-term conservation of Samui Island's natural resources and unique identity.

MATERIALS AND METHODS

Study area and Background

Samui Island is the largest island in the Gulf of Thailand and the second largest after Phuket (Iabsap & Phucharoen, 2025). It covers an area of 236.57 km^2. Samui Island is located between latitudes 9°20' N to 9°40' N and longitudes 99°50' N to 100°10' N (Figure 1). Samui Island is located northeast of Surat Thani Province in the Gulf of Thailand, approximately 84 km off the coast. Samui Island's main topography is a mountainous region in the central part of the island, straddling the northwest to southeast. The highest peak is Khao Pom, at 645 m. high. The surrounding area is a coastal plain, which is why most settlements are located on this terrain (Bai et al., 2021).

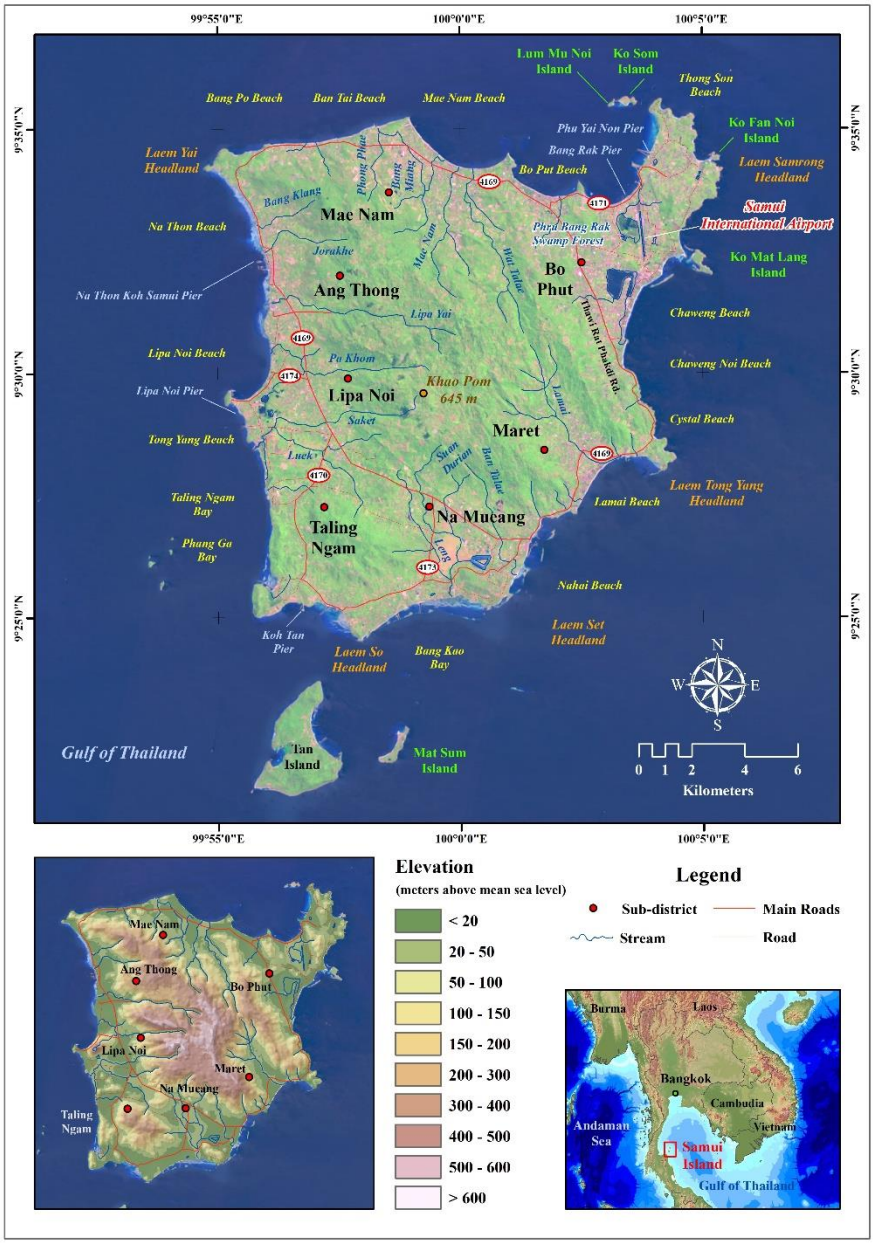

Figure 1. Location of Samui Island, Surat Thani Province, Thailand (Source: Collected and processed by authors)

The largest coastal plain covers the northeastern part of Samui Island, where Bo Phut subdistrict is located. This area has beautiful coastline and beaches, including Chaweng and Chaweng Noi beaches, which are the most beautiful on Samui Island. It is also home to Samui International Airport. The southern part of the island features a narrow coastal plain with beautiful beaches like Lamai and Nahai, located between Laem Tong Yai and Laem Set headlands. The southern part of the island features indented bays, including Bang Kao, Phang Ga, and Taling Ngam bays. The western part of the island features a long coastal plain with important beaches like Tong Yang, Lipa Noi, and Na Thon. Na Thon Beach is home to a major transport pier, Na Thon Koh Samui Pier, for travel between the island and the mainland.

The northern part of the island, from Laem Yai Headland to Laem Samrong Headland, features a long coastal landscape that extends to the northeastern coastal plain. Important beaches include Bang Po, Ban Tai, Mae Nam, Bo Put, and Thong Son beaches (Yeemin et al., 2024). Laem Samrong Headland is also home to important ports for travel

between other major islands in the Gulf of Thailand, namely Bang Rak and Phu Yai Non Pier. Samui Island's drainage system is characterized by a radial drainage system. Controlled by geological features, the central part of the island is a large Triassic igneous rock mountain range (Nazaruddin, 2020). As the mountain range was eroded by rainwater and streams, it formed a coastal plain around Samui Island, covered with modern sedimentary rocks, known as Quaternary Alluvial Deposits. The major drainage systems are: 1) River systems flowing into the Gulf of Thailand to the north, including the Phong Phae, Bang Miang, Mae Nam, and Wat Talea streams. 2) River systems flowing into the Gulf of Thailand to the south, including the Lamai, Ban Talae, Suan Durain, and Leng streams. And, 3) River systems flowing into the Gulf of Thailand to the east, including the Bang Klang, Jorakhe, Lipa Yai, Pa Khom, Saket, and Luek streams.

Tourism on Samui Island began in the 1970s with backpackers seeking the pristine nature, tranquil beaches, and simple island lifestyle. At that time, the main occupation of Samui Island residents was coconut farming, which led to the image of the "Coconut Island" alongside the beauty of the sea. In the 1980s, tourism on Samui Island began to expand rapidly, driven by infrastructure development. A pier and a road around the island, Thawi Rat Phakdi Road (Highway 4169), were built, making travel easier. In 1989, Bangkok Airways Public Company Limited opened Samui Airport, making travel from Bangkok convenient and faster, attracting more premium tourists (Vu & Turner, 2006).

Furthermore, investment in numerous world-class hotels and resorts has enabled Samui Island to cater to a diverse range of tourist groups, from backpackers to high-end travelers. Samui Island also boasts tourism resources, particularly its natural beauty, such as its beautiful beaches, such as Chaweng, Lamai, and Bophut. This has resulted in a variety of tourism activities, including water activities (snorkeling, scuba diving, kayaking, jet skiing, etc.), cultural activities such as temples and local communities, nature and adventure tourism such as trekking to waterfalls, an open zoo, ATV rides, and health tourism such as massage and spas, which are abundant on Samui Island.

Data Preparation

This research collected satellite imagery from Landsat 5TM, 8OLI/TIRS, and 9 OLI/TIRS satellites, covering the years 2006, 2014, and 2024, respectively (Table 1). These satellite images are available from the U.S. Geological Survey. Band combinations were then performed in ArcMap 10.8 software to obtain easily interpretable land cover and various land use patterns to track land use change over time. Band combinations were performed this time. Landsat 5TM satellite imagery has been blended with the R: G: B band of 543, which is a combination of short-wave infrared, near-infrared, and red bands (Thien et al., 2025; Le et al., 2025). Landsat 8OLI/TIRS and Landsat 9OLI/TIRS satellite imagery have been blended with the R: G: B band of 654, which is a combination of short-wave infrared, near-infrared, and red bands (Sales et al., 2023). Once the satellite imagery from the three time periods was acquired, it was processed through the Satellite Imagery Cloud Removal and Correction process, as satellite imagery covering the study area often exhibits cloud cover almost year-round due to the tropical equatorial climate. Radiometric correction using standard deviation was then performed to obtain sharper satellite imagery prior to land cover interpretation (Du et al., 2002; Hantson & Chuvieco, 2011).

METHODOLOGY

The research process includes the Geo-IT process and the CA-Markov model, as shown in Figure 2. Details of each step are briefly explained below:

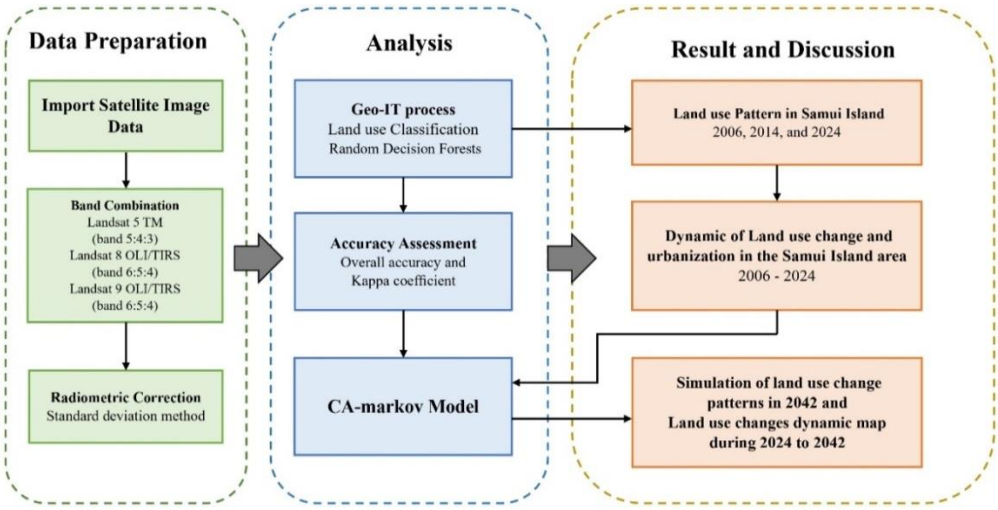

Figure 2. Flow chart of methodology

Geo-IT process

Geo-IT is a process that combines remote sensing and GIS. This research applied Geo-IT to land use and land cover classification. In this step, satellite imagery from three time periods (2006, 2014, and 2024) was imported into ArcGIS 10.8 software to analyze land use classification using machine learning principles. This approach utilises deep learning classification techniques, such as Random Decision Forests (or Random Forest), an ensemble learning method for land use and land cover classification. The Random Decision Forests method is a popular method for efficiently interpreting land use (Phinzi et al., 2023). Random Forest is a classification method that relies on an ensemble of decision trees. By combining the predictions of multiple weak learners, it generally attains higher accuracy than any single tree. The model's final output is produced by aggregating the decisions of all trees in the ensemble, most often through majority voting (Rodriguez-Galiano et al., 2012; Avci et al., 2023). The training process for a Random Forest is incremental, with decision trees added sequentially. After each tree is built, the algorithm assesses the model's performance using out-of-bag (OOB) samples. These samples are run through the forest, and their predicted labels are determined via majority voting (Jamali et al., 2024). The importance or contribution of each feature to an individual tree is then computed as described in Equation 1 (Krishna & Gopinath, 2022).

$$fi_i = \frac{\sum_{j:node\ j\ splits\ on\ feature\ i} ni_j}{\sum_{k \in all\ nodes} ni_j} \quad (1)$$

Where fi_i is the importance of feature i; ni_j is the importance of node j. These can then be normalized to a value between 0 and 1 by dividing by the sum of all feature importance values (Equation 2) (Krishna & Gopinath, 2022):

$$normfi_i = \frac{fi_i}{\sum_{j \in all\ features} fi_i} \quad (2)$$

The final feature importance, at the Random Forest level, is its average over all the trees. The sum of the feature's importance value on each tree is calculated and divided by the total number of trees (Equation 3) (Krishna & Gopinath, 2022):

$$RFfi_i = \frac{\sum_{j \in all\ trees} normfi_{ij}}{T} \quad (3)$$

Where $RFfi_i$ is the importance of feature i calculated from all trees in the Random Forest model; $normfi_{ij}$ is the normalized feature importance for i in tree j; and T is total number of trees. The results of the land use pattern interpretation are displayed as the overall accuracy and Kappa coefficient (KHAT) to assess the accuracy of the classification of various data that appear on satellite imagery (Foody, 2020; Chaaban et al., 2022). Sampling points in the study area were determined based on data from the Land Development Department (LDD), Thailand. To evaluate classification accuracy, this study utilizes the confusion matrix, overall accuracy (OA), and kappa coefficient. The matrix distinguishes between correct assignments (diagonal) and misclassifications (off-diagonal), specifically identifying commission errors (FP) that impact precision and omission errors (FN) that represent missed targets. Overall accuracy is derived from the ratio of correct predictions (TP + TN) to total samples. Additionally, the kappa coefficient accounts for chance-based agreement; values near +1 reflect high model reliability, whereas negative values suggest systematic discrepancies between classified results and reference data. The OA was calculated based on Equation 4 and the kappa coefficient calculated using Equation 5 (Sarvestani et al., 2025):

$$Overall\ accuracy\ = \frac{TP+TN}{TP+FP+TN+FN} \quad (4)$$

where *TP* is the number of correct positive predictions, *TN* is the number of correct negative predictions, *FP* is the commission error, and *FN* is the omission error.

$$\text{Kappa coefficient} = \frac{p_0 - p_e}{1 - p_e} \quad (5)$$

where P_0 is the observed accuracy, and P_e is the expected accuracy.

The validation was performed compared with the data obtained from the classification. The classification criteria were as follows (Herano et al., 2025): < 0 means unacceptable classification data; 0.01 – 0.40 means fair classification data; 0.41 – 0.60 means moderate classification data; 0.61 – 0.80 means good classification data; 0.81 – 1.00 means very good classification data. After validation of the data obtained from the land use pattern interpretation, the data that passed the Overall Accuracy and KHAT criteria were analyzed for land use change using the Change Detection method in the Tabulate area analysis function in ArcGIS 10.8 software. The change detection analysis can be calculated as Equation 6 (Puyravaud, 2003; Kiriwongwattana & Waiyasusri, 2024):

$$\Delta = [(A_2 - A_1) / A_1 \times 100] / (T_2 - T_1) \quad (6)$$

Where Δ is the percentage change in land use pattern. A_1 is the land use type at time one (T_1). A_2 is the land use type at time two (T_2). The results are displayed as the land use proportions of each type on a transition matrix map, which shows the land use change patterns from 2006 to 2024 on Samui Island.

CA-Markov model

The CA–Markov model is a dynamic, multi-scale, spatially explicit, raster-based approach capable of identifying locations with a high likelihood of future land use change (Guan et al., 2011; Jafari et al., 2016; Xu et al., 2023). In this framework, the CA–Markov component functions as the non-spatial demand module, estimating land use transitions over a series of years at an aggregate level. Markov chain analysis, a stochastic method, characterizes how specific conditions evolve step by step within a land use geospatial dataset. The model is built using land use distributions at the start (X_t) and end (X_{t+1}) of a discrete time interval, along with a transition matrix (X_{LU}) that captures the LUC occurring

during that period. The values in this matrix come directly from classifying the three multispectral Landsat images using the maximum likelihood algorithm, expressed as the proportion of each land use category (Adhikari & Southworth, 2012). This matrix is then used to establish the "link'' in the Markov chain, as represented in Equation 7.

$$P_{i,j} \times i_t = i_{t+1}, \qquad \begin{bmatrix} P_{uu} & P_{ua} & P_{uw} \\ P_{au} & P_{aa} & P_{aw} \\ P_{wu} & P_{wa} & P_{ww} \end{bmatrix} \begin{bmatrix} U_t \\ A_t \\ W_t \end{bmatrix} = \begin{bmatrix} U_{t+1} \\ A_{t+1} \\ W_{t+1} \end{bmatrix} \tag{7}$$

where t is the time (Year), $P_{i,j}$ is the transition probability matrix of the land use class i change to class j. i and j are the land use classes in the first year and the second year, respectively. The CA-Markov analysis was used to determine the demand for the probability of each land use pattern, where the probability of transition ($P_{i,j}$) is given for every ordered set of conditions. In a CA-Markov with a limited number of conditions, such as j, a new transition probability matrix is bounded, as in Equation 8 (Butt et al., 2015):

$$V_j \times P_{jk} = [V_1, V_2, V_3, \ldots, V_n] \begin{bmatrix} P_{11} & P_{12} & \ldots & P_{1m} \\ P_{21} & P_{22} & \ldots & P_{2m} \\ P_{31} & P_{32} & \ldots & P_{3m} \\ \vdots & \vdots & & \vdots \\ P_{n1} & P_{n2} & \ldots & P_{nm} \end{bmatrix}, \tag{8}$$

Where $Vj \times Pjk$ is the proportion of land use in the second year; P_{jk} is the land use activity (f) derived from the transition probability matrix; V_j is the proportion of land use in the first year; j is the type of land use in first year and; k is the type of land use in the second year. The results of the model will provide spatially representative land use data for 2042. This data will be used to plan island development and prepare for future spatial changes in the Samui Island area.

RESULTS

Land use pattern in Samui island area

Classifying land use patterns from Landsat satellite imagery from three time periods: 2006, 2014, and 2024, using the Random forest classification method, resulted in this research on the land use patterns in Samui. There are 15 types of island classifications: Paddy field (A1), Perennial crops (A3), Perennial crops (A4), Durian (A403), Coconut (A405), Forest land (F), Grass land (M1), Mineral (M3), Beach (M6), City, Town, Commercial (U1), Villages (U2), Institutional land (U3), Transportation (U4), Recreation area (U6), and Water bodies (W). The overall accuracy assessment of land use classification was 84.1%, 81.7%, and 75.3% in 2024, 2014, and 2006, respectively, with a Kappa coefficient of 0.81, 0.78, and 0.70, respectively. The classification results are considered good to very good.

In 2006, the majority of Samui Island's land use, over 58.03% of the total area (137.28 km²), was used for coconut cultivation. This is because the study area has long been a coconut-growing region, a local economic crop and a fundamental part of the Samui islanders' way of life, earning it the nickname "Coconut Island." The most popular coconut variety is the Samui Cooking Coconut. This variety has been renowned and cultivated for over 100 years due to its large size, good weight, rich and delicious coconut milk, and its acceptance in the market. The second most common land use on Samui Island was Forest land (16.33% of the total area), and Villages (8.60% of the total area), respectively. The second most popular crop after coconut was durian, covering 5.66% of the total area (13.38 km²). The majority of durian plantations are located in the central part of Samui Island. This area is characterized by mountainous and sloping terrain on the island. The most popular durian varieties grown are Monthong, Chanee, and Met Nai Samui. Monthong is the most popular variety for commercial cultivation and export to China. Chanee is primarily grown commercially domestically. Met Nai Samui is a rare local variety currently being developed and propagated on Samui Island.

Table 2. Land use pattern statistics in Samui island area in 2006, 2014, and 2024 (km^2) (Source: Processed by authors)

Land Use Pattern		2006		2014		2024		Area Change (km^2)		
		km^2	%	km^2	%	km^2	%	2006 to 2014	2014 to 2024	2006 to 2024

Dynamic of land use change in the Samui island area during 2006 to 2024

This research found that over the past 18 years, the area planted with coconut trees has decreased by more than 76.09 km², a reduction of over half. This change in coconut plantation area is due to the expansion of the tourism business and changes in the lifestyle of local people, shifting from agriculture to the tourism service sector. In addition, some coconut plantations have been replaced by other agricultural forms and expanded village areas. The trend shows that land use for durian, grass land, and villages is increasing exponentially. For example, durian cultivation has become the largest agricultural crop on Samui Island, surpassing coconuts in terms of production value. Turf land is awaiting conversion from traditional agriculture like coconut cultivation to construction or in preparation for expanding durian cultivation. Land use with less change includes paddy field, minerals, beach, city town and commercial, institutional land, and transportation. The proportions of each land use type are detailed in Figure 3 and Table 2.

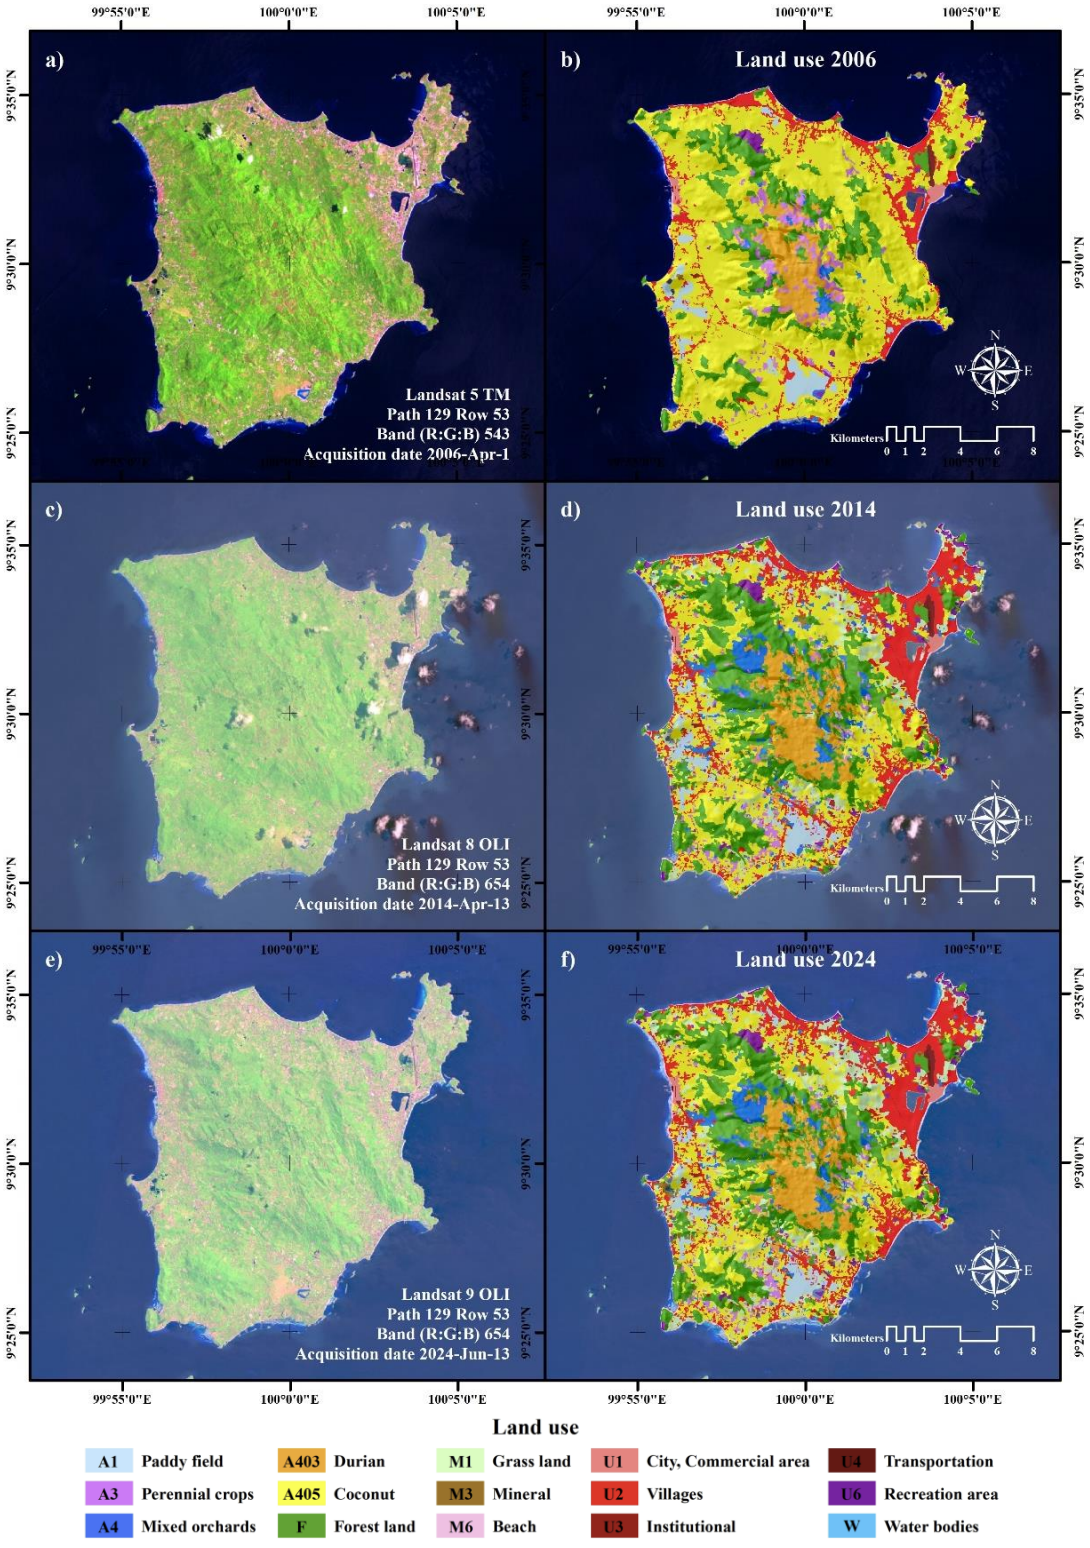

Figure 3. Landsat satellite imagery and land use pattern of Samui island area in 2006, 2014, and 2024 (Source: Collected and processed by authors)

Over the past 18 years, Samui Island has shown spatial changes, including changes in agricultural areas such as coconut, durian, and perennial plantations, as well as an increase in forest areas and urban expansion. Changes in land use between 2006 and 2024 were researched using the tabulate area method in ArcMap. The results are presented in the form of a metric table of LUC as shown in Table 3. This research found that, between 2006 and 2024, the most significant change in land use was observed in Samui Island, with a substantial increase of 1555.13% over the past 18 years. This type of land use, which was originally only 1.51 km², has now increased to 24.99 km².

This area is being prepared for future land use changes, such as durian cultivation, perennial tree plantations, or building construction. The second most significant change was in Orchards (A4), with a rate of change as high as 479.46%. Between 2006 and 2024, the proportion of this land use increased from 1.68 km² to 9.74 km². This is attributed to the increasing commercial cultivation of other fruit trees such as rambutan, mangosteen, and other fruits.

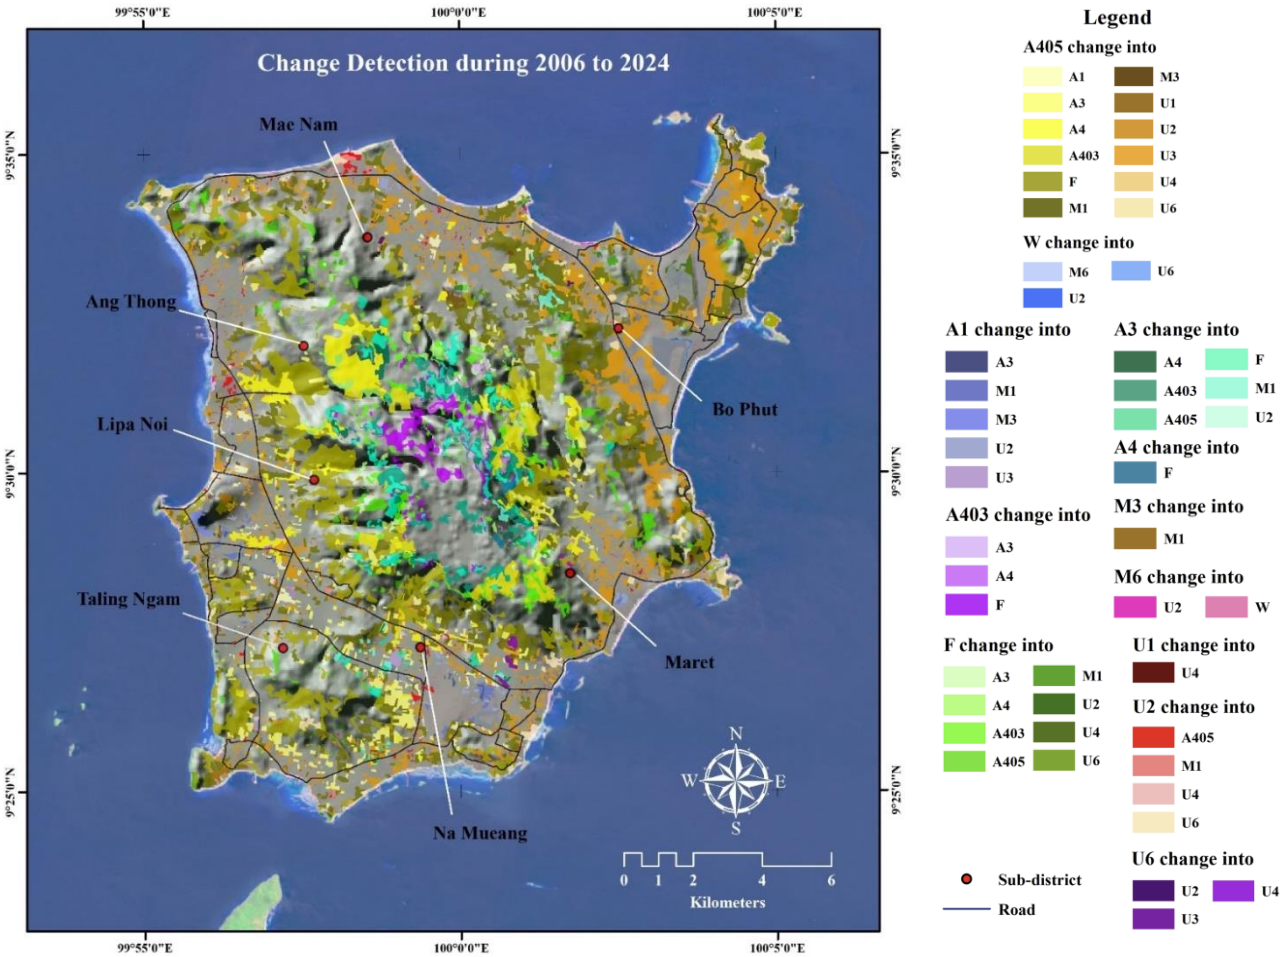

Figure 4. LUC dynamic map during 2006 to 2024 in Samui island area, Surat Thani Province (Source: Collected and processed by authors)

However, if we compare areas with the most significant land use changes, it would undoubtedly be coconut plantations. During 2006 to 2024, this area showed the largest decrease in land area, due to a land area reduction of 76.09 km^2. The coconut plantation area has been transformed into Forest land, Grass land, Villages, Orchards, Perennial crops, Durian, Recreation area, Minerals, Paddy field, Water bodies, Institutional land, Transportation, City Town Commercial, and Beach, respectively. The proportion of land changed to each of these land use types is 20.99, 20.36, 19.51, 5.55, 4.70, 4.22, 2.13, 0.83, 0.82, 0.32, 0.23, 0.21, 0.05, and 0.03 km^2, respectively.

Figure 4 shows the area changes in each land use type. It can be seen that the areas surrounding the sloping mountain range, where the coconut plantation was located, have been primarily transformed into forest land and durian orchards. In most lowlands, coconut plantations have been converted to fruit trees, perennial plants, and villages. Specifically in the southwestern plains of the island, most coconut plantations have been repurposed into fruit trees and perennial plants. The coastal area in the northeast (Laem Samrong) is also affected. In the northern and eastern parts of the island (along the Thawi Rat Phakdi Road (HW 4169)), most coconut plantations have been converted into villages. Coconut cultivation on Samui Island has declined significantly due to economic and land use changes. The expansion of tourism and real estate has led to the conversion of many coconut plantations into resorts and hotels. At the same time, unprofitable coconut prices and reduced competitiveness compared to other production areas have significantly hampered farmers' incentive to continue cultivation. Furthermore, pest infestations such as the black-headed caterpillar and black spiny beetle. In addition, the impact of erratic weather patterns further exacerbates the decline in yields, leading to a gradual decrease in the area planted with coconut trees, which are a symbol of the island.

Simulation of land use change patterns with the CA-markov model in the Samui Island area

The land use pattern simulation using the CA-Markov model shows the results of this research as follows: Over the next 18 years, land use patterns of City, Town, Commercial (U1) and Institutional land (U3) will increase by 1044.05% and 1050.27%, respectively. However, when compared in terms of area, land use patterns of Villages (U2) and City, Town, Commercial (U1) will see increases of 16.43 km^2 and 13.16 km^2, respectively. Table 4 shows the changes in land use patterns, indicating that Grass land (M1), Paddy field (A1), Durian (A405), Recreation area (U6), Forest land (F), Water bodies (W), Beach (M6), Orchards (A4), Perennial crops (A3), Mineral (M3), Institutional (U3), and City, Town, Commercial (U1) will see changes of 4.60, 4.41, and 13.16 km^2 respectively, respectively, as the land is transformed into Villages (U2). 3.22, 1.13, 1.11, 0.66, 0.50, 0.39, 0.37, 0.24, 0.17, and 0.04 km^2, respectively. Figure 4 shows areas with land-use change. In the northeast of Samui Island, in the Bo Phut area, grassland has been transformed into a village. Similarly, in the southern part of Samui Island, in the Na Mueang area, paddy fields have been transformed into villages. The same applies to the western part of Samui Island, in the Taling Ngam area.

Table 4. Matrix of Land use change in Samui Island area during 2024 to 2042 (km^2)

The land use areas, showing the largest decreases, were Paddy field and Mineral, with decreases of -96.76% and -94.82%, respectively. However, when compared in terms of area, the Grass land (U2) land use pattern showed a significant decrease of -19.50 km^2. However, the substantial increases in U1 and U3 land use categories, reaching 1,044.05% and 1,050.27% respectively, are primarily driven by the expansion of tourism in the Koh Samui Island. This growth has catalyzed urban sprawl and infrastructure development, particularly within residential areas, government offices, and commercial tourism zones. Details of the changes in land use proportions between 2024 and 2042 are shown in Table 4. The research results on future land use patterns obtained from the CA-Markov model are shown in Figure 5, and the future land use patterns between 2024 and 2042 in the Samui Island area are shown in Figure 6.

The validation of the CA–Markov simulation was performed by comparing the predicted 2024 map with the observed 2024 map. The results demonstrated an overall accuracy of 81.43% and a Kappa coefficient of 0.742, indicating that the CA–Markov model provides an acceptable and reliable level of simulation performance.

DISCUSSION

Several research studies have applied the CA-Markov model to simulate future land use patterns. In Thailand, this model has been used to study future LUC in major cities, such as Pattaya (Wiboonwatchara et al., 2024), Nakhon Ratchasima (Kukuntod & Wijitkosum, 2025), and key cities in the Eastern Economic Corridor (EEC) (Waiyasusri et al., 2024), all of which are experiencing significant economic growth. The findings from these studies are consistent with this research, which concludes that cities with strong economic and tourism growth inevitably face challenges related to urban expansion and the expansion of agricultural land. Furthermore, this model has also been applied to various regions. Because analysis of potential impact areas, such as results from CA-Markov models, has helped plan and predict agricultural land use in the Mayurakshi river basin, India (Soren et al., 2024).

In Li, Xinjiang, China, research shows a rapid decrease in forest area (Luo et al., 2025). And in Okara district, Pakistan, future land use predictions from such models show urbanization in arid areas by 2044 (Duan et al., 2025). However, these research findings generally conclude with a similar trend of urban expansion, which differs from this research's findings that, in addition to urbanization in the northeast, south, and west of Samui Island, the central area shows a significant expansion of coconut cultivation.

This research forecasts future land use and creates a Matrix of Land Use Change between the current year and the future. This demonstrates the areas experiencing actual land use changes, something previous research did not analyze using this matrix, thus lacking a clear picture of the impact. Furthermore, land use classifications were not as diverse as in this research. The results highlight the predicted spatial and temporal dynamics of LUC in Samui Island, resulting from urban expansion and the expansion of agricultural land, particularly coconut and durian, which are local cash crops. Overall, this research reveals the potential challenges arising from various types of land use changes.

Therefore, it is crucial to monitor sensitive areas, especially paddy fields, grassland, forest land, orchards, and perennial crops, which are easily transformed into urban areas, villages, or coconut and durian plantations. A particularly concerning area is the central part of Samui Island, which is largely susceptible to conversion into coconut and durian plantations due to its hilly and sloping terrain. If neglected, this could lead to soil erosion and future landslides. This research contributes to a concrete understanding by simulating future land use patterns using a CA-Markov model. The data is presented as a spatial database for planning how to address areas sensitive to change. This model is beneficial for sustainable land use planning. Currently, Samui Island needs to adapt to become a sustainable, ecotourism destination. The results of this model will be useful for spatial development planning in coastal tourist cities, focusing on development that minimizes disruption to nature and promotes more environmentally friendly activities.

CONCLUSION

This research applied the CA-Markov model to predict future land use change (LUC) changes over the next 18 years (up to 2042) to support effective spatial planning in coastal tourist cities, using Samui Island as a case study. The predictive model reveals a substantial expansion of urban areas by 2042, with City, Town, Commercial (U1) and Institutional (U3) areas projected to surge dramatically by 1,044.05% and 1,050.27%, respectively.

This urban expansion is heavily concentrated in the northeastern region and progressively spreads along the northern and eastern corridors, driven primarily by intense commercial and tourism-related activities. Consequently, this rapid urbanization induces significant land use pressure on surrounding areas; to compensate for lost agricultural lands, coconut plantations are projected to encroach into forest borders, particularly along the foothill regions across the island. These spatial projections reflect current planning vulnerabilities, such as unmanaged urban density, deteriorating and narrow road infrastructure, and severe traffic congestion—most notably in Bo Phut Subdistrict.

To mitigate these unsustainable trends, urgent land use regulation, updated spatial zoning, and comprehensive infrastructure development must be enforced alongside strict legal compliance. Future research should further enhance model precision by incorporating additional socioeconomic variables, infrastructure constraints, and policy interventions. Ultimately, this study provides critical baseline spatial data to guide sustainable tourism development, directly aligning with Sustainable Development Goals (SDG 8: Decent Work and Economic Growth, SDG 11: Sustainable Cities and Communities, and SDG 15: Life on Land) for Samui Island.

Abstract: Ghardaia, a prominent tourist destination in Algeria, attracts numerous visitors annually, contributing significantly to the region's economy. Known for its rich historical, cultural, and natural heritage, the region's urban landmarksearned UNESCO World Heritage status in 1982. One of its most important traditional industries is the handmade carpet "Zarbia" sector, which has been part of the region's heritage for thousands of years. Despite the challenges posed by modern industries, this eco-friendly craft remains highly valued, providing a source of livelihood for local women and accommodating workers of all ages, from young people to the elderly. However, in recent years, the industry has faced a decline, posing a risk to its survival. The study aims to identify strategies for sustaining the handmade carpet "Zarbia" weaving as a viable income source, while enhancing tourism in Ghardaia and Algeria. This paper explores the relationship between Zarbia production and tourism in Ghardaia, Algeria, using both qualitative and quantitative approaches. The study analyzes survey data, tourism flow statistics, and artisans 'distribution to identify key trends, challenges, and opportunities. The findings suggest that Zarbia production plays a significant role in cultural tourism, but challenges, such as high costs and limited marketing, hinder its full potential. Data analysis utilized SPSS and Excel. The paper concludes with recommendations for integrating Zarbia into the tourism sector and making predictions for future growth.

Keywords: Handmade carpet "Zarbia" weaving, Cultural heritage tourism, Women artisans, Handicraft sustainability, Ghardaia, Algeria

INTRODUCTION

Traditional industries are increasingly recognized as a vital component of intangible cultural heritage, encompassing the practices, skills, and symbolic meanings passed down through generations (UNESCO, 2003). Beyond their cultural value, they are also an important source of livelihood and identity, linking communities to both their history and their socio-economic environment. Recent scholarship highlights that traditional crafts play a dual role: they safeguard heritage while also functioning as economic assets in the growing global market for cultural and heritage tourism (Richards, 2018; Zargham, 2007; Bano, 2021; Geçikli et al., 2024, Tho-Ard et al., 2026). The relationship between handicrafts and tourism has been well-documented, with studies showing that tourism creates new market opportunities for artisans, while traditional crafts add authenticity and cultural depth to the visitor experience (Zargham, 2007; Mustafa, 2011; John, 2014; Kherrour et al., 2020; Boulhila et al., 2022; Kelfaoui et al., 2021; Domniku & Kacamakovic, 2025; Wang et al., 2024; Tran et al., 2025). In many countries, governments invest in craft-based industries not only for heritage preservation but also as tools for economic diversification and rural development (McAreavey & McDonagh, 2011).

In Algeria, for example, traditional crafts contributed nearly 350 billion DA (2.65 billion USD) to GDP in 2022, underscoring their macroeconomic relevance (MFA, 2022). Algeria boasts a diverse range of traditional crafts, including ceramics, carpentry, leatherwork, jewelry, goldsmithing, silversmithing, metalwork, traditional clothing, local cuisine, and handmade carpets "Zarbia" (Figure 2). These crafts form an integral part of the country's regional identity and are actively protected and promoted by government initiatives. One such effort is the Horizon 2020 project, launched in 2009 to support artisans by creating jobs, improving access to financial resources, and enhancing marketing and export opportunities (Brahmi, 2016; Djemai, 2019). The project also aims to integrate traditional crafts into a broader economic framework, ensuring their long-term sustainability while boosting competitiveness. Ghardaia, a province in southern Algeria (Figure 1),

is renowned for its rich artisanal traditions, particularly the handmade carpet industry. Zarbia —a locally crafted carpet— holds deep historical roots, dating back centuries and passed down through generations (Betchim, 2022). Its distinctive geometric patterns, vibrant colors, and intricate motifs (Figure 2) reflect the daily lives and cultural narratives of the crafts women who weave them. More than just a product, each "Zarbia" piece represents an artistic expression of the region's heritage, making it a significant cultural attraction. An annual cultural festival is held in March coinciding with the spring holidays, locally known as "Eid Zarbia" (Figure 3), in the midst of folkloric groups, women's art is highlighted from local heritage and cultural origins, as this event provides an opportunity for artisans to exchange experiences (Domniku et al., 2025; Xie, 2025) market services and products, attract tourism investments, and thus stimulate the commercial and tourism sectors.

Festivals are the preferred destination during the holiday period (Skoultsos, 2014), they act as a bridge of two sides "tourism and culture", combining both the economic and cultural aspects. The province employs a strategic approach to promote tourism and handicrafts through Cultural festivals, they play a crucial role in attracting and promoting tourism, with the aim of showcasing heritage nationally and internationally (Almuqataf, 2026). In addition to evaluating handicraft activities and integrating them into economic development, this strategy includes organizing national demonstrations, participating in international exhibitions and salons, and contributing to local holiday celebrations, with large numbers of visitors (Kelfaoui et al.,2021; Li & Chen, 2024), revitalizing the commercial and economic activities in the region.

Overall, Festivals are a vital event to promote tourism and support the local economy through the preservation and celebration of cultural heritage particularly traditional crafts. Within this context, handmade carpets represent one of the most resilient and marketable craft traditions. Previous research has explored their artistic and historical dimensions (Taheri et al., 2024) as well as the socio-economic roles they play in sustaining households (Bano, 2016). In Ghardaia specifically, the *Zarbia* has long been a symbol of cultural identity and female economic participation (Sharma, 2021). The craft empowers women, many of whom weave carpets at home while balancing family responsibilities, contributing directly to household stability (Pourmoradian et al., 2021). This dedication to quality distinguishes handmade carpets, as the effort invested in their production is reflected in their enduring value (Goswami, 2018).

At the same time, the literature points to serious challenges facing the sector. Modernization, urban migration, and the influx of cheaper, mass-produced carpets have undermined traditional weaving across North Africa (Hassan, 2020; Elgammal & Refaat, 2013). In Ghardaia, artisans face shortages of raw materials, rising costs, weak integration with tourism markets, and limited marketing skills. These constraints mirror global patterns where artisans struggle to compete in increasingly commercialized craft markets (De Munck, 2019). Despite the growing body of work on cultural tourism and handicrafts, two key gaps remain. First, much of the existing research has been tourist-centered, focusing on consumer demand rather than the lived realities of artisans (Sather-Wagstaff, 2008). Second, while several studies analyze the heritage or artistic aspects of carpets, few address the economic and strategic integration of crafts into tourism development frameworks. This study seeks to address these gaps by adopting a mixed-methods approach that combines artisans' perspectives with quantitative data on production and tourism flows. By doing so, it contributes to a more holistic understanding of the interplay between craft heritage, local livelihoods, and sustainable tourism in Ghardaia.

MATERIALS AND METHODS

Study area

Administratively, Ghardaia is located in the northern Algerian Sahara, resulting from the administrative division under Law No. 84-09 of February 4, 1984, concerning the territorial organization of the State. Geographically, our study area lies between latitudes 32.80° and 33.20° N and longitudes 0.40° and 4.30° E (Figure 1).

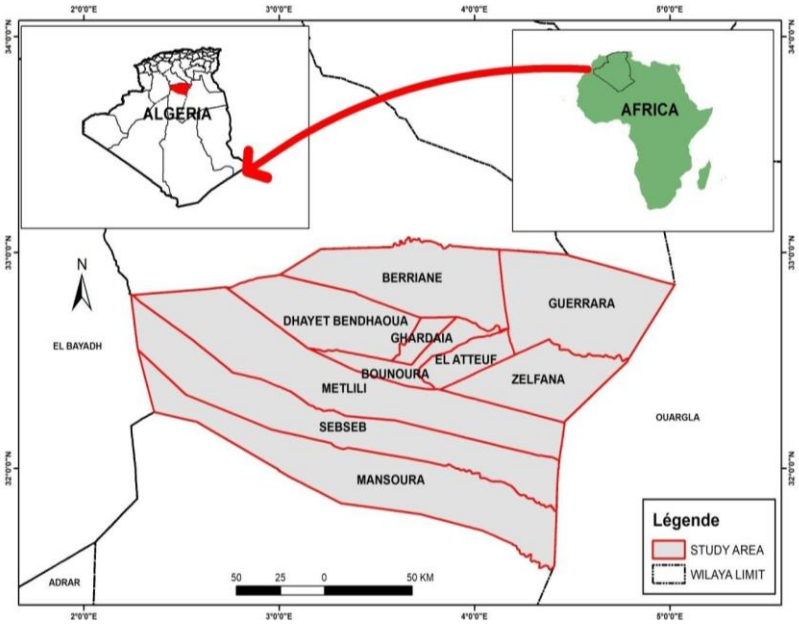

Figure 1.Geographical Situation of the study area, Ghardaia province, Algeria (Source: Generated by authors, 2025)

It is situated approximately 600 km south of Algiers, the capital, with an average elevation of 530 m above sea level and a distance of about 730 km from Oran and Constantine. Ghardaia is accessible via National Road No. 01, which connects Algiers to Tamanrasset. Covering an area of 26,165.13 km², the population was estimated to be 477,953 in 2019, according to the Budget Programming and Monitoring Directorate (DPSB).The province is bordered to the north by Laghouat and Djelfa, to the east by Ouargla, to the west by El Bayadh, and to the south by El Ménia.

It has a dry desert climate, characterized by cold, dry winters and hot, dry summers. According to the Algerian National Office of Meteorology, temperatures range from a minimum of 5°C in winter to a maximum of 50°C in summer. Spring and autumn are mild, and the sky remains clear for most of the year. The area experiences cold northwesterly winds in winter, sand-laden southwesterly winds in spring, and hot southerly winds, known as the Sirocco, in summer. This desert climate provides a comparative advantage for the tourist season. Ghardaia is one of Algeria's oldest cities.

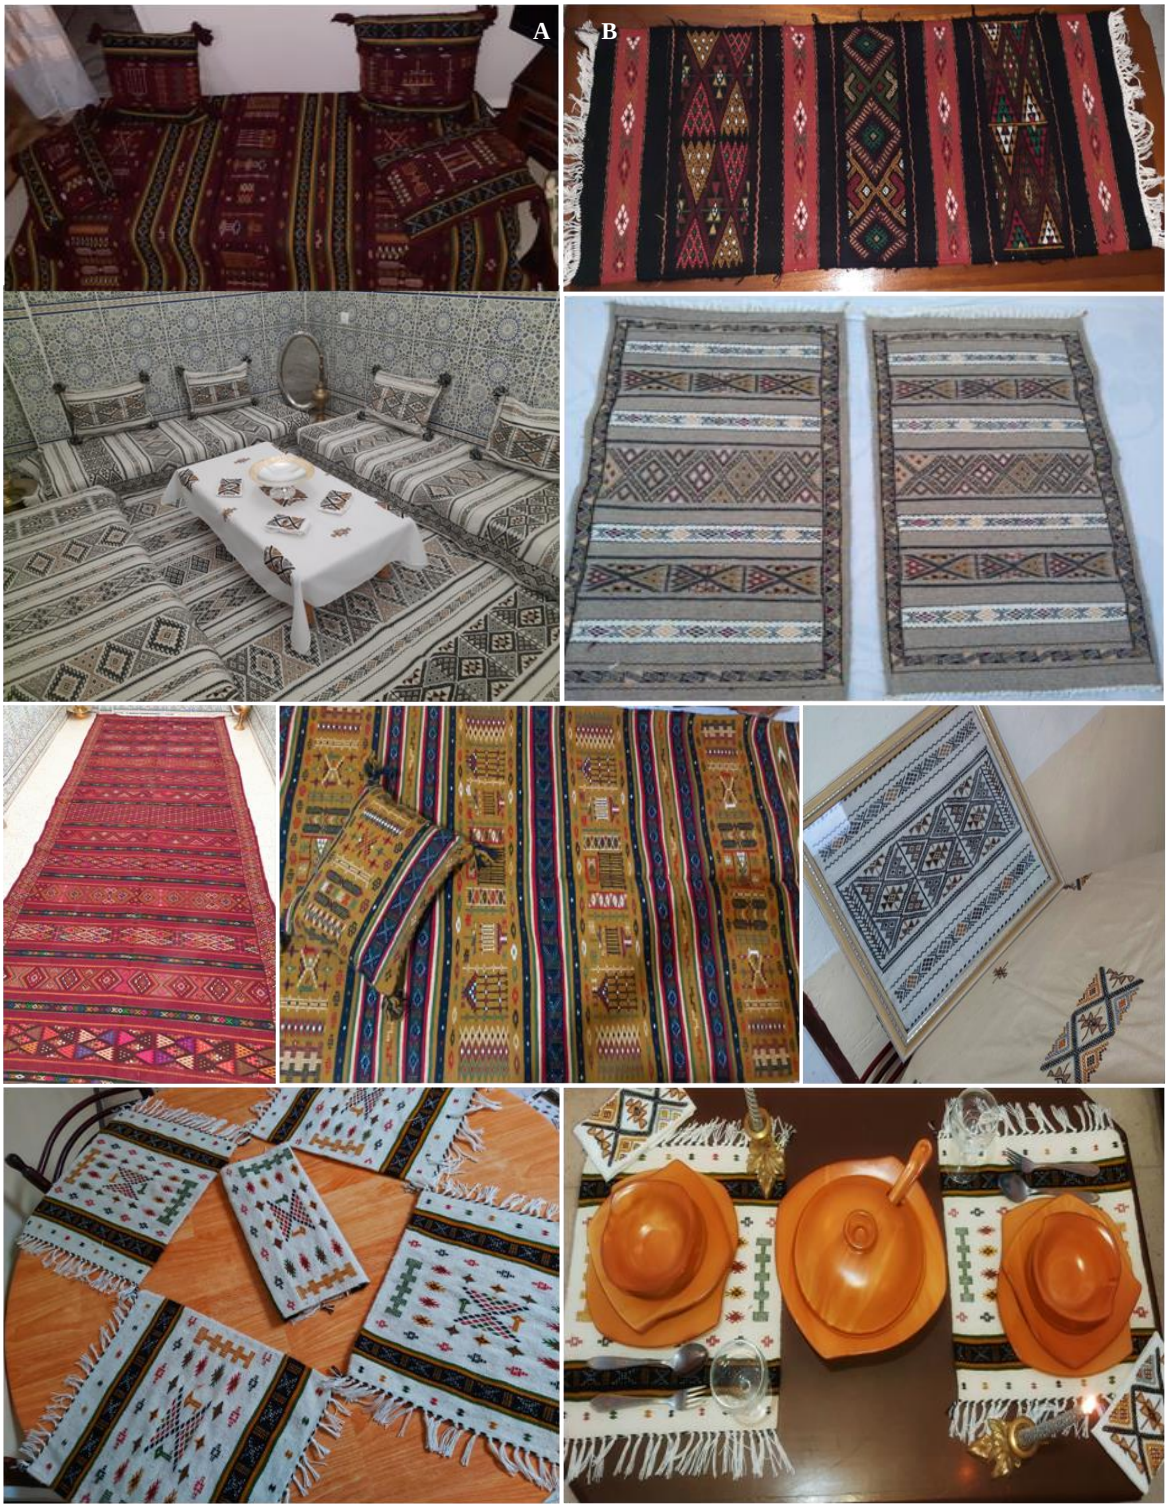

Figure 2. Pictures of Hand made Carpet Industry woven by crafts women
(Source: A and B taken by the authors, 2025, the rest wereprovided bythe Directorate of Tourism and Handicrafts "DTH")

Its historical and cultural significancestems from its wealth of historical landmarks and archaeologicalsites dating back to different eras, many of which remain well preserved today. These include traditional ksour (fortified villages) that form the core of the region as well as its palm groves (Souid, 2025). This rich history and valuable cultural diversity,led to the M'zab Valley zone being designated as part of Algeria'sNational Heritage in 1971and being inscribed as a UNESCO World Heritage Site in 1982. Furthermore, the Algerian Ministry of Culture also designated it as a protected area in 2005.

In addition, Ghardaia's strategic location as a gateway to the Sahara and a crossroads linking Northernand Southern Algeria, as well as eastern and western regions, has established it as a cultural hub, providing the region with considerable tourism and economic potential. The province is endowed with diverse natural landscapes and abundant cultural, thermal, and tourism resources that offer significant potential for rural development and positioning Ghardaia as a prominent tourist destination. It is particularly renowned for its historic palaces, known locally as “Ksour”, notably those in the M'zab Valley ksours (El Atteuf, Bounoura, Beni Isguen, Melika, Ghardaia), ksarMetlili, ksarEl Guerrara and ksar Berriane.

These traditional residential communities are outstanding examples of the region’s urban, historical, and touristic heritage, spanning various historical eras.Their distinctive architectural style, developed over several centuries, has made the region one of the most important examples of Saharan architectural and cultural heritage at both the national and international levels (OPVM).In addition,the region is famous for its oases, which support the cultivation of date palms and other crops, including fruit trees, fodder, and vegetables (Souid et al., 2024). Irrigation is managed traditionally, with unique water division methods. Other natural and cultural features include expansive sand dunes, mineral springs, and an array of traditional industries, such as copperwork, pottery, leather craftsmanship, traditional jewelry, and weaving, particularly handmade carpets "Zarbia"(Figure 2). The region also celebrates folk arts and festivals like Eid El-Zarbia (Figure 3) and Eid EL-Mehri (OPVM), all of which contribute to the rich cultural heritage. These resources position Ghardaia as an ideal site for developing various types of tourism, including cultural, exploratory, thermal, religious, scientific, and commercial tourism.

Figure 3. Pictures of zarbia festivals “Eid Zarbia” (Source: OPVM)

Data Sources

This study integrates primary and secondary data to provide a comprehensive understanding of the relationship between Zarbia production and tourism in Ghardaia. By combining survey evidence with official statistics and scholarly insights, the study ensures both empirical grounding and contextual depth.

- Primary data were collected through a structured survey of Zarbia artisans, focusing on demographics, economic conditions, production practices, market integration, challenges, and perceptions of tourism. The survey was administered in person between January and March 2023, and was designed with both closed-ended (multiple choice, Likert scale) and open-ended questions. A total of *81 artisans participated*, representing a significant share of the active weaving community in Ghardaia. Respondents were selected through purposive sampling, targeting artisans known to be active in the sector. The results were processed using SPSS and Excel to distinguish patterns and generalize the results
- Secondary data were gathered from local authorities knowledgeable in the field of handicrafts and tourism. These stakeholders include heads and members of local associations, directors of vocational training centers, employees of the Directorate of Tourism and Handicrafts, and traders in traditional industries, other data were obtained from official reports of the Ministry of Tourism and Handicrafts (MTH), statistical yearbooks, local development plans, and relevant academic studies. These sources provided contextual information on tourism flows, the contribution of the handicraft sector to employment, and national policies affecting traditional industries. *The detailed methodology* is outlined in the flowchart provided below (Figure 4).

Survey Design and Validation

The survey questionnaire included four sections:

1. Demographic characteristics (gender, age, education, marital status).

2. Economic indicators (profitability, reinvestment, exports, income use).
3. Tourism perceptions and engagement (views on tourism's role, participation in events, integration with markets).
4. Challenges and opportunities (production constraints, marketing strategies, policy expectations).

To ensure content validity, the questionnaire was reviewed by two local experts in cultural heritage and tourism, and piloted with five artisans prior to full deployment. Interviews were conducted in Arabic and French, with translation into English for analysis. The Cronbach alpha test was conducted in order to determine the degree of internal consistency between the questions, andthe result was that Alpha =0,9150.

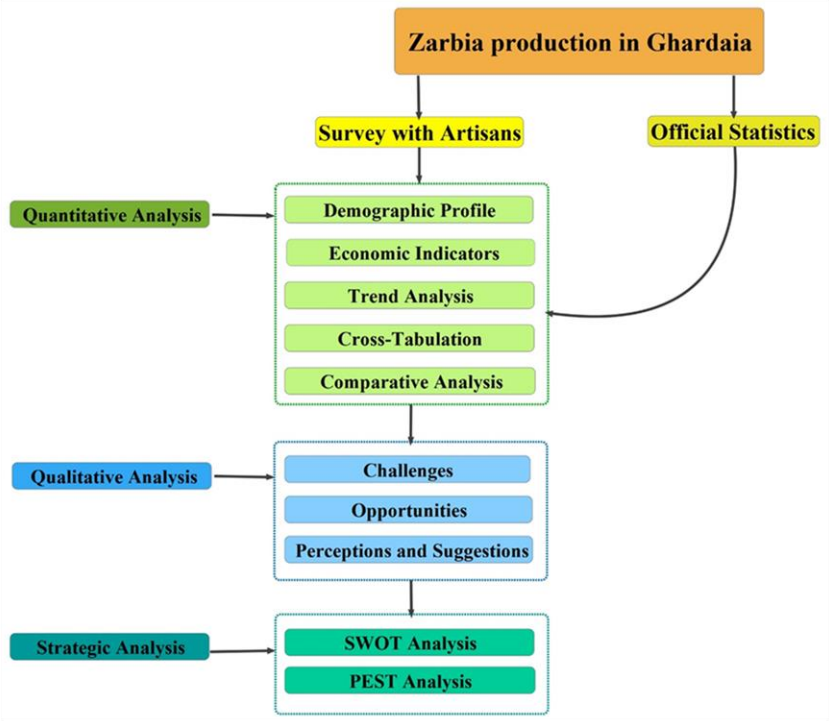

Figure 4. Flowchart illustrating the methodology followed in our study (Source: Generated by the authors, 2025)

Analytical Framework

The study employed a mixed-methods approach, combining quantitative and qualitative analyses:

- Quantitative Analysis
  - Descriptive statistics (frequencies, percentages) to summarize demographic and economic data.
- Trend analysis of tourism arrivals (2015–2023), Artisan participation in events (2019–2023) and the contribution of handicraft sector to employment (2018–2023).
- Tourism perceptions according to artisans'responses.
  - ✓ Cross-tabulation to explore relationships between education level and tourism engagement.
  - ✓ Comparative analysis to assess economic outcomes of artisans engaged in tourism vs. those who are not.
- Qualitative Analysis.
  - Open-ended survey responses were analyzed using thematic analysis, focusing on artisans' narratives of challenges, opportunities, and suggestions for sustaining the craft.
  - This allowed the integration of artisans'lived experiences alongside numerical trends.
- Strategic Analysis.
  - A SWOT analysis was used to identify internal strengths and weaknesses as well as external opportunities and threats.
  - A PESTEL framework (Political, Economic, Social, Technological, Environmental, Legal) contextualized Zarbia production within the broader macro-environment. These frameworks provided a strategic interpretation of the findings and informed recommendations.

Limitations

While the study offers important insights, several limitations should be noted:

- The sample size (81 artisans) does not fully capture Ghardaia's artisan population, though it represents a substantial portion of active weavers.
- The purposive sampling approach may introduce selection bias, as more visible or active artisans were more likely to be included.
- Some survey responses rely on self-reporting, which may involve recall bias or subjective interpretation.
- Tourism-related data are limited, particularly regarding the share of Zarbia sales to tourists; proxy indicators such as total handicraft spending, were used where direct measures were unavailable.

RESULTS

Demographic Profile: we have collected several demographic data regarding the 81 artisans surveyed.

Table 1summarizes the demographic characteristics, including gender, age group, education level, and marital status.

The survey of 81 artisans revealed that Zarbia weaving is overwhelmingly female-dominated, with women representing 97.5% of respondents. The majority of artisans belong to the older age groups (35.8% aged 55–65 and 21% aged over 65), while younger participation is very limited (less than 5% under 34). Educational attainment is also low, with 60.5% of artisans having completed only primary school and just 3.7% holding university degrees. Most participants were married (71.6%).

These findings suggest that Zarbia weaving is sustained mainly by older women with limited formal education, raising concerns about intergenerational transmission and the craft's long-term sustainability.

Table 1. Demographic characteristics of surveyed artisans (Source: generated by authors, 2025)

Variable	Category	Count	Percentage (%)
Gender	Male	2	2.5%
	Female	79	97.5%
Age Group	25–34	4	4.9%
	35–44	12	14.8%
	45–54	19	23.5%
	55–65	29	35.8%
	65+	17	21.0%
Education Level	Elementary School	49	60.5%
	Middle School	24	29.6%
	High School	5	6.2%
	University	3	3.7%
Marital Status	Single	11	13.6%
	Married	58	71.6%
	Divorced	9	3.7%
	Widowed	3	11.1%

Economic Indicators: The surveyed sample were asked if they achieve self-sufficiency by selling their Zarbia and how they use the money they earn. The results are presented in the bar chart (Figure 5) that illustrates the percentage of artisans who reported that Zarbia production is profitable and contributes to their self-sufficiency.

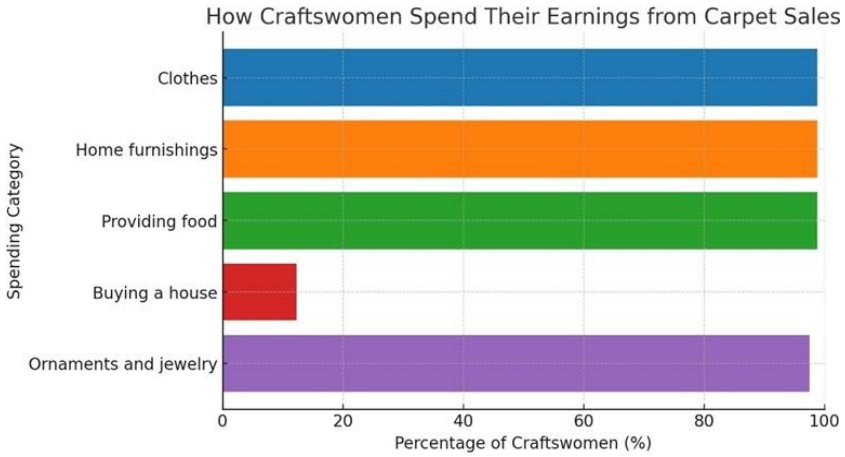

Figure 5. Profitabilityand Self-Sufficiency of ZarbiaProduction (Source: Generated by the authors, 2025)

The Figure 5 shows that: almost all artisans (98.8%) reported that Zarbia weaving is profitable and contributes to household self-sufficiency, with earnings used for essential expenditures such as food, housing, and home furnishings. Importantly, 77.8% reinvest part of their earnings back into production, and 80.2% reported exporting their carpets outside Ghardaia (Table 2). These results highlight the economic centrality of Zarbia weaving, not only for household stability but also for its role in local and regional markets.

Table 2. Investment and Exportation in ZarbiaProduction (Source: Generated by authors, 2025)

Variable	Response	Count	Percentage (%)
Investment	Yes	63	77.8%
	No	18	22.2%
Exportation	Yes	65	80.2%
	No	16	19.8%

Perceptions of Tourism

In order to better understand the relationship between the Zarbia production and tourism, we have asked the surveyed

samples some questions about their perception of tourism integration within their crafts (Table 3). Their answer together with some official statistics from the ministry of tourism and handicraft suggest a complex interaction.

Table 3. Artisans' Perceptions of Tourism's Role in Zarbia Production (Source: Generated by authors, 2025)

Perception	Count	Percentage (%)
Tourism helps maintain tradition	80	98.8%
Tourism improves living standards	80	98.8%
Tourism boosts zarbia sales	65	80.2%

Table 3 illustrates that: The artisans expressed overwhelmingly positive views on the role of tourism. Nearly all respondents (98.8%) believed that tourism helps maintain tradition and improve living standards, while 80.2% considered it a driver of increased Zarbiasales.This indicates that artisans see tourism as both an economic opportunity and a mechanism of cultural preservation, aligning with broader narratives of sustainable cultural tourism.

Trends in Tourism, Artisan Participation in events, and the contribution of handicraft sector to employment

Tourist arrivals (2015–2023): The line chart in figure 6 illustrates the variation in tourist arrivals to the city of Ghardaia from 2015 to 2023. Ghardaia experienced steady growth in tourism until 2019, peaking at 72,775 visitors. Numbers dropped sharply during the COVID-19 pandemic (39,987 in 2020) but rebounded to 69,469 in 2023. Notably, international tourists represented only a small fraction (3,121 in 2023), underscoring the region's reliance on domestic tourism.

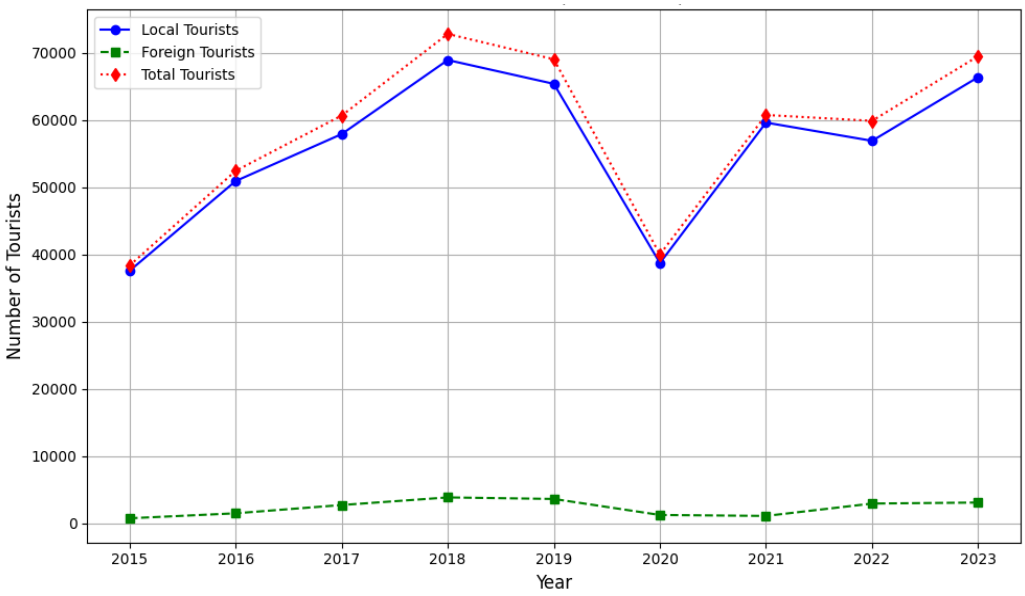

Figure 6. Tourist Arrival Trends (2015–2023) (Source: The authors, generated from the Directorate of Tourism and Handicrafts)

Participation in events: Contribution of culture festivals to tourism. Table 4 shows the number of artisans participating in local, national, and international events from 2019 to 2023. Artisan participation in exhibitions has been uneven. Numbers surged after the pandemic (285 artisans in 2022) but fell again in 2023 (69 + 2 associations), though that year marked the first international presence, with 7 artisans showcasing Zarbia abroad. Together, these trends show that while Ghardaia's tourism sector is recovering**,** international exposure for Zarbia remains limited.

Table 1. Craftsmen Participation in Events (2019–2023)(Source: authors, generated from the Directorate of Tourism and Handicrafts)

Year	Local events	National events	International events	Total participating artisans
2019	45	COVID-19 pandemic		45
2020	64	COVID-19 pandemic		64
2021	64	0	0	64
2022	270 +15 associations	0	0	285
2023	27 + 1 association	35+ 1 association	7	69 + 2 associations

The contribution of the handicraft sector to employment: The Table 5 shows the correlation between the number of artisans and employment in the sector over recent years, from 2018 to 2023. The handicraft sector created 14,180 jobs and employed more than 7,090 artisans by the end of 2023. However, the sector's contribution to job creation fluctuated between 2019 and 2020, with job numbers ranging from 14,908 to 15,122. In 2021, a significant drop occurred, with the number of jobs falling to 13,236 due to the COVID-19 pandemic, which led to the closure of many institutions. In recent years, the sector has shown signs of recovery, with job numbers reaching 14,270 in 2022 and 14,180 in 2023. Therefore, it can be concluded that the handicraft sector significantly contributes to social development by creating jobs and reducing unemployment.

Table 2. The contribution of handicraft sector to employment (2018-2023)
(Source: Authors, generated from the Directorate of Tourism and Handicrafts)

Year	Number of artisans	Employment contribution
2018	7.084	20.909
2019	7.454	14.908
2020	7.561	15.122
2021	6.618	13.236
2022	7.135	14.270
2023	7.090	14.180

Education and Tourism Engagement

Table 6 shows the percentage of artisans engaged in tourism-related activities, broken down by education level.

Cross-tabulation analysis revealed a strong link between education level and participation in tourism-related activities. Notably, 45.7% of the total sample had completed only elementary school engaged in tourism markets, whereasjust2.5% were university graduates, this demonstrates a dual impact ofeducationinthis field, itserves both as a strength and a limitation. On one hand, the accessibility of the tourism market to artisans across various educational backgrounds promotes inclusivity and broad participation, and therefore, navigate business opportunities, and adapt to market demands. On the other hand, limited education particularly in language proficiency can hinder effective communication with international tourists. Therefore, education must be recognized as a critical enabler for global engagement in tourism, and efforts should be made to address the challenges posed by lower educational attainment (Meng et al., 2024).

Table 6. Education level vs. engagement in tourism-related activities (Source: Generated by authors, 2025)

Education level	Engaged in tourism (%)	Not engaged in tourism (%)
Elementary school	45.7%	14.8%
Middle school	27.2%	2.5%
High school	4.9%	1.2%
University	2.5%	1.2%

Economic Benefits of Tourism Engagement

Table 7 compares the economic performance of artisans engaged in tourism-related sales versus those who are not.

Artisans engaged in tourism-related sales consistently outperformed those who were not. They reported higher profitability (96.3% vs. 77.8%), greater self-sufficiency (95.1% vs. 61.7%), and stronger reinvestment in production (85% vs. 56.8%). They were also more likely to export (90% vs.54.3%). Tourism integration appears to amplify economic resilience, reinforcing the value of linking Zarbia to the tourism sector.

Table 7. Economic Performance of Artisans Engaged vs. Not Engaged in Tourism (Source: Generated by authors, 2025)

Economic indicator	Engaged in tourism (%)	Not engaged in tourism (%)
Profitability	96.3%	77.8%
Self-sufficiency	95.1%	61.7%
Investment in production	85%	56.8%
Exportation	90%	54.3%

Challenges and Opportunities

The surveyed sample was asked about the various challenges encountered during the production of their craft. The bar chart (Figure 7) illustrates the key challenges faced by artisans.

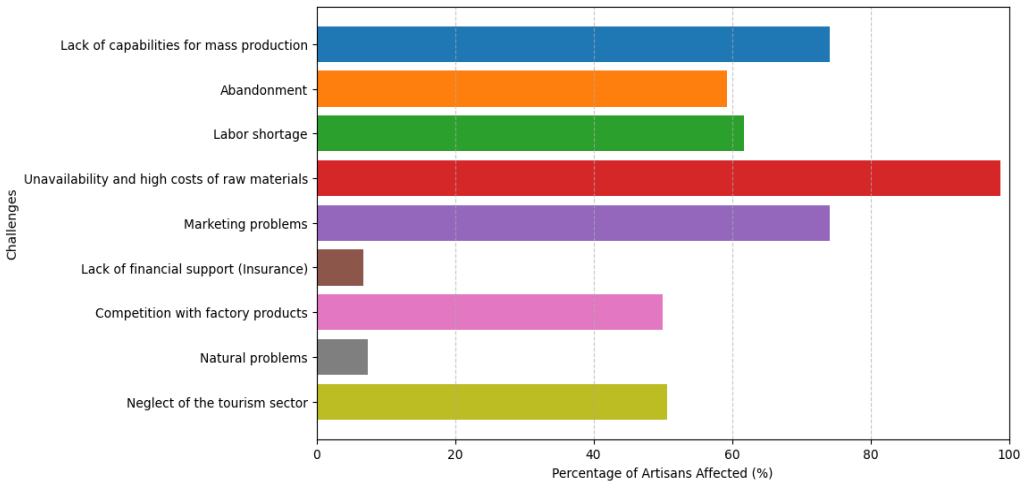

Figure 7. Challenges Faced by Artisans in Zarbia Production (Source: Generated by authors, 2025)

Figure 8. A - Exampleof Factory-Produced Carpets; B - Original Handmade Carpet "Zarbia" (Source: The authors, 2025)

The most critical challenges reported were shortages of raw materials and high production costs (97.5%), followed by competition from cheaper, mass-produced carpets (86.4%) (Figure 8). Conversely, artisans identified three key opportunities (Table 8): government policy support (98.8%), growth through tourism (55.7%), and digital marketing tools (27.2%). These findings suggest that while Zarbia weaving faces serious structural constraints, artisans are aware of emerging strategies, especially digital platforms and policy interventions, that could sustain the craft.

Table 8. Opportunities for ZarbiaProduction (Source: Generated by authors, 2025)

Opportunity	Count	Percentage (%)
Growth through tourism	54	55.7%
Digital marketing	22	27.2%
Policy support	80	98.8%

Strategic Analysis

The SWOT and PESTEL analyses provide a strategic lens through which the dynamics of Zarbia weaving in Ghardaia can be understood. The SWOT results, presented in Table 9, reveal a sector rooted in strong cultural identity and women's economic empowerment but weakened by aging demographics, raw material shortages, and limited marketing skills. Opportunities exist in tourism growth, digital platforms, and international exposure, yet these are offset by threats from machine-made competition and the volatility of tourism flows.

Table 9. SWOT Analysis of Zarbia Production and Tourism Integration (Source: Generated by authors, 2025)

Strengths	Weaknesses
• Unique craftsmanship, UNESCO heritage recognition	• Aging artisan population (56% above 55 years)
• 97.5% female artisans; 98.8% report profitability	• 60.5% with only primary education → weak market access
• 80.2% export beyond Ghardaia	• 97.5% face raw material shortages & high costs
• Strong cultural commitment, community pride	• Limited marketing/digital adoption
Opportunities	**Threats**
• Tourism growth: 70k visitors in 2023, 98.8% see tourism as beneficial	• Competition from machine-made carpets (49.4%)
• Rising interest in digital platforms (27.2%)	• Declining youth participation in weaving only 140 women artisans are graduates in textile in 2023
• Government policy support (Horizon 2020, subsidies, events)	• Economic volatility: fluctuating raw material costs
• First international exposure in 2023 exhibitions	• Tourism vulnerability to crises (COVID-19, instability)

The PESTEL framework presented in Table 10 complements this by situating Zarbia weaving within broader structural forces: political support and cultural recognition create favorable conditions, but economic pressures, low digital adoption, environmental constraints, and weak legal protections undermine resilience. Together, these analyses highlight that while

Zarbia weaving retains significant cultural and economic value, its sustainability depends on targeted interventions, particularly in education, digital integration, and legal safeguarding, to transform vulnerabilities into opportunities.

Table 10. PESTEL Analysis of Zarbia Production and Tourism Integration (Source: Generated by authors, 2025)

Factor	Key Issues	Implications
Political	Horizon 2020 support programs; weak IP protection	Potential for policy-driven growth, but Zarbia patterns risk imitation
Economic	98.8% profitability; 80.2% exports; high raw material costs	Strong income role, but profitability depends on subsidies & trade access
Social	Female-dominated craft; aging artisans; festivals (Eid El-Zarbia)	Empowerment of women; risk of generational discontinuity
Technological	Low digital adoption (27.2% interested); e-commerce potential	Digital tools could expand markets but require training
Environmental	Reliance on wool & dyes; Sahara water scarcity	Risk to production; eco-labeling as a market advantage
Legal	No geographical indication (GI) protection	Weak protection against counterfeit; limits international expansion

DISCUSSION

The findings of this study demonstrate that Zarbia weaving in Ghardaia remains a cornerstone of both cultural identity and economic livelihoods, yet it is also a fragile tradition facing structural challenges. The results highlight a paradox: while artisans overwhelmingly perceive their craft as profitable and central to household self-sufficiency, the sector is constrained by aging demographics, high production costs, and limited integration into the global tourism economy.

The demographic profile shows that Zarbia weaving is almost exclusively practiced by women (97.5%), particularly those above the age of 55. This confirms the literature that situates weaving as both a form of women's empowerment (Azil et al., 2020) and a mechanism for sustaining households (Zargham, 2007). However, the scarcity of younger artisans raises serious concerns about intergenerational transmission, according to the statistics of the Vocational Training Center registrations. This lack of interest among young girls is evident in the data, where only 140 graduates specializing in textiles were recorded in the first quarter of 2023, which is a lower record compared to the past generation when Zarbia weaving was a common household activity and used to be woven in all houses in the region. Similar patterns have been observed in Morocco and Tunisia, where younger generations are reluctant to pursue artisanal professions due to lower prestige and economic insecurity (Ratnam, 2014). Unless mechanisms are put in place to attract and train youth, the continuity of Zarbia weaving is at risk, even as its cultural value increases.

The survey revealed that nearly all artisans (98.8%) consider weaving profitable, with earnings reinvested into households and production. This finding is consistent with global studies showing that crafts contribute significantly to women's financial independence and local economies (Bano, 2016; Goswami & Goswami, 2018; Konjengbam & Chakravarty, 2026). The high percentage of artisans engaged in exports (80.2%) underscores Zarbia's market potential beyond Ghardaia. However, market integration is uneven: interestingly, many artisans with only elementary education engage actively more with tourism and enjoy higher profits, while the majority of university graduates remain marginalized in formal markets, this highlights the dual role of education in this field, it functions both as an asset and a constraint: the artisan sectoris inclusive and capable of accommodating workers with varying educational levels (Ismail & Mohammad, 2020), and those who did not have the opportunity to pursue a professional career, even without formal qualifications still have the chance to learn the craft and benefit financially from it, however education level may act as a barrier for some artisans' limited language or communication skills can hinder direct interaction with tourists, reducing investment opportunities and potential income. This aligns with studies that highlight education as a critical enabler for artisans' participation in tourism economies (Guillén-Peñafiel et al., 2024; Refaat & Hassan, 2025).

Artisans' overwhelmingly positive perception of tourism (98.8% viewing it as a tool for tradition preservation and livelihood improvement) suggests a strong alignment between local knowledge and cultural tourism models. Yet, the results also reveal that Ghardaia's tourism remains highly domestic, with only 3,121 international visitors recorded in 2023. This reliance on local tourism mirrors findings from desert tourism studies in Algeria, which note the underdevelopment of international tourism infrastructure despite strong cultural assets (Ramdan & Mourad, 2025). The participation of artisans in international exhibitions in 2023 is therefore a promising development, marking the first steps toward broader global exposure. The sector attracts a large labour force and has the flexibility to expand (curbing unemployment by Creating new job opportunities: 20,909 jobs / 7,084 artisans in 2018) especially with the availability of raw materials. And it does not require large capital investments, and relies on simple machines (Ismail & Mohammad,2020).These limited possibilities can generate substantial returns when fully exploited, contributing to balanced economic development between rural and urban areas (Aissani & Chanbi,2024). In Australia, in 2012 the number of local and foreign visitors reached 2.82 million people at the festival which contributed to spending more than 58 million AUD (excluding tickets) achieving profits estimated at 62.9 million AUD. As a result, the top 10Festivals contributed to create 790 permanent jobs (Skoultsos, 2014). This is consistent with what (UNESCO, 2015) have asserted that Tourists' discovery of diverse traditions and cultural festivals of traditional crafts and all that is considered intangible cultural heritage generates revenues and provides jobs for local individuals while nurturing a sense of pride in the community and thus providing inclusive economic developmentas one of the criteria of sustainable development (Hu et al., 2024).

The challenges identified, scarcity of raw materials, high costs, and competition from machine-made carpets, are consistent with regional trends across North Africa, where industrial imports increasingly displace traditional crafts (Islam & Burmester, 2020). Importantly, artisans themselves pointed to solutions: policy support (98.8%), tourism growth

(55.7%), and digital marketing (27.2%). These align with broader global findings where digital platforms (e.g., Etsy, Instagram) have expanded artisans' access to international buyers (Singh et al., 2022). Yet, without targeted training in digital literacy, most Ghardaia artisans will remain excluded from these opportunities.

The SWOT and PESTEL analyses confirm that while Zarbia weaving is culturally strong and economically viable, it is structurally fragile. Strengths such as heritage authenticity and export potential are undermined by weaknesses including an aging workforce and limited education. Opportunities such as digital marketing and tourism growth are offset by threats like global crises and competition from mass-produced goods. From a policy perspective, this suggests the need for integrated strategies: securing raw material supply chains, protecting intellectual property (through geographical indications), and investing in artisan training (Wu et al., 2025).

The results of this study have clear implications for the UN Sustainable Development Goals. Zarbia weaving contributes to SDG 5 (Gender Equality) by empowering women artisans, SDG 8 (Decent Work and Economic Growth) through income generation and exports, and SDG 11 (Sustainable Cities and Communities) by preserving intangible cultural heritage (Figure 9). However, without intervention, these contributions are at risk due to demographic and market challenges.

Figure 9. Sustainable Development Goals supported by the development of the Zarbia industry (Source: The authors, 2025)

From a theoretical perspective, this study contributes to debates on the commodification of heritage (Gill-Robinson, 2007), showing that commodification does not necessarily erode authenticity but can provide artisans with economic stability. Practically, the findings point to actionable recommendations:

- Policy interventions to subsidize raw materials and support artisan cooperatives.
- Capacity-building in digital literacy and foreign languages to connect artisans with global markets.
- Youth engagement strategies, such as vocational training programs linking schools with weaving workshops.
- Tourism integration, embedding Zarbia experiences into cultural tours and festivals to increase exposure.

While this study provides valuable insights, it is based on a purposive sample of 81 artisans, which may not fully represent the diversity of Ghardaia's weaving community. Additionally, sales data specific to tourists were unavailable, limiting the analysis of direct tourism–craft linkages. Future research should adopt longitudinal designs to track changes over time, and comparative studies with other North African carpet traditions could further illuminate the regional dynamics of craft survival.

CONCLUSION

This study examined the interplay between Zarbia weaving and tourism in Ghardaia, highlighting the dual role of the craft as both a cultural heritage and a vital source of women's economic empowerment. The results show that while Zarbiaweaving remains profitable and widely practiced among older women artisans, its long-term sustainability is threatened by rising production costs, limited market access, and declining youth engagement. At the same time, artisans overwhelmingly recognize tourism as a key driver of tradition preservation, livelihood improvement, and market expansion.

By integrating survey data, trend analysis, and strategic frameworks, the study contributes to the literature on cultural heritage tourism and women's livelihoods, offering a holistic view that foregrounds artisans' voices. The findings also demonstrate that stronger links between Zarbia production and tourism could generate significant benefits, not only for local households but also for regional economic diversification and Algeria's broader cultural tourism strategy.

To safeguard the future of Zarbia weaving, targeted interventions are needed: policies that stabilize raw material supplies, training programs that enhance digital and marketing skills, legal protections such as geographical indications, and youth engagement initiatives to ensure intergenerational transmission. International exposure and integration into global tourism markets also represent untapped opportunities for growth.

Ultimately, Zarbia weaving embodies more than a craft: it is a living heritage that connects cultural identity with economic sustainability. Preserving and revitalizing this tradition requires coordinated efforts by policymakers, artisans,

and tourism stakeholders. Doing so will not only protect an endangered craft but also position Ghardaia as a model for how intangible heritage can be leveraged for sustainable development in North Africa and beyond.

Explaining tourism and hospitality students' adoption of large language models in higher education: An integrated tam–utaut framework using pls-sem and necessary condition analysis. *Geojournal of Tourism and Geosites*, 67(3), 2047–2057. https://doi.org/10.30892/gtg.67319-1831

Abstract: The rapid integration of large language models (LLMs) in higher education has transformed students' learning practices, particularly in applied disciplines such as tourism and hospitality education. Yet, limited empirical research explains the factors driving their adoption. Drawing on the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT), this study examines tourism and hospitality students' behavioural intention to use LLM-based learning tools by incorporating content reliability, learner motivation, and social influence as extended antecedents. Data were collected from 365 university students enrolled in tourism, hospitality and management courses in addition to the students enrolled in other allied programs having tourism as an elective course in India and analysed using partial least squares structural equation modelling (PLS-SEM) and Necessary Condition Analysis (NCA). The findings indicate that perceived usefulness remains central to adoption, while learner motivation and social influence play critical enabling roles. NCA further reveals that perceived usefulness, learner motivation, and social influence constitute necessary conditions for achieving high adoption intention. By integrating net-effect and necessity-based approaches, the study advances technology acceptance theory in AI-enabled education in tourism and hospitality. It offers practical insights for the responsible integration of LLMs in professional learning contexts.

Keywords: Large Language Models (LLMs), Artificial Intelligence, education, Technology Acceptance Model (TAM), Unified Theory of Acceptance and Use of Technology (UTAUT), Necessary Condition Analysis (NCA)

INTRODUCTION

The increasing integration of artificial intelligence (AI) into higher education has transformed traditional learning environments by redefining how students access information, construct knowledge, and engage with academic tasks. Among recent technological developments, large language models (LLMs) have emerged as powerful educational tools that can generate explanations, examples, feedback, and learning support across diverse academic disciplines, including practice-oriented fields such as tourism and hospitality education. Unlike conventional digital learning systems that primarily facilitate content delivery, LLMs actively participate in cognitive processes through conversational interaction and adaptive responses, thereby reshaping the learner–technology relationship (Hou & Yu, 2023; Monzon & Hays, 2025).

Prior research indicates that AI-supported learning tools can enhance student engagement, self-regulated learning, and perceived learning effectiveness when appropriately integrated into instructional contexts (Gao et al., 2024; Teo, 2019). In tourism and hospitality programs, where applied knowledge, case-based learning, service simulations, and problem-solving are central, LLMs offer new opportunities for contextualised learning support. At the same time, the rapid diffusion of generative AI has raised concerns related to content accuracy, ethical use, and the risk of overreliance on AI-generated outputs, particularly in academic settings where credibility and rigour are paramount (Correia et al., 2024; Misiejuk et al., 2024). As universities increasingly experiment with AI-enabled learning tools, understanding how tourism and hospitality students evaluate and adopt LLM-based systems has become a pressing research concern.

From a theoretical perspective, technology acceptance research offers a robust foundation for examining students' adoption of emerging educational technologies. The Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT) have been widely applied to explain behavioural intention in contexts such as e-learning, mobile learning, and intelligent tutoring systems (Nistor et al., 2019; Teo, 2019), including hospitality and

tourism education settings where technology-mediated learning is increasingly prevalent. These models emphasise perceived usefulness and perceived ease of use as key cognitive beliefs that influence acceptance, while UTAUT further highlights the roles of social influence and facilitating conditions (Palau-Saumell et al., 2019; Venkatesh & Davis, 2000).

Empirical evidence consistently demonstrates that students are more likely to adopt digital learning technologies when they perceive them as beneficial for academic performance and easy to operate (Hou & Yu, 2023; Shahzad et al., 2024). In tourism and hospitality education, where learning outcomes are closely tied to industry relevance and employability, perceived usefulness may be significant. However, scholars increasingly argue that traditional acceptance models need to be refined when applied to AI-enabled learning systems. The autonomous, generative, and interactive nature of LLMs introduces new evaluative criteria—such as trust in AI outputs and perceived content reliability—that extend beyond the scope of core TAM constructs (Al-Zahrani, 2024; Cui et al., 2025). Despite the growing body of research on AI in education, several theoretical and empirical gaps remain evident. Much of the existing literature focuses on the functional benefits of AI tools, such as efficiency and performance gains, while paying little attention to students' concerns about the reliability and credibility of AI-generated content. This gap is particularly salient in tourism and hospitality education, where inaccurate or biased information may directly affect professional judgment and service decision-making. Research on AI hallucination and misinformation suggests that uncertainty about content accuracy can undermine academic trust and weaken sustained adoption intentions (Correia et al., 2024; Misiejuk et al., 2024). Furthermore, although learner motivation has been widely studied in digital learning contexts, its role within extended technology acceptance frameworks for generative AI remains underexplored, particularly in relation to perceived usefulness and behavioural intention (Cerasoli et al., 2014; Huang et al., 2025).

Similarly, while social influence has been examined in general technology adoption research, its role in legitimising the use of LLMs within tourism and hospitality academic communities has received limited empirical attention. As a result, there is a lack of integrative models that examine simultaneously cognitive, motivational, social, and trust-related mechanisms shaping students' adoption of LLM-based learning tools in higher education within tourism and hospitality.

To address these gaps, the present study aims to examine tourism and hospitality students' behavioural intention to use LLM-based learning tools by extending TAM and UTAUT with AI-specific constructs. Specifically, the study investigates perceived usefulness and perceived ease of use as core acceptance beliefs, while incorporating content reliability, learner motivation, and social influence as critical antecedents shaping these beliefs and behavioural intention.

Perceived usefulness is further conceptualised as a central mediating mechanism linking ease of use, content reliability, motivation, and social influence to behavioural intention. By integrating these constructs within a unified theoretical framework, the study offers a more comprehensive explanation of LLM adoption in tourism and hospitality education. The originality of this research lies in its explicit treatment of content reliability as a trust-related construct and its simultaneous examination of motivational and social drivers within an extended acceptance model. In doing so, the study advances technology acceptance theory in the context of generative AI. It provides actionable insights for educators and institutions seeking to integrate LLMs into teaching and learning practices responsibly. Accordingly, this study aims to examine tourism and hospitality students' behavioural intention to adopt LLM-based learning tools by extending the TAM–UTAUT framework with content reliability, learner motivation, and social influence, and to identify the necessary conditions for high adoption intention using an integrated PLS-SEM and Necessary Condition Analysis (NCA) approach.

LITERATURE REVIEW

Theory Relevance and AI Learning

Technology acceptance theories, such as the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT), have been widely applied to explain students' adoption of educational technologies. Within these frameworks, behavioural intention is conceptualised as a learner's willingness to use a technology and is widely accepted as a reliable predictor of actual usage behaviour. Empirical studies in e-learning and online education contexts demonstrate that perceived usefulness and perceived ease of use play a central role in shaping behavioural intention, influencing learners' satisfaction and continued engagement with digital platforms (Hou & Yu, 2023; Teo, 2019). Extensions of UTAUT further highlight the importance of facilitating conditions, hedonic motivation, habit, and self-efficacy in predicting behavioural intention across technology-mediated learning environments (Zheng et al., 2025). These findings suggest that students are more likely to adopt learning technologies when they perceive them as valuable, easy to use, and supported by institutional and social structures. Collectively, this body of research confirms the robustness of TAM and UTAUT in explaining technology acceptance in higher education while also indicating the need for contextual adaptation as learning technologies evolve.

However, the increasing integration of artificial intelligence and large language models (LLMs) into higher education presents challenges that extend beyond the explanatory scope of traditional TAM and UTAUT. Unlike conventional learning technologies, LLMs actively generate instructional content, provide automated feedback, and simulate conversational interactions, raising critical concerns about content accuracy, reliability, and trust. Prior research highlights that students' acceptance of generative AI tools is strongly influenced by perceptions of content quality and the risk of AI hallucinations, which can undermine academic trust and integrity (Correia et al., 2024; Misiejuk et al., 2024). Studies further indicate that trust in AI systems is closely associated with technological performance, transparency, and ethical use, all of which shape behavioural intention toward AI adoption (Al-Zahrani, 2024; Cui et al., 2025). These concerns suggest that learner motivation and perceptions of content reliability are critical determinants of AI acceptance.

Consequently, extending TAM and UTAUT by incorporating AI-specific constructs provides a more comprehensive theoretical framework for understanding students' intentions to adopt LLM-based learning tools in higher education.

Constructs under Study

Behavioural intention (BI) is widely recognised as a core outcome variable in technology acceptance research and represents an individual's willingness to adopt and continue using a technological system. In educational technology contexts, BI has consistently been employed as a reliable predictor of actual usage behaviour, particularly in e-learning and AI-supported learning environments (Hou & Yu, 2023; Teo, 2019). Prior studies demonstrate that students' behavioural intention is shaped by perceptions of usefulness, ease of use, and motivational factors, reinforcing its relevance as a proxy for learning technology adoption (Zheng et al., 2025). Research further highlights the role of facilitating conditions, hedonic motivation, and habit in strengthening behavioural intention toward digital learning platforms, suggesting that both cognitive and affective factors influence students' willingness to engage with technology (Zheng et al., 2025). Additionally, self-efficacy and attitudes toward technology use have been validated as significant predictors of BI in higher education contexts, emphasising the importance of learner confidence and perceived competence (Teo, 2019). Collectively, these findings establish behavioural intention as an appropriate and theoretically grounded dependent variable for examining students' acceptance of LLM-based learning tools.

Perceived Ease of Use and Perceived Usefulness

Perceived ease of use (PEOU) and perceived usefulness (PU) constitute the foundational constructs of the Technology Acceptance Model and have been extensively validated in educational technology research. PEOU refers to the extent to which learners believe that using a system requires minimal effort, while PU reflects the degree to which a system enhances learning performance and outcomes (Teo, 2019). In AI-supported learning environments, these constructs take on greater significance due to the interactive and adaptive nature of intelligent systems. Studies indicate that user-friendly interfaces and conversational designs, such as those used by AI chatbots, enhance learners' perceptions of ease of use, which, in turn, positively influence motivation and engagement (Foroughi et al., 2024; Gao et al., 2024). Moreover, PU has been empirically linked to improved learning outcomes, self-regulated learning, and academic performance in AI-based tutoring systems (Hou & Yu, 2023). Research grounded in UTAUT further demonstrates that performance expectancy and effort expectancy jointly shape learners' acceptance of intelligent learning tools, reinforcing the mediating role of PU between PEOU and behavioural intention (Nistor et al., 2019). These findings confirm the central role of PEOU and PU in explaining students' adoption of LLM-based educational technologies.

Content Reliability

Content reliability in AI-supported learning environments refers to the perceived accuracy, consistency, and trustworthiness of AI-generated or AI-assisted educational content. As LLMs increasingly generate instructional materials and feedback, content reliability has emerged as a critical determinant of student trust and acceptance (Correia et al., 2024). Prior research highlights that discrepancies between AI-generated outputs and human judgment, particularly in assessment and coding tasks, can undermine learners' confidence in AI systems, necessitating hybrid human–AI approaches to ensure reliability (Misiejuk et al., 2024). Studies examining AI-generated text further emphasise the importance of alignment between AI outputs and established knowledge bases to enhance credibility and reduce epistemic uncertainty (Sanz et al., 2012; Virani et al., 2020). Ethical considerations, including algorithmic bias, transparency, and data privacy, also influence perceptions of content reliability, thereby shaping students' trust in AI-supported learning tools (Al-Zahrani, 2024). Additionally, technological performance and explainability have been identified as key antecedents of reliability perceptions, suggesting that reliable AI outputs reduce cognitive effort and enhance perceived usefulness (Cui et al., 2025). These findings position content reliability as a crucial extension to traditional technology acceptance models in AI-enabled education

Learner Motivation and Social Influence

Learner motivation plays a pivotal role in shaping the adoption of educational technologies by influencing students' engagement, persistence, and acceptance of digital learning tools. Research grounded in motivational theories distinguishes between intrinsic motivation, driven by interest and enjoyment, and extrinsic motivation, driven by external rewards and performance outcomes (Cerasoli et al., 2014). Empirical studies demonstrate that both motivational types significantly predict behavioural intention toward LLM-based learning tools, with intrinsic motivation influencing the quality of engagement and extrinsic motivation affecting the frequency of use (Huang et al., 2025). Generative AI systems further support learner motivation by enabling personalised and self-directed learning experiences, thereby enhancing autonomy and academic confidence (Monzon & Hays, 2025). In parallel, social influence—derived from peers, instructors, and institutional norms—has been shown to shape students' perceptions of technology credibility and usefulness (Venkatesh & Davis, 2000). Social cues and endorsements can strengthen trust in AI-generated content, particularly in uncertain learning contexts, thereby increasing behavioural intention (Palau-Saumell et al., 2019). Together, learner motivation and social influence represent critical psychological and social drivers of LLM adoption in higher education

Hypothesis Formulation

Prior research grounded in the Technology Acceptance Model (TAM) consistently demonstrates that perceived ease of use and perceived usefulness are core determinants of behavioural intention in technology-based learning environments. Perceived ease of use reflects how much learners believe interacting with a system requires minimal effort. In contrast, perceived usefulness captures the extent to which a technology enhances academic performance and learning effectiveness.

Empirical studies in e-learning and AI-supported education show that systems perceived as easy to use are more likely to be evaluated as applicable, as reduced cognitive effort allows learners to focus on learning outcomes rather than system operation (Shahzad et al., 2024; Sheppard & Vibert, 2019). Furthermore, perceived usefulness has been identified as a direct predictor of behavioural intention across diverse educational technologies, including AI-based tutoring systems and conversational agents (Li, 2020; Liu & Ma, 2024). In the context of LLM-based learning tools, intuitive interaction and conversational design are expected to strengthen these relationships. Accordingly, the following hypotheses are proposed:

H1: Perceived ease of use positively influences perceived usefulness.

H2: Perceived usefulness positively influences behavioural intention.

H3: Perceived ease of use positively influences behavioural intention.

Beyond core TAM relationships, content reliability has emerged as a critical factor influencing students' acceptance of AI-generated learning materials. Content reliability refers to learners' perceptions of the accuracy, consistency, and trustworthiness of AI-generated outputs. Prior research highlights that concerns related to hallucinations, misinformation, and lack of transparency can undermine trust in AI-supported learning systems, thereby reducing perceived usefulness and adoption intention (Al-Zahrani, 2024; Misiejuk et al., 2024). Conversely, when AI-generated content is perceived as reliable and aligned with established knowledge, learners are more likely to recognise its instructional value and integrate it into their learning processes (Cui et al., 2025). Studies extending TAM and UTAUT further demonstrate that credibility-related constructs significantly enhance the explanatory power of technology acceptance models by strengthening perceived usefulness and behavioural intention (Palau-Saumell et al., 2019; Singh et al., 2025). In LLM-based learning contexts, reliable content is therefore expected to play a central role in shaping students' perceptions and intentions. Thus,

H4: Content reliability positively influences perceived usefulness.

H5: Content reliability positively influences behavioural intention.

Learner motivation has been widely acknowledged as a key psychological driver of technology adoption in higher education. Motivated learners are more inclined to adopt educational technologies when they perceive them as supporting academic goals and self-directed learning. Prior studies grounded in UTAUT highlight performance expectancy and effort expectancy as critical mechanisms through which motivation influences behavioural intention (Nistor et al., 2019). Research on generative AI further indicates that LLMs enhance learner motivation by enabling personalised learning experiences and fostering autonomy, thereby increasing engagement and perceived learning value (Monzon & Hays, 2025). Both intrinsic and extrinsic motivation have been shown to predict behavioural intention toward AI tools, with intrinsic motivation influencing the depth of engagement and extrinsic motivation shaping continued usage (Cerasoli et al., 2014; Huang et al., 2025). As motivated learners are more likely to recognise the benefits of AI-supported learning tools, motivation is expected to strengthen perceived usefulness and behavioural intention. Accordingly,

H6: Learner motivation positively influences perceived usefulness.

H7: Learner motivation positively influences behavioural intention.

Social influence represents an important social determinant of technology acceptance, particularly in educational settings where peer interaction and institutional norms shape learning behaviour. UTAUT posits that social influence affects individuals' perceptions of technology usefulness and their intention to adopt new systems. Empirical studies show that recommendations from peers, instructor endorsement, and institutional support can legitimise emerging technologies and reduce uncertainty associated with their use (Palau-Saumell et al., 2019; Venkatesh & Davis, 2000). In AI-supported learning environments, social cues play a critical role in shaping students' trust in AI-generated content and their perceptions of the system's value. When LLM-based tools are endorsed within academic communities, students are more likely to view them as credible and beneficial for learning (Oc et al., 2025). Consequently, social influence is expected to directly shape both perceived usefulness and behavioural intention toward LLM-based learning tools. Therefore,

H8: Social influence positively influences perceived usefulness.

H9: Social influence positively influences behavioural intention.

In addition to influencing perceived usefulness and intention, recent studies suggest that external factors such as motivation, content reliability, and social influence also shape perceived ease of use in intelligent learning systems. Motivated learners tend to invest greater effort in exploring system features, thereby reducing perceived complexity and enhancing ease of use (Nistor et al., 2019). Similarly, reliable AI-generated content reduces verification effort and cognitive load, leading learners to perceive LLM-based tools as easier to use (Misiejuk et al., 2024). Social influence further contributes to perceived ease of use by facilitating observational learning and knowledge sharing among peers, which lowers perceived operational difficulty (Venkatesh & Davis, 2000). In LLM-based learning environments, these mechanisms suggest that perceived ease of use is not solely a technical attribute but is also shaped by psychological and social factors. Hence,

H10: Learner motivation positively influences perceived ease of use.

H11: Content reliability positively influences perceived ease of use.

Taken together, these hypothesised relationships reflect an integrative extension of TAM and UTAUT tailored to AI-enabled learning contexts. By incorporating content reliability and learner motivation alongside traditional acceptance constructs, the proposed framework captures the cognitive, psychological, and social mechanisms underlying students' adoption of LLM-based learning tools. This integrative approach responds to recent calls for more comprehensive models that address trust, reliability, and motivation in AI-supported education (Xu et al., 2024; Yan et al., 2024). The proposed hypotheses collectively explain how learners evaluate the usefulness and usability of LLMs and how these evaluations

translate into behavioural intention. This framework, therefore, provides a theoretically grounded basis for empirically examining students' acceptance of LLM-based learning tools in higher education.

Mediating Hypotheses

Perceived usefulness (PU) has long been recognised as a central mediating construct within the Technology Acceptance Model, translating users' system evaluations into behavioural intention. In AI-enhanced learning environments, PU plays an even more critical role due to the complexity and autonomy of intelligent systems. Prior studies demonstrate that perceived ease of use enhances perceived usefulness by reducing cognitive effort and increasing learners' trust and engagement with AI tools (Shahzad et al., 2024; Sheppard & Vibert, 2019). Empirical research on AI-based tutoring and LLM-supported learning further confirms that PU mediates the relationship between system characteristics and behavioural intention, particularly when learners perceive AI tools as supporting academic performance and self-regulated learning (Li, 2020; Liu & Ma, 2024). Extensions of TAM and UTAUT incorporating credibility-related constructs also indicate that trust-enhancing factors strengthen PU, which in turn drives adoption intention (Palau-Saumell et al., 2019; Singh et al., 2025). Accordingly, PU is expected to mediate the effects of perceived ease of use, content reliability, learner motivation, and social influence on behavioural intention in LLM-based learning contexts. Thus,

H12: Perceived usefulness mediates the relationship between perceived ease of use and behavioural intention.

H13: Perceived usefulness mediates the relationship between content reliability and behavioural intention.

H14: Perceived usefulness mediates the relationship between learner motivation and behavioural intention.

H15: Perceived usefulness mediates the relationship between social influence and behavioural intention.

RESEARCH METHODOLOGY

This study employed a quantitative, cross-sectional survey design to examine students' adoption of large language models (LLMs) for learning, with a specific emphasis on tourism and hospitality education. The research was conducted in India, a context that is theoretically and empirically relevant for studying AI-enabled learning adoption. India hosts one of the world's largest higher education systems. It has witnessed rapid growth in digital infrastructure, mobile internet penetration, and technology-mediated learning, making it an appropriate setting for examining behavioural intention toward emerging AI tools. Prior research highlights that technology adoption dynamics in emerging economies offer critical insights due to heterogeneous access, rapid diffusion, and evolving institutional norms surrounding digital learning technologies (Palau-Saumell et al., 2019; Venkatesh & Davis, 2000). Data were collected with the assistance of trained enumerators whom the authors directly supervised to ensure data quality and adherence to standardised procedures. Respondents were informed of the study's academic purpose, assured of anonymity and confidentiality, and participation was strictly voluntary. Informed consent was obtained prior to survey administration, in line with established ethical standards for social science research. A structured questionnaire was used as the survey instrument, consisting of previously validated measurement items adapted to the context of LLM-based learning. Screening questions were included to ensure respondent relevance; only students with both an internet-enabled smartphone and a laptop with active internet access were included, as meaningful interaction with LLMs requires consistent multi-device access—the questionnaire measured six constructs. Perceived Ease of Use and Perceived Usefulness were adapted from established TAM scales to capture the ease of learning, operational simplicity, and learning effectiveness of AI tools. Content Reliability was measured using items adapted from tourism and information reliability literature, emphasising accuracy, trustworthiness, bias-free content, completeness, and professional quality. Social Influence items captured peer, instructor, and normative pressure to use AI tools, grounded in TAM and UTAUT (Davis, 2004; Venkatesh & Davis, 2000). Learner Motivation items were adapted from motivation research emphasising enjoyment, curiosity, and the value of learning. Behavioural Intention was measured using intention-to-use items that reflect future reliance on and continued exploration of AI tools.

The final sample comprised 365 valid student responses, meeting established thresholds for PLS-SEM analysis. According to Hair et al. (2019), a minimum sample size of 200 and a sample-to-item ratio of at least 10:1 are sufficient for reliable model estimation and adequate statistical power in complex models. With six latent constructs and reflective indicators, the sample size exceeds the recommended minimum, ensuring analytical adequacy. Descriptive analysis revealed diverse LLM usage patterns, with ChatGPT being the most widely used tool (94.2%), followed by Perplexity (41.4%), Copilot (23.6%), DeepSeek (8.0%), Gemini variants (4.0%), Google alone (0.8%), and Grok (0.8%). Data screening and preliminary analyses were conducted using SPSS 27 to assess missing values, outliers, and distributional properties. Hypothesis testing and structural relationships were examined using SmartPLS, which is well-suited for exploratory models involving multiple predictors and complex causal relationships. This methodological approach ensures rigour, robustness, and alignment with best practices in technology acceptance and AI-in-education research.

RESULTS

Table 1 presents the demographic profile of the respondents. The sample was predominantly male (81.1%) and composed mainly of undergraduate students (90.4%), reflecting the typical demographic structure of technology-intensive programs in Indian higher education. Public and private institutions were almost equally represented, ensuring institutional diversity. A majority of respondents reported daily use of AI tools (64.4%), with most indicating intermediate levels of AI experience (45.5%). Students from tourism and hospitality disciplines constituted the largest group (45.75%), followed by engineering and management students (27.12% each). This disciplinary spread enhances the generalizability of the findings

across applied and professional education domains. The descriptive statistics further confirm that the sample is appropriate for examining behavioural intention toward LLM-based learning tools in a multi-disciplinary academic context.

Table 1. Demographic variables result

Characteristic	Category	Frequency (n)	Percentage (%)
Gender	Male	296	81.1
	Female	69	18.9
Education Level	Undergraduate	330	90.4
	Postgraduate	35	9.6
Type of Institution	Public	181	49.6
	Private	184	50.4
AI Usage Frequency	Daily	235	64.4
	Weekly	130	35.6
Experience with AI	Intermediate	166	45.5
	Beginner	108	29.6
	Advanced	91	24.9
Discipline	Tourism & Hospitality	167	45.75
	Engineering	99	27.12
	Management	99	27.12

Measurement model results

The measurement model was evaluated by examining indicator reliability, internal consistency, convergent validity, and discriminant validity, following established guidelines for PLS-SEM analysis. Indicator reliability was first assessed using standardised factor loadings. All observed indicators load firmly on their respective latent constructs, with values exceeding the recommended threshold of 0.70, indicating that each item explains at least 50% of the variance in the underlying construct (Hair et al., 2019). Specifically, factor loadings ranged from 0.741 to 0.895 for perceived ease of use, 0.834 to 0.884 for perceived usefulness, 0.843 to 0.884 for content reliability, 0.755 to 0.850 for social influence, 0.864 to 0.884 for learner motivation, and 0.876 to 0.886 for behavioural intention. These results confirm the strong reliability of the indicators and justify retaining all measurement items in the model (Table 2). Internal consistency reliability was assessed using Cronbach's alpha and composite reliability.

Table 2. Measurement model results (α: Cronbach's alpha; CR: Composite reliability; AVE: Average variance extracted)

Cosntruct and Items	Code	Loadings	VIF	α	CR (rho_a)	CR (rho_c)	AVE
Perceived Ease of Use (Martínez-Torres et al., 2008; Venkatesh & Davis, 2000)				0.852	0.856	0.901	0.696
It is easy to learn how to use AI tools for my studies.	PE1	0.741	1.475				
I can quickly find what I need using AI tools.	PE3	0.849	2.196				
The steps to use AI tools are simple.	PE4	0.895	2.726				
AI tools are easy to understand and operate.	PE5	0.844	2.269				
Perceived Usefullness (Martínez-Torres et al., 2008; Venkatesh & Davis, 2000)				0.879	0.882	0.916	0.733
AI tools improve my learning in tourism/hospitality/airline courses.	PU1	0.851	2.408				
AI tools help me complete course-related tasks more easily.	PU2	0.884	2.672				
AI tools are more effective than traditional methods for learning tourism	PU3	0.834	2.057				
AI tools help me quickly find useful content for my studies.	PU4	0.855	2.180				
Content Reliability(Ayeh et al., 2013)				0.912	0.913	0.934	0.739
The content from AI tools is accurate.	CR1	0.843	2.391				
The content is trustworthy.	CR2	0.873	2.690				
The content is free from bias.	CR3	0.884	2.844				
The content is complete and relevant.	CR4	0.849	2.324				
The content is professionally written.	CR5	0.849	2.447				
Social Influence (Venkatesh & Davis, 2000)				0.881	0.883	0.913	0.678
My classmates use AI tools for our field of study.	INF1	0.755	1.671				
My teachers encourage the use of AI tools.	INF2	0.833	2.220				
My friends suggest using AI tools for learning.	INF3	0.837	2.206				
People around me think I should use AI tools.	INF4	0.850	2.399				
Successful students I know use AI tools.	INF5	0.839	2.229				
Learner Motivation (Deci et al., 2001)				0.897	0.898	0.928	0.764
I enjoy learning my course topics using AI tools.	LM1	0.864	2.422				
I want to learn more through AI tools.	LM2	0.877	2.547				
AI tools make learning more valuable to me.	LM3	0.884	2.612				
AI tools make me curious to explore my subjects further.	LM4	0.871	2.419				
Behavioural Intention (Venkatesh & Davis, 2000)				0.857	0.859	0.913	0.778
I plan to use AI tools regularly for studying.	BI1	0.876	2.147				
I expect to rely on AI tools next semester.	BI2	0.883	2.090				
I want to explore new topics using AI tools.	BI3	0.886	2.211				

All constructs demonstrate values well above the recommended minimum threshold of 0.70, indicating satisfactory reliability (Hair et al., 2019). Composite reliability values ranged from 0.901 to 0.934, indicating high internal consistency without redundancy. Convergent validity was evaluated using average variance extracted (AVE). All AVE values exceed the recommended cutoff of 0.50, confirming that each construct explains more than half of the variance of its indicators (Fornell & Larcker, 1981). Additionally, variance inflation factor (VIF) values were examined to assess collinearity at the indicator level. All VIF values fall below the conservative threshold of 5, indicating no multicollinearity concerns and supporting the stability of the parameter estimates (Hair et al., 2019).

Discriminant validity was assessed using both the Fornell–Larcker criterion and the heterotrait–monotrait (HTMT) ratio. According to the Fornell–Larcker criterion, the square root of AVE for each construct should exceed its correlations with other constructs (Fornell & Larcker, 1981). This condition is satisfied for all constructs in the model. Furthermore, HTMT values were examined, as this method is considered more sensitive in detecting discriminant validity issues (Henseler et al., 2015). All HTMT ratios are below the conservative threshold of 0.90, confirming adequate discriminant validity. Collectively, these results indicate that the measurement model demonstrates strong reliability and validity, providing a sound basis for subsequent structural and necessity analyses (Table 3).

Table 3. Discriminant validity using Fornell-Larcker criteria and HTMT ratio

Heterotrait-Monotrait ratio (HTMT) ratio						
	Behavioral Intention	**Content Reliability**	**Learner Motivation**	**Perceived Ease of Use**	**Perceived Usefulness**	**Social Influence**
Behavioral Intention						
Content Reliability	0.739					
Learner Motivation	0.751	0.744				
Perceived Ease of Use	0.718	0.817	0.713			
Perceived Usefulness	0.767	0.750	0.875	0.776		
Social Influence	0.864	0.709	0.654	0.788	0.692	
Fornell-Larcker criterion						
Behavioral Intention	0.882					
Content Reliability	0.655	0.860				
Learner Motivation	0.659	0.674	0.874			
Perceived Ease of Use	0.616	0.722	0.622	0.834		
Perceived Usefulness	0.668	0.675	0.781	0.674	0.856	
Social Influence	0.755	0.639	0.583	0.682	0.611	0.823

Path analysis

The structural model was evaluated by examining path coefficients (β), t-statistics, p-values, and the significance of direct and indirect effects (Table 4 & Figure 1). Consistent with the Technology Acceptance Model, perceived ease of use positively affects perceived usefulness ($\beta = 0.201$, $p < 0.01$), indicating that students who find AI tools easier to use are more likely to perceive them as applicable for academic learning. However, perceived ease of use does not directly influence behavioural intention ($\beta = -0.041$, $p > 0.05$), suggesting that ease alone is insufficient to drive adoption unless students also perceive tangible learning benefits. Perceived usefulness significantly predicts behavioural intention ($\beta = 0.163$, $p < 0.05$), reaffirming its central role as a key determinant of technology adoption.

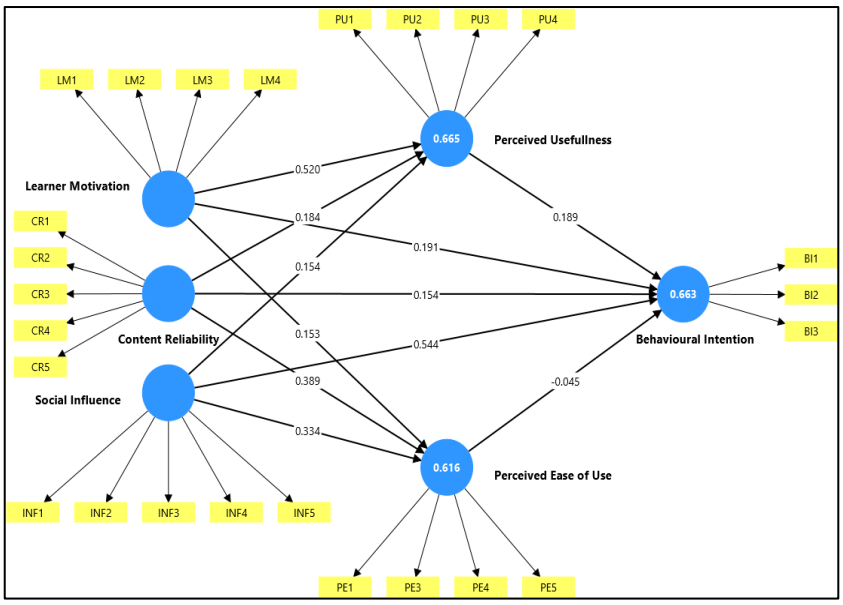

Figure 1. Results of path analysis using PLS SEM

Content Reliability demonstrates a strong positive influence on perceived usefulness ($\beta = 0.199$, $p < 0.01$), highlighting that students' perceptions of accuracy, trustworthiness, and completeness of AI-generated content substantially enhance perceived learning value. Although the direct effect of content reliability on behavioural intention is not significant, this finding suggests that credibility primarily operates through cognitive evaluations rather than directly influencing intention formation. Learner motivation emerges as the strongest predictor of perceived usefulness ($\beta = 0.553$, $p < 0.001$) and also exerts a significant direct effect on behavioural intention ($\beta = 0.175$, $p < 0.05$).

This indicates that intrinsically motivated learners are more likely to recognise the value of AI tools and intend to use them. Social influence significantly affects both perceived usefulness ($\beta = 0.161$, $p < 0.01$) and behavioural intention ($\beta = 0.490$, $p < 0.001$), underscoring the decisive role of peers, instructors, and academic norms in legitimising AI use. Mediation analysis reveals that only the indirect effect of social influence on behavioural intention via perceived usefulness is significant, while other mediating paths are not supported. These findings suggest that social endorsement strengthens adoption primarily by enhancing perceptions of usefulness rather than by altering perceptions of usability.

Table 4. Path analysis results

Path	Beta	Lower	Upper	T statistics	P values	Result
H1: Perceived Ease of Use -> Perceived Usefulness	**0.201**			**2.879**	**0.004****	**Supported**

NCA Analysis

To complement the net-effect logic of PLS-SEM, a Necessary Condition Analysis (NCA) was conducted to determine whether specific antecedents constitute indispensable conditions for achieving higher levels of behavioural intention toward AI-based learning tools. Unlike SEM, which explains average causal effects, NCA focuses on identifying conditions that must be present at minimum levels for an outcome to occur (Dul et al., 2023). The presence of empty spaces in the upper-left corners of the ceiling line charts indicates necessity relationships, suggesting that higher levels of behavioural intention cannot be achieved when key antecedents remain below certain thresholds.

The effect size results (Table 6) reveal that perceived usefulness emerges as the strongest necessary condition ($d = 0.32$), exceeding the threshold for a medium-to-strong necessity effect as proposed by Dul (2016). This indicates that without a minimum level of perceived usefulness, high behavioural intention toward AI tools cannot be attained. Learner motivation ($d = 0.207$), content credibility ($d = 0.21$), and social influence ($d = 0.185$) demonstrate medium necessity effects, suggesting that each of these conditions must reach certain minimum levels to enable higher adoption intention. Perceived ease of use shows a more negligible yet meaningful necessity effect ($d = 0.193$), indicating that usability acts as a basic enabling condition rather than a dominant driver. All permutation tests are significant ($p = 0.000$), confirming that the identified necessity effects are statistically robust and not attributable to random variation.

Table 5. NCA Bottleneck table

	Behavioral intention	Content reliability	Learner motivation	Perceived ease of use	Perceived usefulness	Social influence
0.00%	-4.172	NN	NN	NN	NN	NN
10.00%	-3.645	NN	NN	NN	NN	NN
20.00%	-3.118	NN	NN	NN	NN	NN
30.00%	-2.591	NN	-4.076	NN	-3.913	NN
40.00%	-2.064	-3.232	-4.076	-3.321	-3.08	-3.567
50.00%	-1.537	-3.232	-4.076	-3.321	-3.08	-3.567
60.00%	-1.01	-3.232	-2.64	-3.321	-3.08	-3.567
70.00%	-0.482	-3.232	-2.64	-3.321	-2.556	-3.192
80.00%	0.045	-2.232	-2.459	-3.321	-2.556	-3.192
90.00%	0.572	-1.951	-1.523	-3.058	-1.374	-0.467
100.00%	1.099	-1.753	-1.523	-1.106	-0.64	-0.098

The bottleneck analysis (Table 5) further clarifies the minimum levels required for different degrees of behavioural intention. At lower outcome levels (below 30%), no antecedent imposes a binding constraint, indicating that minimal intention can occur even with low levels of the predictors. However, as behavioural intention increases, clear bottlenecks emerge. For example, achieving moderate adoption levels (50%) requires a minimum threshold for content credibility, learner motivation, perceived ease of use, perceived usefulness, and social influence. At higher outcome levels (70–90%), perceived usefulness and learner motivation impose the most stringent bottlenecks, indicating that firm adoption intention cannot be achieved unless students perceive AI tools as genuinely beneficial and are intrinsically motivated to use them. Social influence also becomes increasingly constraining at higher levels of behavioural intention, highlighting the role of peer and institutional validation in legitimising the use of AI. Importantly, comparison with PLS-SEM results highlights causal asymmetry. While some constructs—such as perceived ease of use and content credibility—exhibit weak or non-significant direct effects in the structural model, NCA demonstrates that they remain necessary conditions at higher adoption levels. This confirms that conditions may be necessary without being sufficient, reinforcing the complementary value of combining SEM and NCA (Dul, 2016). Overall, the NCA findings provide a nuanced understanding of AI adoption by revealing critical bottlenecks that must be addressed to foster students' behavioural intention towards AI-based learning tools.

Table 6. NCA effect size

	Beta Estimate	95.00%	Result
Content Reliability	0.21	0.114	An increase in exogenous construct will increase the outcome, no minimum level of construct needed to ensure the outcome
Learner Motivation	0.207	0.075	Increase in exogeneous construct will increase the outcome, a certain level (bottleneck) is necessary for the outcome
Perceived Ease of Use	0.193	0.113	An increase in exogeneous construct will increase the outcome, no minimum level of construct needed to ensure the outcome
Perceived Usefulness	0.32	0.106	Increase in exogeneous construct will increase the outcome, a certain level (bottleneck) is necessary for the outcome
Social Influence	0.185	0.06	Increase in exogeneous construct will increase the outcome, a certain level (bottleneck) is necessary for the outcome

DISCUSSION AND CONCLUSION

The findings of this study provide nuanced insights into how tourism and hospitality students evaluate and adopt LLM-based learning tools within higher education contexts. Overall, the results reaffirm the central importance of perceived usefulness as the primary driver of adoption intention. Students appear to place greater emphasis on the academic value and learning enhancement offered by AI tools than on their operational simplicity. This observation aligns with prior research suggesting that learners adopt educational technologies when they clearly support performance improvement and knowledge acquisition rather than merely offering convenience (Hou & Yu, 2023; Teo, 2019). Interestingly, perceived ease of use does not directly translate into stronger adoption intention, indicating that contemporary students—already accustomed to digital platforms—may consider usability as a baseline expectation rather than a decisive motivator. In technology-saturated learning environments, ease of use functions as a hygiene factor, necessary but insufficient to stimulate adoption.

This shift reflects the maturation of digital learning ecosystems, in which students increasingly evaluate technologies based on their pedagogical contribution rather than their technical novelty. Consequently, the findings suggest that institutions seeking to promote LLM adoption must foreground the value of learning and the relevance of outcomes rather than focusing solely on interface design or technical accessibility. A second key insight concerns the role of content reliability in shaping students' cognitive evaluations of AI tools. While content reliability does not directly influence behavioural intention, it significantly strengthens perceptions of usefulness, suggesting that students assess credibility before acknowledging the learning value of AI-generated content. This finding resonates with growing scholarly concern over AI hallucinations, misinformation, and epistemic uncertainty associated with generative models (Correia et al., 2024; Misiejuk et al., 2024).

Students appear cautious in integrating AI tools into their academic routines unless the content is perceived as accurate, unbiased, and professionally articulated. Rather than acting as a direct motivator, content reliability operates as an enabling condition that legitimises the perceived benefits of LLMs. This underscores a critical distinction between trust and utility: students may recognise the potential usefulness of AI tools, but sustained adoption depends on confidence in the quality of the content. The findings, therefore, highlight the importance of trust-related constructs in AI adoption research and suggest that content reliability plays a foundational role in shaping meaningful engagement with generative AI in educational settings. Learner motivation and social influence emerge as particularly salient drivers of LLM adoption, reinforcing the importance of psychological and social mechanisms in technology acceptance. Motivated learners are more inclined to experiment with AI tools, recognise their pedagogical value, and integrate them into self-directed learning practices.

This finding aligns with motivational theory, which emphasises the role of intrinsic interest and perceived value in sustaining engagement with learning technologies (Cerasoli et al., 2014; Huang et al., 2025). Social influence further amplifies adoption by shaping normative beliefs and reducing uncertainty surrounding AI use. Peer usage, instructor encouragement, and institutional acceptance appear to legitimise AI tools, thereby strengthening students' intention to adopt them. Notably, integrating PLS-SEM and NCA reveals causal asymmetry: some factors may not exert strong average effects but remain indispensable for achieving higher levels of adoption. These findings challenge linear assumptions embedded in traditional acceptance models and demonstrate that a combination of drivers and constraints shapes AI adoption. Together, these results offer a more nuanced understanding of student decision-making in AI-enhanced learning environments.

Theoretical implications

This study advances technology acceptance theory by extending TAM and UTAUT to reflect better the distinctive characteristics of generative AI systems in tourism and hospitality education. By integrating content reliability and learner motivation alongside traditional acceptance constructs, the study responds to calls for more context-sensitive frameworks that can explain the adoption of autonomous and generative technologies.

The findings reaffirm perceived usefulness as the central explanatory construct, yet demonstrate that trust-related and motivational mechanisms shape usefulness itself. This challenges the sufficiency of conventional acceptance models when applied to AI-driven learning environments and supports emerging scholarship that emphasises trust, credibility, and epistemic evaluation as integral components of AI acceptance (Al-Zahrani, 2024; Cui et al., 2025). Consequently, the study contributes to theory by repositioning content reliability as a foundational antecedent that conditions cognitive evaluations of AI systems rather than acting as a direct behavioural driver.

A second theoretical contribution lies in the methodological integration of net-effect and necessity-based perspectives. While PLS-SEM identifies dominant predictors of adoption intention, NCA reveals the minimum conditions required to achieve higher levels of acceptance. The finding that specific constructs are necessary but not sufficient introduces causal asymmetry into AI adoption research, extending prior work that assumes symmetric causal relationships. This dual-theoretical lens enriches understanding by distinguishing between drivers that increase the likelihood of adoption and conditions that must be present to avoid adoption failure. As such, the study contributes to a more nuanced and realistic theorisation of technology acceptance in AI-enabled education.

Practical implications

The findings offer several actionable implications for educators, institutional leaders, and AI developers seeking to responsibly integrate LLMs into higher education. First, institutions should prioritise demonstrating the academic value of AI tools rather than emphasising technical features alone. Students are more likely to adopt LLMs when they clearly improve learning outcomes, facilitate deeper understanding, and support task completion.

Embedding AI tools into curricula through guided learning activities, reflective exercises, and assessment support can strengthen perceptions of usefulness and encourage sustained engagement. Second, ensuring content reliability is critical. Institutions should develop clear guidelines for AI use, promote verification practices, and encourage transparency regarding AI-generated outputs to build trust and reduce epistemic uncertainty among learners.

Equally important are learner motivation and social norms. Educators can foster positive attitudes toward AI by modelling ethical and purposeful use of LLMs in teaching and assessment. Peer-led demonstrations, instructor endorsement, and institutional support can normalise the use of AI and reduce apprehension about emerging technologies. Although perceived ease of use may no longer serve as a primary motivator, it remains a foundational requirement that enables higher-order evaluations of usefulness and motivation.

Ensuring intuitive interfaces, accessible support, and digital literacy training can therefore create an environment conducive to meaningful AI adoption. Together, these strategies can help institutions move from experimental adoption of AI to a pedagogically grounded, sustainable integration of LLM-based learning tools.

Limitations and future scope

Despite its contributions, this study has limitations that open avenues for future research. The cross-sectional design limits causal inference, suggesting the need for longitudinal studies to examine how students' perceptions and intentions toward LLMs evolve. The sample was drawn from Indian higher education, which may limit generalizability to other cultural or institutional contexts. Future studies could conduct cross-country comparisons or discipline-specific analyses to capture contextual variation. Additionally, future research may incorporate learning outcomes, ethical attitudes, or self-regulated learning behaviours to further enrich AI adoption models. Experimental and mixed-method approaches could also provide deeper insights into how students interact with LLMs in real learning scenarios.

Abstract: Given the growing urgency of sustainable development worldwide, tourism is emerging as a strategic sector to drive the global ecological transition. The main objective of this research was to determine the relationship between sustainable tourism and the green economy in the Peruvian context, comprehensively analyzing its environmental, sociocultural, and economic dimensions. A quantitative approach was adopted, with a correlational scope and a non-experimental, cross-sectional design. The sample consisted of 153 participants in the tourism sector, selected through non-probability sampling based on predefined inclusion criteria. A structured survey of 32 items per variable, using a five-point Likert scale, was used. This survey was validated by expert judgment and demonstrated high reliability (Cronbach's alpha >0.8). Statistical analysis included normality tests (Kolmogorov-Smirnov) and Spearman's rank correlation coefficients. The results revealed a significant moderate positive correlation between the main variables (Rho = 0.501, p = 0.001). Specifically, the sociocultural dimension showed the strongest association (0.560), followed by the economic (0.337) and environmental (0.181) dimensions. The findings indicate that incorporating sustainable practices into tourism aligns with the core principles of the green economy: social equity, environmental protection, and economic growth. It was determined that, in Peru, the transition to a green economic model is facilitated by the promotion of responsible management, resource preservation, and active community involvement. This provides data for the design of empirically grounded public policies and business strategies that promote inclusive, balanced, and resilient development in the country.

Keywords: sustainable tourism, green economy, environmental management, tourism, economic development

INTRODUCTION

Throughout history, humanity has devised a wide variety of activities to satisfy its needs, and currently, in a society that is moving towards a balance between work and private life, rest, entertainment, and leisure are becoming increasingly important. Among the various leisure activities that can be enjoyed today is tourism, which has existed for centuries (Kou et al., 2024; Rakhimzhanova et al., 2025). Conceptually, tourism is considered as the phenomenon that involves the movement (travel) of human beings to multiple destinations far removed from the reality in which they live, classifying as a tourist anyone who stays overnight in that destination. Currently, the tourism industry represents more than just a leisure activity; it is widely considered a significant multidisciplinary activity, encompassing cultural, social, environmental, political, and economic aspects. According to Toubes & Araújo (2022), the tourism sector significantly benefits the global economy. Prior to the pandemic, in 2019, tourism travel contributed a high percentage to global GDP, reaching 10.4% (equivalent to US$9.2 trillion), and accounting for 10.6% of global. In Peru, in 2019, the tourism sector represented 3.66% of the national GDP and employed 1.1 million workers in 2018. However, Peru was not immune to the global impact of COVID-19, which led to border closures and the cessation of most tourism services, resulting in a decline in suppliers such as travel agencies, accommodations, restaurants, and air transport. This meant that tourism was the economic activity that suffered the most negative impacts in the country due to the pandemic. In contrast, and optimistically, the situation has improved by 2025, with the tourism sector's contribution to the national GDP projected to grow to approximately 7.8%, representing 6.6% of national employment (United Nations [UN], 2023).

However, tourism can have effects that are not always positive. It was once believed that tourism only benefited the community, but without proper planning and clear policies for the tourism lifecycle, it could negatively impact local populations, especially in rural or remote areas, and their economies, as well as the environment (Cao et al., 2023; Marvin, 2024; Wang & Cheablam, 2025). Additionally, Ospanova et al. (2022) point out that the green economy aims to reduce the impact of economic activity on the environment. This leads to the modification of the conventional or brown

economy, which aims only to obtain coins and is static, thus demonstrating that the green economy is dynamic and is shaped according to sustainable development, complying with the 17 Sustainable Development Goals and Targets, which include tourism (Manotungvorapun & Gerdsri, 2025; Jiménez et al., 2024).

This research seeks to determine the relationship between sustainable tourism and the green economy in Peru, analyzing its environmental, sociocultural, and economic dimensions. Within this framework, it evaluates how responsible environmental management, community participation, and equitable economic development can be linked to the principles of the green economy and contribute to the country's sustainable development.

LITERATURE REVIEW

Although sustainable tourism and the green economy share common goals, their conceptual frameworks have distinct origins and emphases that must be clearly differentiated. Sustainable tourism, rooted in the Brundtland Report, focuses primarily on managing the impacts of tourism activities, balancing environmental preservation, sociocultural equity, and economic viability at the destination level (Sharpley, 2021). In contrast, the green economy is a broader macroeconomic framework that seeks to improve human well-being and social equity while significantly reducing environmental risks and ecological scarcity (Akadiri & Ozkan, 2026). The critical intersection between both frameworks occurs where tourism's resource efficiency and social inclusion align with the green economy's principles of decarbonization and green employment. However, there is conceptual ambiguity in the literature where both terms are sometimes used interchangeably, generating inconsistencies in the measurement of their actual impacts (Toubes & Araújo, 2022).

Sustainable tourism

According to Yang et al. (2023), defines tourism as the activities undertaken by people when they travel to and stay in places outside their usual environment for a period of less than one year for recreational, business, or other purposes, without involving paid employment. Likewise, the UN indicates that tourist trips can be motivated by various reasons, such as healthcare, professional education, leisure, religious practices, among others. Taken together, all these aspects constitute tourism activities (Zhang et al., 2023).

Tourism evolved from the Grand Tour (17th-19th centuries) and mass tourism (1960s-1970s) towards sustainable tourism in the 1990s. This model integrates economic, environmental, and social dimensions to preserve the environment, culture, and long-term viability. Its fundamental pillars are natural resources, heritage, and community authenticity (Pié & Vilanova, 2012; Streimikiene et al., 2021; Sharpley, 2021; Marques et al., 2022).

Sustainable Development Goals

Regarding the 17 Sustainable Development Goals (SDGs) outlined in the 2030 Agenda, those directly associated with sustainable tourism are: SDG 8, which substantially contributes to economic growth at the local and national levels by creating decent jobs. SDG 11 further links social equity and reduces environmental impact, promoting inclusive, safe, resilient, and sustainable living environments. SDG 12 addresses responsible consumption practices, mitigating environmental impact and encouraging long-term sustainability. Finally, SDG 15 focuses on the preservation and sustainable use of ecosystems; in this case, tourism practices that respect the natural environment would be developed (UN, 2023).

According to Vrana (2023), sustainable tourism is based on three dimensions applicable to the Peruvian context: (1) environmental: responsible use of natural resources and participatory planning to minimize impacts (Akadiri & Ozkan, 2026; Jo et al., 2026); (2) sociocultural: multisectoral collaboration to preserve ancestral traditions and offer authentic experiences (Ferdian et al., 2024; Spadaro et al., 2023); and (3) economic: efficient management that generates sustainable income, equitable distribution of benefits and long-term financial viability (Chen et al., 2025; Xue et al., 2023).

Green economy

Over the years, sustainability has become a relevant issue worldwide, a concept that is and should be included in the development of all sectors, including the economic one. Compared to the discipline of conventional economics, the green economy is a relatively innovative concept that focuses on the free use of resources found in the natural environment within a territory and their distribution among the population to meet their basic needs (Sahabuddin et al., 2026; Surdez et al., 2026). Today, the planet faces environmental threats that hinder the full development of humanity, such as climate change. Therefore, in 2012, approaches were proposed to guide a green economy model, ensuring adequate growth in the countries where it is implemented. These approaches are: economic development and growth, environmental protection, low-carbon development, resilience, resource efficiency, ecological sustainability, human well-being, inclusion, and equity (Gong & Chen, 2023).

Economic development and growth

The current economic model followed by most powerful, industrialized, and more developed countries neglects resource conservation and has serious environmental repercussions, focusing solely on increasing national wealth and rendering it unsustainable for future generations. In Peru, the contemporary economy is driven by the efforts of innovative businesses and entrepreneurs seeking optimal market positioning, with ambitions for exports and international recognition (Berdenov et al., 2025). The growth of these businesses involves interdisciplinary interaction between markets and different economic sectors within the territory to generate income and provide a comprehensive overview that will allow them to offer customers something that meets their needs. As these businesses grow, and simultaneously the country's economy, developing under a green economy concept, as indicated in the guide to a green

economy, entails implementing structured social responsibility policies for the benefit of residents and their well-being, along with the appropriate use of resources in the natural environment (Singh et al., 2025; Guillen et al., 2025).

Several recent studies have explored the relationship between tourism and the sustainable economy, albeit using different methods. In ASEAN nations, Zhang et al. (2023) confirmed that ecotourism contributes to the ecological Gross Domestic Product through the Sustainable Tourism Index; however, its exclusive reliance on macroeconomic figures omitted the perspectives of microeconomic actors, limiting its usefulness for corporate strategies. In contrast, Chen (2023) recognized the benefits of ecotourism for individuals and the environment in ethnic areas of China. Finally, Han & Li (2021) underscored the importance of regulating emissions in low-carbon environments, although their work focused on technical indicators, overlooking essential sociocultural elements for local acceptance.

In Latin America, Esenarro et al. (2024) conducted research on the implementation of ecological corridors in Cusco, Peru, identifying shortcomings in ecological investment and an inequitable distribution of benefits for local communities. While this study is highly relevant to the present one, it focused on a specific location (Cusco) without considering the national landscape of official tourism. Wang & Cheablam (2025) identified beneficial links between sustainability and economic performance. However, their analysis is limited by its failure to differentiate between environmental, sociocultural, and economic aspects, treating them as a single unit. Finally, Singh et al. (2025) studied sustainable tourism techniques in developing nations and determined that corporate social responsibility plays a fundamental role as a mediator. However, they did not consider tourism operators or the public sector.

Table 1. Study Positioning

Zhang et al. (2023)	Macroeconomics, green GDP, ASEAN	Macro-level analysis vs. micro-level (stakeholder perceptions)
Chen (2023)	Ecotourism, ethnic minorities, China	Qualitative approach vs. quantitative correlational design
Esenarro et al. (2024)	Green corridor, Cusco, Peru	Single-destination focus vs. national perspective (Lima)
Wang & Cheablam (2025)	Tourism hubs, Asia	No dimensional differentiation vs. three dimensions analyzed (environmental, sociocultural, economic)
Singh et al. (2025)	CSR, hotel sector, emerging economies	Hotel sector only vs. multiple stakeholder groups

Despite growing interest, the current literature reveals three significant gaps that this analysis aims to describe. First, there is a predominance of a macroeconomic approach that examines the relationship between tourism and sustainable growth at the national GDP level, leaving unexplored how these aspects are perceived and managed at the micro level (stakeholders and businesses) (Chen, 2023; Zhang et al., 2023). Second, there is a clear geographical bias, as most empirical research focuses on developed economies or East Asia, while information from developing nations such as those in Latin America is scarce (Esenarro et al., 2024). Finally, there is an unresolved theoretical tension regarding whether the adoption of sustainable practices is motivated by ethical convictions or by regulatory requirements and profitability, particularly in contexts with high levels of informality.

Responsible resource and waste management, the environmental pillar, is the instrument for achieving ecological efficiency and preserving the environment. Simultaneously, community participation and the safeguarding of heritage, the sociocultural component, align with social inclusion and intergenerational equity. Finally, the generation of decent employment and the boosting of local incomes, the economic dimension, are directly linked to sustainable growth and green employment. From this perspective, the strength of the link between these three pillars is determined by the degree of balance with which they are integrated into the operational practices of the tourism sector.

Given the identified limitations, this study aims to examine the link between sustainable tourism and the green economy in Peru, integrating its environmental, sociocultural, and economic dimensions from the perspective of key stakeholders in Lima. Its contribution is contextual and validating: it adapts and confirms existing theoretical frameworks on sustainable tourism and the green economy within a context marked by institutional constraints and significant ecological diversity, factors that introduce unique challenges.

MATERIALS AND METHODS

This research employed a quantitative approach, aiming to establish cause and effect between two variables or simply determine relationships between variables, which is what was done in this study. It is also known as empirical research because the results are evaluated precisely. Statistical analysis is performed to justify, anticipate, or control phenomena. Furthermore, it incorporates a rational component that moves from the general to the specific. The research had a relational scope, allowing for the analysis of two or more variables within a single group, and a non-experimental, cross-sectional design, which does not involve an experiment. This approach, however, amplifies the variance of individual variables and reduces any potential measurement flaws (Griffith, 2024).

The selection of the 153 participants was based on a non-probabilistic, purposive sampling approach, specifically focused on individuals in the tourism sector in Peru. The main criterion was their direct experience with sustainability practices; this decision allowed access to theoretically relevant information for examining the link between sustainable tourism and the green economy. Recruitment was conducted through institutional contacts and professional networks, prioritizing those with operational experience or decision-making capacity. The sample size was determined based on the requirements of the correlation analysis; therefore, the 153 participants provide sufficient robustness for Spearman's

rank correlation coefficients. Data collection took place in Lima, the country's main tourist hub and decision-making center, which facilitated gathering perspectives from stakeholders with national influence.

As a limitation of research, non-random sampling restricts external generalizability, meaning that the results primarily apply to the profile analyzed. To counteract this, recruitment aimed for balanced representation across groups. Additionally, requiring a minimum of two years of stable work experience ensured informed opinions by effectively filtering out responses from temporary or inexperienced staff.

Data collection was based on a survey technique with closed and multiple-choice questions (Salvador et al., 2021). The questionnaire consisted of 32 items per variable, measured using a five-point Likert scale (from "strongly disagree" to "strongly agree"). Before its implementation, a panel of experts validated the content to confirm that the items reflected the dimensions studied (Flores & Terán, 2022). The assessment of internal consistency using Cronbach's alpha coefficient confirmed the effectiveness of the instrument. The first variable obtained 0.8, while the second reached 0.9, reflecting adequate reliability (Raykov et al., 2024). The survey was conducted anonymously, protecting the privacy of the data provided by the participants. The collected data were statistically analyzed through: (1) a descriptive analysis to define the group and identify patterns, (2) a correlational study to explore the connections between the study variables, and (3) inferential methods for a better interpretation of the results. Presenting the results in tables facilitated the processing, analysis, and discussion of the information (Figure 1).

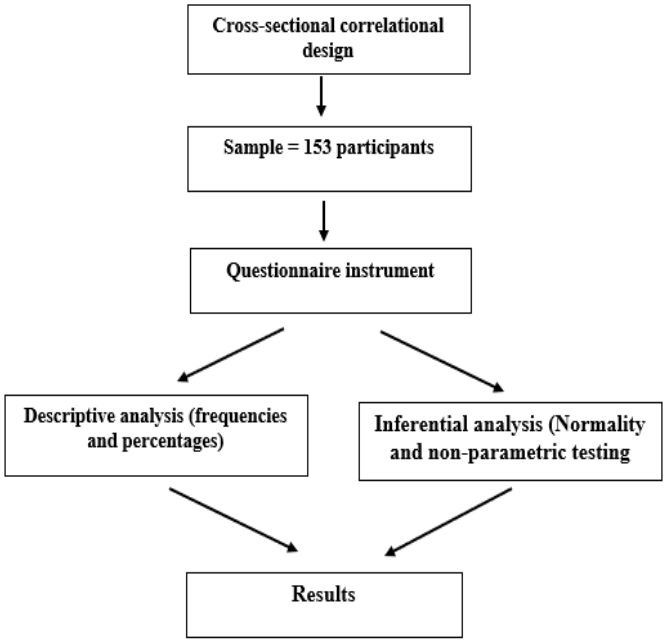

Figure 1. Quantitative analysis process

RESULTS AND DISCUSSION

Of those surveyed, 65.4% (100 participants) expressed agreement with the processes necessary to achieve sustainable tourism, and 31.4% (48 participants) indicated they strongly agreed. Regarding the second variable, the green economy, 62.1% (95 participants) concurred on the importance of implementing programs, guidelines, and business strategies that promote resource efficiency and proper waste management in the tourism sector, while 7.8% (12 people) strongly agreed (Table 2). These results demonstrate widespread recognition among participants of the relevance of sustainable tourism and the green economy in tourism activities, highlighting their close interrelationship. This connection is explained by the fact that sustainability in tourism seeks, among other objectives, to generate economic benefits for local communities, a purpose for which the green economy is fundamental.

Table 2. Frequency and percentage of study variables

	Sustainability		Green Economy	
	f	%	*f*	%
I completely disagree	1	0.7	1	0.7
Disagree	1	0.7	2	1.3
Neither agree nor disagree	3	2.0	43	28.1
OK	100	65.4	95	62.1
Totally agree	48	31.4	12	7.8
Total	153	100.0	153	100.0

In this study, the Kolmogorov-Smirnov normality test was used to examine whether the data collected from the sample followed a parametric or non-parametric distribution and to evaluate possible correlations between the variables (Table 3).

Table 3. Kolmogorov-Smirnov Normality Test

	Sustainable Tourism	Green economy	Environmental	Sociocultural	Economic
N	153	153	153	153	153
Sig. asin. (bilateral)	0.001	0.025	0.001	0.001	0.001

Table 4. Correlation between the variables Sustainable Tourism and the Green Economy

Green Economy			
Spearman's rho	Sustainable Tourism	Correlation coefficient	.501
		Sig. (bilateral)	0.001
		N	153

Statistical analysis shows a Spearman correlation coefficient of 0.501 ($p = 0.001$), indicating a moderate positive association between sustainable tourism and the green economy. Following Cohen's (1988) parameters, where moderate correlations range from 0.30 to 0.49 and strong correlations exceed 0.50, this result suggests that, in practice, stakeholders who perceive a higher level of sustainable practices in tourism demonstrate greater alignment with green economy principles in the Peruvian context (Table 4).

Although the statistical significance ($p < 0.05$) ensures that this connection is not random, the moderate magnitude of the coefficient implies that other factors not analyzed could influence the implementation of these practices. This result supports the proposed hypothesis and aligns with previous studies (Zhang et al., 2023; Chen, 2023), which also link visions of sustainability in tourism with broader economic and environmental frameworks.

Table 5. Correlation between the variables Green Economy and the dimensions of Sustainable Tourism

			Environmental	Sociocultural	Economic
Spearman's rho	Green economy	Correlation coefficient	.181	.560	.337
		Sig. (bilateral)	0.025	0.001	0.001
		N	153	153	153

According to table 5, the results of the Spearman correlation analysis allow for a clear distinction between the statistical significance and the practical significance of the findings. Following the benchmarks established by Cohen (1988), where values between 0.10 and 0.29 are considered weak, between 0.30 and 0.49 moderate, and above 0.50 strong, it is observed that the general correlation between sustainable tourism and the green economy ($\rho = 0.501$, $p = 0.001$) represents a statistically significant moderate association. This suggests that, in practice, the strengthening of sustainable tourism practices is substantially related to the adoption of green economy principles in the Peruvian sector.

The sociocultural dimension was the most important factor for the green economy transition. Participants stated that the green economy transition depends on community participation, cultural preservation, and interaction between tourists and local communities. The economic dimension showed a weak to moderate correlation ($\alpha = 0.337$, $p = 0.001$); it was statistically significant, but its practical importance suggests that the relationship between local economic benefits and the green economy is relevant but not decisive due to factors such as informal employment or income inequality in Lima's tourism sector.

In the case of the environmental dimension, further analysis is required ($\rho = 0.181$, $p = 0.025$), where the p-value less than 0.05 suggests statistical significance, likely due to a sample size of $n = 153$. However, the coefficient $\rho = 0.181$ indicates a very limited practical connection with respect to established standards. In other words, while a statistically measurable relationship exists, its influence in real-world situations is minimal. This weak correlation in the environmental context could be attributed to both theoretical and environmental factors: the environment in Lima, where tourism is important, may not have a strong connection to how people act on environmental issues. This could be because people may say they care about the environment in a survey, but face practical problems that prevent them from doing so, such as high costs, lack of skills, or inadequate facilities. People may be more focused on making quick money from tourism than on investing.

To promote a green economy in Peru's tourism sector, efforts should focus on strengthening the sociocultural aspect, where ties are strongest. On the other hand, for the environmental sphere, specific measures are needed to overcome implementation difficulties, such as tax incentives, technical training, and regulations that clearly link profitability with ecological sustainability. In accordance with the general hypothesis, the correlation results obtained show a significance value of less than 0.05. Furthermore, a moderate positive correlation was observed, reaching a value of 0.01, suggesting that an increase in sustainable tourism is related to a more robust green economy.

Zhang et al. (2023) point out that a place's economy depends on how quickly its tourism industry grows and is environmentally friendly, as well as on the value of money in that place compared to others. The findings of this research align with the study conducted by Chen (2023), who indicated that a tourism-centric green economy model had a positive impact on residents, visitors, and even the ecological and heritage environment itself.

This was observed through the perceptions of tourists while on-site at the destination. According to Vrana (2023), sustainable tourism has three pillars: Environmental, which, according to Akadiri & Ozkan (2026) and Jo et al. (2026), involves the proper management of environmental resources and the protection of biodiversity to avoid harming the environment. This can be achieved through the participation of stakeholders in the tourism sector. The sociocultural factor encompasses stakeholders who must have clear tourism planning and sustainable practices. Furthermore, the traditions of local communities must be preserved, thus providing an authentic experience for tourists. Finally, a tourism-

based economy also arises when tourists' interests are understood and high-quality services are provided. This greatly benefits communities employed in the sector, generating economic returns for the community (Ingaldi & Dziuba, 2022).

Regarding the specific hypothesis, a significance value of less than 0.05 was obtained, proving that a relationship exists between the research variables. A moderate positive correlation was also found, with values of 0.181 obtained between the green economy (the variable) and the environmental dimension. Following the findings of Han & Li (2021), who highlighted the need for tourism sector activities that do not pollute the environment through energy and carbon emission controls, this should be considered in companies' cost planning. In this way, a stronger green economy could be achieved, and the environmental dimension would be enhanced by having a sustainable project to support it.

This is complemented by the research conducted by Esenarro et al. (2024) in Peru highlighted that, in order to achieve sustainable tourism and a green economy model, policies are needed that are geared towards implementing solutions to the problems facing the tourism sector, such as pollution and the lack of fair wages. Therefore, investments focused on reducing carbon emissions and energy consumption, as well as promoting equitable wage distribution, are necessary. According to López & Cisneros (2026), the World Tourism Code of Ethics emphasizes that for the development of sustainable tourism, it is essential to protect species and the natural environment that surrounds them, as well as to consider the carrying capacity of tourism so that the arrival of tourists does not negatively impact the ecosystem.

Regarding the second specific hypothesis, which states that there is a relationship between the green economy and the social dimension, a correlation coefficient of 0.560 was found, indicating a considerable positive correlation between the two parts of the hypothesis. Considering the study by Novovic et al. (2022), which indicates the relevance of implementing responsible social policies and considering the sociodemographic characteristics of workers, such as their education, for the application of green accounting practices, the social dimension of sustainability demonstrates a positive correlation with green economy practices. Furthermore, Luekveerawattana (2024) also affirms that, to achieve effective green tourism management, and therefore green economic development, it is crucial to consider the community and actively involve it in tourism activities, as well as promote the preservation of local culture.

Along the same lines (Butowski, 2021; Marques et al., 2022) mention how, in principle, tourism activity should be related to cultural heritage and the preservation of the authenticity of the culture of local communities. In addition, the tourism industry needs the participation of stakeholders with adequate planning, since in sustainable tourism practices, it is expected to provide a unique experience to tourists (Ferdian et al., 2024; Spadaro et al., 2023).

Next, regarding the final specific hypothesis, which seeks to establish a relationship between the green economy variable and the economic dimension of the sustainable tourism variable, it can be stated that there is a moderate positive correlation, as indicated by the correlation coefficient of 0.337. This is supported by the significance level of 0.001, which reaffirms the relationship between both parts of the hypothesis. Complementing this information, Xue et al. (2023) indicate how to implement economic practices that generate resilient financial benefits and fairly bifurcated compensation, while also promoting access to employment and stimulating investment activity that results in future profits. Similarly, Brel et al. (2020) expand on the topic of economic models in predominant sectors in Russia, including tourism, and explain how the use of green economy practices is indeed realistic and how their implementation could provide a solution to socioeconomic problems within the tourism industry.

Therefore, there is a positive relationship between the concept of green economy and the economic dimension, which concerns sustainable practices for improving the quality of the sector in which they are applied.

One of the main limitations of this research relates to data collection, which was restricted due to the scarcity of available information on the topic. This meant that part of the analysis focused on Peru was based on studies from previous years, as updated data were unavailable. Furthermore, due to time constraints, it was not possible to conduct field visits that would have allowed for a more in-depth and localized analysis.

From a theoretical perspective, this research contributes to understanding how sustainable tourism relates to the green economy and its environmental, sociocultural, and economic dimensions, offering a useful conceptual framework for future studies in similar contexts. In practical terms, the findings can guide museum managers and local authorities in planning inclusive infrastructure and services, promoting more accessible experiences, and fostering the active participation of communities in sustainable tourism activities.

CONCLUSIONS

The findings of this study suggest that the transition to a green economy in the Peruvian tourism sector is not a homogeneous process. While there is a clear link between sustainable practices and ecological principles, the strength of this relationship varies significantly depending on the dimension analyzed. Most importantly, the sociocultural component emerges as the main driver; community participation and the preservation of identity resonate more strongly with stakeholders in the sector than purely environmental measures. This suggests that, in the context of Lima, the social legitimacy of sustainability depends more on human interaction and culture than on the technical management of waste or energy, where a gap is perceived between intention and actual practice.

On the other hand, although the economic dimension shows a positive correlation, its impact is conditioned by the structure of the labor market and income distribution. Simply generating employment is not enough; quality and local reinvestment are crucial for the model to be perceived as truly "green." Therefore, promoting a green economy in tourism requires policies that not only incentivize ecological efficiency but also prioritize the social fabric and ensure that economic benefits effectively reach host communities. Only by balancing these three spheres, with a special emphasis on the human element, can we consolidate resilient and authentic tourism development.

How can a small destination become a "rising star" in the modern competitive tourism market? Evidence from the Philippines. *Geojournal of Tourism and Geosites*, 67(3), 2066–2079. https://doi.org/10.30892/gtg.67321-1833

Abstract: This review study aims to analyze how a small island destination, exemplified by Samal in the Davao Gulf (Philippines), can achieve rapid tourism growth and transition into a competitive regional destination. It seeks to identify key drivers and strategies behind its successful development. The research examines the pathways by which a small island destination can transform into a "rising star" in the contemporary tourism market. The research employed a review-based approach combining secondary tourism data from 2015 to 2024 with a detailed case study analysis of Samal Island. The study employed a destination development framework to evaluate the impact of institutional, environmental, and socio-economic factors on growth. The findings indicate that Samal's tourism growth is driven by interconnected elements, including sustainable practices, the utilization of cultural and natural resources, and collaborative governance. These factors collectively enhanced the island's visibility and competitiveness in Southeast Asia's tourism landscape. The study concludes that even small, resource-limited destinations can reposition themselves successfully in regional tourism hierarchies through sustainable management, effective cooperation among stakeholders, and strategic leveraging of local assets. The contribution of this research lies in providing review evidence from the emerging island context of Southeast Asia, illustrating that even modestly resource-endowed destinations can successfully reposition themselves in regional tourism hierarchies when attractive resources and inclusive governance come together.

Keywords: Samal, tourism development, resources, small destination, review analysis

INTRODUCTION

Tourism is one of the key economic branches of the global economy, with the average contribution of almost 10% to the world GDP in 2023 (UN Tourism, 2024). Tourism represents a key sector for the economic development and social cohesion in the Philippines, with its long and multilayered history which ranges from pre-colonial mobility of people, and exchange, over the colonial period and the formation of the first infrastructural basis, to the modern efforts aimed at the internationalization of the offer and sustainable development. According to Lapuz (2023), the historic reconstruction of tourism development in the Philippines points to the process where the mobility patterns, colonial policies, and local community practices shaped the tourism institutions and practices – contrary to the simplified review which connects the beginning of tourism exclusively with the post-war, mass growth. The analyses of historiography point to the existence of early forms of travels and mobility, which were later institutionalized through the state and private development of the tourism offer (Capistrano & Notorio, 2021; Capistrano & Muñoz, 2022). During the last few decades, tourism in the Philippines has changed from predominantly local and regional to the growing acceptance of international markets thanks to the combination of natural resources (attractive beaches, coral reefs, rich biodiversity), cultural heritage, solid selective types of tourism offer (Fabros et al., 2023; Valencia et al., 2022; Notorio et al., 2025) and international promotion strategic policies. However, this growth was also accompanied by challenges – from spatial and sectoral uneven development, over the poor institutional coordination and the issues of environmental degradation, to the academic criticism which advocated decolonization of tourism research and practices in order to better represent local narratives and interests. Such critical literature emphasizes the need for including the local perspectives into policy-making and tourism research (Dela Santa &

Saporsantos, 2016; Gutierrez et al., 2021; Islam et al., 2018). The contemporary state of the sector is characterized by a strong recovery after the 2020–2021 pandemic standstill: statistical indicators and assessments point to the recovery of international arrivals and the income growth from tourism in the period 2022–2024, even though the levels in certain segments are still below the pre-pandemic (2019) trends. The national and international assessments show that the policies of opening borders, promotional campaigns, and the measures aimed at the support to the sectors of hospitality and air traffic significantly contributed to the recovery, but, at the same time, the needs for growth management, income source diversification, and strengthening destinations' resilience to external shock were highlighted (Philippine Statistics Authority, 2024). The pandemic crisis additionally changed the patterns of travelers' behavior – the importance of health safety was raised, as well as the demand for "closer" and domestic destinations, and the interest for less congested and nature-oriented products, such as eco-tourism and community-based tourism. The studies of post-pandemic tourists' behavior in the Philippines and the region of Southeast Asia point to the generation differences in the readiness to travel, as well as the higher demand for experiential, safe, and locally-based offers. These changes are both an opportunity and a demand for the reform of the destination management model (Fadlurrahman et al., 2025; Santiago et al., 2022; Zhang et al., 2021).

The perspectives of tourism development in the Philippines lie in several simultaneous directions. First, the improvement of sustainable and jointly-led models – community-based tourism (CBT) and creative forms of tourism – can enable a greater distribution of benefits, preservation of cultural and natural resources, and more resilient local development. The empirical research and evaluations of pilot-projects in the Philippines not only show the potential of CBT but also point to the need for institutional capacities, clear income mechanisms, and the support in the market positioning (Aquino, 2019; Fernandez-Abila et al., 2024; Gutierrez, 2022; Gutierrez & Vafadari, 2023). Second, the direction toward market diversification and the improvement of connections (e.g. visa-liberalization policy toward certain market sources) represents short-term measures for speeding up the income recovery, where there must be a balance with long-term sustainable planning (Quevedo et al., 2021). Third, the digitalization of services, data on visits, and strategic destination management will be crucial for the optimization of tourist flow and for minimizing the negative effects on sensitive ecosystems (Moreno & Bucoy, 2024). The research on tourism development in the Philippines requires a balanced approach which integrates historical-cultural insights, actual empirical data on tourist performance and behavior (Aquino & Porter, 2022), as well as critical perspectives which insist on local agencies and decolonization of knowledge. Such an approach enables not only the understanding of changes in the scope and structure of tourism, but also creating the policies which encourage inclusive and sustainable development of the sector.

In the Philippines, as well as in other parts of Southeast Asia, a lot of destinations rely on mass coastal tourism (for instance, the islands of Boracay, Bali, Phuket, etc.), which is why these new island destinations are forced to develop strategies of product differentiation and innovative approaches in management in order to be competitive with larger market actors (Cheer et al., 2018). In the last few years, the Island and the City of Samal, located in the Gulf of Davao in the Philippines, have been experiencing a fast development of tourism and they have often been highlighted as examples of a "rising star" destination, since they achieved significant improvements in the number of arrivals, in the income, and reputation. The aim of this paper is to analyze the key factors which have contributed to the competitive rise of Samal and to provide insights into the theoretical evidence on how small destinations can build market visibility and long-term sustainable position.

In order to achieve that, the research tasks will include the following: 1. Analysis of the historical tourism development trend of Samal (2015–2024); 2. Identification of the elements of tourism product differentiation; 3. Assessment of the impact of the improved transport accessibility on the growth in tourist arrivals and stay length; and 4. Formulation of recommendations for the implementation of good practices of Samal in the development of similar island destinations. The theoretical framework is based on the concepts of multivariate analysis of tourism in the observed destination and assessment of tourism advantages and disadvantages (Aquino & Porter, 2022; Dunets et al., 2020; Savanchiyeva et al., 2023), which show that the success of small destinations depends on a blend of comparative geographical analysis, systematic scientific methods, cartographic techniques, and expert evaluation. The previous research emphasizes the key factors of small island destination competitiveness, such as regional advantages, resources, sustainable development, and management.

MATERIALS AND METHODS

Case study of the Philippines' city and island of Samal

The sustainable development of tourism is especially important for small island destinations which possess extraordinary natural and cultural values, but which are also facing with limited resources and infrastructure, dependence on seasonality, and vulnerability to climate change (Scheyvens & Momsen, 2008). One of the representative examples is the island and the city of Samal in the Philippines. Samal is situated in the Gulf of Davao, in the south of the Philippines. The island is located in the Celebes Sea and within the province of Davao del Norte as one of the southernmost islands of the Philippine archipelago, near the southern coast of Mindanao Island (Figure 1). Samal Island has a surface area of 301 km^2, and it was inhabited by more than 120,000 people in 2020. The average arithmetic population density of the island is 395 people/km^2, and it is not one of the most densely populated islands in the Philippines. The entire island of Samal is within the city limits of the same name city (Samal). The city is divided into several districts, such as Babak, Penaplata, and Kaputian, and with additional 46 smaller settlements (Plasabas et al., 2013). Between the large island of Mindanao and Samal lies the narrow and long Pakiputan Strait. The narrowest point of this strait, between Davao City, the capital of Mindanao, and Babac Town on Samal Island, is only 900 meters wide (Nicolas et al., 2024). The largest island settlement is Samal City, which is also called "Island Garden City of Samal" or "IGACOS" (In Tagalog language: Pulong Harding Lungsod ng Samal). The city had a population of 116,638 in 2020, and it is expected that the total population of Samal city will exceed 120,000 in 2025 (Aguinaldo & Gomez, 2023).

Figure 1. The position of Samal Island in the Philippines

The average annual temperature of the city is 30 °C and the average annual rainfall is 1,297 mm. Depending on the specific location and geographical features, the annual rainfall in Samal varies between 1,200 and 1,600 mm, and short-term rains continue throughout the year. It is possible to describe the December–April period as the "dry season" since it receives the least rainfall, while the May–November period can be described as the "humid season" since it receives more rainfall. For the sea tourism purposes, the period between December and April is more convenient for visits. In Samal city, the daytime temperature averages vary between 29 °C and 31 °C throughout the year, while the nighttime temperature averages vary between 22 °C and 24 °C (Table 1). Briefly, there are no major fluctuations or major differences in both temperature and precipitation throughout the year. Before tourism began to flourish, Samal Island's economy relied primarily on coconut cultivation, large-scale agriculture, and fishing, but these industries were generally low-yielding and poverty was widespread. A wide variety of tropical fruit is produced, which is why Samal is also referred to as the "Philippines' Fruit Island". Coconuts, watermelons, avocados, pineapples, grapefruits, apples, bananas, papayas, and mangos are extensively cultivated throughout the island (Aguinaldo & Gomez, 2023).

Table 1. Monthly Average Temperature Changes in the Samal Island (Source: https://www.worldmeteo.info/en/asia/philippines/)

Months	Monthly Daytime Temperature Averages (°C)	Monthly Night Temperature Averages (°C)	Monthly Total Rainfall (mm)	Total Number of Rainy Days
January	29	22	98	16,4
February	30	22	86	14.3
March	30	22	91	16.3
April	30	22	83	18.5
May	31	23	133	25.3
June	31	24	158	25.0
July	30	24	111	23.8
August	30	24	101	21.9
September	30	24	94	20.8
October	30	24	117	24.4
November	30	23	131	24.3
December	30	22	94	18.7
Annual Average	30	23	1,297	249.7

Samal also produces the world's sweetest mango, known as the "Samal Sweet Mango". At least 2,000 hectares of land within the island's borders are planted with mangoes widely exported all around the world (Joaquin et al., 2021). The western coast of Samal Island is more densely populated and economically more developed than the eastern coast of the island. Therefore, most of the tourist facilities are found on the western coast (Fortaleza et al., 2020). To boost economic growth, the Samal Island Tourism Estate (SITE) Project was introduced, aiming to develop high-end resorts and establish the island as a secondary destination linked to Mindanao. However, initial evaluations indicated that the rural population might face significant challenges in keeping pace with rapid tourism expansion unless investments were also made in essential social infrastructure to help local communities adjust (Salman et al., 2024). With more than 2.5 million people living in the nearby city of Davao, the second largest city in the Philippines, the Samal island, one the other hand, recently became one of the main recreation centers of the metropolis. Since thousands of Davao citizens relax on the Samal Island at the weekends, the coastal parts of the island face big pressure by visitors (Dejadena et al., 2015).

Research methods

This review study examines the selected features of Samal, including economy, geography, ecology, and demographics, classifies its tourism benefits and shortcomings, and evaluates the island's tourism potential. The destination was chosen according to numerous factors (Dalagan & Sy, 2023), which distinguished it from other destinations in the Philippines.

The research was performed between January and October 2025, and it relied on the framework of the multivariate analysis of tourism in the observed destination, and tourism advantages and disadvantages were assessed. The secondary sources represent the available data from the Department of Tourism of Philippines (DOT), Philippine Statistics Authority (PSA), Samal Island City Tourism Office, for the analyzed ten-year period (2015–2024). DOT is the most representative state institution which follows the tourism flow at the national level. This study uses a systematic scientific approach, including comparative expert review method, cartographic and geographical presentations (Island Garden City of Samal — Local Tourism Development Plan, 2025). A key aim of the paper is to highlight Samal Island's resources to the academic community and encourage further research. Notably, this is the first comprehensive evaluation of the island's tourism and recreational potential, based on a two-phase study: 1. Analysis of the tourism resources on Samal Island; Examining Samal Island's accommodation capacities. The first phase involves popular tourism attractions, such as tourist parks and entertainment centers, religious centers, beaches, diving centers, historical and cultural places, etc. A detailed overview of the Island's potentials, which were not known to the academic community until now, will be presented (Table 2).

Table 2. Major Natural and Cultural Tourism Attractions of Samal City (Source: Authors, 2025)

Top 30 Natural Tourism Attractions	**Top 30 Cultural Tourism Attractions**
Giant Clam (Taklobo) Sanctuary	Aqua Water Park Samal
Kaputian Beach Park	Bandera Nature Park
Hagimit Falls	Pinta-IX Art Gallery
Sabang Cliff	ISLA Farms Highlands
Secret Blue Lagoon	Dadatan Bat Conservation Park
Canibad Beach	Floating Island Adventure
Limao Lagoon	Playa Azalea Pool
Talicud Mangrove Sanctuary	The Shoreline
Linosutan White Sand Beach	San Jose Mosque
Monfort Bat Sanctuary	St. Ignatius Spirituality Center
Uraya Beach	Japanese Cave House
Timjin's Cave	Virtu Trattoria House N Café
Sanipaan Marine Park	Kembali Samal Island by Filinvest
Pangubatan Forest Park	General Moncado White House
Coral Garden Marine Park	Aurora's Garden Resort
Malipano Islet	The Cliff Samal Oceanfront Resthouse
Quidopong Sandbar	Pearl Farm Beach Resort
Thunder Forest	Garden Breeze Inland Resort
Blue Bird Deck View	Santo Niño Parish Church
Mushroom Reef	Virgen Dolorosa Parish Church
Dayang Beach	Discovery Samal
Dapia Reef	Maxima Aqua Fun
Puting Bato	Mansud Shores
Enong Sinkhole Tidepool	Treasure Land
The Cliff Samal Oceanfront	Cafe Maañag Samal
Tagbaobo Falls	Al - Rahmaa Mosque
Vanishing Island	Virtuquest Samal Resort and Spa
Angel's Cove	Limao Lagoon Park
Cinco Engracia at Punta Pangubatan	Samal Island Park
Alorro Beach	Virtuquest Samal Resort and Spa

First, the reviewed overview will show the most famous attractions, which are key to the development of tourism through tourism attributes that Samal has. Some of them are the following: The City of Interesting Caves, The City of Magnificent Waterfalls, The City with the Puting Bato Hill, The City with the Giant Clam Sanctuary Nature Reserve, The

City with Breathtaking Views, The City with Historical Catholic Churches and Mosques, The City with Scuba Diving Centers, The City with Small Touristic Islands, The City with Historical Monuments, The City with the Talikud Island, The City with Colorful Festivals, The City with Breathtaking Beaches, and The City with the Sabang Cliff. According to the specified tourism attributes, the parameters for the assessment of the observed locations will be identified within each analyzed group, which will be supported by processing the available data from the statistical documents of the local tourism management authorities. After that, the tourism resources, sights, entertainment and recreation infrastructure will be analyzed. The obtained indicators of the evaluation criteria will be put into the unique measurement system. Then the private indicators of tourism-recreational potentials will be calculated: natural conditions and resources, cultural-historic resources, availability of tourism infrastructure, information technology provision of tourism (Jawad & Naz, 2022).

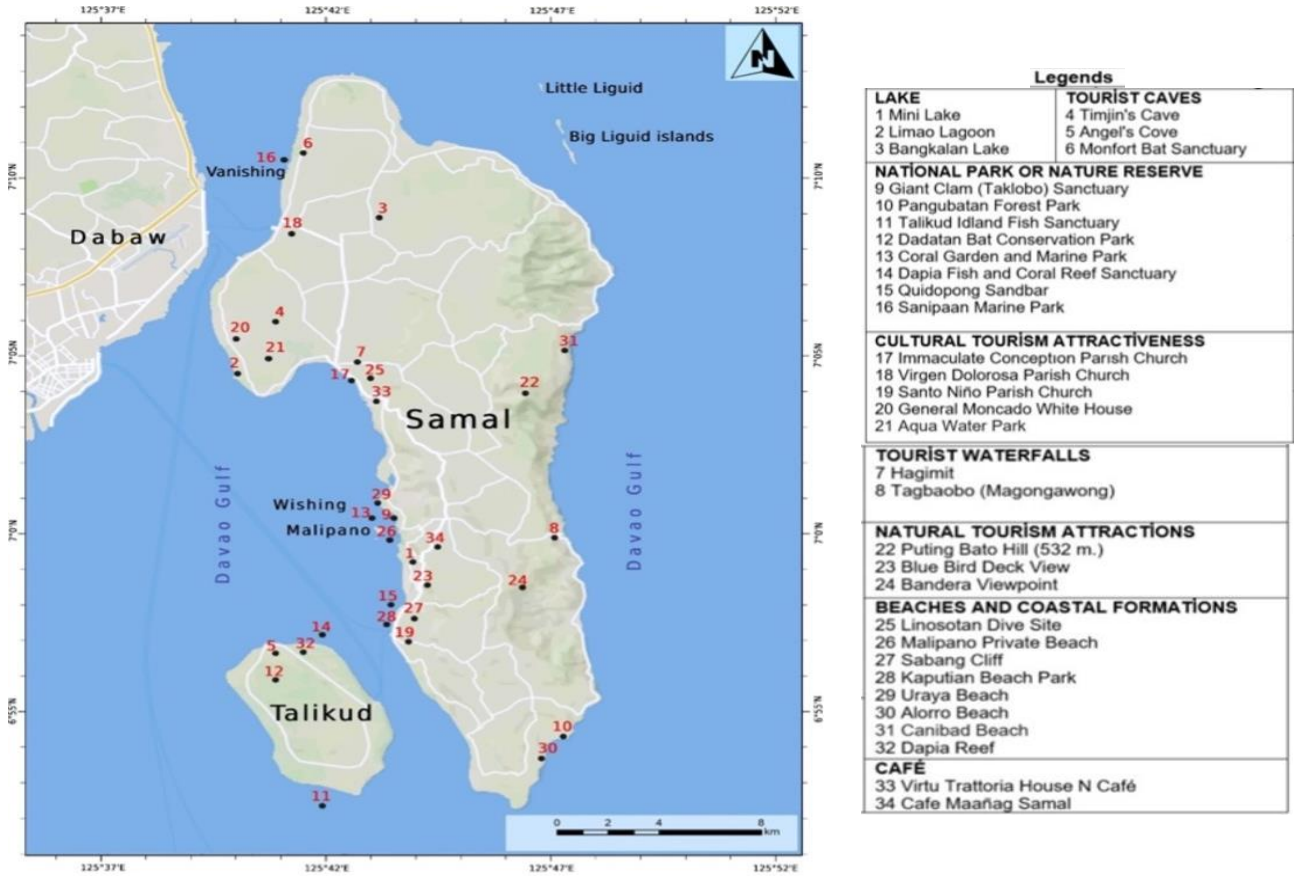

Figure 2. Map of tourist attractions "Island Garden City of Samal" (Source: Authors based on QGIS, 2025)

RESULTS AND DISCUSSION

Analysis of the tourism resources of Samal City

In terms of tourism activities, Samal has been one of the fastest growing Philippine cities of the 21st century and it also has the title of the country's largest "resort city". Samal can arguably be considered the only major Philippine city whose primary focus is tourism and recreation. Samal Island, which is only 2 km away from Davao City by ferry, is one of the most important tourist centers for travelers visiting the capital of Mindanao. This tropical island, which stands out with its pristine beaches, lush fruit orchards, and fascinating snorkeling areas, as well as luxury resorts and budget hotels, is ideal for a seaside holiday throughout the whole year. Samal city administrators organize the Samal summer festivals, which last from April to July every year. Festivals, fairs, congresses, competitions, sports and art events organized during this period attract local and foreign tourists to the city and make it possible for them to have fun. Since typhoons or severe storms are rare on the island, Samal can accommodate tourists 365 days a year. Based on this, the study aimed to create a comprehensive map (Figure 2) to present the the resources clearly and concisely. Some of the tourist features which the Garden City of Samal is famous for are its white sandy beaches and plenty of snorkeling areas, a variety of cheap seafood and fruit, quiet resorts and a wide range of accommodation options to suit every budget, fascinating caves and magnificent waterfalls, interesting marine ecosystem and unique nature reserves, colorful festivals and historical religious centers, and breathtaking diving centers and peaceful bays. Samal reveals its true nature through striking contrasts. The city generally portrays a poor rural picture, but on the other hand, it is full of modern and luxurious hotels. It has neglected suburbs and narrow streets, but also luxury villas with pools and magnificent shopping malls. Samal seems to be far from the world and civilization, but it is also only 2 kilometers away from a large and modern metropolitan city like Davao. It has untouched nature, deserted islands, and isolated shores, as well as lively tourism, noisy traffic flow, and numerous tourist facilities. Samal is a city that is both very close and very far from civilization. Those looking for a place even further from

civilization, even more untouched and more peaceful, are recommended going to the Talikud Island (Azucena & Regidor, 2023). There are many natural and cultural tourism attractions in Samal and they are quite diverse (Figure 2). The most popular tourist attractions among the foreign tourists visiting Samal are as presented in Table 3.

Table 3. The most popular tourist attractions on the Samal

1. Tourist parks and entertainment centers
"Maxima Aqua Fun", "Peñaplata Freedom Park", "Floating Island Adventure", "Playa Azalea Pool", "Precious Garden of Samal", "Aqua Water Park Samal", "Bandera Nature Park", "Aurora's Garden Resort", „Limao Lagoon Park", "Paradise Island Park and Beach Resort", "Treasure Land", "Sunset Beach Park", "Peñaplata Freedom Park", "Babak Baywalk", "Thunder Forest"
2. Tourist religious centers
"Santo Niño Parish Church", "Virgen Dolorosa Parish Church", "Immaculate Conception Parish Church", "St. Ignatius Spirituality Center", "Al - Rahmaa Mosque", "San Jose Mosque", "AL-Farouq Mosque", "Caliclic Masjid", "Mohammad Sharif Afdal Mosque", "Cogon Al Masjid "Al Azraq (The Blue Mosque)"
3. Tourist beaches
"Kaputian Beach", "Alorro Beach", "Canibad Beach", "Kembali Samal Island by Filinvest", "Samalan Camp And Sea", "Kanaan Beach", "Mansud Shores", "Coral Garden Beach Resort", "La Isla Bonita Talikud Island Beach Resort", "Isla Beach Resort", "Whean Beach Resort", "Dayang Beach", "Linosutan White Sand Beach", "La Concha Beach Resort", "Babu Santa", "Pearl Farm Beach Resort", "Babak Bamboo Beach Resort", "Vista Blanco Beach Resort", "Villa Amparo Garden Beach Resort", "Beach Ni Kapitan", "Uraya Beach Resort", "Virat Beach Resort", "Malipano Private Beach"
4. Tourist sea diving centers
"Coral Garden and Marine Park", "Dapia Fish and Coral Reef Sanctuary", "Kidopong", "Sanipaan Marine Park", "Angel's Cove", "Dapia Reef", "Coral Gardens", "Dizon Wall", "Giant Clam Sanctuary", "Linosotan Dive Site", "Babu Santa Minwall", "Mansud Wall", "Malipano Japanese Wrecks", "Talikud Idland Fish Sanctuary"
5. Tourist nature conservation areas
"Coral Garden Marine Park", "Talicud Mangrove Sanctuary", "Mahal Forest Resort", "Giant Clam Sanctuary", "Pangubatan Forest Park", "Dadatan Bat Conservation Park", "Monfort Bat Sanctuary", "Dapia Fish and Coral Reef Sanctuary", "Sanipaan Marine Park", "Linosotan Dive Site", "Babu Santa Minwall", "Mansud Wall", "Malipano Japanese Wrecks", "Talikud Idland Fish Sanctuary"
6. Tourist panorama spots
"Blue Bird View Deck", "Pacific Heights Viewing Deck", "Bandera Viewpoint", "Tañez View", "View Dekz Samal", "Fernandez Peak", "Cafe Maañag Samal", "Oasis Samal Resort", "Puting Bato Highest Peak", "View Dekz Samal", "El Samara Mount FMS", "ISLA Farms Highlands"
7. Tourist historic and cultural places
"General Moncado White House", "Japanese Cave House", "Ois Or Memorial Flight 541 Shrine", "Sinapān Heritage House", "La Vida Art Cafe", "Pinta-IX Art Gallery"
8. Tourist natural beauties
"Limao Lagoon", "Sabang Cliff", "Angel's Cove", "Coral Gardens", "Dizon Wall", "Quidopong Sandbar", "The Cliff Samal Oceanfront Resthouse", "Secret Blue Lagoon, Balet", "Caga San Jose", "Enong Sinkhole Tidepool", "Hagimit Falls", "Muni Muni Beach Resort Samal", "Aundanao", "Tagbaobo Falls", "Acantilado Aqua Farm & Resort", "Cinco Engracia at Punta Pangubatan", "La Patria Chica", "Nelmar", "Monfort Bat Sanctuary"
9. Tourist cafes, bars, and restaurants
"The Shoreline", "Virtu Trattoria House N Café", "Parola Bar", "Cafe Maañag Samal", "Samal View Cafe", "Nimfa's Secret Garden and Kitchen", "Bella italia", "Farmers V Resto & Grill", "Miami Vyce", "Haribar Lounge", "Morning Catch", "Mags Cafe", "The Limestone Brew", "Zagpa Grill and Restobar", "SIP - The Samal Island Promenade", "A Small Deli", "Kino's Bar", "Garden Breeze Inland Resort", "Kasama Coffee","Aznebo Grill & Restaurant", "Farmers V Resto & Grill", "Venus Resort Resto Bar", "Coco Loco Cafe", "Jardin de Ysabelle – Hobbiton Cafe".

Small islands, waterfalls, caves, beaches, churches and mosques, nature reserves, resorts and diving centers are the major tourist attractions in Samal. Snorkeling, trekking in tropical forests, fishing, exploring caves and waterfalls, watching Talikud coral gardens or cockfights, camping in tents, ecotourism, water sports, and beach tourism are the most popular tourist activities in Samal (Olivar et al., 2023). As a result, the destination has earned a variety of interesting epithets:

The City of Interesting Caves

Since there are about 70 caves on the island of Samal (Asdang & Schneider, 2024), speleologists from all over the world carry out scientific studies in these caves. The "Monfort Bat Sanctuary" cave system, consisting of five open caves and containing 1.8 million bats (Plasabas et al., 2013), is one of the must-see places in Samal. The cave system, situated in the northwest of the island of Samal, has been home to a large colony of Rousette fruit bats since the recorded history. More than 75% of the ceiling and walls of the caves, which are about 75 meters long, are covered with bat colonies. The "Montfort Cave System" or "Monfort Bat Sanctuary" is the largest single colony of this species according to the Guinness World Records (Asdang & Schneider, 2024). In addition to bats, the cave system is home to a variety of other animals, including snakes, lizards, and spiders. In short, this location hosts the largest single concentration of bat species in the world. "Timjin's Cave", situated northwest of the town of Penaplata, is another interesting cave formation on the island of Samal, but this small cave is not very well known to tourists and is therefore not visited very often (Joaquin et al., 2021: 33).

The City of Magnificent Waterfalls

There are 4–5 important tourist waterfalls within the borders of the "Island Garden City of Samal" that can appeal to

curious travelers. Even though these waterfalls cannot easily compete with those situated in Luzon, Mindanao, or Negros Island, they are worth seeing as well. Hagimit, Tagbaobo (Magongawong), and Sampao are the most significant of these tourist waterfalls. The famous Hagimit Waterfall, positioned in the Hagimit Valley in the central part of Samal Island, is one of the most beautiful and most popular natural tourism attractions of Samal Island (Asdang & Schneider, 2024).

The visitors can swim in the refreshing waters of the stream or simply enjoy the beauty of the waterfall from the viewing platforms. The famous Hagimit Waterfall, located southeast of the town of Penaplata, is a popular place for picnic and has plenty of benches and tables for the visitors to use. The sparkling clear waters comprise beautiful natural pools in the Hagimit valley. On sweltering hot days, the locals and children in particular go swimming and cool off in this stream. The "Virtuquest Samal Resort and Spa", "Immaculate Conception Parish Church", "Virtu Trattoria House N Café", "Peñaplata Freedom Park", "Maxima Resort Beach", situated very close to Hagimit Waterfall, are among the most interesting tourist places to visit after visiting this famous waterfall.

Tagbaobo Waterfall, also known as "Magongawong Falls", situated on the Tagbaobo River east of Anonang Town in the southeast of Samal Island, is another famous tourist attraction in Samal. The abundance of large-trunk trees in the area and the mist surrounding the waterfall create a mystical and magical atmosphere. Tagbaobo Waterfall, situated deep in the rainforest of Samal Island, is a picturesque waterfall that flows down from moss-covered rocks, creating a mesmerizing sight. Within walking distance of Tagbaobo Waterfall, places such as "Hgd View Deck", "572 Campsite Lanoy Resort", "Hgd Private Resort", "Katagbaoan Beach Farm", and "Thunder Forest" are other tourist attractions in the area that are worth seeing. There is a small but adorable waterfall called "Sofia Falls" in the southeast of Samal Island, west of Pangubatan town and just north of the "Coco Loco Cafe, Resort & Lounge" hotel. Since it is positioned very close to the Tagbaobo waterfall, it would be a good idea to visit these two waterfalls on the same day.

The City with the Puting Bato Hill

The Puting Bato Peak (532 m) is the highest point on Samal Island and offers breathtaking views of the surrounding areas. Hiking to the top is relatively easy and can be completed in less than an hour. However, the heat can be intense, so it is best to start climbing in the early morning or late afternoon. Once you reach the top, sit down and enjoy the breathtaking views of Davao Gulf and Samal Island. Puting Bato is a popular spot for both locals and tourists; therefore, make sure to visit it as early as possible in order to avoid the crowds. You can choose one of two different trails to this famous peak (Tayapoc or Guilon trail) and marvel at the combination of blue waters and lush vegetation while taking in the fresh air once you reach the highest point.

The City with the Giant Clam Sanctuary Nature Reserve

The "Giant Clam (Taklobo) Sanctuary" or "Giant Clam and Oyster Sanctuary", situated in Barangay Adecor, on the western coast of Samal Island, is a conservation area devoted to the protection and nurturing of giant clams, also known locally as "taklobo" (Plasabas et al., 2013). This colorful sanctuary, which is easily explored through a scuba diving tour, is one of the most important marine sanctuaries on the coast of Samal and also an interesting eco-tourism site. The Giant Clam Sanctuary is currently under the protection of the Davao del Norte State College. This marine area, which is home to colorful fish species and rich flora and fauna, offers fascinating mollusks to watch while snorkeling. This interesting marine sanctuary, positioned just across from the "LYR Beach Resort – Almeja Azul" hotel, is home to over 3,700 giant clams. The "Giant Clam (Taklobo) Sanctuary", occupying a marine area of approximately 14 hectares, is one of the most colorful marine sanctuaries in the Philippines.

The City with Breathtaking Views

There are many locations with fascinating scenery on both Samal Island and Talikud Island with beautiful views from the high peaks. Watching the curves of the seacoast, bays and peninsulas, beaches and forests from afar is among the favorite pastimes of every explorer tourist. "Bandera Viewpoint", "Tañez View", "Blue Bird Deck View", "View Dekz Samal", "Fernandez Peak", "Puting Bato Highest Peak", "El Samara Mount FMS", and "ISLA Farms Highlands", positioned within the borders of Samal City, are among the places with the best sea and island views. "Blue Bird Deck View" is one of the most favorite among visitors. For those who wish to watch the ocean while eating in a quality tourist place, the best choice will definitely be "Cafe Maañag Samal". This modern cafe offers delicious food, desserts, and drinks, as well as a breathtaking view of the nature. From the large balcony of "Cafe Maañag Samal", on clear days, the coast of Mindanao Island and the city of Davao is easily visible with the naked eye. Since the "Blue Bird Deck View" and "Cafe Maañag Samal" are positioned very close, both can be visited on the same day.

The City with Historical Catholic Churches and Mosques

Since the largest religious communities in Samal are Catholic Christians and Muslims, it is expected that the largest number of religious centers are churches and mosques. The first Holy Catholic Mass was held in "Santo Niño Parish" church located on Poblacion beach in Kaputian town on January 15, 1958. On May 30, 1983, St. Nino Chapel constituted a separate congregation and thus separated from the main congregation, the Immaculate Conception. This church, situated among vegetation and very close to the seashore, is one of the largest and oldest churches on the island of Samal. It would be a good idea for tourists visiting Kaputian Beach Park to see the architecture of this church. "Virgen Dolorosa Parish Church", located in the town of Babak on the northwestern coast of Samal Island, is certainly the most magnificent religious center on the island. This church, which is within walking distance from the Babak sea port, attracts visitors with

its modern architecture and peaceful, clean environment. "Immaculate Conception Parish Church", positioned in the town of Penaplata on the northwestern coast of Samal Island, is another significant religious center on the island of Samal. The church, positioned just behind "Peñaplata Freedom Park" area, is one of the favorite places for the Catholic community.

The "Al-Rahmaa Mosque" and "San Jose Mosque" are both the most popular Muslim religious centers in Samal and they are also the mosques with the most interesting architecture. The "Al-Rahmaa Mosque", situated in the village of Caliclic in the northwest of Samal Island stands out with its white, red, and green colors and magnificent appearance. This interesting place located just south of Babak Port is considered to be the largest and most modern mosque in Samal. "San Jose Mosque", found in the town of San Jose in the southwest of Samal Island is another big mosque in Samal. The most important mosques in Samal are "Masjid Darul Iman" located in the northeast of Babak town, "Al-Farouq Mosque", and "Caliclic Masjid" situated in the village of Caliclic, "Mohammad Sharif Afdal Mosque" positioned just east of the village of San Isidro, and the "Cogon Al Masjid "Al Azraq (The Blue Mosque)" located in the south of Talikud Island. It should be noted that, since the Muslim population in Samal is small, there are fewer mosques (Asdang & Schneider, 2024).

The City with Scuba Diving Centers

Samal, which is comprised of many islands, is home to many diving spots with colorful coral reefs, rich marine life, and even shipwrecks from World War II. On the west coast of Talikud Island, the most popular diving spot on the island is 150-hectare "Coral Garden and Marine Park", which is the most popular diving spot among the local and foreign tourists. This marine park area, situated off the coast of the "Coral Garden Beach Resort" hotel, has a shallow reef with depths ranging from 5 to 20 meters, offering a perfect diving experience for divers of all levels. This marine reserve is home to a variety of colorful corals such as horn coral, brain coral, and mushroom coral, as well as a variety of reef fish such as clownfish, angelfish, and butterfly fish. Divers can also explore sea turtles, octopuses, and other fascinating marine creatures here on some days. The crystal-clear water and excellent visibility make it an ideal spot for underwater photography. The 150-hectare wonderland "Coral Garden and Marine Conservation Park" is a true scuba diving paradise, home to over 50% of the Philippines' marine corals, sea grasses, and aquarium fish in one location. Other notable dive sites within the Island Garden City of Samal are "Dapia Fish and Coral Reef Sanctuary", "Angel's Cove", "Quidopong Sandbar", "Sanipaan Marine Park", "Linosotan Dive Site", "Babu Santa Minwall", "Mansud Wall", "Malipano Japanese Wrecks", "Talikud Idland Fish Sanctuary", and "Giant Clam (Taklobo) Sanctuary". The "Linosotan Dive Site" is located off the southern coast of Talikud Island. This marine reserve comes to be known for its vibrant coral gardens, diverse marine life, and underwater rock formations. Divers can explore the spectacular wall dive, which extends to depths of 30 meters, where they can see a variety of fish and other marine life. Linosotan's clear waters make it an ideal site for macro photography enthusiasts, and larger marine animals such as turtles, and reef sharks are occasionally spotted.

The "Dapia Fish and Coral Reef Sanctuary" is positioned off the northern coast of Talikud Island. Dapia is a colorful dive site with a sandy bottom and a shallow coral garden. In the Dapia sanctuary, divers can explore the reefs and encounter a variety of marine life, including clownfish, angelfish, and brood fish. The maximum depth in the Dapia sanctuary is only 10 meters, making it convenient for beginners and snorkelers. "Kidopong", situated between Talikud Island and Samal Island, is a popular dive site that offers a variety of underwater topography, including steep submarine walls, sandy slopes, and colorful coral gardens. Here, divers can explore a variety of marine life, including colorful fish, stingrays, and the occasional sea turtle. The maximum depth of "Kidopong" is 25 meters, making it suitable for divers of all levels.

The City with Small Tourist Islands

There are some small islets in the vicinity of Samal Island which contribute to the overall tourism offer. In the northeast of Samal Island, there are two small, but equally beautiful and interesting islands called Little Cruz (Little Liguid) and Big Cruz (Big Liguid). In the northern parts of Pakiputan Strait and in the northwest of Samal Island are the Arboles Island, Vanishing Island, and Sanipaan Marine Park. In the southwest of Samal Island are Talikud Island, Wiching Island, and Malipano Islands. The "Vanishing Island", "Wishing Island", "Malipano Islet" and "Big Liguid Island" are the most visited of these small coastal islets. It is possible to rent a boat from the Samal Island and visit these islands at a very reasonable price. The Vanishing Island is the first of these small tropical islets that should be visited.

This lovely tropical island is easy to reach because it only takes 5–10 minutes by boat from Barangay Tambo to go to the Vanishing Island. The area of Vanishing Island changes according to the tide. Sometimes the entire island is submerged during high tide, while a long sandy beach appears when the tide recedes. Therefore, the Vanishing Island is also called the "vanishable island" or the "coming and going island". You can easily reach this island by a small boat from the Babak Town at a low price. This interesting island, situated on the northwestern coast of Samal Island, in the Pakiputan Strait and 300–400 meters west of Babak Town, is considered one of the natural wonders of Samal.

The "Wishing Island", situated just southwest of the Giant Clam (Taklobo) Sanctuary marine reserve on the western coast of Samal Island, is another interesting tourist islet within the borders of Samal City. This islet, consisting of large rocks, is a fascinating tourist attraction with its breathtaking beauty and serene atmosphere. Plants and trees sprout from volcanic rocks and wild naturecontribute to a special charm of this small island in the middle of the sea.

This picturesque island, found just northwest of Malipano Islet, is famous for its pristine beaches and clear turquoise waters, and also stands out with its rich variety of living species for snorkeling and clear sea waters. A small, neglected water slide, a concrete-covered nature viewing terrace, and a simple picnic area are the only remarkable human elements on the island. The area of the island is so small that it is not convenient for the construction of either a restaurant or a hotel. It can be said that the Wishing Island is only suitable for daily boat tours, water sports, and picnics.

The “Malipano Islet”, situated just south of the Giant Clam (Taklobo) Sanctuary marine protection area on the western coast of Samal Island, is one of the most adorable, best-kept, cleanest, and most aristocratic coastal islets of Samal City. Long secluded beaches, mangrove forests extending along the island coast, luxury tourist facilities are the first remarkable elements of this island. This islet, situated just west of “Pearl Farm Beach Resort”, the most luxurious hotel of Samal Island, has been transformed into a recreation area for the guests of this hotel. In other words, the tourists staying at “Pearl Farm Beach Resort” Hotel generally visit Malipano Islet by boat tours. Malipano Private Beach situated on Malipano Islet is one of the most private and privileged beaches of Samal City. “Big Liguid Island” and “Little Liguid Island”, positioned off the northeastern coast of Samal Island, are deserted and lonely coastal islets. There is no settlement, no market, or tourist facility on these islands. They are islets left alone in the middle of the sea with long beaches and dense forests. Therefore, foreign tourists almost never come to these islands. Nevertheless, for those in search of peace and quiet, “Big Liguid Island” and “Little Liguid Island” are a perfect escape and a hiding place.

The City with Historical Monuments

The most anticipated and most visited architectural works of Samal Island are undoubtedly the “General Moncado White House”. The “Moncado White House”, found in the northwest of Samar Island and northwest of Penaplata Town, offers tourists a journey through time with its carefully preserved period furniture, artifacts, and memorabilia. This historical building, which offers a concrete glimpse into the lifestyle of the Moncado family and the culture of the Filipino elite, also promises the tourists a journey through Samal’s interesting history and a unique cultural experience.

The City of Talikud Island

Samal, officially known as the “Island Garden City of Samal”, has two large islands: Samal and Talikud. Samal and Talikud, positioned within the provincial borders of Davao del Norte, are like conjoined twins. The name of Talikud Island was derived from the Visayan word “licud” meaning “back” and is geographically located “right behind” or “right on the back” of Samal Island. Talikud Island has an area of approximately 28 km2 and a coastline of approximately 21.6 kilometers. The average elevation of the island above sea level is 95 meters (Asdang & Schneider, 2024).

Talikud Island, situated on the southwest coast of Samal Island, is less developed, less populated, and poorer than Samal. However, it is also quieter, more pristine, more peaceful, cleaner, and more natural than Samal. One will not find the noisy traffic and expensive resorts of Samal, nor the crowded tourist masses and urban pollution on Talikud Island.

The beaches and coastline are much more secluded and quieter, making it an ideal escape and resting place for honeymooners, romantic lovers, and families with children. Talikud Island, which lacks modern tourist facilities, has only four small rural settlements: Santa Cruz, Cogon, Linosutan, and Dadatan. Talikud Island, in comparison with Samal Island, has much fewer hotels, bars, restaurants, and tourist facilities. The main hotels on Talikud Island are: “Talikud Island Mangrove Beach Resort”, “Coral Garden Beach Resort”, “JYP Resort”, “Leticia by the Sea”, “Isla Reta”, “Garden of Eden Santa Cruz Paradise and Beach Hotel Resort”, “Pacifica-Verde Beach Resort”, “Tailkud Beach Resort”, “Pacific's Little Secret”, and “La Isla Bonita Talikud Island Beach Resort”. In reality, the total number of accommodation facilities on the island is not more than 20, and there are no luxurious five-star hotels among them. The island is more convenient for day trips and for camping in tents. However, the majority of tourists who come to Talikud Island visit this lovely island either for snorkeling or scuba diving. Water sports, diving activities, ecotourism, and marine tourism are the most popular types of tourism activities on the island. In planning and developing ecotourism, it is essential to ensure that local residents are well-informed so they can take part actively and constructively in the process (Keogh, 1990).

There are many bays, peninsulas, and beaches on the island of Talikud. Almost all of the beaches are free public beaches. The most popular beaches on the island of Talikud are: “Linosutan White Sand Beach”, “Coral Garden Beach Resort”, “Dayang Beach Resort”, “Isla Cristina Beach Resort”, “Cruz Beach”, “Mansud Shores”, “Linden Beach”, “La Isla Bonita Talikud”, “Whean Beach Resort”, “Pacific Little Secret”, “Angels Cove”, “Isla Reta Beach”, “Babu Santa”, “Vailian Precip Resort”, “Treasure Island Adventure Resort and Vacation Estates”, and “Lupa Surga”. As it is evident, the number of popular tourist beaches on the island is less than 20. The must-see tourist attractions on the Talikud Island are the “Talicud Mangrove Sanctuary”, “Dadatan Cave”, “Baga Caves”, “Coral Garden Beach Resort”, “Whean Beach Resort”, “Angels Cove”, “Linosutan White Sand Beach”, “Dadatan Bat Conservation Park”, and “Century-old Balete Tree”.

Talikud Island, in comparison with Samal Island, has much more interesting, much richer, and much more colorful diving sites. For the scuba diving enthusiasts, “Angel’s Cove”, “Dapia Reef”, “Coral Gardens”, and “Dizon Wall” are among the best diving sites. “La Isla Bonita Talikud Island Beach Resort”, “Whean Beach Resort”, “Dayang Beach”, “Linosutan White Sand Beach”, “Babu Santa”, and “Coral Garden Beach Resort” beaches also offer ideal natural environments for both snorkeling and scuba diving. Sparkling clean and warm sea waters, palm tree shadows, and white sandy beaches are the common natural features of these beaches. For those who wish to go for a swim with dense sea grass, coral gardens, and hundreds of marine creatures, the beaches listed above are the diving sites they are after.

The City with Colorful Festivals

Samal, also known as the "Island of Festivals", is a vibrant tourist destination where various unique activities, events, and festivals are celebrated throughout the year. These festivals are a testament to the rich culture and traditions of the island and offer tourists a chance to take part in the colorful festivities in person. IGACOS Festival held every March 7, Kabasan Festival held in Babak every May, the famous White Nights Festival held in Kaputian, and Hugyaw Madayaw Festival held in August (Olivar et al., 2023), are among the most colorful festivals. Indeed, during the festival periods, both the number of tourists and

the cultural and artistic activities and entertainment organizations on Samal Island tend to increase. IGACOS Festival is also known as "Samal Island Garden City Festival" as well as "Samal Island Garden City Foundation Anniversary". This three-day festival is held on the anniversary of the foundation of Samal City, every March 7. This colorful cultural festival commemorates the declaration of Samal as a city in 1998. The anniversary events include sports events, a business fair, an art workshop, cultural and sports shows, live music concerts, various exhibitions, dance competitions, an agricultural trade fair, a fireworks display, and a beauty pageant called the "Garden City of Samal". This exciting three-day festival also includes events such as sand-sculpture competition, a colorful boat river parade, beach volleyball, and a mountain bike tour (Asdang, & Schneider, 2024). Kabasan Festival, organized in May, is a week-long celebration that highlights the island's bountiful harvest. The Kabasan Festival in Babak is held during the last week of May and includes bikini beauty contests, fireworks, tourism exhibitions, street dances, street parties, and motocross events. In the Sama dialect, "kabasan" means "seashells."

Therefore, the festival was named Kabasan to celebrate the pageantry and splendor of the Island City. More importantly, Kabasan Festival is a celebration of gratitude for the bountiful produce of the sea for the people of Samal. Hugyaw Madayaw festival is organized every August and is one of the most anticipated events on Samal Island. It showcases the island's vibrant culture and heritage through street parades, cultural performances, art exhibitions, and culinary shows. Foreign tourists and visitors can watch the traditional dances, music, and costumes that provide a glimpse into the island's rich cultural fabric. Hugyaw Madayaw Festival is a three-day folk celebration filled with entertainment, games, music, dances, and presentations of the Sama tribe cultural practices, attended by the local and immigrant communities. The beauty pageant featuring folk costumes and folkloric elements is one of the most important events of this festival. Hugyaw Madayaw, organized by the Local Government Units and Municipal Authorities of Samal Island, is one of the most enthusiastic main cultural events on Samal Island. Hugyaw Madayaw Samal Festival is an attempt to sustain and preserve the Sama culture, which is gradually assimilated and on the verge of extinction. Consequently, these festivals on Samal Island are an integral part of the local identity, allowing the visitors to interact with the island's culture, traditions, and community (Olivar et al., 2023). They offer a vibrant and welcoming atmosphere, making Samal Island an even more exciting and memorable travel destination.

The City with Breathtaking Beaches

The beaches on the island of Samal can be divided into two large groups, free and fee-paying, and there are more than 70 beach areas throughout the island. Non-guests are generally charged for the beaches that belong to hotels and they are free only for hotel guests. Some of the private hotel beaches are "Pearl Farm Beach Resort", "Costa Marina Beach Resort", "Bluejaz Beach Resort and Waterpark", "Chema's by The Sea", "Samal Sands & Shores Beach Resort", and "Club Samal Resort". The public beaches that do not belong to any business or accommodation facility within the borders of Samal island are open to everyone and they are free of charge. Some of these free public beaches are: "Dalikyat Beach", "SLYap Beach", "La Concha Beach Resort", "Balet Beach", "Canibad Beach", "Isla Beach Resort", "Kanaan Beach Resort", "Joseph Beach Resort", and "Alorro Beach". In conclusion, whether fee-paying or free, the most peaceful, most beautiful and most popular beaches of Samal island are: "Babak Bamboo Beach Resort", "Vista Blanco Beach Resort", "Villa Amparo Garden Beach Resort", "Kaputian Beach", "Alorro Beach", "Canibad Beach", "Kembali Samal Island by Filinvest", "Kanaan Beach", "Pearl Farm Beach Resort", "Bluejaz Beach Resort and Waterpark", "Isla Beach Resort".

The City with the Sabang Cliff

The Sabang Cliff, found just north of Kaputian Town on the southwestern coast of Samal Island, is one of the most interesting, exciting, and magnificent tourist attractions on the island. For foreign tourists who come here, jumping into the sea from the high and steep cliffs on the Kaputian coast can be scary, but it is also incredibly exciting. When enthusiastic travelers and brave tourists jump into the sea from Sabang Cliff, they will be rewarded with a magnificent natural view and an incredible adrenaline rush. The Sabang Cliff, located just north of Kaputian Beach and Kaputian Port, is undoubtedly one of the best natural adrenaline-rush places on Samal Island.

Accommodation Potential of Samal Island

It will be appropriate to offer some tips about the hotels and beaches on Samal Island. The total length of the coast of Samal Island is 116 kilometers and there are many small coves, beaches, and capes on these coasts. Some of the beaches on the island are free public beaches and some are fee-paying hotel or private beaches. The private beach areas that belong to the "Paradise Island Park & Beach Resort" hotel in the town of Caliclic and the "Pearl Farm Beach Resort" hotel near the town of Adecor are considered the best and best-maintained beaches on Samal Island. Tourists who do not want to compromise on comfort and quality can choose to stay at these hotels. Essentially, the "Pearl Farm Beach Resort" is one of the most luxurious and most expensive accommodation facilities on Samal Island (Table 4).

The accommodation facilities on the island of Samal vary greatly in terms of both function and features, as well as in the prices and the number of stars that the hotels have. The "Maxima Aqua Fun Resort" hotel, situated just north of the town of San Jose, is a good choice for those who love water sports and entertainment. The "Chema's by The Sea" hotel is located just south of the town of Adecor on the west coast of the island of Samal. Nestled among the tropical trees and greenery, this hotel is an ideal choice for those who love romantic holidays and peaceful and quiet environment. For those who love rooms with panoramic sea views and white sandy beaches, the "Hof Gorei Beach Resort" near Caputian is a good alternative. Those who are after a more luxurious hotel can prefer the "Club Samal Resort" or "Lankenua Lodgings Samal Island". Those who wish to stay in a budget and affordable hotel with both beachfront and sea view rooms can stay at the "Red Parrot Inn" near Kaputian or "Publikhaus" boutique hotel within walking distance of "Samal Ferry Terminal".

Uraya Beach Resort - Olivia Sands	Lorelei Beach Resort	Kaputian Beach Park
Isla Betita Garden Resort	Villa Nelda Beach Resort	White Sands Hostel

Those in search of a romantic and peaceful holiday in rooms with waterfall and sea view can stay at the “Virtuquest Samal Resort and Spa” holiday village next to the Hagimit waterfall. The travelers seeking for a high-quality facility surrounded by forests and not by the sea can choose the “Castle View Hotel Samal” hotel (Table 5). Today, Samal Island, which has more than 200 accommodation facilities, is regarded as the country's largest "holiday island city" with its rich tourism diversity, world-class resorts and affordable hotels (Tables 4 and 5). In 2019, before COVID-19, at least 1.9 million

tourists on average visited this tropical city annually (PSA, 2024). In general, the western coasts of Samal Island are busier, more polluted, and some parts are intertwined with port activities and industrial facilities. The eastern coasts of the island are more secluded, cleaner, and quieter. Therefore, it is recommended that those who are after a peaceful holiday should stay in the accommodation facilities found on the eastern coast of the island. There are roughly more than 100 hotels and more than 200 accommodation facilities in operation on Samal Island (Tables 4 and 5). The highest density in the number of accommodation facilities is in the Babak–Penaplata region on the northwestern coast. More than half of the accommodation facilities on Samal Island are situated in this region. Serving at European standards, the "Pearl Farm Beach Resort", "Discovery Samal", and "Club Samal Resort" are among the most luxurious accommodation facilities on the island of Samal.

CONCLUSION

The Garden City of Samal Island attracts foreign tourists with its cheerful colors of the sky, the sun shining all year round, its deserted and clean beaches, the innocence of the villagers, the deep blue and crystal sea, mysterious caves and majestic chalets, friendly and cheerful people, peaceful hidden coves, and affordable holiday opportunities. In the 21st century, tourism has been the fastest growing economic sector of this charming city (Philippine Development Plan, 2023–2028). The touristic facilities and hotels have been mushrooming on the coastal areas of the city and thousands of foreign tourists visit this beautiful tourist place every year. Foreign tourists visiting Samal Island can sunbathe on the magnificent beaches of Alorro Beach Resort or Kaputian Beach Park. They can go diving in the blue waters of Coral Garden Marine Park, explore the interesting plants and animals in Pangubatan Forest Park, swim in the cool waters of Limao Lagoon or Tagbaobo Waterfalls, and watch the sunset from the Sabang Cliff. Visitors to Samal Island should definitely visit the Davao City and Talikud Islands, which are situated nearby. The main positive factors that have designated the rapid development of the tourism sector in the Garden City of Samal Island in the last quarter century are as follows:

- The Garden City of Samal Island is located only 2 km from Davao, the capital of Mindanao and the second largest metropolitan city in the country. It is also close to the island of Mindanao and Davao international airport.
- The island has climate characteristics convenient for beach tourism all year round, as it has high temperatures during all the 12 months.
- In comparison with other parts of the Philippines, natural disasters such as earthquakes, tsunamis, volcanic eruptions, and tropical cyclones are very scarce in Samal.
- Samal Island is considered one of the safest, most peaceful, and quietest places in the Philippine Republic, with no security or terrorism problems for foreign tourists.
- The Garden City of Samal has numerous natural tourism attractions. For instance, there are about 70 caves, more than 100 beach areas, and more than 10 waterfalls in Samal.
- There are not many problems such as transportation, communication, internet, and infrastructure within the borders of the city.
- The absence of high and rugged terrain throughout the city makes it easier for individual transportation by bicycles or motorcycles.
- The city has numerous hotels and accommodation facilities that are suitable for every budget. For instance, despite its small surface area, there are more than 200 accommodation facilities, guesthouses, tourist villas, and hotels within the borders of Samal Island.

The study shows that small destinations such as Samal can become a "rising star" through a dynamic interaction between natural wealth, socio-cultural characteristics, and economic development within the theory of sustainable tourism. Theoretically, this study contributes to the wider discourse on the development of island tourism by highlighting the fact that the vicinity of urban centers, favorable climate conditions, and social stability could jointly speed up the growth in tourism in peripheral, but ecologically rich destinations. It strengthens the existing theoretical claims on the models of "location advantage" and "destination competitiveness" (Dwyer & Kim, 2003; Crouch, 2011), and, at the same time, shows that community-led hospitality and ecological attributes jointly shape the tourist experience and destination identity. From the practical point of view, the findings have significant implications for the local government, space planners, and all the stakeholders in a destination. Fast growing of accommodation capacities and tourism infrastructure highlight the economic potential of Samal as a model for balanced regional tourism development. However, this trend also requires strategic management mechanisms in order to mitigate the environmental degradation and cultural commodification. Making sure that the tourism growth is in accordance with the goals of sustainable tourism – especially through capacity management, environmental protection, and community participation – is of vital importance for preserving natural and cultural assets of the island. Nevertheless, this pathway also emphasizes the need for integrated management mechanisms in order to prevent excessive development, environmental degradation, and cultural commodification. The harmonization of tourism policies with the principles of sustainable development – such as environmental management, inclusive participation of local communities, and capacity management – remains crucial for providing long-term sustainability of the tourism sector of the island (Gössling & Hall, 2006; Hall, 2019).

Despite the comprehensive review of tourism advantages of the Island of Samal, this analysis remains with a limited scope due to the lack of empirical data on tourists' satisfaction, transportation capacity, and the impact on the environment. Moreover, socio-economic implications for the local communities and long-term sustainability results require deeper research through quantitative and qualitative methodologies. The analysis is limited to secondary sources and descriptive assessments, with no primary empirical data collected from tourists, local residents, or other key stakeholders. As a result,

important aspects such as tourists' satisfaction, transportation capacity, environmental impacts, and socio-economic effects on local communities could not be systematically measured or validated. In addition, the study adopts a cross-sectional perspective and does not include longitudinal data that would allow for the assessment of long-term sustainability outcomes of tourism growth. Environmental impacts and community perceptions are addressed conceptually rather than through field-based or quantitative evaluations. Moreover, the findings are context-specific to Samal Island, which limits their broader generalizability to other island destinations. These limitations indicate the need for future research employing mixed-method and longitudinal approaches to better understand the long-term sustainability of tourism development in the island.

Future research should examine the cross section between the tourism growth and sustainability of the Island of Samal by including longitudinal data, studies of visitors' perception, and assessment of the impact on the environment. Comparative studies with other island destinations in Southeast Asia could also enhance the theoretical understanding of tourism resilience of small islands and inform the development of adaptive management frameworks suited for similar contexts. Besides, future related studies should adopt a mixed-method approach which integrates quantitative assessments of the impact on the environment with qualitative analyses of community perception and visitors' experience. Longitudinal studies which examine the sustainability of tourism industry of the Island of Samal would additional shed light on long-term effects of tourism growth.

Author Contributions: Conceptualization, A.A.Z., Y.K. and E.A.; literature review, E.A.; methodology, M.D.P. and E.A.; validation, M.D.P.; formal analysis, M.D.P.; investigation, A.A.Z., Y.K. and E.A.; data curation, D.L. and E.T.; writing - original draft preparation, E.A.; writing - review and editing, M.D.P. and D.L.; visualization, E.A.; supervision, D.M.K. Citation: Bader, M., Alrousan, R., & Al-Qudrah, H.M. (2026). Modeling visitor behavior in religious tourism: Mediating and moderating effects in the context of Christian pilgrimage sites in Jordan. *Geojournal of Tourism and Geosites*, 67(3), 2080–2091. https://doi.org/10.30892/gtg.67322-1834

Abstract: Religious tourism has emerged as a significant sector within global tourism, influencing visitor behavior, destination development, and spiritual experiences. Jordan, which is home to several Christian holy sites recognized by the Vatican in 2000, is quite important in terms of pilgrimage, but from a practical perspective, it has still not been fully studied. Understanding the factors that affect visitors' satisfaction and their intention to revisit is crucial for the maintenance of religious tourism sites. This study aims to analyze the behavior of visitors within the scope of religious tourism at five Christian holy sites in Jordan recognized by the Vatican. Specifically, it examines the relationships between travel motivation, religious tourism experience, religious tourism potential, perceived challenges, overall satisfaction, and re-tourism intention. Data were collected from 500 visitors using a convenience sampling technique. The study employed Smart PLS 4 software to analyze the data through partial least squares–structural equation modeling (PLS-SEM). The proposed hypotheses were tested to assess direct, mediating, and moderating relationships among the study variables. The findings reveal significant relationships among the examined constructs. Visit motivation has a strong positive influence on re-tourism intention. Religious tourism experience and overall satisfaction act as significant mediators in this relationship. Furthermore, religious tourism potential and perceived challenges moderate the effect of visit motivation on re-tourism intention. The study advances religious tourism theory by integrating motivational, experiential, and contextual factors within a single framework. Practically, the findings provide valuable insights for Jordanian tourism authorities and destination stakeholders to enhance visitor experiences, address challenges, and strengthen the sustainability of religious tourism in the region.

Keywords: visit motivation, visitors' religious tourism experience, overall satisfaction, religious tourism challenges, religious tourism potential, re-tourism-intention

INTRODUCTION

One of the most significant economic sectors worldwide is travel and tourism, offering enormous financial, sociocultural, and environmental benefits. As per WTTC (2024) with an additional $770 billion over its previous record, travel and tourism will solidify its position as a major global economic force, producing one out of every ten dollars globally. Religion is typically regarded as the earliest type of travel because it has been a primary motivator for travel from ancient times (Tsai, 2021). One of the earliest types of tourism, religious tourism, has a substantial role in the evolution of the travel industry. People who travel for spiritual or religious reasons, visit places of worship, or take part in religious festivals or events are all included in the category of religious tourism (Giușcă, 2020; Hassan et al., 2022; Hassan et al., 2024).

Holy sites, including mosques, cathedrals, and temples, are attracting more visitors from around the globe for leisure, education, and cultural reasons in addition to their spiritual significance (Ionut et al., 2024). The popularity of religious tourism continues to increase in Asia and around the globe (Shinde, 2020). The two wings of the Arab nation, one in Asia and one in Africa, are connected by the Hashemite Kingdom of Jordan, distinguished by the presence of both foreign visitors and Arab tourists who come to enjoy its breathtaking landscapes, exceptional climate, and sacred places. As a relatively stable Middle Eastern country that offers most of the conveniences of a modern Western society while maintaining its traditional roots, Jordan is an ideal destination to visit (Al-Haiaderh & Alrafaiah, 2024).

Tourism is undoubtedly the most important sector of the Jordanian economy. Jordan welcomes millions of foreign visitors yearly because of its many archaeological sites and well-preserved religious and cultural landmarks. Of the many sites that Jordan offers, the religiously motivated sites probably offer the most potential for visitors. Jordan is at the crossroads of the three great world religions. Among the three, Christianity, Judaism, and Islam, hospitality and welcoming the stranger is an essential and a religiously motivated act. Therefore, it is of great value for the development of religiously

motivated tourism, especially in those societies that are predominantly religious in both the religious and secular spheres. Jordan's religiously motivated tourism sector has been growing since 1903, when the Hijaz Railway was built in Amman. In the 1950s and 1960s, the sector was further developed and Jerusalem was the primary destination (Bader, 2012).

The complex nature of religious tourism and its socio-cultural impacts have intrigued the interest of previous empirical studies (Singh & Bhuyan, 2024). Furthermore, studies have investigated several different facets of religious tourism (Liutikas, 2023). These studies have examined how religious tourism affects communities, destinations, and the environment, in addition to the perspectives and motivating factors of tourists(Singh & Bhuyan, 2024). Previous studies have addressed religious tourism's sociocultural and economic impacts on various destinations (Budovich, 2022; Nair & N, 2022; Yan et al., 2024). Sayfullayeva & Barotov (2024) described that religious tourism can lead to long-term sustainability through environmental conservation, social and cultural preservation, economic benefits, infrastructure, accessibility, stakeholder collaboration, education, and awareness. Jiang et al. (2024) research shows that religious tourism boosts the local economy by increasing sales of souvenirs, travel, and housing. According to Song (2025), religious tourism may result in conflicts, the commercialization of culture, and environmental degradation.

Inadequate investigation has been done on how religious tourism potential and its challenges influence behavior in religious tourism (Bhadeshiya, 2024). Overall satisfaction and repeat business might result from recognizing a destination's religious tourism potential and challenges (Cunha & Louro, 2024). By analyzing religious tourism and other forms of tourism and the issues they cause, it is possible to learn more about the preferences and behaviors of tourists, which will ultimately help to maintain sustainability in the tourism sector. Further studies can assist government and stakeholders in anticipating and managing the potential challenges of religious tourism by staying focused on visitor behavior, satisfaction, experiences, and destination management strategies (Korov et al., 2024). It has been discovered that the quantity of publications on religious tourism has grown rapidly. Most studies on religious tourism are conducted in European nations (Ohlan & Ohlan, 2024)Thus, this study expands the existing literature on religious tourism in the context of the Middle Eastern region. There is insufficient research on how visitors' attitudes are affected by their experiences and revisit intention, and the influence of potential and challenges of religious tourism on visitor behavior, and there is a need for more in-depth studies to guide sustainable development (Choe, 2024). Filling these gaps will advance theoretical understanding and guide the expansion of moral and sustainable religious tourism worldwide.

One of the most widely practiced religions worldwide is Christianity, in addition to its churches and Roman Catholic faith, which significantly impact the growth of pilgrimage destinations and the support of religious tourism. In the Catholic tradition, pilgrimage site visits are typically organized as large-scale events to commemorate important dates, anniversaries, and holy site visits. The study focuses on five Christian holy sites that the Vatican recognized as pilgrimage destinations in 2000. After the successful completion of 25 years, on the occasion of the silver jubilee, this study focuses on five religious Christian sites i.e., the Baptism Site, Mount Nebo, the Shrine of Our Lady of the Mountain, Tal Mar Elias, and Mukawir Two of these sites, Mount Nebo, and the Baptism Site, were visited by Popes John Paul II in 2000 and Benedict XVI in 2009 (Al-Zoubi & Yahaya, 2020[a]).

Given the significance and holiness of these locations, these two visits hold great significance for Jordanian religious tourism. This research adds to the current empirical and theoretical literature on religious tourism. International tourists' participation in religious tourism, the impacts of religious tourism experiences on tourists' attitudes and intentions to return to religious sites, this study examines the potential, challenges, and overall satisfaction of religious tourism as well as potential solutions for destination stakeholders.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Religious tourism is the term for adventurous travel that involves going to places of worship (Ebabey, 2024[a]). This research mainly emphasizes the variety of motivations to travel for religious tourism, satisfaction, and the potential and challenges of religious tourism. Researchers have found several factors contributing to religious tourism (O. Carvache-Franco et al., 2024). These include prayer, spiritual experience, touristic reasons, religious causes, and social reasons (Rosak Szyrocka et al., 2022). The government and tourism marketers must understand the motivations behind religious travelers' demands (Mirhoseini et al., 2025). Although religious tourism can boost host communities' economies by bringing in earnings from travel and accommodation as well as souvenir sales, it has also sparked debate about cultural commodification and authenticity (Singh & Bhuyan, 2024). To reduce the adverse effects of religious tourism and maximize its benefits, researchers prioritize sustainable management techniques and community participation (Lin, Ling et al., 2021).

Visit motivation and re-tourism intention

Visit motivation is a multifaceted stimulus (Nian et al., 2023). Several factors can influence a person's decision to travel to a particular place. He et al. (2023) highlighted relaxation, cultural exploration, spiritual enlightenment, and thrilling experiences as goals for travel. Re-tourism intention is the term used to define a visitor's intention to return (Liutikas et al., 2024). There is empirical evidence establishing a connection between the purpose and intent of returning to a study site. Numerous researchers have shown a relationship between these two factors, indicating that if people have strong motivations to visit a place, they are more likely to go there (Hussain, 2021; Çıkı & Akgöz, 2025). Visitors were more inclined to return if they had unique and engaging experiences (Sthapit et al., 2024). Their motivation greatly influences the likelihood of a visitor returning to a site (Rasoolimanesh et al., 2022). This hypothesis clarifies visitor behavior by combining a theoretical framework with empirical evidence on visit motive. Therefore, we hypothesize:

H1. Visit motivation significantly affects tourists' re-tourism intention.

Visit motivation and visitors' religious tourism experience

Religious visitors are drawn to the destination due to their innate spiritual needs, including a desire to fulfil their curiosity and express their practice and faith. Their experiences were mostly noted for their religious (spiritual) involvement rather than their secular (tourist) activities (Rebuya et al., 2020; Lopes et al., 2025). As per Liutikas (2021) the desire to have a religious experience rather than having contact with a deity or engaging in spiritual activities, is more frequently the driving force for pilgrimage site visits, authentic, transcendental religious tourism (Wang et al., 2024) supernatural (Haller & Haller, 2022) or to achieve a lasting and beneficial positive impact (Van Iwaarden & Nawijn, 2024; Brogni et al., 2024). The relationship between visit motivation and religious tourism experience plays an integral role in why people go to places of worship in today's secular world (Raj, 2012). Following the above discussion, therefore, we hypothesize:

H2. Visit motivation significantly affects visitors' religious tourism experience.

Visitors' religious tourism experience and re-tourism intention

Re-tourism intention has been recognized as a critical research topic in the tourism literature (Lin, Chang, et al., 2021). Researchers generally agree that returning visitors are happier, spend more money on consumptive activities, stay longer, create positive word-of-mouth, and require much lower marketing costs than first-time tourists (Suhartanto et al., 2020). A visitor's intention to return to the same area is greatly influenced by their experience during religious tourism (Nguyen-Viet et al., 2025). Positive experiences play a vital role in getting visitors to visit the same site again. A visitor's intention to return to a similar area is greatly influenced by their experience during religious tourism. Numerous studies in the literature confirm that destination culture, historical significance, overall experience, and amenities have an impact on the intention to return (Tien et al., 2021; Pujiastuti et al., 2022; Rasoolimanesh et al., 2023). Following the above discussion, we hypothesize:

H3. Visitors' religious tourism experience significantly affects re-tourism intention

Visit motivation and overall satisfaction

Recently, several significant research studies (e.g. Nanggong et al., 2022; Ribeiro et al., 2022; Hamdy et al., 2024) have confirmed the relationship between visit motivation and overall satisfaction. Esubalew & Singh (2020) supported the valuable impact of visit motivation on overall satisfaction. Kim & Chen (2021) suggested that the visitors' activities had minimal impact on the overall experience or the advantages they received. The most reliable indicator of the visit motivation was the sensation of connecting spiritually and emotionally, ultimately resulting in a shift in visitors' devotion to pilgrimage experiences and overall satisfaction (Jyotsna & Sai, 2022; Hendar et al., 2025). Following the above discussion, therefore, we hypothesize:

H4. Visit motivation significantly affects overall satisfaction.

Overall satisfaction and re-tourism intention

According to previous research, re-tourism intention is significantly influenced by overall satisfaction (Baghirov et al., 2023; Lim et al., 2024). It appears to directly influence behavioral intentions, and visitor satisfaction with the event and destination is crucial for a favorable outcome and an indicator of intention to return (Al-Dweik, 2020). Visitor satisfaction is a predictor of revisit intention (Khoo, 2022; Hari & Mohan, 2025). Following the above discussion, we hypothesize:

H5. Overall satisfaction significantly affects re-tourism intention

Prior empirical studies have examined the intricate relationship between visitors' travel motivation, religious tourism experiences, and re-tourism intention (Rasoolimanesh et al., 2022). Parthenis et al. (2023) religious tourism experiences affect how visitors behave and how much they like a place. Thowayeb Hassan et al. (2022) discovered that a positive religious tourism experience positively contributes to the re-tourism intention of visitors. Hassan et al. (2024) research indicates that visitors' religious tourism experience acts as a mediator between visit motivation and revisit intention. Religious and spiritual people are more likely to seek out life-changing experiences in places of worship (Johnmeyer et al., 2025). Additional investigation is required to ascertain whether the visitor's religious tourism experience works as a mediator between visit motivation and re-tourism intention (Huddin et al., 2024). This hypothesis examines how tourists behave in religious tourism environments by using their experiences as a mediator. It also provides insight into re-tourism intention. The mediation model demonstrates how visit motivation, religious tourism experience, and re-tourism intention are interconnected. Therefore, we hypothesize:

H6. Visitors' religious tourism experience significantly mediates the relationship between visit motivation and re-tourism intention.

It has been discovered that the intention to revisit a place and visit motivation are significantly mediated by overall tourist satisfaction (Torabi et al., 2022; Ningsih & Muslichah, 2025). Visitor satisfaction increases the likelihood that they will return to a destination (Kumar & Bhinder, 2024). Nguyen-Van (2021) also verified that overall satisfaction mediates the link between visit motivation and re-tourism intention. Therefore, we hypothesize:

H7. Overall satisfaction significantly mediates the relationship between visit motivation and re-tourism intention.

Moderating effects of the religious tourism potential

Research regularly demonstrates that there is a considerable correlation between people's motivation for visiting a religious site and their willingness to return (Kayal, 2023;M. Carvache-Franco et al., 2024). Perceived value, infrastructure, and attractiveness as a destination for religious tourism are collectively referred to as the "religious tourism potential" of a place. This notion may strengthen or weaken the association between visit motivation and revisit intention, which can function as a moderator (M. Carvache-Franco et al., 2024[b]; Yuliviona et al., 2025). Re-tourism intention can be influenced by religious tourism potential (Choe, 2024). Nguyen Viet et al. (2020) outlined a gap in tourism potential that can serve as a

strong moderator between satisfaction and re-tourism intention. The suggested moderation model clarifies the connection between the visit motive, religious tourism potential, and the re-tourism intention. Therefore, we hypothesize:

H8. Religious tourism potential moderates the relationship between visit motivation and re-tourism intention.

The relationship might be weakened or strengthened by religious tourism challenges (Benmehdi, 2025). Relationships can be disrupted if a pilgrim feels insecure at a temple. Even if they were initially inspired by faith, they may be less inclined to return. Relationships will be reinforced (Varo & Emiroğlu, 2025). For example, a pilgrim may feel more accomplished and more motivated to return after overcoming a challenging journey to a sacred destination (Huang & Pearce, 2019). Religious tourism challenges can affect both individual experiences and the broader expansion of religious tourism destinations by influencing visit motivation and the intention to return (Choe, 2024). Religious tourism challenges can adversely affect revisit intention (Hasan et al., 2017). The suggested moderation model clarifies the connection between the visit motive, religious tourism challenges, and the re-tourism intention. Therefore, we hypothesize

H9. Religious tourism challenges moderate the relationship between visit motivation and re-tourism intention

RESEARCH METHODOLOGY

Study Area

The study focuses on five Christian holy sites approved by the Vatican in 2000 as pilgrimage destinations. Following the successful completion of 25 years, on the silver jubilee, this study focuses on five Christian religious sites in Jordan, namely the Baptism Site, Mount Nebo, the Shrine of Our Lady of the Mountain, Tal Mar Elias, and Mukawir. The study area's location map is shown in Figure 2. Two of these sites, Mount Nebo and the Baptism Site, were visited by Popes Benedict XVI in 2009 and John Paul II in 2000 (Al-Zoubi & Yahaya, 2020[b]). As the 25th anniversary approaches, His Beatitude Cardinal Pierbattista Pizzaballa, the Latin Patriarch of Jerusalem, Rasmi Al-Khazaleh, urge people to travel to Jordan and experience its profound holiness (Jordan News Agency, 2025).

Sampling and data collection

As per MOTA (2024) Mount Nebo received 1,63,830 international visitors, the Baptism site received 67,198, and the Tal Mar Elias received 11,243. The Shrine of Our Lady of the Mountain and Mukawir also received thousands of visitors in 2024. A survey was conducted at every location for the entire 30 days from 1st February to 2nd March 2025 to obtain a representative sample. Due to the large number of visitors at certain sites, the researcher administered 100 questionnaires at each site and ensured 100 valid responses to confirm a substantial level of confidence.

Data collected from 500 visitors. Five postgraduate students and two faculty members made up the research team; they were employed to collect the data from international visitors and received training for the survey. Visitors were informed of the study's aim during data collection, and those who agreed to participate were requested to complete the questionnaire. Data collected from visitors after attending religious sites at the exit point/parking area. Fieldwork was carried out on weekdays and weekends. The questionnaire was filled out using a convenience sample technique.

A copy of the questionnaire, which took around ten minutes to complete, was delivered to those who granted their approval. To minimize non-response bias, the researcher asked the subsequent visitor to complete the questionnaire after the first one declined. To prevent response biases, researchers chose various times for data collection each day.

Questionnaire design

This study created a questionnaire based on its hypothesis and research framework. To confirm content validity, the survey questions were adapted from literature reviews. All the items in the data collection instrument were taken from scales of existing literature. The constructs were assessed using a seven-point Likert scale, with 1 denoting "strongly disagree" and 7 denoting "strongly agree." To ensure respondents understood the questionnaire items, the researchers administered a pretest in a small group of 40 foreign visitors to Mount Nebo. Before using the questionnaire in the official survey, the researchers made additional changes to enhance its readability and reliability based on the pretest results. Using exploratory factor analysis, the

study specifically tried to remove items that did not load on a factor sufficiently and items with low adjusted item-to-total correlation values to purify the instrument. There were thirty items in the completed questionnaire. As shown in Table 1, which includes six constructs: VM (5 items), RI (3 items), VRTE (6 items), OS (5 items), RTP (4 items), and RTC (6 items).

Common method bias: As per Vomberg & Klarmann (2022) simple questionnaire instructions are vital for letting respondents know that there is no right or incorrect response and that all answers will be kept anonymous. This is a quick and easy way to lessen common method bias (CMB). As a result, the authors assured respondents during the data collection process that there would be no right or incorrect answers and that their identities would not be revealed. The CMB of the data was also confirmed using the Harman single-factor test (Harman, 1976).

Analytical methods

Once the respondents' attributes have been described using descriptive statistics, exploratory and confirmatory factor analysis, as well as the validity and reliability of the measurement model, and the structural model (path analysis) were analyzed using structural equation modeling (SEM) with the partial least squares (PLS) algorithm in SmartPLS 4.0, that has gained popularity and interest among researchers in recent years (Silaban et al., 2023; Vafaei-zadeh., 2024).

The study assessed the structural model's explanatory ability using common evaluation metrics, including R^2, F^2, and statistical significance of path coefficients. PLS-SEM is a practical approach that may be used to model latent constructs in non-normality situations and has few limitations on measurement scales (Chang et al., 2016).

The study was required to confirm the measurement model's reliability and validity for ordinary least squares regression (PLS-SEM), and structural model linkages for the latent and manifest variables in a non-iterative manner. Finally, the study assessed the statistical importance of the bootstrap resampling technique for the structural routes.

Table 1. Questionnaire items and their sources

Visit motivation (VM): source: Rybina & Lee (2021)	
VM1	I do like visiting religious sites because it allows me to reach my full spiritual potential.
VM2	I experience a sense of intimacy and connection with something sacred when I visit religious sites.
VM3	My present scenario gets replaced by a new one when I visit religious sites.
VM4	I may show my love and respect for God by going to holy places.
VM5	I constantly pray in the religious site.
Re-tourism intention (RI): source: Bhatti & Alawad (2023)	
RI1	I plan to visit Jordan's religious Christian sites in the near future.
RI2	I would recommend Jordan's religious Christian sites to friends or family members.
RI3	In the future, I would like to prioritize visiting Jordan's religious Christian sites over other travel destinations.
Visitors' religious tourism experience (VRTE): source: Rebuya et al. (2020)	
VRTE1	My love and reverence for God are expressed through my religious travel.
VRTE2	A visit to a spiritual location provides me with a sense of forgiveness.
VRTE3	I get closer to God when I visit religious sites.
VRTE4	Religious sites help me to recognize the region's historical significance.
VRTE5	The religious attraction/activity broadens my understanding by showcasing historical and cultural significance.
VRTE6	The religious site is in harmony with the local environment.
VRTE7	The hospitality of the local people is good
Overall satisfaction (OS) : source: Hughes et al. (2013)	
OS1	I deemed the visit to be worthwhile.
OS2	The visit was just as excellent as I had expected.
OS3	I was enchanted by everything I read, heard, and saw.
OS4	I discovered the information to be fascinating.
OS5	I believe I benefited from being here today.
Religious tourism potential (RTP): source: Rivera et al. (2009)	
RTP1	I found good facilities and infrastructure (access, cleanliness, facilities, physical layout)
RTP2	I found Jordan's religious Christian sites' economic (price of admission, price of food)
RTP3	I found good sensory stimulants (use of technology and exhibits)
RTP4	I found sufficient site-specific attributes (Christian themes, spiritual activities, information about the Bible, and inspirational experience)
Religious tourism challenges (RTC): source: Kumar & Rao (2022); Ebabey (2024)	
RTC1	Convenient and trustworthy transportation choices are available to religious sites.
RTC2	Signage to religious sites is well-marked and informative.
RTC3	There is sufficient institutional or governmental assistance for religious tourism.
RTC4	Religious sites have adequate security measures in place.
RTC5	The staff and guides at the religious site are informed and supportive.
RTC6	I feel safe while visiting Jordan, despite the ongoing cross-border conflicts.

RESULTS

Demographics

Table 2 presents the demographic aspects of 500 respondents. The sample's general gender distribution was (59.2%) male and (40.8%) female, in contrast to previous studies that suggested older ages were more interested in religious tourism, with respondents aged 31 to 50 making up the majority (72% of the entire survey). Most visitors were European (37.6%), followed by North Americans (23.4%), With a share of (37.6%), It needs to be noted that European tourists are

more interested in visiting Jordanian Christian sites, and ove[r] half of the sample was highly educated (61.4%), with bachelor's degrees or more. However, over two-thirds of the respondents were regarded as upper middle class, with (63.2%) earning between (31,000 and 70,000 $), while (50.8%) were employed and (34.6%) were businessperson.

Table 4. Discriminant validity – Fornell-Larcker criterion (Source: Author's calculation)

Constructs	VM	RI	VRTE	OS	RTP	RTC
VM	0.903					
RI	0.542**	0.897				
VRTE	0.654**	0.639**	0.943			
OS	0.621**	0.532**	0.639**	0.840		
RTP	0.598**	0.540**	0.589**	0.625**	0.901	
RTC	0.609**	0.528**	0.513**	0.539**	0.662*	0.882

Notes: Significant at two-tailed *p<0.05 and **p<0.01. The square root of the average variance extracted (AVE) for each construct is displayed by the diagonal numbers in italics; VM = visit motivation; RI = re-tourism intention; VRTE = visitors' religious tourism experience; OS = overall satisfaction; RTP = religious tourism potential; RTC = religious tourism challenges

Measurement model

The convergent validity of each construct was demonstrated by the average variance extracted (AVE) values above the 0.50 threshold (Fornell & Larcker, 1981). The inter-consistency reliability was assessed by computing Cronbach's alpha and composite reliability values for each construct. The analysis's findings revealed that Cronbach's values were higher than the cutoff point of 0.70, as specified by Taber (2018). The items in each construct group have a high level of internal consistency, as indicated by the respective values for each construct, which were 0.959, 0.927, 0.963, 0.956, 0.943, and 0.916, respectively, and appropriate factor loadings as displayed in Table 3. Additionally, the suggested cutoff limit of 0.70 was exceeded by the CR readings. Tables 3 and 4 illustrate that the discriminant validity is sufficient, as per Garver & Mentzer (1999), as the

correlation coefficients for each component were less than the average variance extracted (AVE) square root. This implies that every construct is distinct from the others and does not strongly correlate with others (Fornell & Larcker, 1981).

Table 5. The PLS method's coefficient of determination (Source: Author's calculation)

Constructs	R-square	R-square adjusted	Q^2 predict
RI	0.381	0.367	0.316

Structural Model

Once the measurement model had been evaluated, the structural model, also known as the inner model, was the focus of the next investigation. The R^2 value was first computed to assess the variation explained by the constructs associated with the (endogenous) dependent variables. Ozili (2023) show that, depending on the research environment, the R^2 evaluation results fall into three categories: 0.09 (poor), 0.13 (moderate), and 0.26 (high). The inner model graphically represents the interdependencies between the elements in the conceptual model. The R^2 values for the study's (endogenous) dependent variable show that the direct impact model accounts for 55.8% of the variation in OS and 31.4% of the variation in VRTE. These findings imply that changes in these parameters can be predicted by VM and moderated variables. Additionally, an investigation shows that the computed coefficient of determination (R^2) for the RI is 0.381. Thus, about 38.1% of the variation in RI may be explained by the variables VRTE, VM, RTC, RTP, and second, the predictive relevance (Q^2) by cross-validation redundancy was computed to quantify the conceptual model's assessed significance.

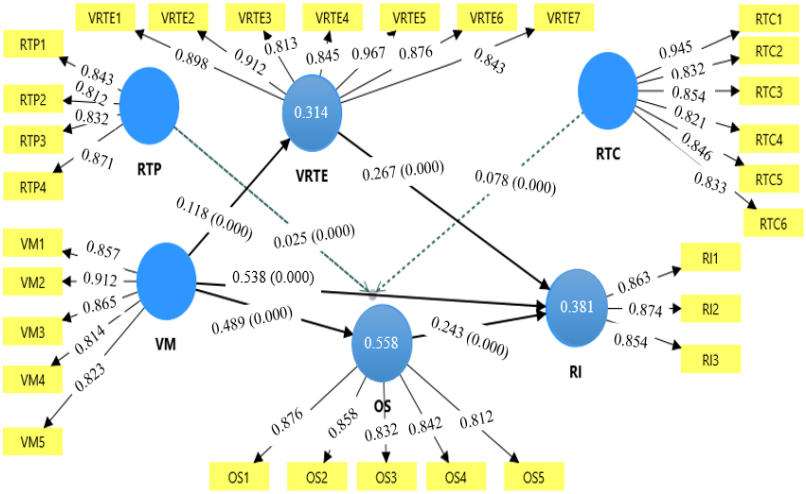

Figure 3. PLS-Path analysis based on 5000 bootstrapped samples

The direct effect model has sufficient predictive significance, as demonstrated by Table 5, where all endogenous latent variables have Q^2 values greater than zero (Q^2 = 0.277 for the direct VM and VRTE, Q^2 = 0.543 for the VM and OS, and Q^2 = 0.316 for the indirect impact of VM on RI). As per Table 6 and Figure 3. Hypotheses from H1 to H5 were accepted because VM had a positive and statistically significant direct effect on RI (β = 0.538, t = 14.904, p < 0.05), similarly comparable substantial positive impact for VM on VRTE (β = 0.118, t = 4.398, p < 0.05), VRTE on RI (β = 0.267, t =

5.388, $p < 0.05$), VM on OS ($\beta = 0.489$, $t = 2.066$, $p < 0.05$), and OS on RI ($\beta = 0.243$, $t = 2.126$, $p < 0.05$). The relation between VM and RI is mediated by VRTE, according to the study. Similarly, OS mediates the relationship between VM and RI. The indirect impact of VM on RI through VRTI was significant ($\beta = 0.031$, $t = 3.213$, $p < 0.05$).

Moreover, there was a substantial indirect effect of VM on RI through OS ($\beta = 0.028$, $t = 4.765$, $p < 0.05$).H6 and H7 were thus also approved. Furthermore, the relationship between VM and RI was shown to be significantly moderated by RTP ($\beta = 0.025$, $t = 4.389$, $p < 0.05$). The association between VM and RI was also significantly moderated by RTC ($\beta = 0.078$, $t = 0.787$, $p < 0.05$). Therefore, H8 and H9 were also accepted.

DISCUSSION

The study explores the dynamics of visitor behavior in locations related to religious tourism and the outcomes of applying concepts pertinent to the study's framework. By examining the relationships between visitors, travel motivations, religious tourism experiences, potential, challenges, and intention to return, the study investigates the complex relationships that foster destination loyalty and intention to return. The study uses both empirical data and a theoretical framework to clarify the complex features of religious tourism. For those in destination management looking to enhance their plans and initiatives for sustainable tourism growth.

First, it was hypothesized that re-tourism intention is significantly impacted by visit motivation. The current study's findings suggest that motives for the visit have a significant effect on re-tourism intention. If their initial travel goals were satisfied, tourists are more inclined to return to a place. Most researchers reported a sound relationship between their re-tourism intention and visit motivation (Esubalew & Singh, 2020; Ayoub et al., 2024). As per Mishra & Maheshwari (2025), to create individualized visitor experiences and marketing strategies, it is necessary to understand the motivations of visitors, which may include spiritual enrichment or learning about the host culture.

Secondly, it was hypothesized and study findings suggest that visit motivation significantly affects visitors' religious tourism experience. As per Lachlali et al. (2019), at a religious site, different motives result in different behaviors, expectations, and overall experiences. Religious tourists travel for a variety of motives, including cultural immersion, spiritual growth, sightseeing, and personal development. Therefore, to improve the religious tourism experience, destination stakeholders should concentrate on genuine and interesting linkages with religious heritage and traditions.

Third, it was hypothesized that visitors' religious tourism experience significantly affects overall satisfaction. The study's findings aligned with the body of existing literature. Previous research has demonstrated that religious tourism experiences have a positive effect on re-tourism intention (Rehman et al., 2022). A study by Bhandari et al. (2024) found a strong, favorable relationship between tourists' religious tourism experiences and their inclination to return. Fourth, it was hypothesized that visit motivation significantly affects overall satisfaction. Results aligned with the earlier findings. Previous research has revealed that travel motivations have been demonstrated to be significant indicators of overall satisfaction (Esubalew & Singh, 2020). Similarly, previous studies have mostly focused on the relationship between overall satisfaction and several variables associated with visit motivation, such as push and pull factors.

Fifth, it was hypothesized that overall satisfaction significantly affects re-tourism intention. By the study's findings, M. Lin (2024) satisfied tourists are more likely to make plans to return. Studies repeatedly demonstrate that there is a positive correlation between satisfaction and the intention to return. Sixth, it was hypothesized that visitors' religious tourism experience significantly mediates the association between visit motivation and re-tourism intention. By providing unique experiences, tourism destinations may increase visitor engagement. Because of this, visitors are urged to come back and recommend the location. Travelers' experiences, motivation, and desire to return are all intertwined in religious tourism (Carvache-Franco et al., 2024).The results emphasize how essential it is for destination stakeholders to manage the destination holistically. Prior research conducted by Bhatti & Alawad (2023) confirmed that visitors' religious tourism experience significantly mediates the association between visit motivation and intention to return.

Seventh, it was hypothesized that overall satisfaction significantly mediates the association between visit motivation and re-tourism intention. The reason for traveling is known as the motive of the visit. Researchers have suggested that understanding visit motivation could be the key to overall satisfaction and re-tourism intention. Research continuously demonstrates that visit motivations and re-tourism intention are significantly mediated by overall tourist satisfaction (Esubalew & Singh, 2020). Further, between the initial motivation for the visit and the ultimate decision to return, satisfaction acts as a connection. The essential aspect that turns motivation into a desire to return is the satisfaction gained from the experience, not because motivation only results in the intention to return.

Eighth, it was hypothesized that religious tourism potential would be a moderator between visit motivation and re-tourism intention. In line with the results of the Rehman et al. (2022) study, which showed that the perceived religious tourism potential of a place might affect the degree of the association between an individual's motivation for visiting that location and their intention to return. For the ninth hypothesis, it needs to be noted that religious tourism challenges have a significant moderating effect on the relationship between visit motivation and re-tourism intention, which supports the research Zhou et al. (2023) that found that religious tourism challenge is a favorable moderator between visit motivation and re-tourism intention. Different challenges at destinations may deter visitors from visiting. Overtourism, inadequate infrastructure, and disturbances to nearby populations are a few examples of these difficulties (Rybina & Lee, 2021).

CONCLUSION

This study contributes to the understanding of religious tourism by examining the relationships among visit motivation, religious tourism experience, overall satisfaction, destination potential, destination challenges, and re-tourism intention in

the context of Christian pilgrimage sites in Jordan. The findings confirm that visit motivation directly and indirectly influences re-tourism intention through the mediating roles of religious tourism experience and overall satisfaction. Furthermore, destination potential and destination challenges significantly moderate these relationships, demonstrating that visitors' behavioural intentions depend not only on their motivations but also on the quality and management of the destination. These findings extend the theoretical understanding of religious tourism by providing empirical evidence of the sequential mechanisms through which motivation is transformed into future behavioural intentions. From a practical perspective, the results offer valuable guidance for destination managers, policymakers, and tourism marketers in developing effective strategies to strengthen pilgrimage destinations. Improving destination infrastructure, reducing operational challenges, enhancing interpretation services, and adopting digital tools such as mobile applications and virtual guides can enrich visitors' experiences and increase satisfaction and revisit intentions. Regular monitoring of visitor motivations, experiences, and satisfaction through surveys and digital feedback systems will support evidence-based destination management. Overall, this study provides a comprehensive framework for promoting the sustainable development and long-term competitiveness of religious tourism destinations in Jordan and similar pilgrimage contexts.

Limitations and Future Research

Every investigation has inherent limitations, and every study offers opportunities for improvement. The current study also has several shortcomings. Only five Christian worship sites recognized by the Vatican in 2000 were the focus of this study; more research should focus on other sites that are also connected to Christianity in Jordan. Second, while the current study was cross-sectional, future research should concentrate on a variety of data collection techniques, such as longitudinal studies, mixed methods, and interview-based investigations. Third, to consider stratified sampling in future research to guarantee wider representativeness and address the drawbacks of convenience sampling (such as overrepresenting visitor groups). The sample and conditions of the study may restrict generalizability. Future studies may examine the effects of sustainable tourism practices on visitor preferences and destination competitiveness in the context of religious tourism as sustainability becomes popular. Studying religious tourism and other niche tourism categories like wellness tourism and volunteer travel can be the way to investigate the relationship between visitor experiences and motivations. Future research can fill these gaps and investigate new aspects of religious tourism to sustain religious tourism destinations worldwide and improve theoretical and practical understanding.

Developing local wisdom–Based tourism products in Bireuen regency, Aceh Province: Integrating cultural heritage, community empowerment, and sustainable tourism strategies. *Geojournal of Tourism and Geosites*, 67(3), 2092–2107. https://doi.org/10.30892/gtg.67323-1835

Abstract: Local wisdom-based tourism is increasingly seen as a strategic approach to achieving sustainable, inclusive, and competitive destination development, particularly in areas with rich cultural heritage and vibrant traditional social systems. Bireuen Regency, Aceh, boasts tourism potential stemming from relatively well-preserved natural resources and deeply embedded sociocultural values within its communities. This study explores the development of local wisdom based tourism products in Bireuen Regency, using the something to see, something to do, and something to buy framework integrated with sustainable tourism strategies. This research method uses an exploratory qualitative approach. Data were collected through in-depth interviews with key informants, including tourism site managers and members of indigenous communities, selected using snowball sampling. Additional data were obtained through observation and documentation. Data analysis involved systematic stages of data reduction, data display, interpretation, and conclusion drawing. Results of the reseach reveal that Bireuen Regency possesses diverse local wisdom-based tourism potentials encompassing natural landscapes, tangible and intangible cultural heritage, and traditional social systems. Cultural traditions such as *Meugang*, *Khanduri Laôt*, and *Khanduri Blang* emerge as authentic cultural tourism attractions. Local knowledge and community social practices support the development of experiential and educational tourism. Furthermore, local crafts and culinary products including *plik u*, *purun* weaving, crafts from coconut powder, *sate matang*, *kuah beulangong*, and Acehnese noodles contribute significantly to community-based economic empowerment. A SWOT analysis positions tourism development in Quadrant I, indicating strong internal strengths and external opportunities, thereby supporting an aggressive development strategy centered on cultural preservation and digital promotion.

Keywords: local wisdom, sustainable tourism, tourism product development, cultural heritage

INTRODUCTION

Tourism is a service-based sector characterized by extensive horizontal and vertical linkages across multiple economic and social domains. Owing to these interconnections, tourism plays a strategic role in development agendas, as it is expected to generate significant contributions to economic growth at both national and regional levels while simultaneously enhancing community well-being (Cong et al., 2021). Beyond its economic significance, tourism also contributes to cultural preservation and the reinforcement of local identity, positioning it as a multidimensional development instrument. In the Indonesian context, the discourse on local wisdom–based tourism development has gained increasing prominence alongside growing awareness of the importance of cultural values in strengthening destination competitiveness. Local wisdom is no longer understood merely as inherited traditions; rather, it encompasses a broader system of values, knowledge, and social practices that underpin community life and guide collective behavior.

This perspective aligns with contemporary approaches to sustainable and community-based tourism, which emphasize cultural integrity, social inclusivity, and local participation. In Aceh Province, local wisdom constitutes a central element shaping the cultural character of society, as reflected in diverse traditions, customary practices, and religious expressions that are deeply embedded in everyday life. These socio-cultural foundations offer a distinctive context for tourism development that is both culturally grounded and socially meaningful.

Within this regional setting, Bireuen Regency demonstrates considerable potential for the development of tourism rooted in local cultural resources. The presence of tangible and intangible cultural heritage that has been identified as a potential cultural tourism asset indicates that Bireuen possesses valuable cultural capital that can be strategically

developed as an authentic tourism attraction (Novalita et al., 2023). Beyond its cultural potential, Bireuen Regency also possesses natural tourism resources that serve as prominent destinations for local communities. On the other hand, Aceh is widely recognized as a region that applies the concept of halal tourism by integrating customary and religious values into tourism practices. This approach not only strengthens cultural identity but also enhances destination competitiveness in a global tourism market that increasingly demands unique, authentic, and sustainable experiences.

Accordingly, the development of local wisdom–based tourism products in Bireuen is strategically important, as it integrates cultural values, natural potential, and the principles of halal tourism that have become a defining characteristic of Aceh. Despite its considerable potential, tourism development in Bireuen Regency faces several challenges. Strategies for tourism product development that utilize local culture have not yet been optimally integrated.

Community participation in tourism management and promotion remains limited, while innovation in branding and marketing of local tourism products has not been maximized. In addition, cultural and environmental preservation has not been fully addressed, creating risks of cultural commodification. Furthermore, policies and regulatory frameworks that support the development of local wisdom–based tourism remain limited.

The development of local wisdom–based tourism has become a central focus in sustainable destination development, as it integrates cultural preservation, community empowerment, and enhanced destination competitiveness. Scholarly attention to the role of local wisdom in tourism management has continued to grow, with emerging trends emphasizing ecotourism, community-based tourism, and cultural heritage conservation as key thematic areas (Judijanto, 2025).

Local wisdom–based tourism development strategies further highlight the importance of integrating cultural values into tourism product design, whereby cultural and natural assets function as primary attractions while simultaneously contributing to local community welfare (Oematan et al., 2022). Destination differentiation strategies that foreground local values have been shown to enhance tourist experiences and strengthen destination appeal (Gai et al., 2024).

In this regard, local wisdom serves as an essential medium for cultural preservation and the empowerment of community-based cultural values. Consequently, tourism development should be grounded in region-specific potential, the authenticity of village-based products, the reinforcement of local culture, and efforts to maintain environmental sustainability (Yusri & Hajar, 2025).

Effective tourism development should be grounded in regional potential, the authenticity of village-based products, the strengthening of local culture, and the protection of environmental sustainability. In line with this perspective, sustainable tourism or ecotourism emphasizes the responsible use of resources, respect for local traditions, and the implementation of sustainable practices across all tourism sectors. Sustainable tourism prioritizes social equity, economic viability, and environmental responsibility, while actively involving local communities to generate economic opportunities and support cultural preservation (Litheko, 2022). A holistic approach to destination management is also essential. This approach underscores the need for comprehensive destination planning, sustainable development, and effective governance to ensure that the benefits of tourism can be sustained over the long term (Kalaitan et al., 2021).

In the tourism industry, a product is understood as a set of interrelated elements whose utilization occurs simultaneously. More broadly, tourism products encompass a combination of tangible goods and intangible services or facilities that can be accessed, experienced, and enjoyed by tourists throughout their journeys. The tourist travel process is designed to create meaningful experiences, beginning with departure from the place of origin, engagement at the destination, and concluding with the return journey. Tourism products are commonly classified into primary and secondary products. Primary products constitute the main attractions that motivate tourists to visit a destination, whereas secondary products support the travel experience but do not serve as the primary reason for visitation, such as accommodation and catering services. These secondary products exhibit a complex character, as they involve interactions between tangible and intangible elements and encompass broader geographical and thematic scopes (Benur & Bramwell, 2015). The development of sustainable tourism products emphasizes the responsible use of resources, respect for local traditions and culture, and the implementation of sustainable practices to ensure benefits for communities without generating negative impacts (World Tourism Organization, 2016; Mishra, 2025). One of the key strategies in this approach is the utilization of local wisdom, which encompasses unique values embedded in community life and shapes patterns of thinking, attitudes, and behaviors that are harmonious with the environment (Magdalena et al., 2021).

These cultural values influence how community express emotions and interact with their surroundings, serving as life guidelines that encompass both material and immaterial dimensions (Miller, 2012). The integration of local wisdom into sustainable tourism product development enables the creation of destinations that are authentic, attractive, and capable of empowering local communities. Tourism is highly dependent on the socio-cultural dimensions of society.

Furthermore, tourism development drives changes in destination characteristics, resulting in complex socio-cultural implications (Artal-Tur, 2018; Mkhize & Hlengwa, 2024; Zhuang et al., 2019). Cultural heritage provides crucial support to various development efforts, particularly in driving social and economic growth in many rural areas (Mashele et al., 2025). The social and cultural impacts of tourism activities emphasize the importance of preserving local traditions and cultural heritage. Therefore, responsible tourism development that respects local values deserves continued support.

This step aims to prevent overexploitation of culture and the erosion of traditional lifestyles and community wisdom (Ferdos et al., 2026). Therefore, community-based tourism development requires an effective strategy to ensure maximum benefits in sustainable development in the tourism industry (Durrah et al., 2026). Based on this background, this study aims to explore the development of local wisdom–based tourism products in Bireuen Regency, Aceh, through the integration of cultural heritage, community empowerment, and sustainable tourism strategies.

MATERIALS AND METHODS

This study employed an exploratory qualitative research method. A qualitative approach was adopted to obtain in-depth information through naturalistic inquiry, in which the researcher served as the primary instrument for data collection and analysis. In addition, the use of an exploratory approach aimed to achieve a comprehensive understanding of the phenomena under investigation. Figure 1 presents the overall research framework employed in this study. The research was conducted in four main stages: formulation of research objectives, application of research methods, data analysis, and formulation of research outputs. Based on Figure 1 exploratory research seeks to examine the underlying causes of a phenomenon rather than to describe variables, symptoms, or conditions contextually. Nevertheless, this approach facilitates the development of comprehensive data through observation, surveys, interviews, policy studies, and documentation. The analysis was conducted based on observations gathered from various activities across several tourist attractions within the geographical area of Bireuen Regency. Data sources consisted of primary data derived from field research and secondary data obtained through library research. Data collection was carried out through several stages: (a) observation, involving direct and spontaneous observation of tourism objects in Bireuen Regency using both on-site field notes and pre-prepared observation checklists; (b) interviews with key informants, namely indigenous community members and tourism site managers in Bireuen Regency, Aceh Province selected using a snowball sampling technique; and (c) documentation studies derived from field activities. Data trustworthiness was ensured through credibility, transferability, dependability, and confirmability. Data analysis techniques included data reduction, data display, SWOT analysis, and conclusion drawing (Kotler, 2002). Furthermore, the variables examined in the SWOT analysis comprised strengths, weaknesses, opportunities, and threats.

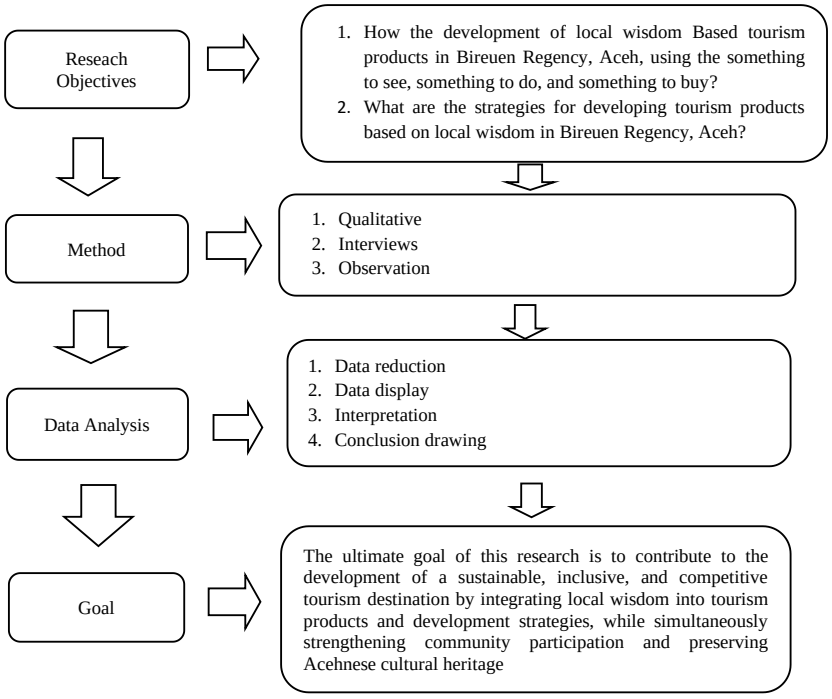

Figure 1. Research Methodology Steps (Source; Reseachers, 2025)

RESULTS

This study was successfully conducted as planned. The following results focus on exploring the development of local wisdom–based tourism products in Bireuen Regency, Aceh Province, viewed through the dimensions of something to see, something to do, and something to buy, as well as the strategies for developing local wisdom–based tourism products. The research findings are presented as follows.

Something to See in Bireuen Regency. Attractions

Bireuen Regency is well known for its coastal natural beauty and local culture, which constitute the primary capital for the development of its tourism attractions. Its coastal landscape is characterized by scenic beaches complemented by rows of coastal pine trees that enhance the visual appeal of the area. Bireuen Regency possesses a variety of tourism attractions. In general, tourism objects and attractions in Bireuen Regency are classified into three main categories, as outlined below.

Natural Tourism Attractions

In general, nature-based tourism refers to recreational and tourism activities that utilize natural potential to appreciate environmental aesthetics, whether in relatively pristine conditions or areas that have undergone cultivation or management processes, with the expectation of attracting tourist visits. The distribution of various types of natural tourism attractions found in Bireuen Regency is presented in Figure 2. Based on Figure 2, which presents the map distribution of natural tourism attractions in Bireuen Regency, it can be concluded that Bireuen Regency possesses highly diverse natural tourism

potential that is distributed across almost all subdistricts. The dominant types of tourism attractions include coastal tourism, natural bathing sites, waterfalls, wetlands (*paya*), as well as hilly landscapes and ecotourism areas. Coastal tourism attractions are predominantly found in subdistricts located along the coastline, such as Samalanga, Simpang Mamplam, Jeumpa, Kuala, Pandrah, Gandapura, Jangka, and Peudada. This distribution indicates that Bireuen's coastal areas hold significant potential for the development of marine and coastal tourism. Meanwhile, freshwater-based tourism attractions, including river bathing sites, wetlands, and waterfalls, are distributed across central and inland subdistricts such as Juli, Peusangan, Peusangan Siblah Krueng, Kota Juang, and Gandapura. Subdistricts such as Samalanga, Simpang Mamplam, Juli, and Gandapura are recorded as having a relatively higher number of natural tourism attractions compared to other areas, suggesting their potential to serve as centers for priority tourism development. The presence of diverse tourism attractions, ranging from coastal tourism to ecotourism and white-water rafting, indicates that Bireuen Regency possesses rich natural resources that can be developed in a sustainable manner. Overall, the distribution of natural tourism attractions in Bireuen Regency demonstrates substantial potential to support regional tourism development, enhance local economic activity, and function as an attraction for both local and regional tourists, provided that these resources are managed effectively.

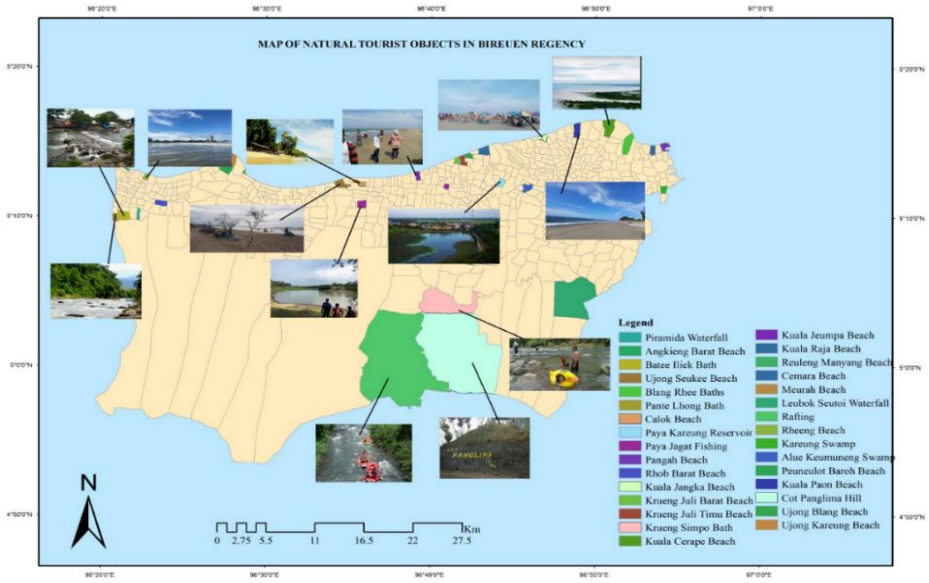

Figure 2. Map Natural Tourist Objects in Bireuen Regency (Source: Data Processing, 2025)

Cultural Tourism Attractions

Cultural heritage tourism, which involves visits to historical sites, cultural attractions, and locations of cultural significance, is an effective way to learn about the history and development of a destination (Khoa et al., 2025). Bireuen Regency possesses considerable potential in cultural tourism attractions. This is evident from the presence of various historical sites and heritage remains distributed across subdistricts throughout Bireuen Regency. Figure 3 illustrates the spatial distribution of cultural tourism attractions in Bireuen Regency.

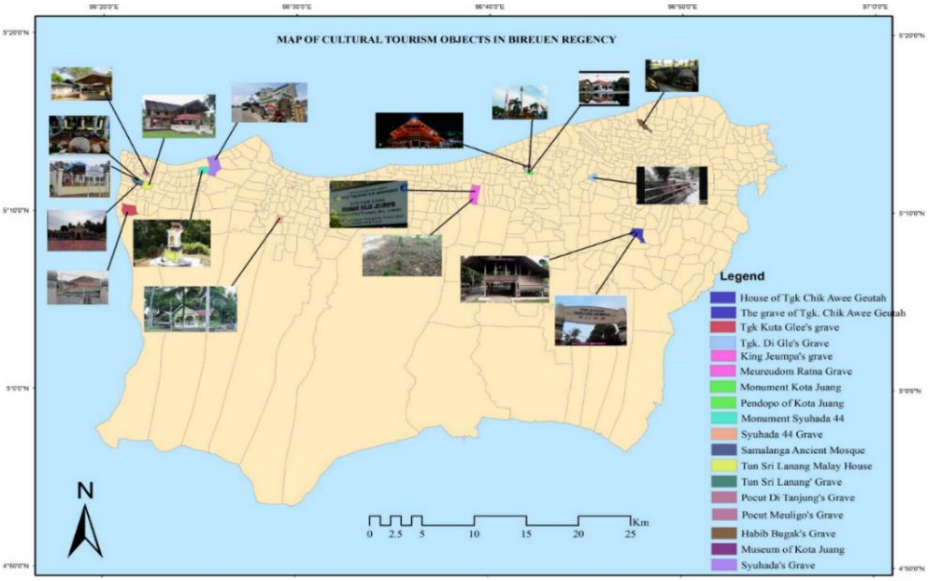

Figure 3. Map Cultural Tourism Objects in Bireuen Regency (Source: Data Processing, 2025)

Based on Figure 3, which presents the map distribution of cultural tourism attractions in Bireuen Regency, it can be concluded that Bireuen Regency possesses a rich cultural tourism heritage with high historical value, characterized by an almost even distribution of attractions across various subdistricts. The majority of cultural tourism sites consist of the graves of historical figures, religious scholars, and heroes, as well as commemorative monuments, reflecting the historical trajectory, struggles, and the development of Islam in the Bireuen region. Samalanga Subdistrict stands out as a central hub of cultural tourism, as it hosts the highest number of cultural attractions, including the graves of prominent figures, an ancient mosque, and the Tun Sri Lanang cultural house. This distribution highlights Samalanga's historical role as one of Aceh's centers of civilization, religious life, and intellectual activity in the past. In addition, other subdistricts, such as Kota Juang, also feature important cultural tourism sites in the form of monuments, museums, and the regent's official residence, which represent the region's governmental history and local struggles. Cultural tourism attractions associated with themes of struggle and heroism are found in subdistricts such as Simpang Mamplam, Pandrah, Jeunib, and Jangka, as indicated by the presence of martyrs' graves and commemorative monuments. Meanwhile, cultural and religious values are also reflected in subdistricts including Jeumpa, Peusangan, Peusangan Siblah Krueng, and Kuta Blang through the graves of kings and religious scholars, as well as traditional Acehnese houses. Overall, the distribution of cultural tourism attractions in Bireuen Regency demonstrates substantial potential for the development of historical, religious, and cultural educational tourism. If managed and promoted optimally, these cultural tourism assets can strengthen regional identity, preserve historical values, and serve as tourism attractions that support sustainable tourism development in Bireuen Regency.

Man-Made Tourism Attractions

In addition to natural and cultural tourism attractions, Bireuen Regency also possesses man-made tourism attractions. These man-made attractions are distributed across various subdistricts in Bireuen Regency. For further details, the spatial distribution of man-made tourism attractions in Bireuen Regency is illustrated in Figure 4. Based on Figure 4, which presents the map distribution of man-made tourism attractions in Bireuen Regency, it can be concluded that man-made tourism attractions in Bireuen Regency are distributed across several subdistricts and are generally associated with water infrastructure as well as fisheries and recreational activities. The dominant types of man-made tourism attractions include dams, reservoirs, irrigation systems, and fishing facilities, which serve dual functions as infrastructure supporting local livelihoods and as recreational tourism sites. Jeumpa Subdistrict has the highest number of man-made tourism attractions, primarily in the form of dams and freshwater fish cages, indicating the productive utilization of water resources with potential for development as educational and recreational tourism. Meanwhile, Peusangan Subdistrict is also notable for the presence of dams and reservoirs that can be utilized as water-based tourism and fishing destinations. Although the number of man-made tourism attractions in other subdistricts such as Jeunib, Peudada, Kota Juang, and Juli is relatively limited, these sites continue to play an important role as local tourism destinations, particularly for surrounding communities. The presence of fishing areas and reservoirs provides accessible and relatively affordable family-oriented tourism alternatives. Overall, the distribution of man-made tourism attractions in Bireuen Regency demonstrates potential for the development of infrastructure-based and water recreation tourism. With appropriate spatial planning, improved facilities, and effective promotion, these man-made attractions can complement natural and cultural tourism, thereby enriching the diversity of tourism destinations in Bireuen Regency.

Figure 4. Map of Artificial Tourist Attractions in Bireuen Regency (Source: Data Processing, 2025)

Local Culture

Local communities have ample opportunities to participate in ecotourism development. This role is crucial because the success of community-based tourism depends on the commitment and readiness of local residents to actively participate, as well as their understanding of the importance of preserving cultural values and environmental sustainability in their areas (Nizamiev et al., 2025). Developing cultural tourism in traditional villages generally involves utilizing local knowledge that has been passed down through generations. This knowledge is not only a vital part of a valuable cultural heritage but also serves as a foundation for implementing sustainable tourism practices that are in harmony with the environment and the lives of local communities (Sumarmi et al., 2026). One of the most prominent traditions that embodies the depth of local cultural meaning in Bireuen Regency is the *Meugang* tradition, along with *Khanduri Laot* and *Khanduri Blang*. The *Meugang* tradition is a distinctive Acehnese cultural celebration held two to three days before major Islamic holidays, particularly *Ramadan***,** Eid al-Fitr, and *Eid al-Adha*. During this period, traditional markets become vibrant centers of community activity as residents purchase beef and buffalo meat to prepare traditional Acehnese dishes, such as *kuah beulangong* and Acehnese rendang. Beyond its culinary significance, Meugang serves as a powerful expression of gratitude, togetherness, and social solidarity. Communities gather to prepare, share, and enjoy traditional meals, reinforcing family relationships, strengthening mutual cooperation, and preserving cultural values that have been passed down through generations. For visitors, *Meugang* offers an authentic cultural tourism experience through opportunities to observe local culinary traditions, participate in communal celebrations, and interact directly with the friendly local community. In Bireuen Regency, *Meugang* is not only an important element of Acehnese cultural heritage that deserves preservation but also a valuable cultural tourism asset with significant potential to attract both domestic and international tourists while promoting community-based tourism and the preservation of local cultural traditions.

The *Khanduri Laot* tradition is a cultural practice of coastal communities. *Khanduri Laot* represents a ritual through which coastal community express gratitude to Allah SWT. This communal feast serves as a form of thanksgiving by fishermen for the marine harvests they have obtained over time. In addition, it functions as a forum for social bonding aimed at fostering shared awareness of the importance of preserving marine life so that ecosystems and habitats remain protected (Figure 5). *Khanduri Laot* is typically held once a year at a time agreed upon by the *Panglima Laot*, traditional leaders who regulate customary maritime law in Aceh. On the day of the ceremony, community members gather along the coastline or at river estuaries, bringing various dishes, marine products, and a goat or cow to be sacrificed. The ritual begins with a collective prayer led by a religious figure, seeking safety for fishermen and blessings for future catches. Following the ritual, the community shares a communal feast along the seashore. For tourists, *Khanduri Laot* in Bireuen Regency offers an authentic cultural experience rich in ecological meaning. This tradition not only enriches Aceh's cultural heritage but also conveys important values related to environmental conservation, social solidarity, and the spiritual life of coastal communities.

Figure 5. Community Gathering During the *Meugang* Celebration Reflecting the Values of Gratitude, Togetherness, and Social Solidarity (Source: Data Analysis, 2025)

Figure 6. Preparation of Traditional Communal Meals During the *Khanduri Laot* Celebration Reflecting Gratitude, Social Solidarity, and the Preservation of Coastal Cultural Heritage (Source: Data Analysis, 2025)

In addition, the *Khanduri Blang* tradition refers to a communal meal accompanied by collective prayers held prior to the commencement of rice field plowing activities. *Khanduri Blang* is performed before farmers begin cultivating their rice fields. The ceremony is led by a *keujruen blang*, an individual or elder appointed as the leader among farmers. The *keujruen blang* is responsible for regulating all activities conducted in the rice field area, including the organization of customary rituals. During *Khanduri Blang*, a sheep or buffalo is typically sacrificed. The ritual begins with *samadiah* or collective prayers, followed by *peusijuek* rituals for the rice seeds to be planted and for the *lueng ie* (water gate). Agricultural tools used for plowing are also required to undergo the *peusijuek* ritual. The ceremony then continues with a communal meal involving all members of the community (Figure 6). Following the implementation of *Khanduri Blang*, *samadiah* or collective prayers are held in the evening for a period ranging from three to seven nights. On the seventh day after *Khanduri Blang* is conducted, farmers may begin cultivating the rice fields. When the rice plants start to turn green a stage locally referred to by the Bireuen community as *padèe ka dara* another ritual known as *Khanduri Ie Bu* is performed. *Khanduri Ie Bu* symbolizes a process of overseeing the rice crops as they enter the pre-harvest stage (Figure 7).

Something to Do in Bireuen Regency

Local Knowledge - Intangible cultural heritage refers to the various practices, representations and knowledge systems that are passed down from generation to generation and maintained in the lives of people, thus contributing to the formation of cultural identity and sustainability (Zhang, 2026). In social life, the people of Bireuen Regency highly uphold the values of mutual cooperation (*gotong royong*) and deliberation. The tradition of *peumulia jamee* (honoring guests) forms an integral part of community identity. This value is reflected in various customary activities such as *khanduri*, *meugang*, and *khanduri laot*, in which all community members actively participate regardless of social status. Local knowledge is also evident in the traditional Acehnese house architecture commonly found in rural areas. These stilt houses are constructed using natural materials such as wood and are designed to be resilient to earthquakes and floods while ensuring adequate tropical air circulation. The underlying philosophy emphasizes a balance between comfort, safety, and aesthetic harmony.

In the field of traditional medicine, the people of Bireuen Regency utilize herbal remedies derived from plants such as betel leaves, turmeric, and tree roots to treat minor illnesses. This practice reflects a deep understanding of the surrounding natural environment and its prudent use. In addition, local communities possess knowledge related to seasonal patterns known as *keunong* or *keuneunong*. *Keunong* refers to seasonal conditions determined by the alignment of the Kala star and the moon in the sky. Furthermore, the community maintains extensive knowledge of various fish species, including *Sure*, *Kareueng*, *Geurape*, *Yee*, *Bawai Itam*, *Bawai Puteh*, *Paroe*, *Sisek*, *Bileh*, *Blaneuk*, *Turok*, *Jeunara*, *Lameukan*, *Udeueng Tima*, *Udang Wat*, *Noh*, *Bieng*, *Bieng Laot*, *Kreueng*, and *Tirom.*

Local Social Processes - The community of Bireuen Regency maintains a social system deeply rooted in the value of *ukhuwah* (brotherhood). Centers of social interaction are typically located in the *meunasah*, a multifunctional building that serves as a place of worship, deliberation, religious study, and social activities. The *meunasah* functions as a symbol of social unity, where community members engage in discussion, collectively resolve issues, and strengthen interpersonal relationships. Bireuen society is characterized by a distinctive social organizational system known as the *gampong* structure. The *gampong* is led by a *keuchik* and supported by *tuha peut* (the customary deliberative council) and the *imam meunasah*. This structure reflects a combination of formal governance systems and Acehnese customary values.

In everyday life, social organization in Bireuen Regency also includes informal groups such as fishermen associations, farmer groups, religious study groups, and youth organizations. These groups serve as platforms for interaction, cooperation, and the maintenance of social harmony. The social system of Acehnese society is inseparable from the values of Islamic law (*syariat Islam*), which function as moral and legal guidelines in community life. Principles such as deliberation and consensus (*musyawarah mufakat*), justice, and mutual cooperation are applied in social decision-making processes. In Bireuen society, social conflicts are generally resolved through customary mechanisms and deliberation. Customary institutions such as the *tuha peut* and *keuchik* play an important role as mediators. Conflict resolution is conducted through a familial approach that prioritizes peace and the preservation of harmonious relationships among community members, in accordance with the principle of *peusijuek* (a ritual symbolizing reconciliation and blessing).

Something to Buy in Bireuen Regency

Local Skills -Local skills and traditional products constitute important tourism resources in Bireuen Regency. Handicrafts hold a special appeal for tourists because they are often purchased as souvenirs with symbolic value, serving as lasting reminders of their travel experiences. In addition to preserving local cultural heritage, handicraft production creates employment opportunities for local artisans and contributes to community income (Ahmad et al., 2026) (Figure 8).

The people of Bireuen Regency produce a variety of traditional handicrafts made from coconut leaves, coconut fiber, and *purun*, including *bleut* (woven mats used for seating or drying agricultural products). The region is also well known for its distinctive local products, such as *pliek U* (fermented coconut paste), *boh giri Matang* (Matang citrus), banana chips, and *Sate Matang*, a traditional Acehnese-style satay that has become one of Bireuen's culinary icons. These handicrafts and

local products not only preserve Acehnese cultural identity but also provide economic benefits for local communities while enhancing the attractiveness of Bireuen Regency as a destination for cultural and gastronomic tourism (Figure 9).

Figure 8. Community Members Producing Traditional Handicrafts from Coconut Fiber and Other Local. These Handicrafts Reflect Local Creativity, Preserve Cultural Heritage, and Contribute to Sustainable Livelihoods and Community-Based Tourism (Source: Data Analysis, 2025)

Figure 9. *Pliek U*, a traditional fermented coconut product representing local culinary heritage and a value-added product that supports community-based tourism and the local economy (Source: Data Analysis, 2025)

Overall, the local handicrafts, traditional culinary products, and agricultural specialties of Bireuen Regency represent valuable cultural assets that strengthen community-based tourism. Handicrafts made from coconut fiber and natural materials, together with distinctive local products such as *pliek U*, *boh giri Matang*, and *Sate Matang*, not only preserve Acehnese cultural heritage but also create sustainable livelihood opportunities for local communities. By promoting these authentic local products, Bireuen Regency can enhance its appeal as a cultural and gastronomic tourism destination while supporting local economic development and the long-term sustainability of its cultural traditions (Figure 10 and 11).

Strategy for Developing Local Wisdom Based Tourism Products in Aceh

The development of tourism products based on local wisdom has strong potential as a tourism attraction, as it embodies cultural values and unique characteristics inherent in Acehnese society. The importance of developing Aceh's local wisdom–based tourism products lie in ensuring that tourism in Aceh remains sustainable through the continued existence of tourism products rooted in local wisdom. Based on the Cartesian diagram mapping constructed using weighted scores for each factor, the results of the SWOT analysis indicate that the selected strategy is the SO strategy, or an aggressive strategy. Accordingly, the following section presents the formulation of strategies for developing local wisdom–based tourism products in Aceh. Based on the Table 1, the total internal analysis score is 2.92 (1.77 + 1.15), indicating that strengths outweigh weaknesses to a considerable extent.

Table 1. Internal Factors Analysis (IFAS): Strengths and Weakness (Source: Researcher, 2025)

No.	Internal Factors	Weight	Rating	Score
Strengths				
1	Strong Acehnese local wisdom (customs, language, culture, Islamic values)	0.08	4.0	0.31
2	Diverse and attractive natural tourism resources (beaches, mountains, natural bathing sites, tourism villages)	0.08	4.0	0.31
3	Local wisdom–based products with potential to enrich national cultural heritage	0.08	3.5	0.27
4	Openness of local communities toward visitors	0.08	3.5	0.27
5	Tourism products containing local cultural values (culinary products, handicrafts, traditions)	0.08	4.0	0.31
6	Strong Acehnese cultural identity suitable for tourism branding	0.08	4.0	0.31
Subtotal Strengths		**0.46**		**1.77**
Weaknesses				
1	Low level of community awareness regarding the preservation of local wisdom	0.08	2.5	0.19
2	Limited human resources related to local wisdom–based tourism information	0.08	2.0	0.15
3	Bireuen Regency has not yet become a national or international tourism activity center	0.08	2.5	0.19
4	Limited data and information on Acehnese local wisdom	0.08	2.0	0.15
5	Lack of detailed planning for local wisdom–based tourism development	0.08	2.0	0.15
6	Inadequate tourism facilities	0.08	2.0	0.15
7	Limited accessibility to rural tourism destinations	0.08	2.0	0.15
Subtotal Weaknesses		**0.54**		**1.15**
Total Internal Factors		**1.00**		**2.92**

Table 1 presents the Internal Factor Analysis Summary (IFAS), matrix, which identifies the strengths and weaknesses influencing the development of local wisdom-based tourism in Bireuen Regency. The analysis produced a total internal factor score of 2.92, indicating that the internal condition of tourism development is moderately strong and provides a favorable basis for future development. The main strengths include the strong Acehnese local wisdom reflected in customs, language, culture, and Islamic values; the diversity of natural tourism resources; tourism products containing local cultural values; and a strong cultural identity that can be utilized as a destination branding strategy.

In addition, the openness of local communities toward visitors and the availability of local wisdom-based products further increase the attractiveness of tourism destinations. However, several internal weaknesses remain, including limited community awareness of preserving local wisdom, inadequate human resources with expertise in local wisdom-based tourism, insufficient tourism facilities and accessibility, limited documentation of Acehnese local wisdom, and the absence of comprehensive planning for tourism development. These findings indicate that while Bireuen Regency possesses considerable cultural and natural assets, strengthening institutional capacity, infrastructure, and human resources is essential to maximize the potential of sustainable tourism development.

Table 2. External Factors Analysis (EFAS): Opportunities and Threats (Source: Researcher, 2025)

No.	External Factors	Weight	Rating	Score
Opportunities				
1	Global tourism trends favoring authenticity and local culture	0.11	4.0	0.44
2	Growth of halal tourism at national and international levels	0.11	3.5	0.39
3	Advances in digital technology and platforms	0.11	4.0	0.44
4	Opportunities to develop various special-interest tourism packages	0.11	4.0	0.44
5	Potential collaboration with travel agencies, influencers, and arts and cultural communities	0.11	3.5	0.39
Subtotal Opportunities		**0.56**		**2.11**
Threats				
1	Competition with local wisdom–based tourism products from other regions	0.11	2.5	0.28
2	Decline of local wisdom–based tourism products due to environmental degradation	0.11	2.5	0.28
3	Loss of local cultural identity due to foreign cultural influences through tourism	0.11	2.5	0.28
4	Insufficient regulation or supervision of mass tourism that may damage natural and cultural resources	0.11	2.0	0.22
Subtotal Threats		**0.44**		**1.06**
Total External Factors		**1.00**		**3.17**

Table 2 presents the External Factor Analysis Summary (EFAS), which identifies the external opportunities and threats influencing the development of local wisdom-based tourism in Bireuen Regency. The analysis produced a total external factor score of 3.17**,** indicating that the external environment provides substantial opportunities for tourism development despite the existence of several challenges. The most significant opportunities include the growing global demand for authentic cultural experiences, the rapid expansion of halal tourism at both national and international levels, advances in digital technology and online tourism platforms, opportunities to develop special-interest tourism packages, and the potential for collaboration with travel agencies, social media influencers, and cultural communities. These opportunities create favorable conditions for promoting Bireuen Regency as a destination that emphasizes Acehnese local wisdom and cultural heritage. However, several external threats must also be considered, including increasing competition from other regions offering similar local wisdom-based tourism products, environmental degradation that may reduce the quality of tourism resources, the erosion of local cultural identity due to globalization and foreign cultural influences, and inadequate regulations or supervision of mass tourism that may negatively affect natural and cultural assets. Overall, the relatively high EFAS score suggests that Bireuen Regency is well positioned to capitalize on external opportunities while implementing appropriate strategies to mitigate potential threats and achieve sustainable tourism development.

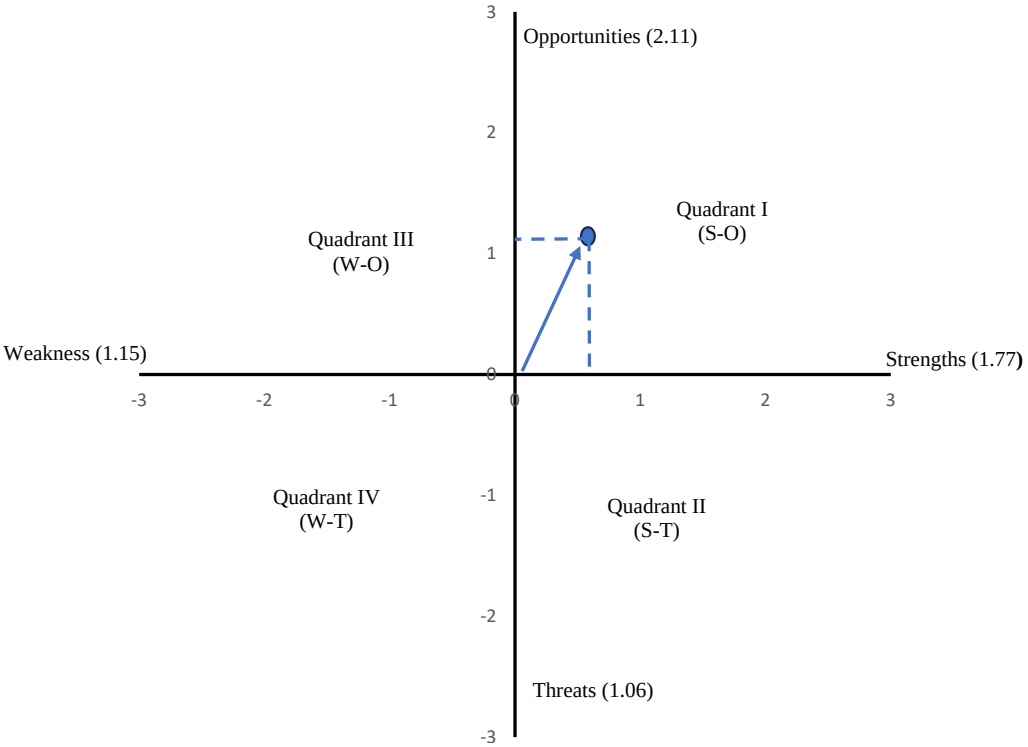

Figure 12. Cartesian Diagram of SWOT Strategic Positioning (Source: Data Analysis, 2025)

Figure 12 illustrates the strategic position of local wisdom-based tourism development in Bireuen Regency based on the SWOT analysis. The Internal Factor Evaluation (IFE) produced a total score of 2.92**,** consisting of strengths **(**1.77) and weaknesses **(**1.15**),** while the External Factor Evaluation (EFE) yielded a total score of 3.17**,** consisting of opportunities **(**2.11**)** and threats **(**1.06**).** Based on these results, the SWOT coordinates are calculated as X = 0.62 (Strengths − Weaknesses) and Y = 1.05 (Opportunities − Threats), placing the strategic position in Quadrant I (Strengths–Opportunities)**.** This quadrant indicates that Bireuen Regency possesses strong internal resources and favorable external opportunities to support tourism development. Therefore, an aggressive growth strategy is recommended by maximizing the region's cultural heritage, Acehnese local wisdom, natural tourism attractions, and community participation to strengthen destination competitiveness. Strategic priorities include diversifying local wisdom-based tourism products, enhancing destination branding, improving tourism infrastructure and accessibility, strengthening the capacity of local communities and tourism stakeholders, and fostering collaborative governance to ensure sustainable tourism development.

Rangkuti (2016) explains that strategy fundamentally serves as a set of tools used to achieve organizational objectives. He categorizes strategy into three main types: managerial strategy, investment strategy, and business strategy.

Managerial strategy is typically formulated by decision-makers at the macro level and encompasses aspects such as product development, pricing decisions, market expansion, and financial management. Meanwhile, investment strategy focuses on capital investment initiatives aimed at promoting more aggressive growth.

Business strategy, or functional strategy, involves operational activities such as distribution, marketing, strengthening organizational structures, and improving production processes. Based on the analysis of internal and external conditions, these various types of strategies can be employed as a foundation for formulating the strategic direction of local wisdom–based tourism product development in Bireuen Regency, Aceh, as presented in Table 3.

Table 3. SWOT Matrix for the Development Strategy of Local Wisdom–Based Tourism Products in Bireuen Regency, Aceh (Source: Data Analysis, 2025)

No.	SO Strategy (Strength–Opportunity)	ST Strategy (Strength–Threat)	WO Strategy (Weakness–Opportunity)	WT Strategy (Weakness–Threat)
1	Developing integrated tourism packages (nature, culture, and culinary tourism) based on Acehnese local wisdom	Strengthening regulations and service quality standards for local wisdom–based tourism to address competition from other regions	Improving tourism infrastructure (access, public facilities, cultural information signage) through government support and investment	Establishing destination management standards to prevent unpreparedness in facing sudden increases in tourist arrivals
2	Positioning Acehnese local wisdom as the core destination branding of Bireuen tourism	Preserving local culture through regular festivals to prevent cultural erosion due to globalization	Providing professional training for tourism actors who lack knowledge of modern tourism management	Providing assistance to cultural MSMEs to enhance their competitiveness against external products
3	Strengthening the local creative economy through cultural products such as traditional cuisine, handi-crafts, and performing arts	Establishing local wisdom–based tourism attractions as competitive advantages that are difficult for other regions to replicate	Developing Aceh cultural information centers to address limited information on local wisdom for tourists	Reorganizing poorly managed destinations to prevent environmental degradation or damage caused by tourism exploitation
4	Collaborating with travel agencies, influencers, and national and international tourism platforms to expand promotion	Developing environmentally friendly tourism management systems to mitigate the risk of environmental degradation due to increased tourist activity	Designing training curricula for local tour guides focusing on history, culture, and foreign language skills	Enhancing community literacy regarding the importance of cultural preservation amid modernization
5	Enhancing community capacity in cultural tourism services and homestay management	Strengthening Acehnese cultural identity as a distinctive hallmark to remain relevant amid global tourism trends	Expanding marketing efforts through digital platforms to compensate for previously suboptimal promotion	Formulating clear regulations for the protection of local culture and destination ecosystems
6	Developing integrated tourism zones that highlight local cultural values	—	Establishing academic collaborations with universities for research and development of local culture as a tourism attraction	—
7	Optimizing digital promotion (websites and social media) to showcase local wisdom–based attractions	—	—	—

DISCUSSION

The development of local wisdom–based tourism products in Bireuen Regency, Aceh, as demonstrated by the findings of this study, reflects a sustainable tourism approach that places culture, nature, and local communities at the core of destination development. The results indicate that Bireuen's tourism potential is derived not only from its rich natural resources but also from the continuity of socio-cultural practices that remain active and functional in the everyday lives of local communities. These living cultural practices contribute to the authenticity and distinctiveness of the destination. This finding aligns with the global paradigm of sustainable tourism, which emphasizes that the future competitiveness of tourism destinations is largely determined by their capacity to preserve cultural authenticity while simultaneously empowering local communities (World Tourism Organization, 2016). In this context, the integration of local wisdom into tourism product development in Bireuen represents not merely a cultural asset but a strategic foundation for sustainable destination development.

Something to See: Tourism Attractions as Representations of Local Identity

From the *something to see* perspective, the findings of this study indicate that Bireuen Regency possesses a complex and layered tourism landscape comprising natural, cultural, and man-made attractions. The presence of coastal areas, rivers, waterfalls, wetlands (*paya*), and hilly landscapes reflects the richness of ecosystems that remain relatively well preserved. In contemporary tourism literature, such natural attractions are commonly conceptualized as nature-based tourism, which holds high value due to its capacity to offer visual appeal, tranquility, and emotional connections with nature (Buckley, 2020). Modern tourists increasingly avoid mass tourism destinations and tend to seek spaces that provide calmness, authenticity, and ecological sustainability. Beyond natural attractions, the findings further demonstrate that cultural tourism attractions in Bireuen Regency possess strong historical and symbolic significance. The existence of the graves of religious scholars and traditional leaders, historical struggle sites, traditional Acehnese houses, and museums indicates that tourism spaces in Bireuen function as sites of collective memory. Cultural tourism rooted in local history can strengthen place identity and foster emotional bonds between tourists and destinations. Accordingly, cultural tourism attractions in Bireuen serve not merely as objects to be observed but as narrative media through which Acehnese history and identity are articulated and sustained.

Local traditions such as *Meugang*, *Khanduri Laot*, and *Khanduri Blang* enrich the *something to see* dimension through their embodiment of intangible cultural heritage. These traditions illustrate how spiritual values, social solidarity, and human nature relationships are harmoniously integrated within everyday cultural practices. Qiu et al. (2022) emphasize that

tourists are increasingly attracted to destinations that offer experiences of living culture rather than artificially staged cultural performances. In this regard, Acehnese traditions practiced in Bireuen demonstrate substantial potential as authentic and sustainable cultural tourism attractions. Culture has evolved into one of the core products in the international tourism market, with tourists participating in cultural activities accounting for approximately 40% of total international arrivals in 2016 (World Tourism Organization, 2016). Consequently, many destinations leverage their cultural assets to adapt and enrich tourism offerings in response to growing visitor interest in cultural attractions. Furthermore, local potential and local wisdom can be utilized in the development of geotourism as part of the tourism sector, contributing to economic growth, strengthening regional image, and enhancing the welfare of local communities (Hasmira et al., 2023).

The development of cultural tourism functions not only as a medium for showcasing local cultural richness but also as a crucial mechanism for safeguarding its continuity. By presenting traditions, arts, culinary practices, and local knowledge to visitors, communities are encouraged to continuously practice and preserve their ancestral heritage, thereby fostering cultural pride and strengthening awareness of the importance of preservation. At the same time, cultural tourism development must be grounded in principles of mutual respect and appreciation of diversity, ensuring that interactions between tourists and local communities enrich cultural experiences, cultivate harmonious relationships, promote tolerance, and reinforce diversity as a shared asset. The success and sustainability of culture-based tourism are largely determined by the involvement and collaboration of multiple stakeholders. These include government actors responsible for policy formulation, infrastructure provision, and destination promotion; tourism businesses that deliver supporting services; local communities as the primary custodians of cultural heritage and beneficiaries of economic gains; academics and non-governmental organizations that contribute through research, capacity building, and sustainable policy development; and tourists as consumers who drive demand for cultural products. Such stakeholder synergy not only enhances economic outcomes but also ensures the protection of cultural heritage for future generations. Accordingly, strengthening customary institutions, improving collaboration, developing tourism attractions, upgrading the physical condition of traditional elements, and establishing community-based groups become essential components of sustainable cultural tourism development (Fattah et al., 2025). Furthermore, cultural tourism development is closely interconnected with the reconfiguration of public spaces, with each reinforcing the other. Development processes within a particular area should therefore contribute meaningfully to the overall quality of surrounding spaces. Tourism activities, events, or programs as cultural products can only function optimally when supported by conducive environmental and contextual conditions. In this regard, the atmosphere and character of space constitute integral elements of attraction that play a decisive role in the success of cultural tourism initiatives (Hornyák et al., 2025).

Something to Do: Tourism Experiences and Social Participation

The *something to do* dimension in this study demonstrates that Bireuen Regency offers a rich array of tourism experiences grounded in local knowledge and community social processes. Values such as mutual cooperation (*gotong royong*), *peumulia jamee* (honoring guests), deliberation (*musyawarah*), and the role of the *meunasah* as a center of social activity reflect an inclusive and participatory social system. In the tourism context, these elements closely align with the concept of experiential tourism, in which visitors are not merely passive observers but actively engage in the social and cultural activities of local communities (Pine & Gilmore, 2020). Local knowledge practices including seasonal calendrical systems (*keunong*), knowledge of fish species, traditional medicine, and Acehnese vernacular architecture indicate the presence of valuable local ecological knowledge. Tourism based on such local knowledge has the potential to generate meaningful learning experiences for visitors while simultaneously encouraging the preservation of traditional knowledge that is increasingly at risk of decline. Accordingly, tourism activities in Bireuen can be developed in the form of educational tourism, cultural tourism, and special-interest tourism that positions local communities as the primary holders and transmitters of knowledge.

Local social processes rooted in the *gampong* structure, along with the roles of the *keuchik*, *tuha peut*, and *imam meunasah*, indicate that communities in Bireuen Regency possess strong institutional capacity. This finding supports the concept of community-based tourism (CBT), in which the success of tourism development is largely determined by the level of local community participation and control (Goodwin & Santilli, 2021). The use of customary mechanisms and deliberation (*musyawarah*) for conflict resolution further demonstrates the presence of strong social capital, which is essential for maintaining tourism sustainability and preventing social conflicts arising from tourism activities. Moreover, community-based tourism emphasizes the involvement of local communities in tourism planning and management, including resource conservation, economic development, and project ownership. This approach encompasses three main dimensions: community involvement through ownership, power and control over tourism management, and outcomes that support community self-reliance and sustainability (Mayaka et al., 2019). The effectiveness of this model ultimately depends on the capacity of local communities to acquire and apply the skills required for tourism business operations (Khunnikom et al., 2022).

Something to Buy: Local Products and Culture-Based Creative Economy

Within the framework of sustainable tourism, the development of cultural heritage can be classified into three main components: cultural heritage itself, cultural artifacts, and efforts to protect cultural assets (Ginting et al., 2024). The attractiveness of a tourism destination is shaped by the integration of multiple interrelated factors and conditions that collectively sustain visitor interest and enhance the competitiveness of a particular destination or location (Kadyrbekova et al., 2024). From the something to buy perspective, the findings of this study demonstrate that the local skills of communities in Bireuen Regency possess substantial potential to support the development of a tourism-based creative

economy. Handicrafts such as weaving, coconut-based products including *pliek* and coconut oil, traditional culinary products, as well as local fisheries and agricultural products reflect a close interconnection between culture and economic activities. These products embody cultural meanings while simultaneously serving as sources of livelihood for local communities. The level of cultural development within a society is closely associated with the increasing diversity of food types, the complexity of processing techniques, and the precision of presentation methods (Harsana et al., 2019). Culinary activities can therefore be regarded as an important indicator of a community's cultural advancement (Rijal et al., 2020). Traditional local gastronomy has a very important role in understanding and preserving intangible cultural heritage (Phrammanachot et al., 2026). In this context, Acehnese ethnic cuisine refers to a variety of traditional foods prepared using distinctive techniques and ingredients that represent the cultural identity of the Acehnese people. Consequently, local culinary and craft products in Bireuen not only function as commodities for tourist consumption but also act as cultural expressions that reinforce local identity within the tourism experience.

To date, Acehnese communities continue to maintain the consumption of a wide range of traditional dishes, including *pliek*, *pulut ijo*, *thimpan*, *sate Matang*, *kuah beulangong*, and *mie Aceh*. Within the socio-cultural context, Acehnese ethnic culinary traditions are commonly practiced during customary events as a form of honoring guests through practices known as *khanduri*, namely communal dining activities aimed at strengthening togetherness, unity, and social harmony. The advancement of cultural tourism plays a crucial role in increasing awareness of a region's existence while simultaneously supporting the preservation of its cultural heritage.

Culture also functions as a tourism attraction that can enhance income generation and create employment opportunities for local communities (Patabang et al., 2023). Culinary tourism, or gastronomy tourism, has emerged as one of the most dynamic sectors within the global tourism industry (Rivza et al., 2025). This form of tourism encompasses visits to food producers or restaurants, participation in culinary festivals, and the experience of tasting or enjoying local food, which often serves as a primary motivation for tourists (Hall & Sharples, 2003).

More broadly, gastronomic tourism can be understood as any tourism experience that enables individuals to learn about, appreciate, or consume distinctive local cuisine (Smith & Honggen, 2008). Gastronomic tourism places particular emphasis on food and tourists' dining experiences (Marine-Roig et al., 2019) and highlights the close relationship between cuisine and local culture, a linkage that has been widely examined in tourism studies (Ghanem, 2019; Fusté-Forné, 2022). Traditional gastronomy plays an important role in sustaining cultural traditions and values, while the relationship between food and tourism destinations has become a central issue in contemporary culinary tourism research (Raji et al., 2020). Cultural heritage in the field of gastronomy can serve as a significant driver of regional tourism when managed effectively through an experience-based economic approach.

One of the main advantages of gastronomic tourism lies in its capacity to deliver multisensory experiences that extend beyond taste and aroma to include sound and the unique atmosphere of tourism locations, thereby deepening tourists' engagement with local cultural heritage (Rivza et al., 2022).

Development Strategy: SWOT Analysis and Its Implications

The results of the SWOT analysis indicate that the development of local wisdom–based tourism products in Bireuen Regency, Aceh, is positioned in Quadrant I, reflecting relatively strong internal and external conditions. The SO strategy, or aggressive strategy, is therefore considered an appropriate choice, as it enables the optimization of internal strengths to capitalize on external opportunities, including the growing demand for authentic tourism experiences, the expansion of halal tourism, and advances in digital technology. This finding is consistent with Ruhanen et al. (2022), who argue that culture-based destinations need to adopt proactive strategies to maintain competitiveness amid the dynamic global tourism landscape. Nevertheless, several weaknesses such as limited human resources, low awareness of cultural preservation, inadequate facilities, and accessibility constraints suggest that tourism development in Bireuen requires a well-planned and sustainable approach. Scheyvens et al. (2021) emphasize that without community capacity building and careful planning, local wisdom–based tourism risks cultural commodification and the erosion of local values. In this regard, the advancement of cultural tourism is essential not only to increase awareness of a region's presence but also to safeguard its cultural heritage. Moreover, culture can function as a tourism attraction that contributes to income generation and job creation for local communities (Patabang et al., 2023).

Based on the SWOT matrix, the development strategy for local wisdom–based tourism in Bireuen Regency, Aceh, emphasizes the importance of leveraging regional strengths and opportunities to create sustainable tourism competitiveness while simultaneously minimizing existing weaknesses and threats. The integration of natural, cultural, and culinary tourism potentials into integrated tourism packages, along with the reinforcement of local wisdom as a core identity and destination branding, emerges as a key strategy for attracting tourist interest. The development of the local creative economy, enhancement of community capacity, and optimization of digital promotion and multi-stakeholder collaboration further strengthen Bireuen's tourism position at both regional and national levels. At the same time, defensive strategies are directed toward strengthening regulatory frameworks, improving service quality standards, promoting environmentally friendly destination management, and safeguarding cultural heritage and ecosystems to address competition and the adverse effects of globalization and modernization. Efforts to improve infrastructure, enhance human resource capacity through training, provide support for cultural MSMEs, and develop cultural information and research centers are also critical in addressing internal limitations. Overall, the success of these strategies is highly dependent on synergy among government institutions, local communities, tourism businesses, academics, and other stakeholders to ensure that local wisdom–based

tourism development not only contributes to regional economic growth but also sustains Acehnese cultural heritage in the long term. Accordingly, the economic, social, and environmental impacts of tourism influence community quality of life, which in turn shapes public perceptions and levels of support for tourism development (Halim, 2022).

CONCLUSION

Based on the findings of this study, it can be concluded that the development of local wisdom–based tourism products in Bireuen Regency, Aceh, demonstrates strong potential to be directed toward a sustainable tourism model. This potential is derived not only from relatively well-preserved natural resources such as coastal areas, rivers, wetlands, and hilly landscapes but also from the continuity of social and cultural values that remain embedded in the everyday lives of local communities. Tourism attractions in Bireuen represent an authentic local identity through natural tourism, historical sites, customary traditions, and cultural practices that function as spaces of collective memory and expressions of living culture. Local traditions, the presence of traditional houses, the graves of religious figures, and various customary rituals further reinforce Bireuen's position as a destination that offers not only visual appeal but also rich historical narratives and profound cultural meanings.

Beyond visible attractions, tourism development in Bireuen is also supported by a wealth of activities and experiences rooted in community social participation. Values such as mutual cooperation, hospitality toward guests, the role of customary institutions, and local knowledge related to nature, seasonal cycles, fisheries, traditional medicine, and architecture demonstrate the capacity of local communities to act as primary agents of tourism development.

These conditions create opportunities for the development of educational tourism, cultural tourism, and community-based tourism that position local communities as subjects rather than mere objects of development.

At the same time, local products including handicrafts, traditional cuisine, and agricultural and fisheries outputs—reflect the close interrelationship between culture and economic activity, thereby offering significant potential to strengthen the local creative economy and enhance community welfare through tourism.

The strategic analysis further indicates that the internal and external conditions of Bireuen Regency are relatively supportive of the development of local wisdom–based tourism, thereby necessitating an aggressive and proactive development strategy. Nevertheless, challenges related to limited human resources, inadequate facilities, accessibility constraints, and low awareness of cultural preservation must be addressed through integrated and sustainable planning. Overall, this study confirms that the integration of tourism attractions, tourism experiences, and local products provides a strong foundation for Bireuen's tourism development as a competitive and inclusive destination capable of safeguarding Acehnese local wisdom amid the dynamics of modern tourism.

In summary, the findings reaffirm that the development of local wisdom–based tourism products in Bireuen Regency, Aceh, is underpinned by a robust foundation for sustainable destination development. The integration of something to see, something to do, and something to buy demonstrates that tourism in Bireuen extends beyond visual consumption to encompass experiential engagement, learning processes, and community empowerment. These findings contribute to the tourism literature by providing empirical evidence that Acehnese local wisdom can serve as an effective strategy for building destinations that are competitive, inclusive, and sustainable.

A dynamic causal modelling framework for prioritising greenhouse gas emission reduction strategies in agro-tourism land use and sustainable territorial development in Thailand. *Geojournal of Tourism and Geosites*, 67(3), 2108–2118. https://doi.org/10.30892/gtg.67324-1836

Abstract: This research aims to examine the priority order of the influence of causal factors affecting the formulation of future greenhouse gas emission management strategies arising from land use for agritourism in Thailand. The study develops an advanced model called the Path Analysis based on Probit Government Model (PA-Probit-G model), which is an enhanced model derived from previous models by incorporating their key strengths to serve as an important tool for formulating national management strategies toward sustainability, given that agritourism is one of Thailand's leading sources of income. The research findings reveal new insights that enable the prioritization of causal factors in determining strategies to reduce greenhouse gas emissions from land use for agritourism in Thailand. The socio-cultural sector is identified as the most influential factor, with indicators used as new scenario policies including the urban culture rate and stakeholder acceptance rate, alongside the government sector, which must urgently and concretely promote renewable energy development in the future. These indicators are considered critically important for reducing greenhouse gas emissions resulting from the promotion and expansion of agritourism as a main source of income for Thailand and for achieving the green economy target by 2050. Furthermore, the results demonstrate that the new scenario policies proposed in this study can continuously drive greenhouse gas emissions to levels below the carrying capacity, thereby contributing to the long-term success of Thailand's national management plan.

Keywords: agrotourism, socio-cultural sector, BCG economy, urban culture, sustainability, stakeholder acceptance

INTRODUCTION

Thailand, together with 193 United Nations member states, has endorsed the 2030 Agenda for Sustainable Development, which serves as a global framework for achieving sustainable social, economic, and environmental development while leaving no one behind (The World Bank: Energy Use (Kg of Oil Equivalent Per Capita) Home Page, 2026; Office of the National Economic and Social Development Council (NESDB, 2026). According to recent Sustainable Development Reports, Thailand ranks 43rd out of 166 countries assessed worldwide (National Statistical Office Ministry of Information and Communication Technology, 2026). Thailand has pursued sustainable development continuously from the past to the present (1992–2025), with a strong commitment to enhancing efficiency across all dimensions of development (NESDB, 2026; Hasanein & Ayad, 2025). In particular, economic development has demonstrated clear and consistent growth, as Thailand's economic system has expanded steadily over time (Ahmed et al., 2025; Muna et al., 2025).

Although certain years have presented significant obstacles to economic progress, the government has remained steadfast in promoting economic growth while continuously seeking new export markets, resulting in substantial inflows of capital into the country (Salama et al., 2025; ONEP, 2026). In addition, Thailand has persistently promoted tourism in various forms for both domestic and international visitors. This is reflected in the highly developed tourism management system, which has positioned tourism as one of the leading sources of national revenue through increased employment across regions (Office of Natural Resources and Environmental Policy and Planning (DEDE), 2026). Notably, ecotourism has emerged as the most popular form of tourism and has been designated by the government as a key national policy priority (Thailand Greenhouse Gas Management Organization (Public Organization), 2026). In addition, investment in

various industries, particularly policies that encourage foreign direct investment, has been a core and continuous strategy in Thailand's national administration (OECD, 2026; Junsiri et al., 2024). From a social perspective, Thailand has experienced substantial development in the socio-cultural sector, leading to profound transformations of traditional Thai societies across regions. Urbanization has gradually expanded, resulting in the erosion of long-standing social and cultural practices to the extent that, by 2025, very little of the traditional way of life remains visible (Sutthichaimethee et al., 2025).

Across the country, the general population has gained greater access to higher levels of education, improved living standards, and comprehensive healthcare, while unemployment rates remain relatively low (Energy Policy and Planning Office, 2026). Although agriculture continues to be a primary occupation in Thailand, significant changes have occurred in agricultural livelihoods, cultural practices, and operational methods (Ministry of Natural Resources and Environment, 2026; Winyuchakrit et al., 2021). Land use for agriculture has been transformed dramatically from the past to the present, leaving almost no trace of its original patterns (Xiao et al., 2025). In response, the government has sought to implement a wide range of important measures, particularly those promoting sustainable agricultural land use and climate-smart agricultural practices**.** These measures emphasize the adoption of clean technologies and efficient resource management to support environmental sustainability**.** Such changes have also influenced agricultural practices and local livelihoods as communities throughout Thailand continue to undergo social and economic transformation (Sutthichaimethee et al., 2025).

However, regardless of the extent to which Thai society has transformed into an urbanized society, it is essential to preserve cultural values and traditional ways of life as much as possible (Sutthichaimethee et al., 2025). The rapid changes experienced in the past have not been particularly beneficial to the livelihoods and occupations of Thai farmers; instead, they have led to increasingly negative impacts (Waiyasusri et al., 2024). People have developed more self-centered values and cultural attitudes, especially with regard to environmental conservation, which is often neglected because it is perceived as not being personal property. Individuals compete for opportunities and continue to consume and exploit resources without restraint, causing significant harm to ecosystems (ONEP, 2026). This is evident in the continuous rise in wastewater pollution in communities, the sharp increase in household solid waste, and the substantial growth in plastic bag consumption, among other issues. Although the government has actively promoted environmental campaigns, these efforts have not succeeded in fostering a culture of social responsibility or a sense of collective stewardship within communities, as originally intended under sustainable development policies. From a social perspective, this indicates that government implementation has not yet achieved its intended outcomes. Furthermore, from an environmental standpoint, greenhouse gas emissions have continued to increase steadily from the past to the present (NESDB, 2026).

In particular, greenhouse gas emissions generated from agricultural occupations and businesses have risen at one of the highest rates nationwide, especially within the agritourism sector. This is largely due to the extensive use of land converted for agritourism activities, which has caused substantial changes to local communities. Large-scale land-use transformation aimed at attracting foreign revenue has resulted in immediate and direct damage to ecosystems (DEDE, 2026).

Once agritourism operations are established, both domestic and international population flows increase significantly, and the associated activities further intensify direct ecological impacts (NESDB, 2026). As a consequence, traditional Thai communities have undergone profound transformations, to the extent that authentic traditional communities have nearly disappeared. At the same time, urban expansion has encroached upon rural areas, exacerbating environmental degradation nationwide. Data from all relevant agencies responsible for greenhouse gas emission management in Thailand indicate that agritourism ranks among the leading contributors to environmental loss and degradation. As tourism becomes increasingly popular, the tourism industry continues to expand, driven by both domestic growth and foreign investment, leading to deeper and more irreversible damage. Land-use changes for agritourism have altered the country's geographical and spatial systems beyond recognition, while traditional ways of life have been fundamentally transformed (NESDB, 2026; ONEP, 2026). Moreover, these developments have continuously increased greenhouse gas emissions, despite ongoing governmental efforts to implement preventive measures and policies aimed at reducing emissions from agritourism activities. Nevertheless, such measures have failed to curb the rising trend of emissions. For these reasons, this research was conducted in response to the researcher's recognition of Thailand's persistent environmental problems arising from land use for agriculture and agritourism. The study therefore develops an integrated dynamic model under a sustainability policy framework to identify effective approaches for reducing future greenhouse gas emissions to levels below the carrying capacity, thereby supporting Thailand's long-term success. This research fundamentally differs from previous studies by adopting a comprehensive analytical approach that examines all relevant components simultaneously, allowing for a true prioritization of causal factors and enabling more precise and effective policy solutions.

MATERIALS AND METHODS

In this research, an advanced smart model was developed. The model construction was adapted from previous models by identifying their weaknesses and integrating the strengths of each in order to achieve the highest analytical efficiency. The proposed model is called the Path Analysis based on Probit Government Model (PA-Probit-G model). This model consists of a structural model and measurement equations for constructing the variables used in the analysis.

In general research practice, measurement scales are typically constructed from sets of statements or questionnaire items related to the variable of interest. These items are quantified and summed to produce a composite score for the measurement scale. Although such scales may demonstrate construct validity, directly summing the items implicitly assumes that each item carries equal weight (Bentler & Chou, 1987). A key conceptual difference between the proposed model and previous models lies in the treatment of core variables (which may function as either independent or dependent

variables). These core variables are latent variables that cannot be directly observed or measured. Therefore, they must be represented by manifest variables (Kline, 2015). Consequently, solving the model equations requires an analysis of the causal influences and relationships among the manifest variables associated with each latent construct. Since latent variables cannot be directly measured, their values are inferred from the corresponding manifest variables, which serve as indicators of the latent constructs (Bentler & Chou, 1987; Kline, 2015). The PA-Probit-G model is particularly suitable for analyzing strategies aimed at reducing carbon dioxide emissions in the future. In addition, the model can effectively assess changes following increases or decreases in energy consumption, as well as variations in other factors included in the model. The causal relationships among the factors within the PA-Probit-G model are illustrated as follows (Baltagi, 2021).

$$L_i = \beta_1 + \beta_2 X_i \quad (1)$$

From Equation (1), let X_i denote an observed variable, which can be measured to determine whether a particular action or decision is undertaken. This decision is revealed when the value of an underlying index i ncreases and reaches a critical threshold, denoted by L_i^*, which represents the critical index value. If $L_i > L_i^*$, this indicates that a policy is implemented. Conversely, if $L_i < L_i^*$, it implies that the policy is not implemented at all. The variable L_i itself is not directly observable; however, it is directly related to probability. Therefore, the probability of the occurrence of a given event can be expressed in the form of a cumulative distribution function, as follows (Harvey, 1980).

$$P_i = P(Y = 1|X) = P(L_i \geq L_i^*) = P(Z_i \leq L_i) = F(L_i) \quad (2)$$

From Equation (2), let Z_i be an observed variable in the model, which follows a standard normal distribution, $Z \sim N(0,1)$. Let F denote the cumulative distribution function, which defines the probability of the occurrence of the case $Y = 1$, as expressed below (Hoyle, 1995).

$$F(L_i) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{L_i} e^{\frac{-Z^2}{2}} dz \quad (3)$$

$$F(L_i) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\beta_1 + \beta_2 X_i} e^{\frac{-Z^2}{2}} dz \quad (4)$$

From Equations (3)–(4), the value of L_i can be calculated using the inverse function of Equation (4).

$$L_i = F^{-1}(L_i) = F^{-1}(P_i) = \beta_1 + \beta_2 X_i \quad (5)$$

From Equation (5), the relationship can be expressed in the form of a general equation as follows.

$$Y^* = \beta X_i' + \varepsilon \quad (6)$$

From Equation (6), let X_i' denote the vector of observed variables, β the coefficients of the observed variables**,** and ε the error term, which follows a normal distribution with mean μ and variance σ^2 , $\varepsilon \sim N(\mu, \sigma^2)$. The outcome variable is defined such that $Y = 1$ if $Y^* > 0$, and $Y = 0$ when $Y^* \leq 0$. Therefore, the probability of the event occurring ($Y = 1$) can be written as follows.

$$P(Y = 1|X_i) = P(Y^* > 0|X_i) = P(\varepsilon > -\beta|X_i) \quad (7)$$

From Equation (7), the distribution is normal and symmetric, which leads to the following formulation.

$$P(Y = 1|X_i) = P(Y^* > 0|X_i) = P(\varepsilon > -\beta|X_i) = \emptyset(\beta X_i') \quad (8)$$

From Equation (8), $P(Y = 1|X_i)$ represents the probability that the event occurs, which is determined by X_i , and $\emptyset(\beta X_i')$ denotes the standard normal cumulative distribution function**,** referred to as the Probit Government Model, as expressed below (Byrne, 2001).

$$P(Y = 1|X_i) = \int_{-\infty}^{\beta X_i'} \emptyset(t)dt = \emptyset(\beta X_i') \quad (9)$$

$$P(Y = 1|X_i) = \int_{-\infty}^{\beta X_i'} \frac{1}{\sqrt{2\pi}} e^{\frac{-t^2}{2\sigma^2}} dt \quad (10)$$

From Equation (10), by assuming that $\varepsilon \sim N(\mu, \sigma^2)$ substituting $\mu = 0, \sigma^2 = 1$ into Equation (10), the following expression is obtained (MacKinnon, 1991).

$$P(Y = 1|X_i) = -\frac{1}{\sqrt{2\pi}} \left(\frac{-e^{\frac{-(\beta X_i')^2}{2}}}{\beta X_i'} \right) \quad (11)$$

From Equation (11), it can be observed that the probability function is nonlinear. Therefore, the analysis must be conducted under a path analysis framework to appropriately specify the equations and to avoid potential problems arising from the proposed model, including autocorrelation, multicollinearity, and heteroskedasticity. Accordingly, an estimation approach is employed in which $F(\beta X_i')$ represents the probability that the event occurs, with a joint probability density function, as follows (Dickey & Fuller, 1981; Byrne, 2001).

$$Pr(Y_1 = y_1, Y_2 = y_2, \ldots, Y_n = y_n|X_i) = L = \Pi_{y_i=0}(1 - F(\beta X_i')) \Pi_{y_i=1}(F(\beta X_i')) \quad (12)$$

From Equation (12), the complete and revised formulation can be expressed as follows.

$$lnL = \sum_{y_i=0} \ln(\ 1 - \emptyset(\beta X_i') + \sum_{y_i=1} \ln(\emptyset(\beta X_i') \qquad (13)$$

A review of relevant domestic and international literature reveals that no previous study has developed an integrated model employing advanced statistical techniques in this manner for the purpose of formulating national management strategies to achieve sustainable development in the future. Existing studies have generally failed to conduct fully integrated analyses across all sectors, making it difficult to adequately capture interconnections, as well as direct and indirect effects among them. Moreover, insufficient attention has been given to the relative importance of individual indicators that truly drive these influences. As a result, scenario models have not been accurately specified, limiting their applicability for policy formulation and national planning in Thailand.

In this study, the researcher develops a comprehensive model capable of simultaneously prioritizing both direct and indirect relationships across all sectors. This approach provides significant advantages for advancing sustainable development in line with the long-term objective of achieving a green economy by 2050. Considering all sectors concurrently offers substantial benefits for national policy and planning, as it enables a clearer understanding of how new policy scenarios should be formulated in the future and how they differ from past approaches that were implemented but did not achieve full success. This, in turn, facilitates effective learning and appropriate integration across sectors. The following section presents the research methodology and procedural steps undertaken in this study.

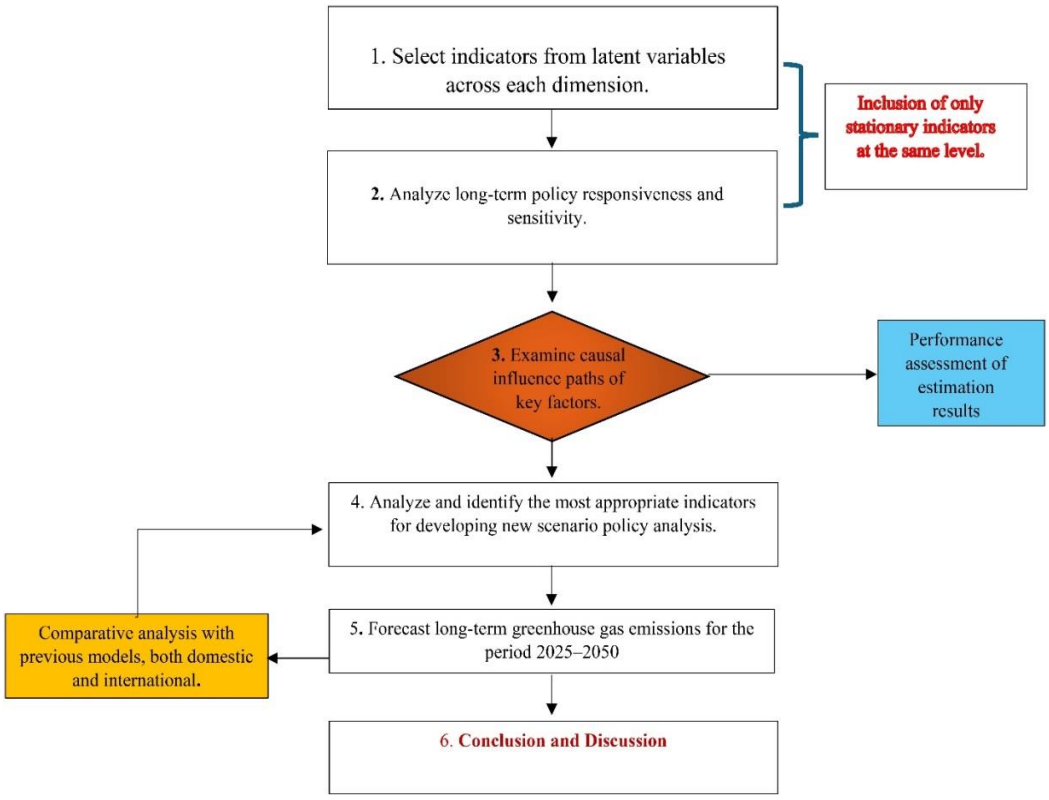

Figure 1. Research Methodology Framework

Figure 1 illustrates the research procedures employed to analyze the influence of causal factors affecting changes in the socio-cultural, economic, environmental, and government sectors arising from transformations in agricultural land use toward Thailand's future sustainability.

RESULTS

Selection of Observed Variables Based on Model Diagnostic Criteria

The findings of this study employ the PA-Probit-G model, which is designed to analyze the pathways of influence among four latent variables: the socio-cultural sector, economic sector, environmental sector, and government sector. The researcher utilizes observed variables derived from indicators that meet all required statistical properties.

All indicators included in the analysis are those that Thailand has consistently used in national development planning and are obtained as secondary data from the relevant responsible agencies, namely the National Economic and Social Development Council (NESDC), the Office of Natural Resources and Environmental Policy and Planning (ONEP), and the Ministry of Agriculture and Cooperatives (MOAC). These data sources are therefore considered appropriate and reliable for the purposes of this analysis. In total, 26 observed variables are included in the model, such as Political Stability (P_1), Solar cell rate (P_2), Biomass energy rate (P_3), renewable energy rate (P_4), green material rate (P_5),

waste biomass rate (P_6), Biofuel oil consumption rate (P_7), Biofertilizers rate (P_8), electric vehicle rate (P_9), Smart grid rate (P_{10}), Drying & Storage Agricultural Products (P_{11}), industrial structure rate (L_1), foreign investment rate (L_2), Ecotourism rate (L_3) Infrastructure (L_4), BCG rate (L_5), Health and wellness rate (A_1) Public participation rate (A_2), Education rate (A_3), Income distribution rate (A_4), Protection rate (A_5), Urban culture rate (A_6), Energy intensity rate (N_1), Carbon dioxide emissions (N_2), Methane emission (N_3), and Nitrous oxide emission N_4). The results of the statistical tests are presented as follows.

Table 1. The results of the selection of observed variables that exhibit no unit root

Table 1 presents the results of the selection of observed variables with no unit root. The findings indicate that all observed variables are free from unit roots at the first-difference level, demonstrating statistical significance at the 99% confidence level. This confirms that all observed variables are stationary, with constant means and covariances that do not change in response to irregular fluctuations or external shocks. Consequently, the researcher incorporates all of these observed variables into the PA-Probit-G model to further analyze the pathways of causal influence among the factors under investigation.

Results of Path Analysis of Causal Factors

This section presents the results of the path analysis of causal factors. In this study, four causal dimensions are specified: the socio-cultural sector, economic sector, environmental sector, and government sector. The PA-Probit-G model is employed to analyze the causal pathways among these factors, allowing the direction of relationships to be clearly identified. At the same time, the model enables the assessment of sensitivity through sensitivity analysis, which is used to prioritize policy options and to formulate future new scenario policies. The results are presented as follows.

Table 2. The results of the path analysis of causal factors based on the PA-Probit-G model

Dependent Variable	**Type of effect**	**Independent Variable**			
		Socio-cultural sector	**Economic sector**	**Environmental sector**	**Government sector**
Socio-cultural sector	DE	-	0.52***	0.76***	0.51***
	IE	-	0.12***	-	-
Economic sector	DE	-	-	-	0.40***
	IE	0.10***	-	-	-
Environmental sector	DE	0.12***	0.64***	-	0.12***
	IE	0.81***	0.09***	-	0.09***
Government sector	DE	0.43***	-	-	-
	IE	-	0.19***	-	-

Note: *** denotes significance α = 0.01, DE is direct effect and IE is indirect effect

Based on Table 2, the results of the path analysis of causal factors derived from the PA-Probit-G model indicate that each causal dimension exhibits both direct and indirect effects. The model satisfies all measurement and goodness-of-fit criteria, with a Chi-square statistic of 2.79, Root Mean Squared Residual (RMSR) of 0.05, Root Mean Square Error of Approximation (RMSEA) of 0.09, Standardized Root Mean Square Residual (SRMR) of 0.01, Normal Fit Index (NFI) of 0.95, Non-Normed Fit Index (NNFI) of 0.95, Comparative Fit Index (CFI) of 0.99, and Adjusted Goodness-of-Fit Index (AGFI) of 0.90. In addition, white noise diagnostic tests reveal no problems of autocorrelation, multicollinearity, or heteroscedasticity, indicating the robustness and novelty of the proposed model. The results further show that, at a statistical significance level of α = 0.01, the government sector exerts direct effects on changes in the socio-cultural, economic, and environmental sectors. At the same time, the socio-cultural sector also has a direct influence on changes in the government sector in the same direction, reflecting a reciprocal causal relationship.

Importantly, this study identifies a novel finding that differs from previous research and past national governance approaches: the socio-cultural sector has a direct effect on changes in the environmental sector, with the highest magnitude at 0.81% in the same direction. This effect is substantially stronger than that of the economic sector, which also has a direct effect on changes in the environmental sector but at a lower magnitude. Moreover, the economic sector has a direct effect on changes in the socio-cultural sector at 0.54% in the same direction, indicating that economic growth directly contributes to the development of the socio-cultural sector. The economic sector also influences changes in the environmental sector indirectly, operating through the socio-cultural sector. These findings imply that if the government intends to formulate effective policy measures, priority should be given to interventions in the socio-cultural sector, as this sector exhibits the strongest influence on changes in the environmental sector and simultaneously transmits indirect effects to the economic sector. Such an approach is therefore both cost-effective and highly appropriate for achieving maximum efficiency and effectiveness in policy implementation.

In this study, once the influence relationships have been clearly identified, the next analytical step involves ranking the relative importance of these influences to determine which indicators the government should address first in order to achieve the greatest policy impact. Accordingly, sensitivity analysis based on the PA-Probit-G model is conducted, and the results are presented in the following section.

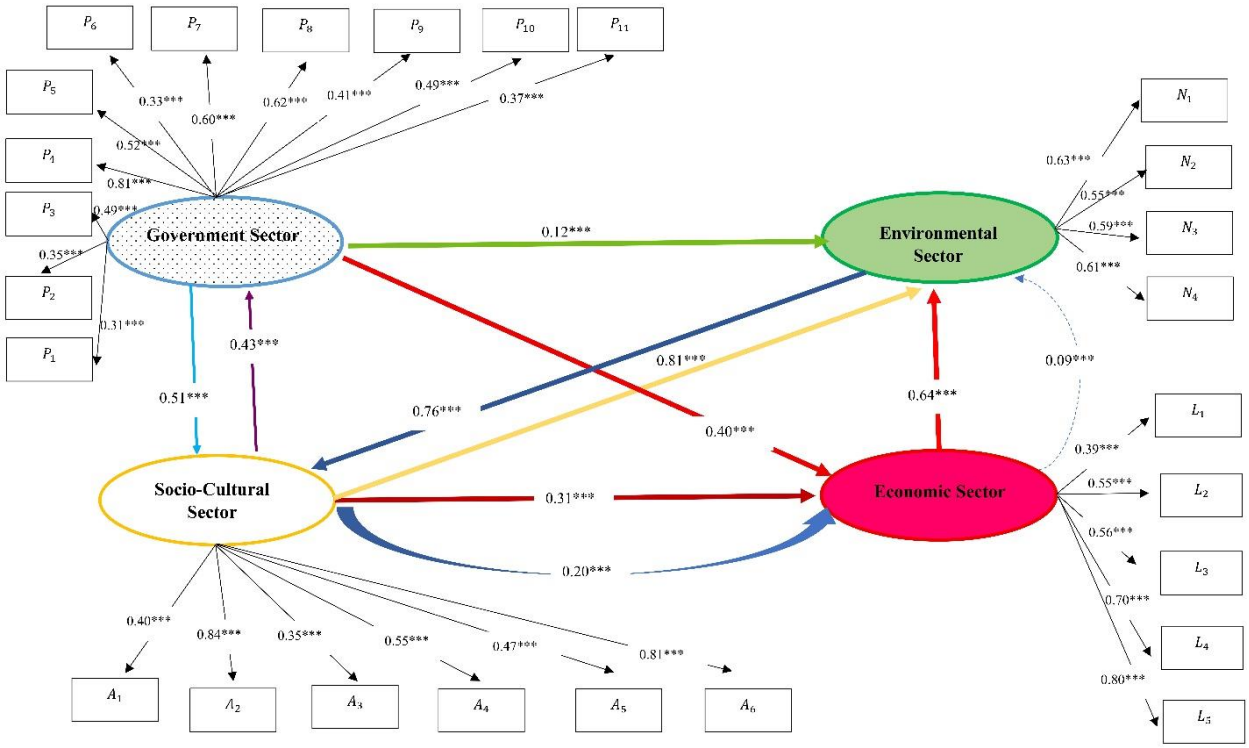

Figure 2. The results of the sensitivity analysis conducted to identify new scenario policies based on the PA-Probit-G model

As shown in Figure 2, the PA-Probit-G model effectively demonstrates the outcomes of the sensitivity analysis used to identify new scenario policies from the observed variables. The results indicate that the sensitivity of government policy related to the adoption of renewable energy is the highest, at 81%. In addition, within the sensitivity range of 80-100%, two other observed variables exhibit similarly high sensitivity levels: the urban culture rate and the stakeholder acceptance rate. These findings suggest that although the government has implemented numerous measures within the government sector to reduce greenhouse gas emissions, a lack of comprehensive and detailed consideration may obscure the importance of certain key indicators. Therefore, prioritizing indicators based on their relative influence on change is critically important and should be carried out on a continuous basis in order to achieve long-term success in line with the green economy

objective. Furthermore, despite the government's continued emphasis on the Bio-Circular-Green (BCG) economic model, the results of the analysis demonstrate that the influence of changes in the economic sector on the environmental sector is weaker than the influence exerted by changes in the socio-cultural sector.

Long-Term Forecasting Results of Greenhouse Gas Emissions (2025–2050) from Agricultural Land Use

In this study, the performance of the PA-Probit-G model is evaluated by comparing it with conventional models used in previous research. The evaluation employs Mean Absolute Percentage Error (MAPE) and Root Mean Square Error (RMSE) as statistical measures to assess the model's capability for long-term forecasting of greenhouse gas emissions resulting from agricultural land use over the period 2025-2050, which corresponds to Thailand's green economy target. The results are presented as follows.

Table 3. The comparison of the performance of the PA-Probit-G model with traditional models (Source: Author's Estimate (2026)

Forecasting Model	MAPE (%)	RMSE (%)
OLS model	10.45	11.99
CNN model	5.10	5.37
ANN model	5.05	5.25
Fuzzy model	4.05	4.77
LSTM model	3.80	4.00
ANIF model	3.75	3.92
ARIMAX model	3.55	3.75
PA-Probit-G model	1.05	1.57

Based on Table 3, the researcher compares the PA-Probit-G model with conventional models previously used in Thailand as well as in international studies, including the Autoregressive Integrated Moving Average with Exogenous Variables (ARIMAX) model, Adaptive Neuro-Fuzzy Inference System (ANFIS) model, Long Short-Term Memory (LSTM) model, Fuzzy model, Artificial Neural Network (ANN) model, Convolutional Neural Network (CNN) model, and Ordinary Least Squares (OLS) model. The test results indicate that the PA-Probit-G model demonstrates the highest forecasting performance, with MAPE and RMSE values of 1.05% and 1.57%, respectively. The ARIMAX model ranks second, with MAPE and RMSE values of 3.55% and 3.75%, respectively, followed by the ANFIS model (MAPE = 3.75%, RMSE = 3.92%), the LSTM model (MAPE = 3.80%, RMSE = 4.00%), the Fuzzy model (MAPE = 4.05%, RMSE = 4.77%), the ANN model (MAPE = 5.05%, RMSE = 5.25%), the CNN model (MAPE = 5.10%, RMSE = 5.37%), and the OLS model, which exhibits the lowest performance (MAPE = 10.45%, RMSE = 11.99%). Accordingly, the PA-Probit-G model is the most appropriate model for long-term forecasting of greenhouse gas emissions over the study period.

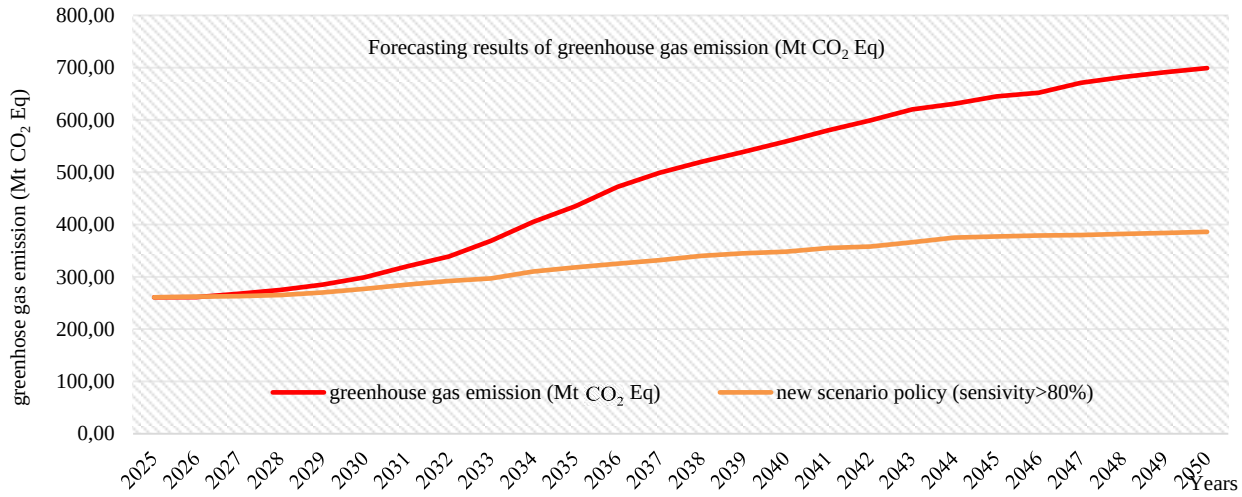

Figure 3. Long-term forecasting results of greenhouse gas emissions from 2025 to 2050 using the PA-Probit-G model

Figure 3 illustrates the projected greenhouse gas emissions over the period 2025-2050. The results indicate that agricultural land use leads to a continuous increase in greenhouse gas emissions throughout this period. Despite Thailand's long-standing implementation of sustainable development policies from 1992 to 2025, these measures have not been sufficient to curb the steadily rising growth rate of emissions. The analysis shows that greenhouse gas emissions are projected to increase to 396 Mt CO_2 eq by 2050, a level that poses significant risks to ecosystems because it exceeds the defined carrying capacity of 350.50 Mt CO_2 eq. However, this study develops the PA-Probit-G model and identifies a new scenario policy centered on renewable energy as the highest-priority policy requiring concrete government action. This policy must be implemented in parallel with improvements in the urban culture rate and stakeholder acceptance rate in order to safeguard the environmental sector, stabilize its growth trajectory, and reduce greenhouse gas emissions to the greatest extent possible without exceeding the established carrying capacity.

Under the new scenario policy, the forecasting results indicate that by 2050 greenhouse gas emissions would increase at a substantially lower level, reaching approximately 275 Mt CO_2 eq, representing a growth rate of only 75.09% and remaining below the carrying capacity threshold of 350.50 Mt CO_2 eq. Nevertheless, to sustain economic and socio-cultural development, the government should continue to advance the Bio-Circular-Green (BCG) economy framework, which remains essential for supporting Thailand's long-term national development strategy.

Despite the government's long-standing implementation of sustainability policies up to the present, final energy consumption has continued to increase at a steady and substantial rate, reaching a growth rate of 65.4%, which exceeds the government's target ceiling of 40%. However, when the new scenario policy, comprising the solar cell adoption rate, biomass utilization rate, and public participation rate, is applied using the GMM-PAXi model, the growth rate of final energy consumption declines to only 31.75%. This level falls within a range that makes progress toward the net-zero emissions target by 2065 feasible. These results demonstrate that the formulation of appropriate new scenario policies, together with the selection of a suitable analytical model, can effectively guide strategic planning toward the intended long-term goals. Accordingly, the researcher proceeds to forecast greenhouse gas emissions over the period 2025-2065.

DISCUSSION

The development of Thailand's agricultural sector toward sustainability is critically important for the country's long-term development. Agriculture has been an integral part of Thai society from ancestral times to the present, with a large proportion of the population engaged in agricultural occupations and most of the country's land area devoted to agricultural use. Therefore, if Thailand is to achieve sustainable national development in line with established targets, the agricultural sector should be prioritized as the first and most fundamental sector. Under Thailand's green economy goals within its sustainability policy framework, sustainability is intended to be achieved across all sectors simultaneously. Nevertheless, the agricultural sector remains the most essential sector for the Thai population, even as urbanization continues to expand across the country. Despite this urban expansion, agriculture continues to serve as the primary livelihood for much of the population. Consequently, environmental conservation and protection constitute an urgent, spatially grounded priority that must be addressed in both the short and long term to ensure the successful and sustainable achievement of national goals, while also preserving the environment as a legacy for future generations. However, although Thailand has implemented sustainable development policies continuously from 1992 to 2025, these efforts have not effectively reduced greenhouse gas emissions.

Furthermore, the designation of agritourism as a national agenda has intensified land use, altered geographical conditions, and significantly increased consumption levels among both domestic populations and international tourists. These dynamics have led to profound transformations within the socio-cultural and environmental sectors, accelerating urbanization across nearly all regions of the country. As a result, traditional Thai culture and indigenous ways of life have gradually diminished, while ecosystems have become increasingly degraded and have exceeded established environmental thresholds. The research findings further indicate that, if current trends persist, greenhouse gas emissions are projected to continue rising beyond the carrying capacity, directly contradicting the government's declaration of the green economy as a national agenda. This agenda seeks to achieve its targets 15 years ahead of the original timeline, with completion by 2050, at which point greenhouse gas emissions are expected to be reduced and balanced by absorption rates to achieve net-zero emissions. Nevertheless, it is now evident that these plans have not only failed to achieve their stated targets but have also been unable to constrain greenhouse gas emission growth to levels below the carrying capacity. This persistent trend poses escalating risks to ecological systems and will continue to adversely affect biodiversity, human well-being, and other living organisms in the future.

In managing Thailand's agricultural sector, the government has undertaken extensive efforts to achieve national objectives by introducing key measures, most notably the Alternate Wetting and Drying (AWD) rice cultivation policy. This policy aims to reduce greenhouse gas emissions by lowering methane CH_4 emissions by up to 30% through controlled water management that alternates between flooded and dry conditions, allowing oxygen to penetrate the soil and inhibit methane-producing bacteria. In addition to mitigating emissions, AWD reduces water consumption, fertilizer and chemical use, lowers production costs, and generates additional income through carbon credits, while aligning with the Bio–Circular–Green (BCG) economic strategy, a core national development framework. However, the rapid expansion of land use for agritourism, driven by growing international demand, has exacerbated ecosystem degradation, intensifying environmental pressures beyond those generated by domestic agricultural activities alone.

Agritourism development has accelerated land-use transformation at a much greater scale, amplifying ecological disruption and increasing the severity of environmental impacts over time. Despite the government's strong commitment and intensive implementation of these policies in accordance with established targets and plans, greenhouse gas emissions have not declined to the levels specified in national objectives. This shortfall is primarily attributed to limitations in existing governance and planning models, which lack sufficient accuracy and integration to effectively support sustainable national management. In response, this study develops an improved model that enables research findings to be more effectively applied to government decision-making processes in the long term.

The results further demonstrate that the formulation and implementation of government policies, whether domestically designed or adopted from international frameworks, will fail to achieve their intended goals if they do not account for indicators that genuinely and significantly influence outcomes. This study therefore finds that while the implementation of BCG economic measures has generated substantial benefits in terms of economic growth, such growth alone is insufficient to ensure reductions in greenhouse gas emissions without alignment with the most influential causal indicators.

Nevertheless, one critical measure that has not been prioritized by the government in policy formulation is the promotion of renewable energy, which constitutes a highly significant, and indeed the most crucial, measure for the agricultural sector in reducing greenhouse gas emissions. This measure must be implemented in parallel with two indicators that require immediate and urgent action: the urban culture rate and the stakeholder acceptance rate.

This urgency arises because Thai society has historically not embedded environmental conservation as a core cultural value. Across generations, the environment has largely been perceived as a public good that anyone may use, with greater individual use often viewed as yielding greater personal benefit, rather than as a shared resource that must be protected and preserved for future generations. Therefore, to maximize policy effectiveness, all sectors, public, private, and civil society, must undergo a cultural transformation that emphasizes environmental stewardship, collective responsibility, and the sustainable use of natural resources. Consequently, the urban culture rate and stakeholder acceptance rate are essential factors in advancing Thailand's sustainable development and in enabling the country to transition toward a green economy by 2050 in a durable and effective manner. The findings of this study are consistent with those of several prior studies, including Waiyasusri et al. (2024), Hasanein & Ayad (2025), Ahmed et al. (2025), Salama et al. (2025), and Salama et al. (2025). However, the implementation of renewable energy is well suited to Thai society and Thailand, particularly when considering spatial analysis within the agricultural sector. Nevertheless, the long-standing cultural characteristics of Thai society and the continuous process of urbanization are likely to influence future transitions. Cultural change among the population cannot be achieved through coercive measures alone; rather, it requires proactive incentive-based policies that encourage shifts in mindsets and lifestyles. Environmental conservation must be positioned as a primary priority in daily life, which inherently requires time and sustained government support. If current approaches are maintained without significant adaptation, Thailand is unlikely to achieve its long-term objectives, including the green economy target by 2050, and it will certainly fall short of attaining the net-zero emissions goal by 2065.

Recommendation

Based on the findings of this study, the researcher identifies several significant insights that are highly beneficial to the public interest. This research successfully identifies a new scenario-based policy that differs from government policies implemented from the past to the present and demonstrates the potential to reduce greenhouse gas emissions to levels below the carrying capacity. Accordingly, the following recommendations are proposed for public and policy relevance:

1) With regard to land use for the development of agritourism, it is crucial for the government to prioritize infrastructure factors, as infrastructure constitutes a core foundation for national development toward sustainability and is among the most influential factors demonstrating the relationships that drive various forms of change. If infrastructure development is implemented appropriately, negative spillover effects on other sectors can be avoided, thereby preventing further damage to ecosystems. To date, land use for agritourism has already imposed substantial pressure on land resources; consequently, inadequate or poorly planned infrastructure would accelerate ecological degradation and lead to more rapid ecosystem deterioration than previously experienced.

2) Support measures to address fine particulate pollution caused by biomass burning in forest areas: Air pollution has emerged as a critical environmental issue, particularly during periods of forest fires, haze, and smog in northern Thailand. During the severe haze crisis in early 2023, concentrations of fine particulate matter (PM2.5) were found to increase continuously each year. More than 100,000 accumulated hotspots were detected, with the majority located in forested areas. Of these, approximately 48% were found in protected forest areas, followed by 37.99% in national reserved forests, and 14.23% in agricultural areas and land reform zones (Sor Por Kor), along with other land-use categories. Given these circumstances, effective prevention and mitigation strategies in forest areas are essential. These should include strengthening area-based mechanisms, enhancing coordination and collaboration with local communities and surrounding areas, improving fuel management and combustion efficiency, developing and deploying more effective technologies, and expanding the use of monitoring, surveillance, and hotspot-tracking technologies to enable timely intervention and long-term environmental management.

3) Enhance local capacity for water planning and management: Water resource management has become increasingly challenging due to rising water demand, climate variability, and changes in rainfall patterns and distribution that are difficult to predict. Surface water sources have been encroached upon, altered, and degraded over time. Moreover, the occurrence of more severe and prolonged El Niño events is likely to significantly affect water availability, thereby constraining the ability to manage water resources in a manner that equitably meets diverse demands. Accordingly, there is an urgent need to strengthen capacity for water planning and management at the community and local levels, particularly in areas vulnerable to flooding and drought. This should be achieved through comprehensive capacity-building initiatives that enhance knowledge and skills in the application of information and communication technologies (ICTs) for water resource management, enabling more accurate water forecasting and more effective, adaptive decision-making.

4**)** Support urban green space assessment and planning: Rapid urban expansion, together with a continuous increase in the registered urban population, the presence of transient populations, tourists, and visitors, has led to the replacement of natural green spaces with built structures and infrastructure. This transformation has adversely affected urban temperatures, water retention capacity, biodiversity, and the availability of recreational spaces. Therefore, it is recommended that municipalities at all administrative levels be supported in conducting systematic surveys and developing area-based urban green space management plans that align with national public green space targets and established operational guidelines for advancing sustainable urban green space management.

5) Study environmental changes and impacts on cultural and artistic heritage sites: A well-preserved cultural and artistic environment enhances the aesthetic value and significance of heritage sites. However, ongoing urban expansion and transformation, both physical and social, along with tourism pressures and natural hazards, increasingly threaten the environmental context and intrinsic value of cultural and artistic heritage. Consequently, in-depth studies and impact assessments are needed to analyze environmental changes affecting these sites, particularly historic urban areas, in order to safeguard cultural and artistic heritage as a vital national legacy for future generations.

Limitations of the Research

This study is based exclusively on quantitative research methods, which constitutes a limitation in terms of the absence of complementary qualitative analysis. Qualitative data, particularly from practitioners directly involved in policy implementation, may be subject to incomplete reporting, bias, or constraints in providing fully accurate information. Such limitations could potentially lead to errors in analysis and interpretation. For this reason, the researcher deliberately chose not to incorporate qualitative methods in this study. Integrating biased or incomplete qualitative information into the analysis could result in misguided interpretations and, if applied to national governance and policy formulation, could generate adverse consequences for Thailand's development trajectory.

Reliance on unverified beliefs or non-informational inputs may distort strategic decision-making and lead to policy directions that contradict national objectives. Accordingly, the quantitative approach employed in this research is considered sufficient and appropriate for informing long-term national strategic planning and governance decisions.

CONCLUSIONS

This study, entitled "A Dynamic Causal Modelling Framework for Prioritising Greenhouse Gas Emission Reduction Strategies in Agro-tourism Land Use and Sustainable Territorial Development in Thailand," examined the priority order of the causal factors influencing the formulation of future greenhouse gas emission management strategies arising from agro-tourism land use in Thailand. To achieve this objective, the study developed the Path Analysis based on the Probit Government Model (PA-Probit-G model), an enhanced analytical framework derived from integrating the principal strengths of previous models. The model enables the simultaneous examination of direct and indirect relationships among the socio-cultural, economic, environmental, and government sectors, while also identifying the indicators that should be prioritized in future national management strategies.

The findings demonstrate that the socio-cultural sector is the most influential factor affecting changes in the environmental sector. In particular, the urban culture rate and stakeholder acceptance rate are identified as critically important indicators for formulating new scenario policies. These indicators should be implemented in parallel with concrete government measures to accelerate renewable energy development. The results therefore confirm that the effective management of greenhouse gas emissions from agritourism land use cannot depend exclusively on economic development or technological interventions. Rather, it requires the integration of renewable energy policies with socio-cultural transformation, environmental stewardship, and stakeholder acceptance.

The forecasting results further demonstrate that continuing existing policy conditions would cause greenhouse gas emissions to exceed the established carrying capacity by 2050. In contrast, implementing the proposed new scenario policies can maintain greenhouse gas emissions below the carrying capacity throughout the forecasting period. These policies are therefore essential for mitigating the environmental impacts associated with the promotion and expansion of agritourism, while supporting Thailand's green economy target by 2050. Accordingly, the PA-Probit-G model provides an effective evidence-based instrument for prioritizing causal factors, formulating national greenhouse gas emission management strategies, and supporting sustainable territorial development. Integrating renewable energy development, the urban culture rate, and the stakeholder acceptance rate will strengthen Thailand's capacity to balance agritourism-based economic development with socio-cultural continuity and environmental protection. The application of this framework can therefore contribute to the long-term success of Thailand's national management plan and its transition toward sustainable development.

Abstract: Geodiversity underpins geoheritage, yet systematic and quantitative assessments of geosites remain unevenly distributed globally, with Africa particularly underrepresented despite its exceptional geological diversity. This limits both effective geoconservation and the development of geoparks seeking international recognition. Here we present a comprehensive quantitative assessment of seven geosites within the Arusha National Geopark, Northern Tanzania, using a standardized evaluation framework. We assess the scientific, educational, and touristic value, together with degradation risk, of seven representative geosites. The selected geosites, which include Ngurdoto Crater, Momella Debris Avalanche Deposit (DAD), Momella Lakes, Mt. Meru Ash Cone, Little Meru, Socialist Peak, and Tephra Fallout Deposits, were evaluated. Results show that all geosites possess moderate to high scientific value, reflecting their geological significance in illustrating volcanic, geomorphological, and sedimentary processes linked to the evolution of Mount Meru. Degradation risk varies, with Little Meru and Socialist Peak showing low vulnerability, while Momella Lakes and Tephra Fallout Deposits exhibit moderate to high risk due to erosion, weathering, and human activity. Ngurdoto Crater and Momella DAD demonstrate the highest educational and touristic potential, supporting their prioritization for geotourism development and outreach initiatives. The findings highlight the importance of strategic geoconservation planning to protect fragile geosites while enhancing their value for scientific research, education, and sustainable tourism. This assessment contributes to ongoing efforts to strengthen the geopark's geosite inventory and supports the development of Arusha National Geopark toward meeting UNESCO Global Geopark designation standards. More broadly, our results demonstrate the critical role of quantitative geosite assessment in advancing geoconservation, supporting sustainable geotourism, and strengthening the scientific foundation for UNESCO Global Geopark designation in underrepresented regions.

Keywords: geosites, inventory, Arusha National Geopark, assessments, geotourism

INTRODUCTION

Geodiversity encompasses the variety of geological features like rocks, minerals, fossils, landforms, soils, hydrological systems, and the processes that create them (Gray, 2008; 2018). These components form the basis of geoheritage, which includes sites and features of geological importance that document Earth's history, climate changes, and biological evolution. They are also valuable for scientific investigation, education, and geotourism (Brilha, 2018; Prosser et al., 2013; Singh et al., 2021). To protect these resources effectively, it is crucial to accurately identify and assess them, making a systematic inventory of geological heritage a fundamental initial step.

Geoparks serve as structured frameworks for the conservation and promotion of geological heritage by employing a comprehensive approach that integrates geodiversity, biodiversity, and cultural values (Ansori, 2018; Newsome & Dowling, 2018; Hadian & Suganda, 2023). As noted by Brilha (2015, 2016), Henriques & Brilha (2017), geoparks are defined territories of notable geological significance, managed through strategies designed to advance sustainable development, geotourism, and public education. The primary aims include the protection of geoheritage, reinforcement of regional identity, encouragement of sustainable economic growth, and the enhancement of public understanding and appreciation of Earth sciences (Frey et al., 2006; Hose, 2006; Briggs et al., 2021; Mastika et al., 2023; Reinhart et al., 2023; Simbaña-Tasiguano et al., 2024). Geological sites within geoparks serve as accessible spots where local

communities can participate in scientific education, recreation, and sustainable resource use (Newsome & Dowling, 2018; Prosser et al., 2013). These areas often carry scientific, educational, aesthetic, and tourism value, so assessing them properly is essential for effective geopark planning and management. While there are several methods available for evaluating geosites and geomorphosites (e.g., Coratza & Giusti, 2005; Bruschi & Cendrero, 2005; Pereira & Pereira, 2012; Kubalíková, 2013; Brilha, 2016; Tavares et al., 2020), choosing the right criteria depends on the objectives of geopark management, which must balance scientific significance with educational and touristic appeal.

Despite increasing global research on geoheritage and geoparks, quantitative geosite assessment studies remain limited in Africa, particularly in Tanzania. The Arusha National Geopark represents an area of significant geological importance, yet systematic quantitative evaluation of its geosites remains insufficient.

Therefore, this study aims to: (1) identify and inventory geosites within the geopark, (2) evaluate their scientific, educational, and touristic value, (3) assess their degradation risk, and (4) provide recommendations for conservation and sustainable development. This study contributes to filling the existing research gap in Africa and supports the sustainable management and international recognition of the Arusha National Geopark.

LITERATURE REVIEW

Geodiversity and Geoheritage: Concepts and Scientific Relevance

Geodiversity encompasses the natural diversity of geological, geomorphological, and soil features, such as rocks, minerals, fossils, landforms, sediments, and hydrological systems, along with the processes that create and alter them (Gray, 2008, 2018). These elements form the basis of geoheritage, which includes geological sites and features with significant scientific, educational, cultural, and aesthetic importance, illustrating Earth's history, environmental change, and biological development (Brilha, 2018; Prosser et al., 2013). Geoheritage plays a fundamental role in understanding geological processes and contributes significantly to geoscience research, education, and geotourism (Singh et al., 2021).

In recent years, geoheritage has gained increasing recognition as a key component of sustainable development and environmental conservation (Reynard & Brilha, 2018; Sengar & Shah, 2025). Systematic geoheritage inventories have been identified as essential tools for geoconservation planning and management, particularly in regions with high geological diversity but limited documentation (Carrión-Mero et al., 2022).

However, several limitations remain in current geoheritage research. Gray (2018) highlighted the lack of standardized assessment frameworks, which leads to inconsistencies in geosite identification and evaluation. Similarly, Prosser et al. (2013) emphasized that many geoheritage inventories focus primarily on scientific value while overlooking educational and touristic potential. Furthermore, Sengar & Shah (2025) noted that geoheritage remains underrepresented in conservation policies, particularly in developing countries, where geological resources are increasingly threatened by human activities.

These limitations highlight the need for systematic, quantitative, and comprehensive assessment methods to support effective geoheritage conservation and sustainable management.

Role of Geoparks in Geoheritage Conservation and Sustainable Development

Geoparks represent an integrated territorial management approach that combines geoheritage conservation, geotourism, education, and sustainable development (Newsome & Dowling, 2018). They are defined as areas with internationally significant geological heritage that are managed using holistic strategies to promote conservation, education, and regional economic development (Brilha, 2015; Henriques & Brilha, 2017).

Recent studies have demonstrated the significant contribution of geoparks to sustainable regional development. Mastika et al. (2023) reported that geoparks enhance local economic growth through geotourism development, while Reinhart et al. (2023) highlighted their role in improving public awareness and geoscience education. Similarly, Simbaña-Tasiguano et al. (2024) emphasized that geoparks support biodiversity conservation and strengthen regional identity.

Despite these benefits, several challenges limit the effective implementation of these measures. Newsome & Dowling (2018) identified insufficient scientific documentation and a lack of detailed geosite inventories as major obstacles. Carrión-Mero et al. (2022) further noted that many geopark projects fail to meet international standards due to inadequate quantitative geosite assessment. Moreover, Reynard et al. (2016) emphasized that limited research in developing countries, particularly in Africa, represents a significant gap in global geopark development.

Quantitative Assessment of Geosites: Methods, Advances, and Limitations

The quantitative assessment of geosites is widely recognized as a fundamental step in geoheritage conservation and geopark development (Brilha, 2016). Various assessment methods have been proposed to evaluate geosite value based on scientific, educational, and touristic criteria. Early methods focused mainly on scientific importance (Coratza & Giusti, 2005; Bruschi & Cendrero, 2005), but these approaches were criticized for neglecting educational and tourism aspects. Later methods incorporated additional evaluation criteria, including accessibility, aesthetic value, and cultural significance (Kubalíková, 2013; Pereira & Pereira, 2012). However, these methods often lacked standardization and were affected by subjectivity. The quantitative assessment method proposed by Brilha (2016) represents a significant advancement, as it provides a comprehensive and standardized framework for evaluating Scientific Value (SV), Potential Educational Value (PEV), Potential Touristic Value (PTV), and Degradation Risk (DR). This method has been widely applied in geopark studies worldwide due to its reliability and reproducibility.

Recent studies using this approach include Carrión-Mero et al. (2022), Mastika et al. (2023), and Simbaña-Tasiguano et al. (2024), who successfully identified priority geosites for conservation and geotourism development. However, several

limitations have been identified. First, although quantitative, the method still involves expert judgment, which may introduce subjectivity (Reynard et al., 2016). Second, many studies lack integration with Geographic Information Systems (GIS), limiting spatial analysis and management applications (Carrión-Mero et al., 2022). Third, most studies have been conducted in Europe, Asia, and South America, while Africa remains significantly underrepresented.

These limitations highlight the need for further quantitative geosite assessment studies, particularly in developing countries and geoparks undergoing UNESCO Global Geopark evaluation.

Recent Geosite Assessment Studies

Several recent studies have applied quantitative geosite assessment methods in geopark development. Carrión-Mero et al. (2022) conducted a quantitative assessment of geosites in Ecuador and identified several sites of high scientific and tourism value. However, the study lacked a detailed degradation risk analysis. Mastika et al. (2023) evaluated geosites in Indonesian geoparks and demonstrated their importance for sustainable tourism development. However, the study did not fully integrate educational value assessment. Reinhart et al. (2023) assessed geoheritage in European geoparks and emphasized the importance of geosite evaluation for UNESCO Global Geopark designation. However, the findings were less applicable to developing countries. Simbaña-Tasiguano et al. (2024) conducted a geosite assessment in Ecuador and identified priority conservation areas, but the study lacked spatial analysis. Hadian & Suganda (2023) conducted a geosite inventory and assessment in Indonesia and highlighted the importance of geoheritage conservation for sustainable development, although their study did not fully evaluate degradation risk. These studies demonstrate the importance of quantitative geosite assessment but also highlight significant geographical gaps, particularly in Africa.

MATERIALS AND METHODS

Study area. Geographical location

Arusha National Geopark (Figure 1) is located in Northern Tanzania, Northeast of Arusha city. It covers an area of 552 square kilometres. It is 25km east of Arusha, 58km from Moshi, and 35km from Kilimanjaro International Airport (KIA). It takes about a 40-minute drive from Kilimanjaro International Airport to reach the park. The park has a scenic landscape with distinct features such as Meru Crater in the west, Ngurdoto Crater in the southeast, and shallow alkaline Momella lakes with varying algae colours in the northeast of the park. The name was derived from the Waarusha people, who used to live in the area. The population around Mt. Meru is primarily concentrated in Arusha town on the southern flanks of the volcano. There are also dispersed rural populations on all flanks, except within the National Park boundaries on the eastern flank. The arid western flank, heavily impacted by tephra deposits from recent Holocene eruptions, has the lowest population density. The geological sites within the Arusha National Park (Figure 2) are linked to the collapse of Mt. Meru and the subsequent formation of the area's geomorphology. These sites vividly illustrate how geological processes have influenced the landscape, ecology, and culture of the region and serve as a living laboratory for Earth science education, providing visitors with insight into its evolution over time. Furthermore, they offer scenic views for visitors to appreciate, while also serving as a reminder to the community of potential geohazards associated with volcanic eruptions, tectonic movements, and landslides.

Figure 1. Map of Arusha National Geopark from Google Earth displaying some prominent features of the park (Source: Modified from Scoon, 2021)

Geological description

Arusha National Geopark is dominated by Mount Meru, the fourth-highest summit in Africa, and a giant stratovolcano located on older, faulted volcanic terranes in northern Tanzania. Mt. Meru is the main volcanic centre,

with the smaller centres of Meru West and Little Meru on its flanks, and small parasitic cones and craters on the lower slopes and surrounding plains (Dawson, 2008). The main cone (Figure 1) has a diameter of 25km and was built up from numerous, explosive, Plinian-style eruptions that occurred between 0.20 Ma and 80,000 BP (Scoon, 2018).

Little Meru is on the northeastern flank of Mt Meru and is a steep-sided symmetrical volcano with a height of 3800m (Roberts, 2002). As documented by Bennett et al. (2021), most rocks in the area are Pleistocene volcanic-sedimentary sequences, with older sequences dating back to the Miocene-Pliocene. The region's lithology is dominated by volcanic rocks, lava flows, pyroclastic deposits, and debris avalanche deposits (DADs) from Mount Meru.

Lava flows are primarily at higher elevations on the main cone and southern flank, while DADs, ash deposits, alluvium, alluvial fan deposits, and lake deposits are found at lower elevations around the base. Pyroclastic deposits are mainly on the western flank, and DADs are dominant on the eastern and northern flanks. Pumice and ash deposits cover much of Mt. Meru's western slopes and parts of the northern and southern flanks. These deposits include sequences of pumice fall, ash fall, and reworked materials, visible in drainage valleys. Roberts (2002) categorized them into near-vent pumice, early/proximal pumice fall, and main pumice fall deposits. The Mt. Meru debris avalanche deposit, resulting from a collapse about 8600 years ago, formed a 5 km wide and 8 km long horseshoe-shaped crater open to the east (Wilkinson et al., 1986), covering ~390 km². Initially thought to be a lahar, Delcamp et al. (2008) confirmed its hummocky nature, which confirmed it as a debris avalanche deposit with an estimated volume of 28 km³, one of the largest recorded. The exact cause of the collapse remains unclear, but the pumice and ash deposits likely preceded this event. Post-collapse volcanic activity at Mt. Meru has been confined to the crater, including the formation of an ash cone, a nephelinite lava dome, and subsequent lava flows (Roberts, 2002). The most recent eruption was in 1910, with ongoing fumarolic activity reported until 1953 and intermittent steam emissions in recent years (Roberts, 2002). The geological interpretations are primarily based on Wilkinson et al. (1986), with subsequent revisions by Delcamp et al. (2008), who reclassified deposits previously identified as lahars as debris avalanche deposits (DADs). Additionally, features originally mapped as tholoids by Wilkinson et al. (1986) have been reinterpreted as lava domes in the updated mapping of Bennett et al. (2021).

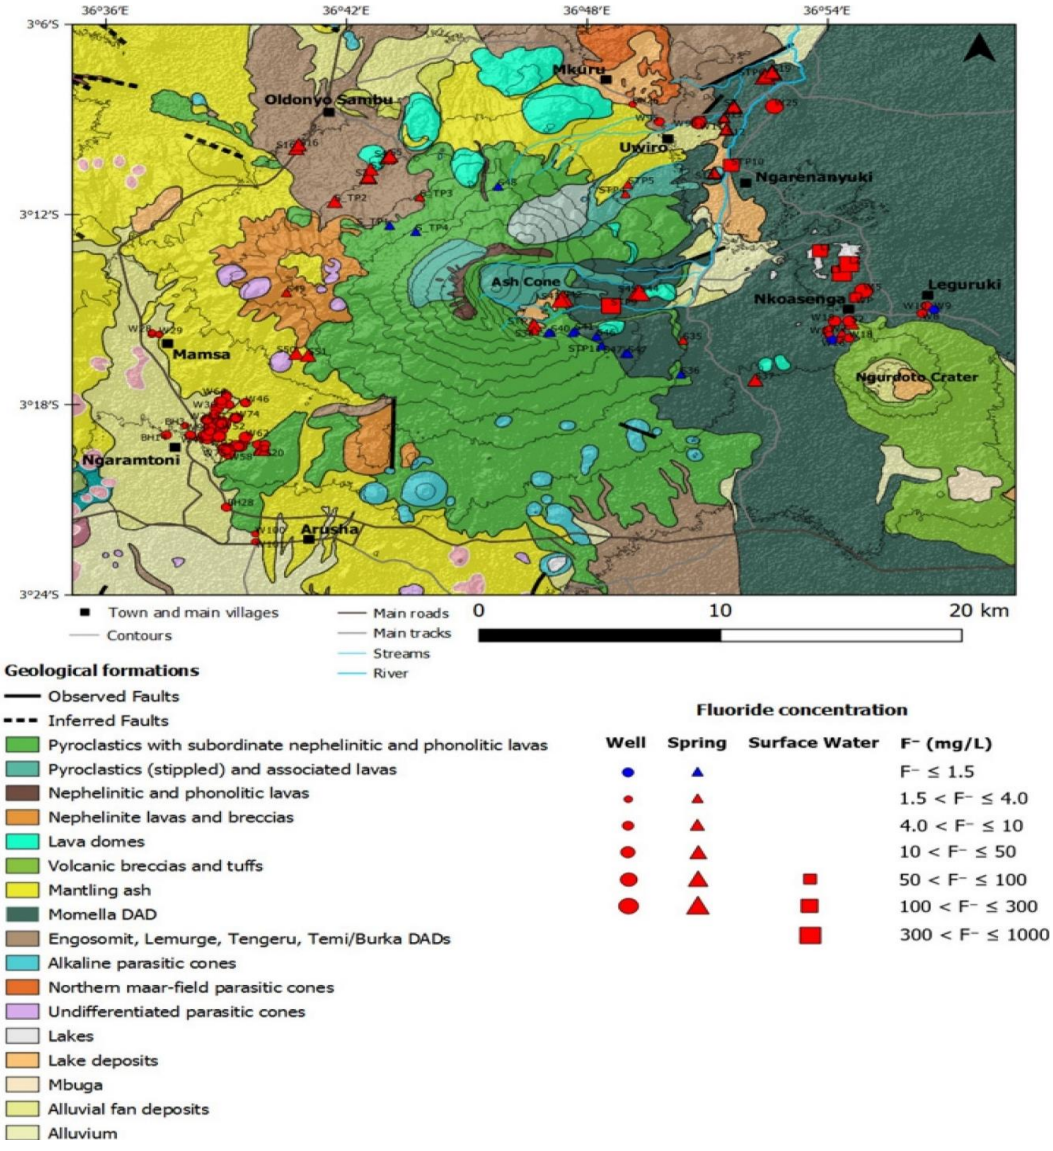

Figure 2. Geological map of the study area (Source: Bennett et al., 2021), illustrating the various geological formations

Quantitative Assessment of Geosites

A quantitative assessment of the potential geosites was conducted by employing the principles and procedures set out by Brilha (2016). This approach enables the differentiation of criteria across four key aspects: scientific value (SV), potential educational use (PEU), potential touristic use (PTU), and degradation risk (DR). For each of these dimensions, dedicated indicators and corresponding tables are utilised in the evaluation process: Table 1 for scientific value, Table 2 for degradation risk, and Table 3 for both educational and touristic potentials.

Each geosite is appraised using a four-point rating scale, ranging from 1 to 4, with the option to assign a score of zero when applicable. Individual criteria, linked to each of the four aspects, are scored independently from 1 to 4 points. The overall scores for scientific value, degradation risk, educational potential, and touristic potential are determined by calculating the weighted sum of the scores attributed to each relevant criterion, as presented in Tables 1, 2, and 3.

Table 1. Weight percent of the various criteria for the final evaluation of the scientific value of geosites (Brilha 2016)

Scientific value	
Criteria	**Weight**
A. Representativeness	30%
B. Key locality	20%
C. Scientific knowledge	5%
D. Integrity	15%
E. Geological Diversity	5%
F. Rarity	15%
G. Use limitation	10%
Total	**100%**
Total weighted	**SV**
<200	Low
201-300	Moderate
301-400	High

Table 2. Weight percent for the different criteria used for the assessment of degradation risk (DR) of geosites (Brilha, 2016)

Degradation risk		
Criteria		**Weight**
A. Deterioration of geological elements		35%
B. Proximity to areas/activities with potential to cause degradation		20%
C. Legal protection		20%
D. Accessibility		15%
E. Density of population		10%
Total		**100%**
Total weighted	**Degradation risk**	
<200	Low	
201-300	Moderate	
301-400	High	

Table 3. Weight percent for the different criteria used for the assessment of the potential educational and touristic uses

Potential use			
Educational	Weight	Touristic	Weight
A. Vulnerability	10%	A. Vulnerability	10%
B.Accessibility	10%	B.Accessibility	10%
C.Use limitations	5%	C.Use limitations	5%
D. Safety	10%	D. Safety	10%
E.Logistics	5%	E.Logistics	5%

G. Association with other values	5%	G. Association with other values	5%
H. Scenery	5%	H. Scenery	15%
I. Uniqueness	5%	I. Uniqueness	10%
J. Observation	10%	J. Observation	5%
K. Didactic potential	20%	K. Didactic potential	10%
L.Geological diversity	10%	L.Economic level	5%
		M. Proximity of recreational areas	5%
Total	**100%**	**Total**	**100%**
Total weighted		**EPU/PTU**	
<200		Low	
201-300		Moderate	
301-400		High	

The scientific value was assessed based on seven criteria: representativeness (30%), key locality (20%), scientific knowledge (5%), integrity (15%), geological diversity (5%), rarity (15%), and use limitation (10%). Each criterion's weight reflects its importance in the overall scientific evaluation, as shown in Table 1. The risk of degradation was evaluated using these factors (Table 2) deterioration of geological elements (35%), proximity to areas or activities that could cause

degradation (20%), legal protection status (20%), accessibility (15%), and population density (10%). A geosite faces the highest degradation risk when geological elements are highly susceptible to deterioration from human or natural causes, it is near potential sources of degradation, lacks legal protection or access restrictions, is easily accessible, and is situated in a densely populated area. The potential for educational use was assessed using 12 criteria: Vulnerability (10%), Accessibility (10%), Use limitations (5%), Safety (10%), Logistics (5%), Population density (5%), Connection with other values (5%), Scenery (5%), Uniqueness (5%), Opportunity for observation (10%), Didactic potential (20%), and Geological diversity (10%). Similarly, touristic potential was measured across 13 criteria: Vulnerability (10%), Accessibility (10%), Use limitations (5%), Safety (10%), Logistics (5%), Population density (5%), Connection with other values (5%), Scenery (15%), Uniqueness (10%), Opportunity for observation (5%), Interpretative potential (10%), Economic level (5%), and Proximity to recreational areas (5%). Each criterion is assigned a specific weight based on its significance within the evaluation of educational and touristic potential uses (Table 3). The graphical data of the weight percent of the different criteria used in the evaluation of the geosites is presented in Figure 3.

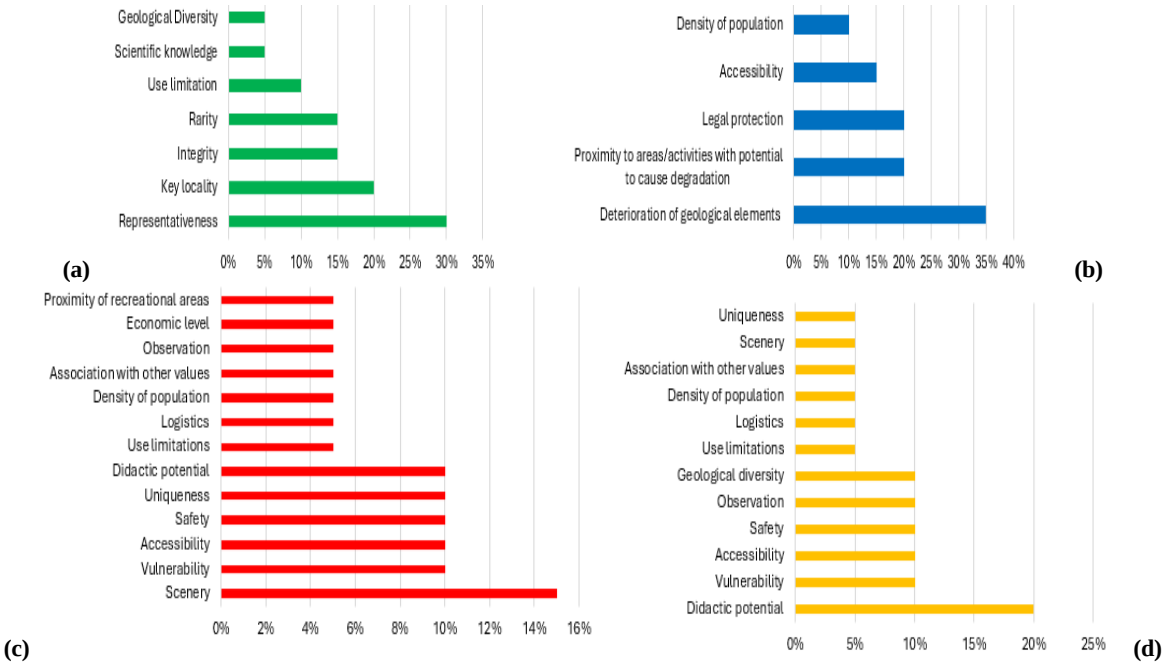

Figure 3. (a). Weight percent of the various criteria for the final evaluation of the scientific value of geosites (b). Weight percent for the different criteria used for the assessment of degradation risk (DR) of geosites (c). Weight percent for the different criteria used for the assessment of the potential touristic use (d). Weight percent for the different criteria used for the assessment of the potential educational use

Definition of Geological Framework

The definition of the geosite inventory method is fundamentally determined by the overarching purpose of the inventory. According to Lima et al. (2010), this involves addressing four key components: object, value, scope, and utility. In the context of this study, the approach focused on identifying and selecting geosites located in the Arusha National Geopark, Tanzania. This was achieved through an integrated methodology that combined a comprehensive review of relevant literature with field observations and an aerial view of each geosite. Additionally, the literature review served to enhance and contextualise the field observations, offering insights into the geological processes linked with the observed geosites.

The methodology adopted for this study encompassed both the inventory and the quantitative assessment of the geosites, ensuring a systematic and evaluative approach to geosite documentation and analysis.

Description and evaluation of geosites

The evaluation focused on seven selected geosites within Arusha National Park. They include Ngurdoto Crater, Momella Debris Avalanche Deposits (DAD), Momella Lakes, Mt. Meru Ash Cone, Little Meru Mountain, Socialist Peak, and Tephra Fallout Deposits. In line with UNESCO's mandate of managing a unified geographical area by holistically combining the protection of its geological resources with educational and sustainable development, these seven geosites were prioritized based on criteria such as their scientific relevance, socio-economic and cultural importance, aesthetic characteristics, and their educational potential.

Ngurdoto Crater

Ngurdoto Crater is a volcanic crater located at 3^0 17' 30.76'' S and 36^0 55' 39.30'' to the east of Mount Meru, within the Arusha National Park, approximately twenty-eight kilometers from the city of Arusha. It is protected by the Tanzania National Parks Act 1973 (Cap. 282)**,** the act is part of the Laws of Tanzania, which outlines the roles, responsibilities, and powers of the Tanzania National Parks Authority (TANAPA). Its accessibility is very easy via a well-maintained network of roads within the park. Visitors typically enter the park through the Momella gate, which is linked to the main roads

leading to Arusha city. Within the park, there are designated viewpoints and trails that allow visitors to observe the crater because direct access to the floor of the crater is restricted to minimize human impact.

Ngurdoto Crater (Figure 4a & 4b) is a volcanic caldera formed by a series of eruptions and subsequent collapse of a volcanic cone. It measures around 3.6km in diameter and about one hundred meters deep, with steep-sided walls (Scoon, 2016). The current pear-shaped configuration of the crater suggests that during its waning stages of activity, two cones existed in proximity. As the underlying molten rock receded to deeper layers, the cones lost support, leading to their collapse and the formation of the present-day crater (Scoon, 2021). The crater floor is a flat, swampy area that supports a variety of plant species and hosts permanent water sources. The volcanic origin and its well-preserved structure make it an important site for geological study, highlighting the volcanic history of the region and caldera formation processes.

The crater's geological features, including its steep walls and volcanic formations, are sensitive to natural weathering and erosion, and unregulated human activities such as trampling, hiking, and other tourism-related activities can accelerate the natural weathering and erosion. The crater is also home to many distinct flora and fauna, including unique species adapted to its specific environment. The ecosystem within the crater is fragile and susceptible to disturbances from human activity.

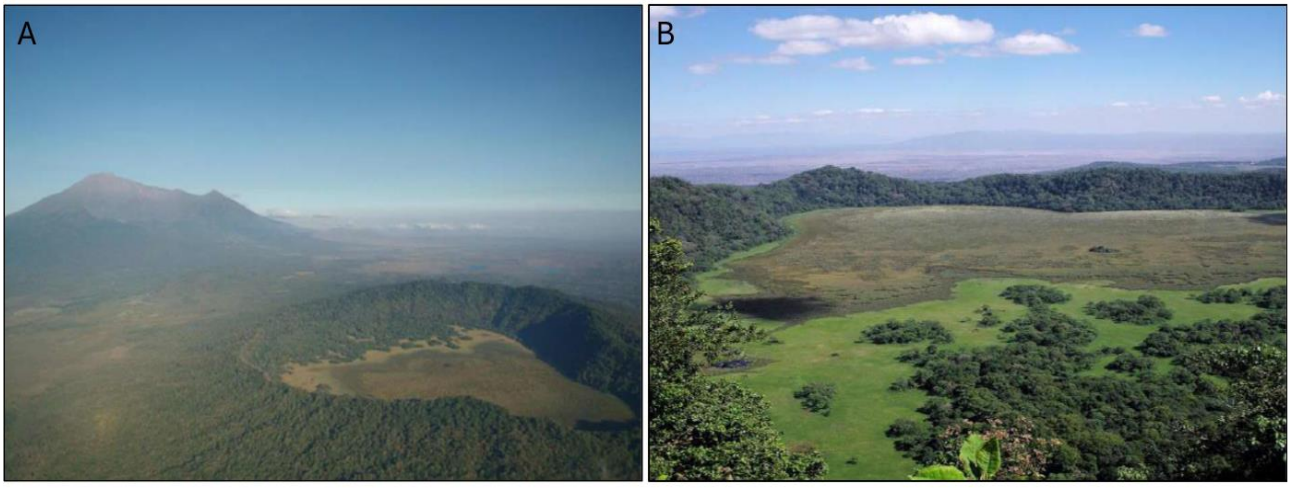

Figure 4. (A) Ngurdoto Crater from the aerial view, (B) Ngurdoto Crater from the close view (Source: Arusha National Geopark)

The Momella Debris Avalanche Deposit (DAD)

The Momella Debris Avalanche Deposit (DAD) (Figure 5) is located at latitude 3^0 16' 25.83'' S and longitude 36^0 53' 04.93''E within the Arusha National Park and protected under the national law of the Tanzania National Parks Act 1973 (Cap. 282)**.** Tanzania National Parks Authority (TANAPA) manages Arusha National Park. Once inside the park, the geosite is easily accessible on foot via the established trails. However, due to the extent of the geosite in terms of area, one can easily observe it from the viewpoint. The Momella Debris Avalanche Deposit (DAD) is an important geological feature that formed because of a massive volcanic landslide that occurred on Mount Meru (Delcamp et al., 2008). This debris avalanche is notable for its size and the insights it highlights into the volcanic processes, landslide dynamics, and sedimentary deposition (Scoon, 2021). It ranks as the largest of its kind recorded for a continental volcano worldwide.

Figure 5. The debris avalanche deposits on the lower eastern slopes of Meru form characteristic hummock ground (Source: Arusha National Geopark)

The sector collapse occurred approximately 8,600 years BP (Wilkinson et al., 1983, 1986), generating deposits that cover an area of about 390 km². These deposits were initially interpreted as laharic in origin (Wilkinson et al., 1983); however, their hummocky morphology and the presence of a horseshoe-shaped collapse scar are diagnostic of a debris-avalanche deposit

(Delcamp et al., 2008). Based on the volume of the missing volcanic sector, Roberts (2002) estimated the debris-avalanche volume at approximately 28 km³, ranking it among the largest documented debris-avalanche deposits worldwide.

Although most Debris Avalanche Deposits are prone to weathering and erosion because they consist of fragmented rock and loose material, Momella DAD remains in excellent condition. Its large size may have helped preserve it.

Momella lakes

The Momella Lakes are located at coordinates around 3^0 13' 19.04'' S and 36^0 54' 32.19''E in the northeastern region of the park, around 40km from the city of Arusha. The lakes are part of the protected area of Arusha National Park, managed by the Tanzania National Parks Authority (TANAPA), under the national law of the Tanzania National Parks Act 1973 (Cap. 282)**.** Accessibility is quite easy once you are in the park; visitors can access the lakes via the paved road on foot or by safari vehicles. Guided canoeing tours are also available on some of the lakes. There are designated viewpoints and pathways as well. As documented by Scoon (2021), the lakes are formed in depressions created by volcanic activity, which formed a hummocky landscape associated with Momella debris avalanche deposits. Momella lakes comprise three large lakes fed by subterranean streams, as well as smaller lakes, ponds, and marshes (Ghiglieri et al., 2012). They show distinct variations in chemical composition and alkaline levels despite originating from the same deposit (Ghiglieri et al., 2012; Bennett et al., 2021). Big Momella Lake (Figure 6B), reaching depths of 10 to 30 meters, has moderate alkalinity. Conversely, Small Momella Lake (Figure 6C) is renowned for its scenic charm, features shallower waters ranging from 4 to 10 meters (Scoon, 2021), with central sections characterized by alkaline and saline properties. Rishateni Lake (Figure 6D), though diminutive in size, stands out for its exceptionally high concentration of dissolved fluorine, stemming from the erosion of alkaline-rich volcanic rocks, potentially marking one of the highest levels recorded in natural lakes (Bennett et al., 2021). These distinct mineral compositions influence the growth of algae in each lake, contributing to their individual colours. They serve as crucial rest stops for a diverse array of migratory birds traveling between Europe, East Africa, and Southern Africa.The lakes and their surrounding wetlands are delicate ecosystems that support a variety of flora and fauna. The water levels of the lakes fluctuate seasonally and are influenced by rainfall and evaporation rates. Changes in climate or water usage upstream can significantly affect the lake's ecosystems.

The Ash Cone

The Ash Cone of Mountain Meru (Figure 7) is located at 3^0 14' 17.67'' S and 36^0 45' 47.29''E on the eastern side of Mountain Meru, within Arusha National Park. The ash cone, like the rest of Mountain Meru, is protected under the authority of Arusha National Park, which is managed by Tanzania National Park Authority (TANAPA) under the national law of the Tanzania National Parks Act 1973 (Cap. 282)**.** Accessibility is difficult due to its location at the summit of mountain Meru. However, there is a trail leading to the various parts of Mount Meru, including the Ash Cone, but due to the difficulties of the trails, visitors typically need to be accompanied by park rangers or guides, ensuring safety and compliance with the conservation rules. As documented by Scoon (2021), the Ash Cone is a pyramid-shaped formation that extends to around 1.5 kilometres in width and rises approximately 200 metres above the crater floor. It features dark ash and vesicular pumiceous blocks, some reaching diameters of up to thirty centimetres. Situated at the western base of the ash cone

lies a nephelinite lava dome, measuring 350 meters in diameter and standing 70 meters tall. From this dome, numerous subsequent lava flows emerged, cascading down the collapse scar and extending up to 7 kilometres. The exposed layers of volcanic materials offer a clear view of the stratification, allowing geologists to study past eruptive events and understand the volcano's history. The Ash cone can be easily eroded by heavy rains because of its loose volcanic materials. In addition, sparse vegetation on the cone provides little protection against erosion, making it particularly vulnerable. Mt. Meru may still be active, but the last eruption recorded on the Ash Cone was in 1910 (Scoon, 2021), so there is always a potential risk of volcanic activity, which could pose threats to the cone and its surroundings.

Figure 7. Mt. Meru Ash Cone (Source: Arusha National Geopark)

The Little Meru

Little Meru (Figure 8) is located on the eastern slope of Mountain Meru within the Arusha National Park, with the geographical coordinates of 3^0 12' 44.63'' S and 36^0 46' 27.49''E. It is part of Arusha National Park, protected under the management of the Tanzania National Parks Authority (TANAPA). This statutory protection ensures the conservation of unique geological, ecological, and cultural features, with regulations in place to manage and protect the natural environment from human impacts. Once you are in the National Park, Little Meru is accessible via well-maintained hiking trails beginning from the Momella Gate. Due to the difficulties in climbing it, the climb to Little Meru is typically included as an acclimatization hike for those ascending Mount Meru. The trail is clearly marked and suitable for trekkers with moderate fitness levels. Hikers are required to be accompanied by a licensed guide, which enhances safety.

As documented by Roberts (2002), Little Meru is part of the larger Mountain Meru volcanic complex, which has a history of volcanic activity. It is composed of volcanic rocks, including basalt and trachyte. It is a monogenetic volcanic cone, which ascends to 3800 meters in elevation northeast of the primary Meru cone. Its proximity to the main Meru cone has resulted in its southern slopes being enveloped by erupted lava, rendering it the most accessible route to the summit of Mt. Meru. The mountain's slopes contribute to local hydrological systems, with streams and rivers originating from its higher elevations. It is part of the Meru volcanic complex, which offers stunning views of the surrounding landscape, including the city of Arusha and Kilimanjaro on clear days.

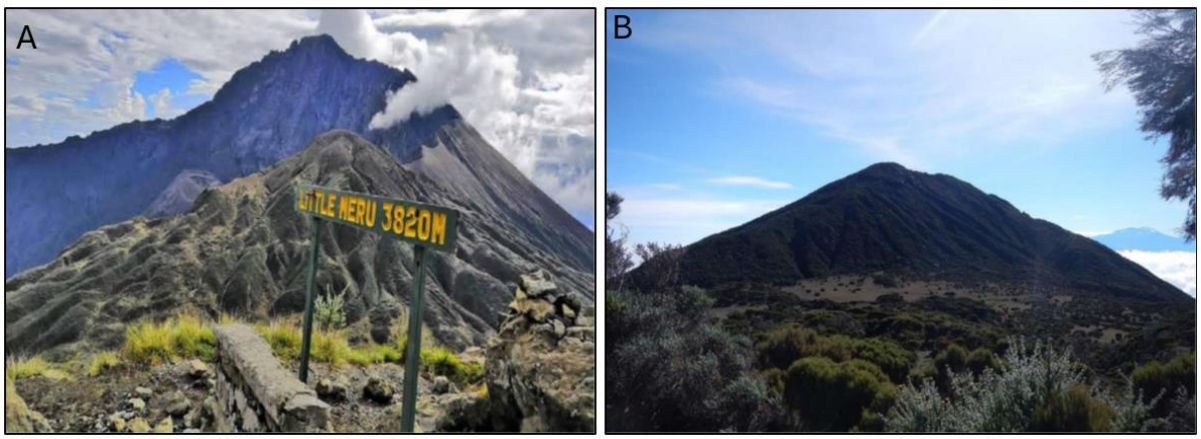

Figure 8. (A) Little Mt. Meru summit (B) Little Mt. Meru from the side view (Source: Arusha National Geopark)

The "Socialist Peak" of Mt. Meru

The socialist peak (Figure 9) is located at 3^0 14' 35.37'' S and 36^0 44' 59.30E. It is the highest point on Mountain Meru and stands 4566m above sea level. It is part of Mount Meru, which is protected under Arusha National Park and managed by the Tanzania National Parks Authority (TANAPA) under the national law of the Tanzania National Parks Act 1973 (Cap. 282)**.** Once you are in the park, Socialist Peak is accessible from the starting point of the trails leading to the summit of mountain Meru, at the Momella gate. However, to reach the summit of the mountain, one requires a multi-day trek along well-established trails. The trek usually takes 3-4 days. The licensed guides and porters, for safety and guidance, must accompany visitors. The Socialist Peak stands as the mountain's highest summit, representing the second generation of the Meru stratovolcano. According to Scoon (2021), after the formation of Mt. Meru's main cone about 200,000BP- 80,000BP, there was a period of volcanic inactivity, which was followed by erosion, during which gullies and ridges were carved out of the main cone. Around 60,000BP, a new burst of activity resulted in the formation of the Summit Group, a capping of lavas that include phonolite and nephelinite. The Summit Group forms a prominent, partially eroded 150m-high rock dome that includes the highest point on the mountain, Socialist Peak (Figure 9A & B). Interlayered deposits of fine and coarse-grained ash are prominent on the summit ridge. The ash deposits are intercalated with phonolite lava that has phenocrysts of alkali feldspar. From Socialist Peak, one can enjoy a clear and close view of Mt. Kilimanjaro, often accompanied by a triangular shadow cast during sunrise.

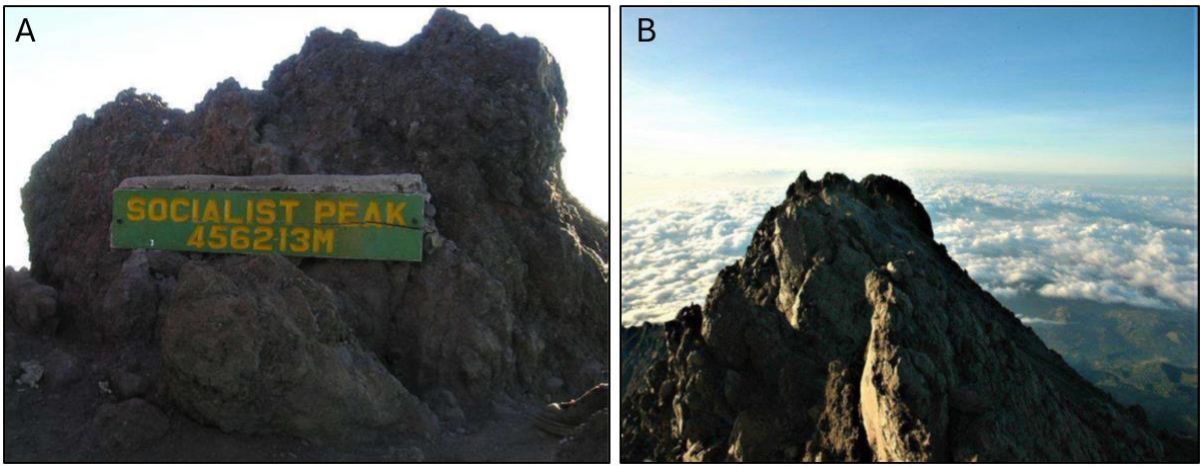

Figure 9. (A) The Socialist Peak from a close view. (B) The Socialist Peak from the aerial view (Source: Arusha National Geopark)

Tephra fall deposits geosite

This geosite is approximately located at 30 09' 13.63''S and 360 49' 27.49''E. It is part of Arusha National Park, protected under the management of Tanzania National Parks Authority (TANAPA) under the national law of the Tanzania National Parks Act 1973 (Cap. 282). This statutory protection ensures its conservation under the National Park. Once you are in the National Park, this geosite is located on the north-western slope of Mountain Meru, on the main road of Arusha-Nairobi, close to a Maasai village. According to Vye-Brown et al. (2014), the geosite consists of a gorge approximately 10 m deep that exposes a thick (>2.7 m) tephra fallout sequence, overlain by multiple tephra and ash-fall layers. These units are, in turn, capped by a pumice-rich deposit about 70 cm thick. The main fallout layer is clast-supported and composed predominantly of light-grey pumice clasts, with a low lithic content.

Phenocrysts are clearly visible within the pumice fragments, which typically measure around 3 cm in diameter, with frequent clasts reaching up to 5cm. Kisaka et al. (2021) did a well-documented study on composite stratigraphic succession representing three distinct explosive events. This geosite will be a good place to study tephra stratigraphy of the area because it has at least three tephra fall deposits, all of which are pumice-supported with abundant lithics. This geosite is vulnerable to natural erosion and weathering, especially during the rainy season.

RESULTS AND DISCUSSION

Quantitative Assessment of Scientific Value (SV) and Degradation Risk (DR)

The results for scientific value (Table 4) and degradation risk (Table 5) are in accordance with Brilha's methodology (2016). The evaluation reveals that all seven geosites have substantial scientific value with scores ranging from 275 to 325 out of the possible 400 points (Table 4). However, the DR varies across the geosites with values ranging from 65 to 205 out of 400 (Table 5). Geosites like Little Mt. Meru, The Ash cone and Socialist Peak have low degradation Risk, while Tephra fallout deposits and Momella Lakes have moderate degradation risk.

Table 4. Evaluation of geosites based on their scientific values

Quantitative Assessment of Educational and Touristic Potential Uses

The quantitative assessment on potential educational use (Table 6) and potential touristic use (Table 7) reveals that the evaluated geosites have varying levels of potential for educational and touristic use. Ngurdoto Crater, Momella lakes, and Momella DAD have the highest potential, making them prime sites for both learning and tourism. Conversely, Tephra Fallout Deposits have the lowest potential in both categories.

Table 6. Quantitative evaluation of geosites based on their potential educational use

A geosite is defined as an outstanding geological location where unique elements of geodiversity hold scientific, educational, cultural, or touristic value (Brilha, 2005). As a result, cataloguing geosites is essential for understanding

geoconservation. In recent decades, geoconservation practices (Sharples et al., 2002) have gained widespread recognition and now play a significant role in broader nature conservation efforts (Prosser et al., 2013). Growing environmental degradation caused by increasing human activity has highlighted the necessity to document, protect, and promote both biodiversity and geodiversity (Gray, 2013). The conservation of geological heritage has become an essential consideration for future legislation and policy development, facilitating more effective management of the natural environment through the protection of geosites (Gordon et al., 2018). To fulfil these objectives, implementing geosite conservation practices is necessary to mitigate both anthropogenic and natural deterioration and destruction (Prosser et al., 2013).

However, before planning or undertaking specific geoconservation measures, particularly in areas where such efforts can be enhanced, such as geoparks, it is critical to conduct thorough geosite assessments. These assessments identify their significance, potential threats, and the necessity for protection (Prosser et al., 2013; Crofts et al., 2020). Beyond geoconservation, geoparks also aim to foster sustainable development and generate economic benefits for local communities through geotourism and educational initiatives. Central to their mission is connecting people with nature and linking geodiversity with biodiversity, cultural heritage, and local communities (Gordon et al., 2018; Gordon, 2019; Farsani et al., 2014). Geotouristic and educational activities organized by geoparks play a vital role in disseminating geoscientific knowledge and geoconservation principles to the public (Farsani et al., 2014).

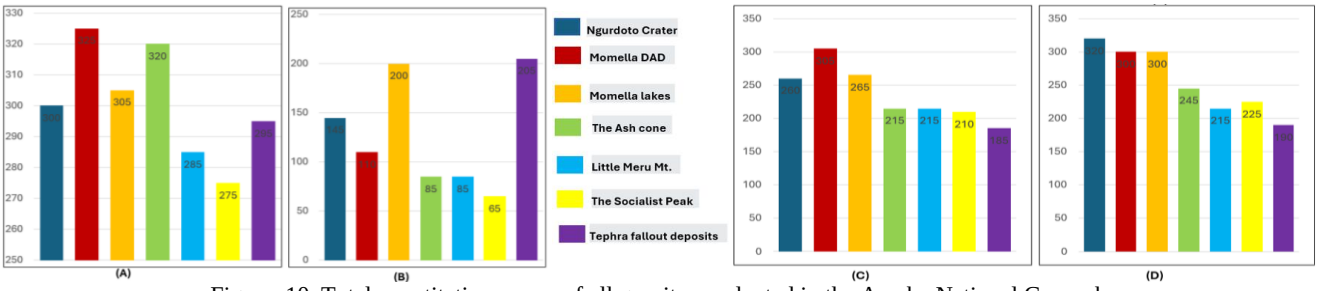

Figure. 10. Total quantitative scores of all geosites evaluated in the Arusha National Geopark
(A), Scientific Value (B), Degradation Risk (C), Potential Educational Value (D), and Potential Touristic Value

Based on the quantitative assessment (Figure 10), Ngurdoto Crater, Momella DAD, Momella lakes, Ash Cone, and the Tephra Fallout Deposits hold substantial scientific value (Table 4, Figure 10A) due to their unique geological formation and ecosystem as expressed by their representatives (120 points), contributing approximately 40% of the total score in all the geosites. The other contributing factors include integrity, scientific knowledge, and rarity (Table 4).

Momella lakes and Tephra Fallout Deposits have moderate degradation risks (Figure 10B) because of their high accessibility (60 points), and deterioration of geological elements (140 points) resepetively (Table 5). The moderate scientific value of the Tephra Fallout Deposits is threatened by its high degradation risk. Out of the 205 score for degradation risk, 140 points (68% weight) came from the criterion 'deterioration of geological elements' (Table 5). This geosite, therefore, needs urgent conservation efforts to prevent erosion and other forms of damage. Ngurdoto Crater has a moderate degradation risk, which can be managed by controlling access to the geosite. On the other hand, the trio of Ash Cone, Little Meru, and the Socialist Peak has a low degradation risk due to their poor accessibility, low density population, and distance from activities that have the potential to cause damage of geological elements.

All the geosites except Tephra Fallout Deposits have moderate to high potential for educational use (Figure 10C) because of their didactic potential, geological diversity, association with other values, uniqueness, accessibility, and safety (Table 6). The poor scenery (0 points) of the Tephra Fallout Deposits contributes to its low potential educational use, limiting the current use of the site. A strategic development to protect and promote this geosite is therefore required.

Ngurdoto Crater, Momella DAD, and Momella lakes all have a high potential touristic value because of their scenery, interpretation potential, accessibility, safety, and uniqueness. The Socialist Peak geosite has moderate scientific value (275 points) and low degradation risk (65 points). It also has moderate educational and touristic potential. This can be attributed to its poor accessibility, specifically the difficulties in ascending it and the lack of excellent infrastructure in place.

The high educational and touristic potentials of the Ngurdoto Crater suggest it is well suited for educational programs and tourism, if conservation measures are enforced to mitigate the impact from increased human activity. Similarly, the high scientific and educational values of the Momella DAD highlight its importance as one of the most remarkable geosites in the geopark. Its low degradation risk also reflects the favourably maintained conservation status of the geosite. However, the site needs interpretative materials and guided tours to improve its touristic appeal.

The Momella lakes geosite has substantial scientific (305 points) and touristic values (300 points), particularly for studies on hydrogeology and biodiversity. However, the higher degradation risk calls for stringent conservation measures to protect the water quality and surrounding habitat from human and natural impacts.

The Mt. Meru Ash Cone has high scientific value (320 points) due to its volcanic features and relatively low degradation risk, indicating good stability. However, its moderate educational (215) and touristic (245) scores suggest a need for improved accessibility and interpretative resources to enhance its use and appreciation by visitors and scholars. Little Meru Mountain shows moderate scientific value (285) and low degradation risk (85), making it a stable geosite. Its moderate educational and touristic potentials indicate underutilization, suggesting a need for development of infrastructure and educational programs to maximize its geoconservation benefits.

CONCLUSION

The seven geosites evaluated within the Arusha National Geopark highlight their considerable scientific, educational, and touristic significance, reflecting the exceptional geodiversity associated with Mount Meru's volcanic history. All evaluated geosites exhibit moderate to high scientific value, confirming their relevance for geological research and heritage interpretation. However, the degradation risks vary significantly, with sites such as Momella Lakes and Tephra Fallout Deposits requiring urgent conservation measures to mitigate erosion, human impacts, and environmental threats. Ngurdoto Crater, Momella lakes, and Momella DAD emerged as the most promising sites for educational and touristic development, indicating their strong potential for geotourism and community engagement. Overall, there is a need for tailored geoconservation strategies, improved interpretative infrastructure, and sustainable tourism planning to enhance the visibility, protection, and utility of the geosites. Strengthening these efforts will support the geopark's aspirations for UNESCO Global Geopark status and reinforce long-term stewardship of Tanzania's unique geoheritage.

Abstract: This study examines how tourism development dimensions influence the effectiveness of conserving marine cultural heritage in Thanh Hoa Province, Vietnam, and clarifies the mediating role of overall tourism development and the moderating role of conservation policy. A mixed-methods design was adopted, including semi-structured interviews with 45 stakeholders and a questionnaire survey that produced 540 valid responses. The quantitative data were analyzed using Cronbach's Alpha, exploratory factor analysis, confirmatory factor analysis, and structural equation modeling. The findings indicate that tourism development policy, tourism infrastructure, heritage-based products, community participation, and human resource quality all have positive and statistically significant effects on overall tourism development. Among these factors, heritage-based products and tourism infrastructure exert the strongest effects. Overall tourism development, in turn, has a strong positive effect on heritage conservation effectiveness and mediates the effects of the five development dimensions on conservation outcomes. The moderation analysis further shows that conservation policy strengthens the relationship between overall tourism development and conservation effectiveness, meaning that tourism growth is more likely to generate conservation benefits when regulations, monitoring, sanctions, carrying-capacity management, and reinvestment mechanisms are effectively implemented. The study contributes an integrated empirical model for understanding how tourism resources and governance mechanisms jointly support marine cultural heritage conservation at the provincial level. The results suggest that Thanh Hoa should prioritize authentic heritage-based products, synchronized infrastructure, trained human resources, substantive community participation, and conservation policies that activate and guide tourism development toward sustainable conservation outcomes.

Keywords: community participation; conservation policy, heritage conservation; marine cultural heritage, Thanh Hoa Province, tourism development, Vietnam

INTRODUCTION

Marine cultural heritage (MCH) refers to the cultural form, culture and practice based on the interaction between coastal people and sea, and tangible and intangible heritage resources related to sea environments (Ounanian et al., 2021). It is also becoming apparent as an underwater cultural heritage that is inextricably linked with marine ecosystems and that requires more integrated conservation strategies that link cultural and ecological stewardship (Meyer-Kaiser & Mires, 2022). Due to the integrated nature of the coastal management and planning of cultural-heritage management, MCH can be effectively protected through integrated governance, since it is deeply embedded in dynamic coastal systems and across multiple jurisdictions (Breen et al., 2024; Flannery et al., 2022; Khakzad et al., 2015).

New syntheses also indicate a fast increase in the scope of MCH studies, as well as the correlation with the agendas of coastal management and sustainable tourism (Huang et al., 2024; Phuong & Lam, 2025). Regarding tourism, MCH could be converted to heritage-related products that convey the local significance of the context, e.g., cultural and cuisine customs, and create genuine experiences of visitors (Dai et al., 2021; Phrammanachot et al., 2026).

Applied research also indicates that incorporating MCH into the coastal management system can facilitate the protection of the coastal systems in a broader sense (Holly et al., 2022).

Heritage-based tourism can also be used to create awareness and enhance local dedication towards conservation when developed sustainably (Nguyen, 2025). Nevertheless, commercialization and excessive tourism may erode cultural identities and perceived authenticity to underpin conservation in the long run because human development pressures affect these issues (Quang et al., 2022). Thanh Hoa has a long coastline and a rich marine cultural landscape (festivals, fisheries, cuisine, relics, and scenic sites) and has also been among the localities with rapid growth in coastal tourism in recent years (Nguyen & Lam, 2025). However, management practice indicates that the effectiveness of conserving

marine cultural heritage is substantially influenced by the level of synchronization of infrastructure and environmental services, the quality of human resources (especially interpretive/guiding capacity), the degree of community participation, governance capacity, as well as the effectiveness of conservation policy implementation in coordination and supervision (Thanh Hoa Provincial People's Committee, 2024).

This suggests that conserving marine cultural heritage is a composite outcome, dependent on how destinations transform tourism development inputs into resources and conservation governance mechanisms.

According to the literature, the dimensions of tourism development are often addressed in terms of groups of factors: (i) institutions/policy; (ii) technical-physical conditions (infrastructure); (iii) market-product; (iv) social factors (community); and (v) resources (human resources), and the outcomes of heritage conservation are also associated with these factors (UNWTO, 2018). Stakeholder engagement and community involvement are consistently mentioned in works on the topic concerning coastal and marine settings as one of the major strategies to facilitate the alignment of tourism development with conservation objectives (Breen et al., 2024; Pham-Do & Pham, 2020; Quang et al., 2023; Rasoolimanesh et al., 2017; Sumarmi et al., 2026). Spatial zoning and information-supported decision-making tools also become more widely used to ensure that the development of ecotourism in the marine sphere is balanced between exploitation and conservation (Shabrina et al., 2026). Newer research in the Vietnamese heritage studies also focuses on interactive strategies that bridge heritage investigation and sustainable tourism evaluation (Azzopardi et al., 2023; Do & Kieu, 2026 ; Truong & Knight, 2025). Moreover, alternative tourism is mentioned as one of the ways to diversify products and promote territorial development by means of participatory governance (Fatnassi et al., 2026).

Despite the previous literature recognizing the contributions of the factors, empirical data are still almost divided on the basis of the sets of variables and hardly ever consider the causal pathway of factors in tourism development dimensions tourism development to conservation effectiveness of the marine cultural heritage at the local scale. Specifically, the conservation policy as a moderating mechanism to activate/amplify the effect of tourism development to conservation efficacy has not been explicitly measured using structural modeling on the case of Vietnam coastal provinces.

The study aims to examine how tourism development dimensions (tourism development policy, tourism infrastructure, heritage-based products, community participation, and human resource quality) affect overall tourism development and, through it, influence the effectiveness of conserving marine cultural heritage in Thanh Hoa; it also investigates whether conservation policy amplifies the relationship between overall tourism development and conservation effectiveness. To address these questions, the study proposes an integrated model (Figure 1) and operationalizes the concepts following a concise measurement logic with consistent terminology as follows: CS refers to the adequacy and effectiveness of the institutional framework promoting tourism development; HT refers to the availability and quality of connectivity infrastructure and public, environmental, and digital services supporting the visitor experience; SP refers to the diversity and attractiveness of heritage-based experience packages; TG refers to the substantive participation of the community in co-management, service provision, and benefit sharing; NL refers to the level of service skills and interpretive / guiding capacity; PT refers to the destination's overall development in terms of growth and competitiveness; QT refers to the clarity and effectiveness of implementing conservation regulations and standards, monitoring and sanctions, carrying-capacity management, and reinvestment mechanisms; and BT refers to the attainment of conservation objectives regarding authenticity/integrity, the continuation of cultural practices, and improvements in governance and interpretation quality.

MATERIALS AND METHODS

Study area and research design

The research was done in Thanh Hoa Province, which paid attention to the coastal and near-coastal tourism space and communities practicing marine cultural traditions (Government Portal, 2023). The study was carried out using a mixed-methods methodology to integrate the advantages of qualitative studies (context clarification and refinement of

measurement tools) and quantitative studies (model and hypothesis testing) according to the guidelines of mixed-method studies in the social sciences (Creswell & Plano Clark, 2017).

Qualitative phase: The study conducted semi-structured interviews with 45 participants from the following groups: government officials, management boards/cultural units, businesses/accommodation providers, community representatives, and experts. Semi-structured interviews were selected because they ensure consistency through an interview guide while remaining flexible enough to elicit context-specific information (Kallio et al., 2016). The number of participants met the "data saturation" logic in qualitative research (Guest et al., 2006). Qualitative findings were used to review the content of observed variables, standardize terminology, and refine questionnaire wording prior to the large-scale survey.

Quantitative phase: The study used a questionnaire survey with a 5-point Likert scale (Likert, 1932), collecting 540 valid responses for factor analysis and structural modeling (Hair et al., 2010). The data were cleaned, coded, and used to describe sample characteristics; the sample structure is presented in Table 1.

Table 1. Characteristics of the survey sample (n = 540) (Source: Author's survey data)

Characteristic group	Category	Frequency	Percentage (%)
Gender	Male	291	53.9
	Female	246	45.6
	Prefer not to answer	3	0.6
Age	18-25	20	3.7
	26-35	173	32.0
	36-45	128	23.7
	46-55	103	19.1
	Over 55	116	21.5
Respondent group	Residents	139	25.7
	Tourists	210	38.9
	Businesses/accommodation providers	128	23.7
	Government agencies	63	11.7
Education level	High school	64	11.9
	Vocational/college	173	32.0

	Postgraduate	21	3.9
Main occupation	Agriculture/fisheries	126	23.3
	Tourism services	187	34.6
	Government	150	27.8
	Students	77	14.3

Scales, research variables, and the questionnaire

The research model comprises eight constructs in the context of marine cultural heritage in Thanh Hoa. The five exogenous variables include CS (tourism development policy), HT (tourism infrastructure), SP (heritage-based products), TG (community participation), and NL (human resource quality). PT (overall tourism development) serves as the mediating variable; BT (heritage conservation effectiveness) is the dependent variable; and QT (conservation policy) is the moderating variable. The questionnaire uses a 5-point Likert scale (1 = strongly disagree; 5 = strongly agree), which is appropriate for measuring perceptions/attitudes in social research (Likert, 1932). The scale development and refinement process followed standard scale-development logic: defining constructs, developing observed variables, expert/stakeholder content review, and refinement through qualitative work prior to the formal survey (DeVellis, 2016). The coding and content of the observed variables are presented in Table 2.

Table 2. Measurement scales and coding of observed variables (Likert 1-5) (Source: Author's research results)

No.	Factor	Code	Description of observed variable
1	Tourism development policy CS)	CS1	Local policies prioritize tourism development linked to marine heritage.
2		CS2	Procedures/permits for coastal tourism activities are clear and transparent.
3		CS3	Incentive mechanisms (tax, land, credit) support sustainable tourism projects.
4		CS4	Tourism planning integrates objectives for conserving marine cultural heritage.
5	Tourism infrastructure (HT)	HT1	Transportation to marine heritage sites is convenient.
6		HT2	Water supply/drainage and waste services for tourism meet demand.
7		HT3	Visitor facilities (piers/parking/service areas) are adequate.
8		HT4	Digital infrastructure (digital maps, Wi-Fi, digital signage) supports the experience.
9		HT5	On-site signage/interpretation at heritage sites is clear and bilingual.
10	Heritage-based products (SP)	SP1	There are many cultural marine experience products (festivals, craft villages, cuisine, etc.).
11		SP2	Heritage visit routes/tours are designed to be attractive.
12		SP3	Products are distinctive and reflect local identity.
13		SP4	Heritage performances/introductions are organized regularly.
14		SP5	Destination information (website/app/social media) is sufficient and easy to access.
15	Community participation (TG)	TG1	The community participates in management and tourism service provision.
16		TG2	Residents benefit fairly from tourism activities.

17		TG3	Community opinions are consulted when new tourism projects are proposed.
18		TG4	Tourism does not disrupt local livelihoods/traditions.
19		TG5	The community is willing to work with visitors to protect resources and heritage.
20	Human resource quality (NL)	NL1	Personnel have expertise and a professional service attitude.
21		NL2	Guides/interpreters are knowledgeable about marine cultural heritage.
22		NL3	Businesses/accommodation providers comply with civilized codes of conduct.
23		NL4	Training and upskilling are conducted regularly.
24	Overall tourism development (PT)	PT1	Local tourism has grown steadily in recent years.
25		PT2	Tourism improves community income and welfare.
26		PT3	A destination image/brand is built around marine culture.
27		PT4	Tourism management is coherent and oriented toward sustainability.
28	Conservation effectiveness (BT)	BT1	Community/visitor awareness of conservation has improved.
29		BT2	Conservation activities are carried out regularly and effectively.
30		BT3	Heritage retains authenticity, limiting excessive commercialization.
31		BT4	The environment/landscape associated with heritage is improved.
32		BT5	Tourism benefits contribute to reinvestment in conservation.
33	Conservation policy (QT)	QT1	Clear regulations/criteria exist for conservation in tourism exploitation.
34		QT2	Resources (finance/personnel) for conservation are ensured.
35		QT3	Monitoring and sanctions for violations involving heritage are enforced.
36		QT4	Cross-sector collaboration (culture-tourism-environment-government) is effective.

Data analysis procedure

To be sure that measurement reliability and validity could be achieved before hypothesis testing, quantitative data were processed according to a conventional scale development and structural equation modeling (SEM) sequence (Hair et al., 2010; Kline, 2023). Scale reliability: Scale internal consistency was determined with Alpha of Cronbach (Cronbach, 1970).

EFA: EFA was carried out as a technique of investigating the structure of factors that lay behind the observed variables and to eliminate those variables that failed to meet the factor-loading requirements (Hair et al., 2010).

CFA: CFA was conducted to assess the measurement model (factor loadings, the whole model fit, and the construct validity). The assessment of the model fit adhered to commonly used recommendations of SEM fit (Hu & Bentler, 1999; Kline, 2023). Convergent and discriminant validity: The AVE/CR method was used to test convergent validity and the Fornell-Larcker criterion was used to evaluate discriminant validity comparing shared variance among constructs (Fornell & Larcker, 1981; Hair et al., 2010). SEM Structural equation modeling was used to test the hypothesized relationships between constructs and to estimate the direct and indirect effects (Hair et al., 2010; Kline, 2023).

Mediation test: The research investigates the mediating effect of PT of the correlation between CS/HT/SP/TG/NL and BT with nonparametric bootstrapping with 5,000 resamples, and presents normal bias-corrected confidence intervals (CIs). The 95 percent confidence interval can be found not to contain zero on an indirect effect to determine that this effect is statistically significant (Hayes, 2022). The study also gives a rough estimate with the use of the product of coefficients method, i.e. multi-plying the standardized coefficients along the component paths (e.g. CS → PT and PT → BT) to allow the comparison of the direction and relative strength of the indirect pathways (Hayes, 2022). Moderation testing: The interaction term (PT × QT) tested as moderating the effect of conservation policy (QT) was standardized in the structural model, which is similar to conditional process and interaction-effect testing (Hayes, 2022; Kline, 2023).

RESULTS AND DISCUSSION

Research results

1. Scale reliability (Cronbach's Alpha)

Scale reliability was assessed using Cronbach's Alpha to examine the internal consistency of the observed variables within each construct (Cronbach, 1970). Following common practice in behavioral and social research, observed variables with a corrected item-total correlation (CITC) below 0.30 are considered to contribute weakly to the scale and should be considered for removal to improve reliability (DeVellis, 2016). In addition, an Alpha value of 0.70 or above is generally regarded as acceptable for research purposes (Nunnally & Bernstein, 1994).

The results show that four observed variables with low CITC values were removed: CS3, TG1, TG4, and QT2. After refinement, the scales achieved moderate to good reliability, with Alpha coefficients ranging from 0.748 to 0.843, indicating adequate internal consistency for subsequent factor analysis and structural modeling (Hair et al., 2010). Specifically, the CS scale increased from 0.665 to 0.762 after removing CS3; the TG scale increased from 0.665 to 0.781 after removing TG1 and TG4. For QT, QT2 was removed and the scale was adjusted according to the model, retaining QT1 and QT3 with an Alpha of 0.748, which meets the minimum acceptable threshold (Nunnally & Bernstein, 1994). The detailed reliability results are presented in Table 3.

Removing observed variables with low CITC values helps improve reliability without altering the conceptual meaning of the construct, while also providing a foundation for EFA/CFA to test factor structure and scale validity (DeVellis, 2016). Notably, the QT scale retained only two items after refinement, which should be monitored in the CFA step (factor loadings and measurement model fit), because a small number of observed variables may affect estimation stability; however, in applied SEM, short scales can still be acceptable if factor loadings and overall model fit are satisfactory (Kline, 2015).

Table 3. Cronbach's Alpha and deleted items (Source: Author's data analysis results)

Scale group	Initial no. of items	Initial Alpha	Deleted items (CITC < 0.3)	Alpha after refinement
CS - Tourism development policy	4	0.665	CS3	0.762 (3 items)
HT - Tourism infrastructure	5	0.839	None	0.839 (5 items)
SP - Heritage-based products	5	0.837	None	0.837 (5 items)
TG - Community participation	5	0.665	TG1, TG4	0.781 (3 items)
NL - Human resource quality	4	0.814	None	0.814 (4 items)
PT - Overall tourism development	4	0.810	None	0.810 (4 items)
BT - Conservation effectiveness	5	0.842	None	0.842 (5 items)
QT - Conservation policy	4	(before deletion)	QT2 (and model-based refinement)	0.748 (2 items: QT1, QT3)

2. EFA: Assumptions and factor structure

After the scales were screened for reliability using Cronbach's Alpha, the study proceeded with exploratory factor analysis (EFA) to (i) assess the suitability of the data for factor analysis and (ii) examine the preliminary factor structure of the measurement instrument (Hair et al., 2010). Regarding assumptions, the KMO index reflects the adequacy of the correlation matrix for factor extraction, while Bartlett's test indicates whether the correlation matrix differs significantly from an identity matrix; these are two widely used prerequisite tests prior to EFA (Field, 2018).

The results indicate that the data met the conditions for EFA, with KMO = 0.921 (a "very good" level) and a statistically significant Bartlett's test (Sig. = 0.000), suggesting that the observed variables were sufficiently intercorrelated to form latent factors (Hair et al., 2010). The cumulative variance explained reached 53.734%, with eight factors having eigenvalues > 1, indicating that the scale structure had adequate explanatory power and was appropriate for proceeding to CFA in the next stage. The summary results are presented in Table 4.

Table 4. KMO/Bartlett and total variance explained (EFA) (Source: Author's data analysis results)

Indicator	Value
KMO	0.921
Bartlett - Approx. Chi-Square	6,887.841
Bartlett - df	465
Bartlett - Sig.	0.000
Total variance explained (cumulative)	53.734%
Number of factors extracted	8

Regarding factor structure, after EFA the observed variables loaded onto the expected construct groups, and the primary loadings were generally at an acceptable level, indicating the clarity and consistency of the scale structure (Hair et al., 2010). In applied practice, factor loadings of approximately ≥ 0.50 are often considered practically meaningful in the context of large samples; therefore, the primary loadings in these results support retaining the observed variables for the CFA step (Hair et al., 2010; Field, 2018). A summary of the factor structure is presented in Table 5.

Table 5. Factor structure after EFA (Source: Author's data analysis results)

Factor	Construct group	Observed variables loading on the factor (primary loading)
1	SP	SP5 (0.764), SP2 (0.722), SP4 (0.701), SP3 (0.660), SP1 (0.603)
2	HT	HT3 (0.780), HT4 (0.762), HT1 (0.717), HT5 (0.675), HT2 (0.589)
3	BT	BT5 (0.785), BT4 (0.717), BT1 (0.692), BT3 (0.683), BT2 (0.651)
4	NL	NL1 (0.792), NL3 (0.710), NL4 (0.708), NL2 (0.645)
5	PT	PT3 (0.780), PT2 (0.682), PT4 (0.681), PT1 (0.662)
6	TG	TG3 (0.778), TG2 (0.719), TG5 (0.672)
7	CS	CS2 (0.739), CS1 (0.713), CS4 (0.639)
8	QT	QT1 (0.848), QT3 (0.713)

The EFA results confirm an eight-factor structure consistent with the proposed conceptual model and indicate that the scales exhibit good convergent patterning within each construct. Notably, QT comprises only two observed variables; therefore, in the CFA step it is necessary to closely monitor standardized loadings and measurement-model fit, and to clearly report convergent and discriminant validity indices (CR/AVE) to strengthen the argument for the scale's validity.

3. CFA: Convergent and discriminant validity

The study employed confirmatory factor analysis (CFA) to evaluate the measurement model, including (i) overall model fit and (ii) scale validity through convergent and discriminant validity (Hair et al., 2010).

Fit indices were interpreted based on commonly recommended SEM fit thresholds (Hu & Bentler, 1999). The CFA results indicate that the measurement model achieved a good fit: Chi-square = 589.450; df = 406; Chi-square/df = 1.452; GFI = 0.934; CFI = 0.972; TLI = 0.968; RMSEA = 0.029; PCLOSE = 1.000. This set of indices supports the conclusion that the measurement model demonstrates good fit and is appropriate for proceeding to structural model testing in the SEM step (Kline, 2015). The CFA model is illustrated in Figure 2.

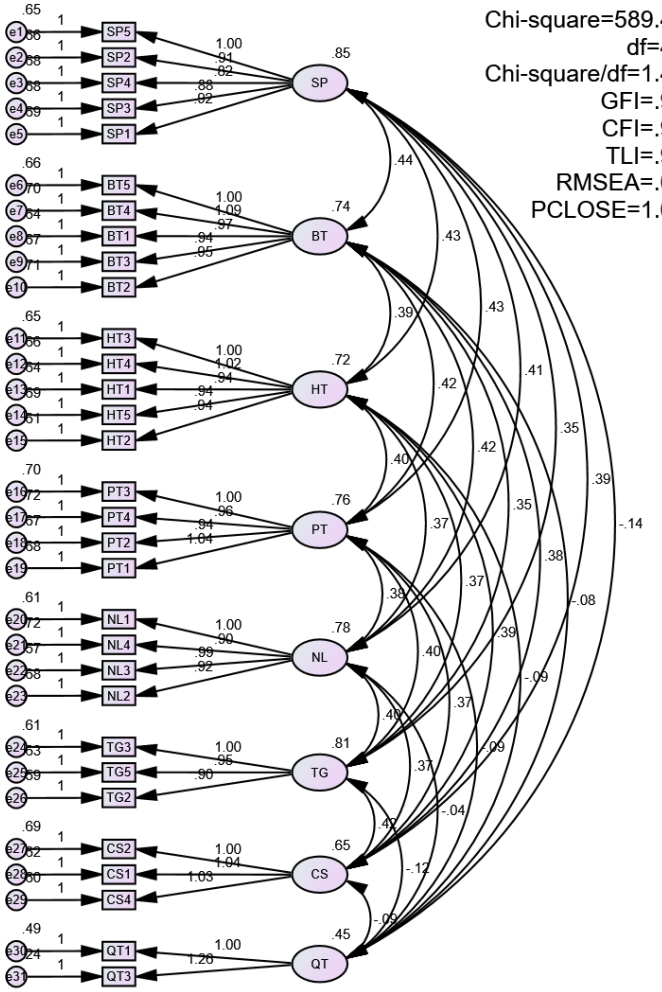

Figure 2. Overall fit of the measurement model (CFA) (Source: Author's research results)

Next, convergent validity was assessed using Composite Reliability (CR) and Average Variance Extracted (AVE), where CR reflects the composite reliability of the scale and AVE indicates the proportion of variance explained by the latent construct (Fornell & Larcker, 1981). Discriminant validity was examined using the criterion MSV < AVE, meaning that the maximum shared variance of a construct with another construct must be smaller than its average variance extracted, to ensure that constructs are distinct at the measurement level. The summary results in Table 6 show that all scales met the required thresholds: CR ≥ 0.757 and AVE ≥ 0.507, and MSV < AVE, confirming both convergent and discriminant validity.

Table 6. CR, AVE, and MSV (Source: Author's CFA results)

Scale	CR	AVE	MSV	Remarks
SP	0.837	0.507	0.309	Convergent and discriminant validity achieved
BT	0.843	0.517	0.311	Convergent and discriminant validity achieved
HT	0.839	0.510	0.318	Convergent and discriminant validity achieved
PT	0.811	0.517	0.311	Convergent and discriminant validity achieved
NL	0.814	0.523	0.310	Convergent and discriminant validity achieved
TG	0.781	0.544	0.333	Convergent and discriminant validity achieved
CS	0.762	0.517	0.333	Convergent and discriminant validity achieved
QT	0.757	0.612	0.051	Convergent and discriminant validity achieved (very strong)

Following the process of reliability refinement, the observed QT2 was dropped; hence, the QT scale had two observed indicators. The few indicators notwithstanding, QT has shown good reliability and convergent validity, with CR = 0.757 (> 0.70) and AVE = 0.612 (> 0.50). Moreover, MSV = 0.051 is lower than the AVE, which means that the discriminant validity has also been guaranteed. In addition, both the measurement model and structural model had acceptable overall model estimates (CFA: 2/df = 1.452, RMSEA = 0.029, CFI = 0.972, TLI = 0.968; SEM: 2/df = 1.663, RMSEA = 0.035) which also helps to justify the acceptability of the QT scale in the study setting. The CFA results reinforce that the measurement instrument is appropriate for capturing the constructs in the research model. Notably, although the QT scale contains a small number of observed variables (two items), it still achieved strong CR and AVE values and a very low MSV. This suggests that QT's convergent and discriminant validity remain well supported in the measurement model; however, in international reporting it is important to clearly emphasize the CR/AVE evidence and the overall model fit as presented above.

4. SEM: Model fit and hypothesis testing

Structural equation modeling (SEM) was used to simultaneously test (i) the effects of the five tourism development dimensions (CS, HT, SP, TG, NL) on overall tourism development (PT) and (ii) the effect of PT on conservation effectiveness (BT). The analysis also evaluated mediation effects (via PT) and the moderating effect of conservation policy (QT), in line with recommendations for structural modeling.

4.1. Model fit: CFA and SEM

Fit indices indicate that both the measurement model (CFA) and the structural model (SEM) achieved good fit. Specifically, the CFA yielded $\chi^2/df = 1.452$ and RMSEA = 0.029, while the SEM produced $\chi^2/df = 1.663$ and RMSEA = 0.035. In addition, comparative fit indices (CFI/TLI/IFI) were all greater than 0.95, consistent with commonly used SEM fit thresholds (Hu & Bentler, 1999). The full set of fit indices is summarized in Table 7.

Table 7. Model fit indices (CFA and SEM) (Source: Author's research results)

Index	CFA	SEM	Suggested threshold
χ^2/df	1.452	1.663	< 5 (good if < 2–3)
GFI/AGFI	0.934 / 0.919	0.928 / 0.913	> 0.90
RMR	0.044	0.075	The smaller, the better
CFI	0.972	0.962	> 0.90 (good if > 0.95)
TLI	0.968	0.957	> 0.90
IFI	0.972	0.962	> 0.90
NFI	0.916	0.910	> 0.90
RMSEA	0.029	0.035	< 0.08 (good if < 0.05)
PCLOSE	1.000	1.000	> 0.05
HOELTER .05	416	365	> 200

Both the CFA and SEM models achieved good fit. The CFA results show $\chi^2/df = 1.452$ and RMSEA = 0.029; the SEM results show $\chi^2/df = 1.663$ and RMSEA = 0.035; and CFI/TLI/IFI are all > 0.95. The SEM model is shown in Figure 3.

The fact that SEM fit indices remained good after moving from CFA to SEM indicates that the hypothesized relational structure fits the data and that the model can be used to interpret direct and indirect effects with confidence (Hair et al., 2010).

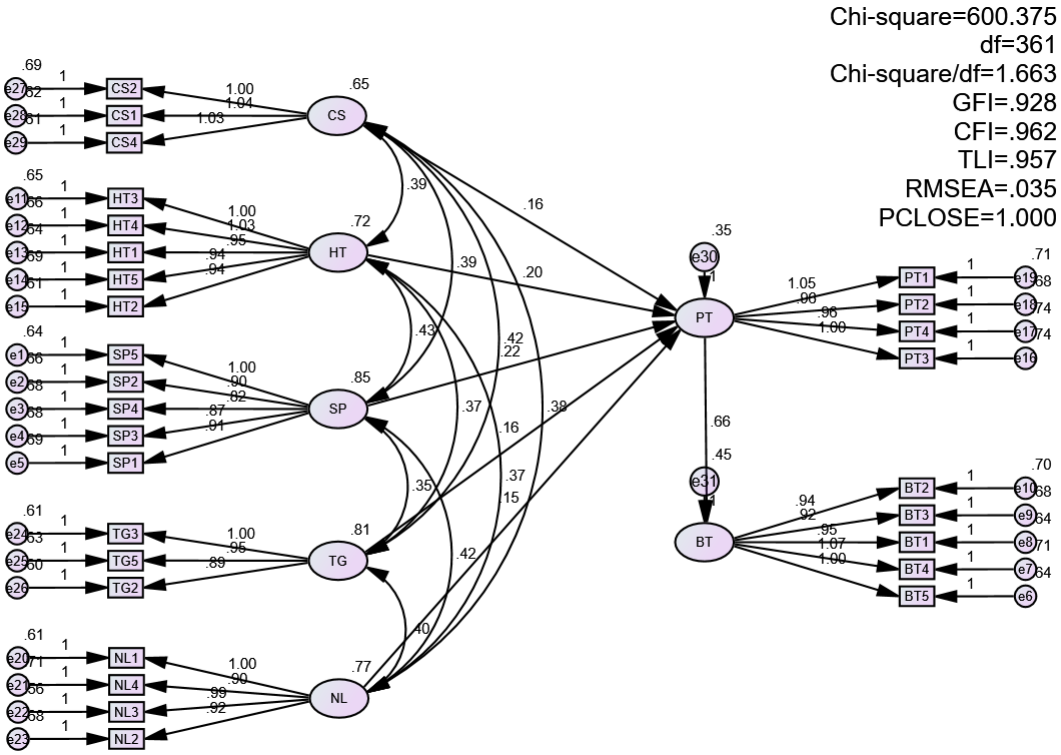

Figure 3. SEM model (Source: Author's research results)

4.2. Hypothesis testing: direct effects

SEM results indicate that CS, HT, SP, TG, and NL all have positive and statistically significant effects on PT, thereby supporting hypotheses H1-H5. Among these dimensions, SP has the strongest effect on PT ($\beta = 0.235$), followed by HT ($\beta = 0.198$). In addition, PT has a very strong effect on BT ($\beta = 0.639$), supporting H6 and reinforcing the argument that overall tourism development is an important channel through which development resources are transformed into conservation outcomes (Kline, 2015). The direct effect estimates are reported in Table 8.

Table 8. SEM results: direct effects (Source: Author's SEM results)

Relationship	β	p-value	Conclusion
PT ← CS	0.157	0.023	H1 supported
PT ← HT	0.198	0.001	H2 supported
PT ← SP	0.235	< 0.001	H3 supported
PT ← TG	0.173	0.005	H4 supported
PT ← NL	0.157	0.007	H5 supported
BT ← PT	0.639	< 0.001	H6 supported

4.3. Indirect effects via PT: mediation testing

Due to the high impact of PT on BT, the impact of CS/ HT/ SP/ TG/ NL on BT will be indirectly mediated by PT. The study also indicates indirect effects following the recommendation of the reviewer with nonparametric bootstrapping (5,000 resamples) having a 95% bias-corrected confidence interval (CI) to identify statistical significance; an indirect effect is significant when 95% CI excludes 0. Table 9 also presents an approximate estimate, based upon the product of coefficients method (i.e. the product of standardized coefficients along the component paths), to compare the direction and relative magnitude across the indirect pathways to supplement the current presentation. This pattern implies that interventions at the dimension level-especially heritage-based products and infrastructure-contribute to conservation primarily by raising the overall level of tourism development (PT), rather than producing immediate direct effects on BT.

Table 9. Indirect effects via PT (Source: Synthesized from the author's SEM results)

Indirect pathway	Approx. coefficient	Significance	Remarks
CS → PT → BT	≈ 0.100	p < 0.01	Positive, significant
HT → PT → BT	≈ 0.127	p < 0.01	Positive, relatively strong
SP → PT → BT	≈ 0.150	p < 0.001	Strongest
TG → PT → BT	≈ 0.111	p < 0.001	Positive, significant
NL → PT → BT	≈ 0.100	p < 0.01	Positive, significant

4.4. Moderation testing: the role of conservation policy (QT)

To test H7, the study standardized variables (Z-scores) and introduced the interaction term PT × QT into the model. The results show that: (i) standardized PT has a strong positive effect on BT (Estimate = 0.419; p < 0.001); (ii) standardized QT alone is not statistically significant at the 0.05 level (p = 0.100); but (iii) the PT × QT interaction is clearly significant and positive (Estimate = 0.258; p < 0.001; standardized coefficient = 0.266). According to moderation logic, this indicates that QT amplifies the effect of PT on BT-that is, when conservation policy is implemented more effectively, the extent to which tourism growth is translated into conservation effectiveness becomes higher (Hayes, 2018). The moderation results suggest an important governance implication: conservation policy is not merely an "independent input" but acts as an "activating mechanism" that enables PT to generate better BT outcomes. In other words, tourism development can create resources and incentives, but the effectiveness of implementation, monitoring and sanctions, carrying-capacity management, and reinvestment mechanisms determines whether that growth is translated into conservation outcomes.

Table 10. Moderation results (standardized Z-scores) (Source: Author's moderation analysis results)

Relationship	Estimate	S.E.	C.R.	p-value	Standardized coefficient
Z_BT ← Z_PT	0.419	0.037	11.351	***	0.419
Z_BT ← Z_QT	-0.060	0.037	-1.645	0.100	-0.060
Z_BT ← PT×QT	0.258	0.036	7.232	***	0.266

The SEM results show that the dimensions CS, HT, SP, TG, and NL all positively affect overall tourism development (PT), with heritage-based products (SP) exerting the strongest influence, followed by infrastructure (HT). PT strongly affects conservation effectiveness (BT) and serves as a mediator for the indirect effects. At the same time, conservation policy (QT) moderates the relationship in a strengthening direction; that is, better implementation effectiveness of QT helps PT translate more clearly into BT (Hair et al., 2010; Hayes, 2018; Kline, 2015).

The prominent roles of SP and HT are consistent with the argument that destination competitiveness is determined by experience quality (products) and accessibility/service capacity (infrastructure) (UNWTO, 2018). The PT → BT result reinforces the view that "tourism can support conservation" by generating resources, raising awareness, and improving governance conditions, if managed appropriately (UNESCO, 2015). The moderating effect of QT aligns with the observation that conservation improves only when clear regulations, monitoring and sanctions, and implementation capacity are in place-especially under pressures of overcrowding and commercialization (ICOMOS, 2022; UNESCO, 2003).

CONCLUSION

This study tested a model of how tourism development dimensions affect the effectiveness of conserving marine cultural heritage in Thanh Hoa, while clarifying the mediating role of overall tourism development (PT) and the moderating role of conservation policy (QT). The results show that tourism development policy, infrastructure, heritage-based products, community participation, and human resource quality all positively influence PT, with products and infrastructure

emerging as two prominent drivers. PT strongly affects conservation effectiveness, and most effects of the dimensions on conservation occur indirectly through PT. QT moderates in a strengthening direction, implying that when conservation policy is implemented effectively, tourism development is more clearly translated into conservation outcomes.

Based on these findings, the study recommends prioritizing the development of heritage-based tourism products in ways that enhance experiential value while protecting authenticity; investing in infrastructure and environmental infrastructure; improving human resource quality; promoting community participation and benefit sharing; and designing conservation policy to manage carrying capacity, strengthen monitoring and sanctions, and operate reinvestment mechanisms for conservation to ensure sustainable development linked with conservation.

The research possesses a number of limitations: (i) the cross-sectional and self-reported data might cause common method bias; (ii) due to refinement, the QT scale consisted of only two indicators that were observed; and (iii) the research was limited to one locality and therefore cannot be generalized. Even though QT once again was in the satisfactory CR and AVE values and the overall model fit was high, the few number of indicators possibly diminished the coverage of the construct in the content. The next generation of studies needs to extend the design both in time and in different destinations, include more objective data, and create/add more data on the QT, which should be re-evaluated on the scale of reliability and validity.

Assessment of the recreational potential of lakes in the Esil river basin (Within the north Kazakhstan region). *Geojournal of Tourism and Geosites*, 67(3), 2143–2152. https://doi.org/10.30892/gtg.67327-1839

Abstract: Lakes represent primary physiographic features that attract significant tourist flows. Their presence, distribution, hydrological regimes, hydrochemical profiles, and other characteristics serve as critical determinants for the development of the tourism industry. The lacustrine systems of the North Kazakhstan Region function as natural biomes for semiaquatic and aquatic nesting and migratory birds; furthermore, they contain concentrated stocks of ichthyofauna, therapeutic muds, sapropels, and brine (rapa). To date, a comprehensive assessment of the recreational potential of these lakes for integration into the tourism sector has not been previously conducted. This comprehensive evaluation encompasses four primary dimensions: functional, sanitary-hygienic, aesthetic, and technological. The assessment was based on an integrated analysis of ten criteria: morphometric, hydrological, hydrochemical, and hydrobiological indicators, as well as climatic factors, aesthetics, transport accessibility, current economic utilization, and the sanitary-ecological state. Each criterion comprised a specific set of variables. In total, 20 distinct parameters were examined, including: linear dimensions, surface area, water mass volume, mean depth, mineralization (salinity), average water and air temperatures, wind velocity, among others. Thirty-three key lakes within the Esil River basin were selected as focal points for this study. A specialized database was developed, and geoinformation mapping was performed using the ArcGIS 10.8 software suite. The evaluation employed a point-based scoring system. During the scoring process, the weight of each criterion was accounted for through the application of a significance coefficient. As a result of the study, the recreational potential of the region's lakes was determined, followed by their classification and physiographic regionalization based on suitability for the tourism sector. The obtained results allowed us to identify 5 levels of the recreational potential of the lakes of the studied region: low, below average, medium, increased/good high, very high. Specific types of tourist and recreational activities were proposed for designated lake clusters.

Keywords: lake, recreational potential, North Kazakhstan Region, assessment, Esil River basin

INTRODUCTION

In the modern scientific paradigm, the study of natural and recreational potential acquires strategic significance, forming the methodological basis for the development of the tourism industry. The transformation of tourism into a significant sector of the national economy and an instrument of sustainable development determines the growing need for comprehensive research aimed at assessing recreational potential (Wendt, 2020; Dmitriyev et al., 2025; Sagatbayev et al., 2025).

Lakes as multifunctional natural-territorial complexes possess significant recreational potential, determining their strategic importance for tourism development and sustainable regional development (Agybetova et al., 2023; Mukayev et al., 2020; Rakhimzhanova & Mussina, 2025). The recreational value of lake ecosystems is formed under the influence of a complex of natural and anthropogenic factors, creating unique conditions for the organization of various types of recreation, fishing, and health tourism (Akhmedenov, 2020; Valeyev et al., 2024; Tokpanov et al., 2021; Sagatbayev et al., 2019).

The hydrological characteristics of lakes, including temperature regime, duration of ice cover and swimming season, chemical composition of water and features of the coastline, act as key determinants of their recreational attractiveness (Sabri et al., 2025; Nazarova et al., 2019; Fomin et al., 2020). A review of international scientific publications led to the general conclusion about the need for a balanced approach combining the development of tourist infrastructure with the preservation of the natural environment and the introduction of sustainable methods of recreational stress management. The common denominator of all the work is the search for a balance between the economic development of lake territories and the ecological sustainability of their ecosystems (Gündüz, 2025; Rajkovic et al., 2025; Tessar, 2025). The natural and

recreational potential favorable to tourism development in the North Kazakhstan region is determined by the high concentration of lakes, and the region ranks first in Kazakhstan in terms of the number of lakes. According to the state register, the number of lakes with an area of more than 10 hectares is 2,328 water bodies (Dmitriyev et al., 2018).

The numerous lakes of the region have limited economic application, mainly for fishing and in isolated cases for the use of therapeutic mud for balneological purposes (Kolomin, 2004; Dmitriyev et al., 2023).

To date, the level of use of lake systems does not meet the potential capabilities of water bodies and has not been fully studied. In this regard, the research and comprehensive assessment of the recreational potential of lakes in the North Kazakhstan region is an urgent task. The objective of the study was to conduct a comprehensive assessment of the recreational potential of the lakes within the North Kazakhstan Region situated in the Esil River basin.

Study Object

In the study, 33 lakes located in the Yesil River basin were selected. The schematic map of the location of the lakes under consideration is presented in Figure 1.

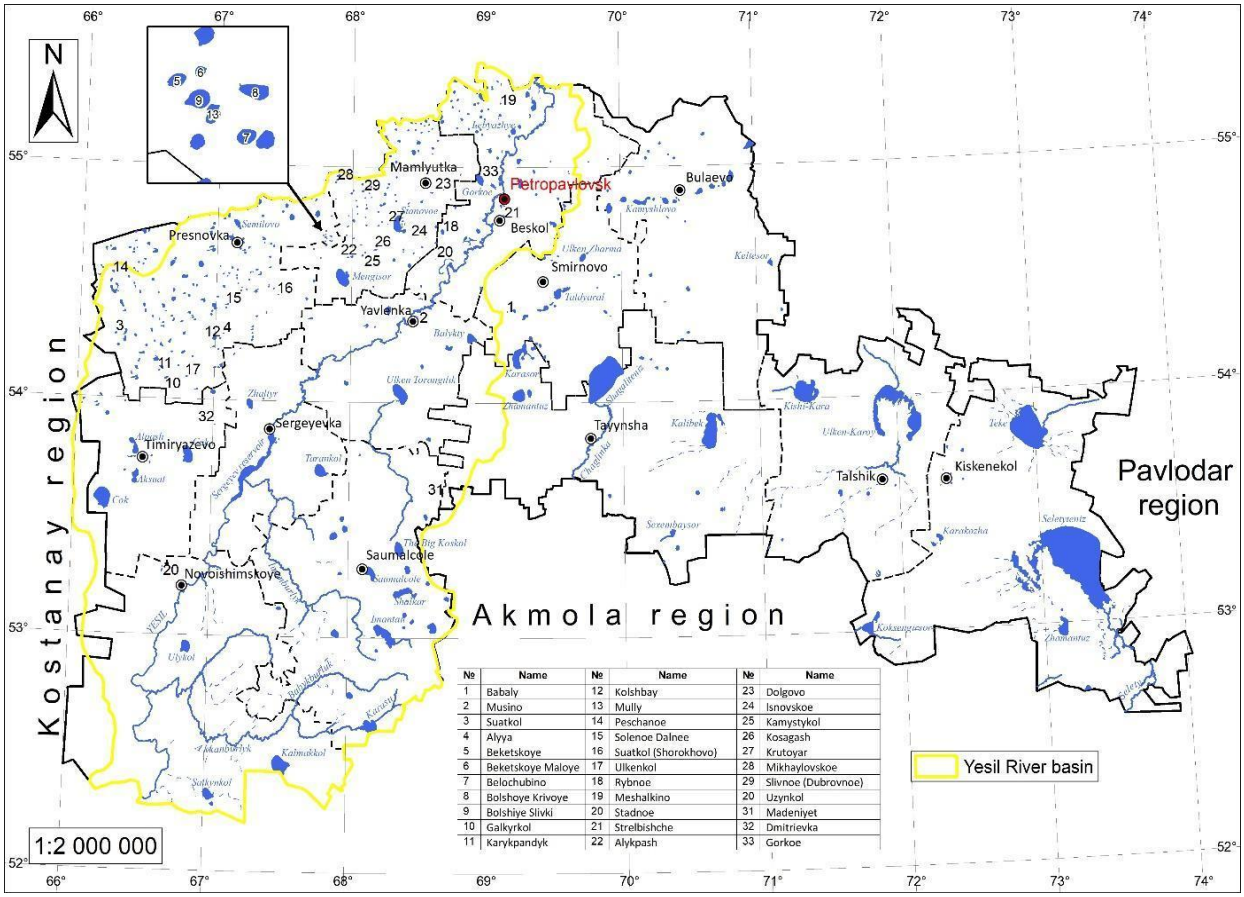

Figure 1. Schematic map of lakes locations (Source: developed by the authors)

The lakes are located within the boundaries of 9 administrative-territorial units of the North Kazakhstan Region (NKR): Akkaiynsky, G. Musrepov, Yesilsky, Zhambylsky, Kyzylzharsky, Mamlyutsky, Tayynshinsky, Timiryazevsky districts.

According to the genetic classification of lake basins, the lakes under consideration belong to the floodplain terraces of the Yesil River valley, floodplain, hollow-hilly-ridge types (Beletskaya et al., 2022). The source of nutrition for most lakes is the water mass coming from the catchment area during spring snowmelt. Underground waters play a small role in the hydrological regime of individual water bodies. The sizes of the lakes vary within significant limits from 3.1 ha Lake Madeniet (Tayynshinsky district) to 1,282 ha Lake Gorkoe (Kyzylzharsky district). For the most part, the lakes are small. By size, lakes can be grouped into small with an area not exceeding 10.0 ha; small, whose sizes vary within 10-50 ha (14 lakes - 43%); medium - 50-100 ha (12 lakes - 36%); large - 100-150 ha (4 lakes - 12%) and large - with an area exceeding 150 ha (3 lakes - 9%). The shape of the lakes is mainly oval. The bottom is flat with a gradual depression, usually covered with silty sediments. In some lakes, the bed is covered with organomineral accumulations (sapropel) (Kirillov et al., 2011; Dmitriyev et al., 2023). The slopes are low and gentle. The shores are slightly indented, accumulative.

Lakes are characterized by insignificant depth. Their maximum depth reaches 3 m - Lake Peschanoye (Zhambylsky district) and Lake Madeniet (Shunkyrkol) (Tayynshinsky district). The smallest depth indicator is noted on Lake Solenoe Dalnee (Zhambylsky district) - 0.55 m. The predominant part of lakes (15 or 45.5%) have depths from 1.0 to 2.0 m. Among the lakes under consideration, 15 (45.5%) have a depth from 2.1 to 3.0 m. The depth of 3 (9%) lakes does not exceed 1.0 m.

Due to the significant difference in the size and depth of lakes, the volume of their water mass varies from 0.095 million m³ Lake Madeniet (Shunkyrkol) (Tayynshinsky district) to 31.18 million m³ Lake Gorkoe (Kyzylzharsky district). According to this parameter, lakes are conditionally united into several groups: small, whose water mass volume does not exceed 1 million m³ (15 lakes - 45.5%); small - the volume of water mass is 1.1-2.1 million m³ (8 lakes - 24.2%); medium - the volume of water mass is equal to 2.1-4.0 million m³ (6 lakes - 18.3%), above average - 4.1-6.0 million m³ (3 lakes - 9%) and high-water - more than 6 million m³ (1 lake - 3%) (Dmitriyev et al., 2018). Most lakes are endorheic, and as a result, become final receivers of salts brought by surface runoff, groundwater and wind. The chemical composition of lake waters is characterized by great diversity and inconstancy of total mineralization and salt composition. Wide seasonal and multi-year fluctuations in salt concentration and their composition are associated with the extreme instability of the water regime of water bodies. The salinity of lakes sharply decreases during spring floods and increases by autumn, and in shallow lakes it also increases in winter due to ice formation. The mineralization of lake waters ranges from 141 mg/dm³ Lake Mully to 261,377 mg/dm³ Lake Solenoe Dalnee (Zhambylsky district). According to the degree of water salinity, the lakes under consideration can be divided into three groups: fresh - with mineralization up to 1 g/dm³, 20 lakes (61%) are assigned to this group; brackish - with mineralization from 1 to 25 g/dm³ - 12 lakes (36%), and hypersaline with mineralization more than 40 g/dm³ - 1 lake (3%). The indicator of water hardness of lakes differs significantly - from 2 meq./dm³ Alykpash (Mamlyutsky district) to 132.5 meq./dm³ Lake Solenoe Dalnee (Zhambylsky district). According to the degree of water hardness, lakes can be divided into 4 groups: with soft water - up to 4 meq/dm³, 9 lakes (27.3%) are assigned to this group; with water of medium hardness - from 4 to 8 meq/dm³ - 7 lakes (21.2%); with hard water - from 8 to 12 meq/dm³ - 9 lakes (27.3%); with very hard water - over 12 meq/dm³ - 8 lakes (24.2%). The value of oxidizability varies from 0.51 mg/dm³ Lake Belochubino to 35.6 mg/dm³ Lake Solenoe Dalnee (Zhambylsky district). For plain lakes, the values of permanganate oxidizability should not exceed 5-12 mg/dm³. For recreation, 15-30 mg/dm³ is allowed. In 13 (39%) lakes, this indicator exceeds the established norm, which indicates a high content of organic substances in the water.

The content of dissolved oxygen varies from 5.39 mg/dm³ Lake Stadnoe to 8.24 mg/dm³ Lake Gorkoe (Kyzylzharsky district). In general, the content of oxygen dissolved in water in lakes is favorable for most species of fish and invertebrates. The area of lake overgrowth differs significantly. The lowest rate of overgrowth is noted on Lake Gorkoe (Kyzylzharsky) - 3.2%, the highest on Lake Rybnoe (Zhambylsky district) - 98% (Dmitriyev et al., 2018; Kolomin, 2004).

Emergent and submerged plants play the main role in the overgrowth of water bodies. Among emergent plants, the leading place in the overgrowth of water bodies (in terms of area occupied and production of organic matter) belongs to common reed (*Phragmites australis*). In addition to reed, narrow-leaved cattail (*Typha angustifolia*) and lake rush (*Schoenoplectus lacustris*), flowering rush (*Butomus umbellatus*), common water-plantain (*Alisma plantago-aquatica*) and various species of sedge (*Carex* spp.) are of great importance in overgrowth.The degree of overgrowth of water bodies with aquatic vegetation is largely determined by the depth of the water body; the higher the depth, the lower the degree of overgrowth. This is explained by the biological characteristics of one or another species of aquatic vegetation. Thus, the most common type of rigid emergent vegetation - lake reed occupies areas with depths, as a rule, not exceeding 2.5 m. Among submerged plants, the leading place in lake overgrowth belongs to fennel pondweed (*Stuckenia pectinata*), shining pondweed (*Potamogeton lucens*), perfoliate pondweed (*Potamogeton perfoliatus*) and water milfoil (*Myriophyllum aquaticum*). The degree of overgrowth of water bodies with submerged vegetation changes not only by seasons of the year (its value reaches a maximum in July-August), but can differ greatly by years.

The hydrological regime of water bodies is generally favorable for the habitation of certain species of fish. The hydrochemical parameters of lakes are favorable for the habitation of certain species of fish, with the exception of Lake Solenoe Dalnee. The ichthyofauna is represented by 5 species from 2 families. Four species from the carp family (*Cyprinidae*) live in the lakes: silver crucian carp (*Carassius gibelio*), goldfish (*Carassius carassius*), roach (*Rutilus rutilus*) and tench (*Tinca tinca*), one species - Chinese sleeper (*Perccottus glenii*) from the sleeper family (*Odontobutidae*). The latter is non-commercial, acclimatized. The most widespread species is silver crucian carp. This species is native and has commercial significance. The wide distribution of this species in the lakes of the region is determined by the low requirement for the content of oxygen dissolved in water. There are no fish listed in the Red Book of Kazakhstan and the IUCN. Fish stocks in lakes vary within significant limits. The largest reserves (75.19 t) are noted in Lake Gorkoe (Kyzylzharsky district). The smallest volume of fish reserves among the lakes under consideration (0.531 t) was revealed in Lake Beketskoye (Zhambylsky district). In 4 lakes: Lake Stadnoe (Kyzylzharsky district), Lake Solenoe Dalnee (Zhambylsky district), Lake Kosagash (Mamlyutsky district), Lake Dmitrievka (Timiryazevsky district), not a single representative of ichthyofauna was caught, which indicates its absence in these water bodies.

Economic use and anthropogenic impact. The lakes under consideration are not included in the list of fishery water bodies and are not currently used for fishing and aquaculture purposes. A number of lakes are used for cattle watering (Lake Uzynkol, Musino, Isnovskoye, Mikhailovskoye, etc.). Many water bodies near settlements are used for water intake by filling special tanks (barrels) (Lake Mikhailovskoye, Isnovskoye, etc.) for watering gardens and household needs. Lake Gorkoe (Kyzylzharsky district) is part of the water supply facilities of Petropavlovsk city. It is a second-order storage pond for sewage treatment facilities of Limited Liability Partnership (LLP) (Kyzylzhar su LLP, 2025).

MATERIALS AND METHODS

Within the framework of the study, the recreational potential of lakes is considered as a set of natural, engineering-technical, ecological conditions and resources that are necessary to ensure the possibility of developing various types of recreational and tourist activities. Lakes as objects of recreation can be used for various types of recreation (beach-swimming,

fishing, walks, etc.). In this regard, the task of the study was not only to assess the recreational potential, but also to determine the most suitable type of recreation that can be recommended for the organization for the lakes under consideration.

To assess the recreational potential of North Kazakhstan Region lakes, a complex of criteria was determined, including morphometric, hydrological, hydrochemical, hydrobiological, sanitary-hygienic, aesthetic indicators and parameters.

A total of 20 evaluated parameters were selected: lake area, km²; average depth, m; volume of water mass, million m³; water mineralization, mg/dm³; water hardness, meq./dm³; oxidizability (permanganate), mg/dm³; dissolved oxygen in water, mg/dm³; overgrowth with emergent vegetation, %; fish resource reserves, t; diversity of ichthyofauna (species composition); character of the shore; character of the shallows (beach); approach to water; air temperature in summer during daytime, °C; air temperature in winter during daytime, °C; water temperature, °C; wind speed in summer and winter period, m/s; landscape diversity; transport accessibility, km; anthropogenic load. The assessment of the recreational potential of the region's lakes was carried out in 4 aspects: functional, sanitary-hygienic, aesthetic and technological. Lakes were evaluated from the standpoint of favorable conditions for the organization of recreational activities (presented in Figure 2).

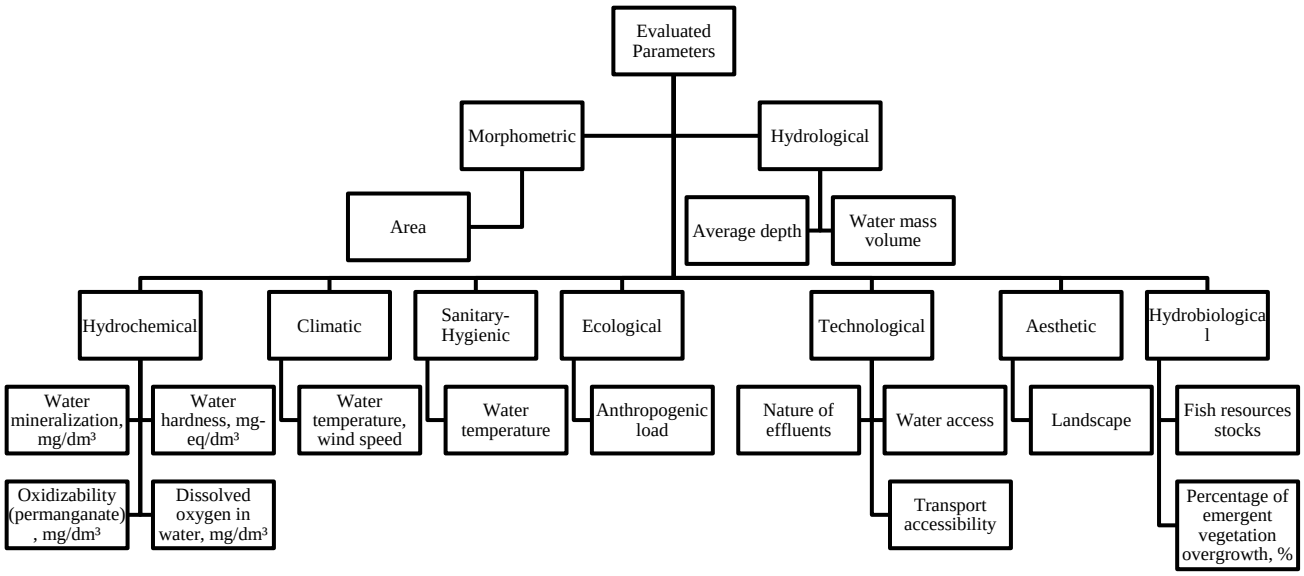

Figure 2. System of Evaluation Parameters and Indicators (Source: developed by the authors)

The necessary data for the assessment were obtained based on the analysis of available literary, cartographic materials, information provided by specialized institutions, as well as measurements and calculations carried out from satellite images, field research (2023-2025). The sources of initial data on morphometric, hydrological, hydrochemical, hydrobiological parameters of lakes were water body passports, hydrographic bulletins of the Branch of the Republican State Enterprise (RSE) "Kazhydromet" for the NKR, reports on the biological justification of lakes of the Communal State Institution (KSU) "Department of Natural Resources and Regulation of Nature Management of the Akimat of the NKR", Republican State Institution (RSU) "Yesil Basin Inspectorate for the Regulation of Use and Protection of Water Resources of the Committee on Water Resources of the Ministry of Ecology, Geology and Natural Resources of the Republic of Kazakhstan". The necessary climatic parameters were obtained based on the analysis of data from meteorological and climatic bulletins of the Branch of the RSE "Kazhydromet" for the North Kazakhstan Region for the period 2000-2024. Based on observations from meteorological stations and agricultural posts closest to the lakes, interpolation was used to calculate indicators of air temperature, wind speed for the warm and cold periods of the year (July, January) near the coastline and coastal zone of water bodies. Remote sensing data processing. To determine the surface temperature of water bodies, satellite images from the Landsat 8 satellite in the far infrared spectrum (Band 10) with wavelengths of 10.30-11.30 μm were used. Image processing consisted of the following stages:

1. The calculation of the spectral radiance of the upper atmospheric layers (Lλ) was performed in accordance with the official Landsat 8 radiometric calibration methodology published on the U.S. Geological Survey website (USGS, 2025):

$$L_\lambda = M_L \times Q_{cal} + A_L$$

where: L_λ - spectral radiance in channel 10, W/(m²·sr·μm); M_L - multiplicative coefficient (Radiance_Mult_Band_10); Q_{cal} - digital pixel value (DN) from Band 10 raster; A_L - additive coefficient (Radiance_Add_Band_10).

2. Calculation of brightness temperature of the upper atmosphere layers (USGS, 2025):

$$TB = K_2 / \ln(K_1/L_\lambda + 1)$$

where: TB - brightness temperature of the upper atmosphere layers, K; K_1, K_2 - thermal calibration constants; ln - natural logarithm; L_λ - spectral radiance in channel 10.

The implementation of this calculation was carried out in the Raster Calculator module of the ArcGIS software environment or similar spatial analysis tools. This formula allows converting digital pixel values from the raster (DN)

obtained from satellite images into a physically measurable quantity - radiance, expressed in watts per square meter per steradian per micrometer (presented in Figure 3). This is the first and necessary stage of thermal data calibration, without which it is impossible to conduct accurate temperature. The calculated brightness temperature (TB) is typically used as an intermediate metric for the subsequent determination of Land Surface Temperature. However, the obtained value does not reflect the physical properties of the underlying surface, particularly its emissivity. Therefore, to improve calculation accuracy and ensure physical interpretability, an additional correction accounting for the emissivity coefficient was applied.

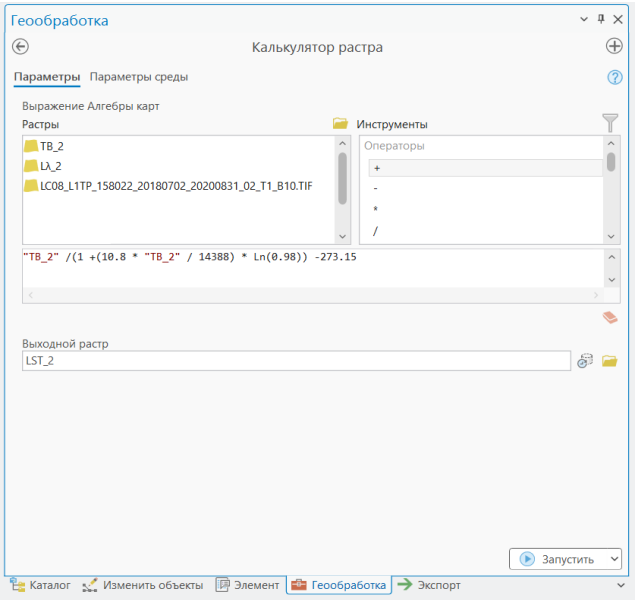

Figure 3. Example of a calculation in the Raster Calculator in ArcGIS Pro

3. Calculation of land surface temperature (LST):

At this stage, the formula for calculating land surface temperature (Land Surface Temperature, LST) was used, which allows converting brightness temperature into values close to the actual temperatures of land surface objects. This enabled a more accurate assessment of microclimatic conditions and facilitated a comparative analysis between different land cover types, including green spaces, water bodies, and residential areas (Le et al., 2015). To derive Land Surface Temperature (LST) from brightness temperature, a correction for surface emissivity is applied. The formula accounting for emissivity is presented below (Artis & Carnahan, 1982).

$$LST = \left(\frac{TB}{\left(1+\left(\lambda\times\frac{TB}{c_2}\right)\times ln\ln\left(\varepsilon\right)\right)}\right) - 273.15$$

where: LST - land surface temperature, °C; TB - brightness temperature of the upper atmosphere layers, K; λ = 10.8 μm - wavelength for Band 10 channel; c_2 = 14,388 μm·K - Planck's second constant; ε = 0.98 - surface emissivity coefficient; ln - natural logarithm (Artis et al., 1982; Kurolap et al., 2023).

Assessment methodology. The character of shallows and shores determine the ecological stability of the coastal strip and biodiversity of the coastal zone. Accessibility to water reflects the practical possibilities of using the lake for recreational purposes. Along with this, these characteristics ensure the safety, convenience and comfort of recreationists, the possibility of beach recreation. The above parameters were determined and evaluated during field research, as well as morphometric analysis of satellite images and photographs of water bodies. Landscape diversity is important for the visual perception of the lake and its surrounding landscape. This indicator was determined expertly during field research, as well as through visual perception and evaluation of a series of photographs of the water bodies under consideration.

Transport accessibility - the distance from the nearest paved road to the lake was calculated from satellite images (GoogleEarth) in the ArcGIS Pro program with clarification during field surveys. The evaluation parameters were collected and systematized in a single database. The latter was linked to the cartographic base. Geoinformation mapping of lakes was carried out using topographic maps with the involvement of electronic cartographic resources (GoogleEarth, Gis-lab.info, etc.). GIS mapping and spatial analysis was performed using the ArcGIS 10.8, ArcGIS Pro software package. To assess the level of recreational potential of the lakes, a composite (integrated) index (Ri) was applied, calculated using the Weighted Linear Combination (WLC) method, which is widely employed in multi-criteria spatial analysis (Malczewski, 1999; Eastman, 2012). The index was computed as the weighted average of the analyzed parameters, taking into account their relative significance. The calculation was performed using the following formula (USGS, 2025):

$$R_i = \sum k_i \sum a_i$$

where k_i - indicators of the i-th parameter, points; a_i - coefficient of importance of indicators k_i, unit fractions (weight) ($\sum a_i = 1$)

This approach allows simultaneously taking into account many factors affecting recreation comfort and obtaining comparable values for different water bodies. The assessment was carried out using a point system. Due to the fact that the selected parameters are characterized by significant heterogeneity, for the possibility of their comparison, absolute units of measurement were converted into relative ones (points). 5 points were assigned to the most favorable conditions for recreational use of lakes, 1 point - to unfavorable ones. Each evaluated indicator-parameter (i) was assigned a weight coefficient of significance (k_i), reflecting its contribution to the recreational use of lakes.

The methodology for determining the coefficient of significance included several steps. The significance of indicators was preliminarily evaluated expertly and ranked by 5 levels (very high, high, medium, low, etc.). Indicators were grouped into five blocks important for recreational use of lakes. Thus, indicators assigned to higher levels of significance received greater weights, less significant ones - smaller weights, while maintaining the overall consistency of the weight system. This ensured a certain hierarchy of evaluated parameters. The normalization of the initial indicators was carried out using the linear standardization method, whereby each parameter value was converted into a relative proportion within the overall set of analyzed indicators. This approach ensures the comparability of heterogeneous data (Malczewski, 1999). The calculation was performed using the following formula:

$$a_i = \frac{si}{\sum_{k=1}^{n} sk},$$

With this, $\sum a_i = 1$, which makes the weights comparable with each other. The higher the initial level of significance s_i, the greater the weight a_i, which means the stronger the influence of this indicator on the final recreational index.

The obtained values were normalized taking into account weight coefficients, and their sum became the resulting assessment of the recreational potential of lakes.

The following scale for assessing the recreational potential of lakes was adopted in the study (Table 1).

Table 1. Assessment of Recreational Potential of Lakes (Source: Developed by the authors, based on data from Kyzylzhar su LLP, 2025; USGS Landsat data USGS, 2025; RSE Kazhydromet, 2025)

Evaluation Criteria	Score Values					Weighting Coefficient
	5	4	3	2	1	
Area, km²	>150	150-100	100-50	50-10	<10.0	0.07
Average depth, m	>3.0	3.0-2.6	2.5-2.1	2.0-1.1	<1.0	0.09
Water mass volume, mln. m³	>6.0	6.0-4.1	4.0-2.1	2.0-1.1	<1.0	0.03
Water mineralization, mg/dm³	<1000.0	1000.1-1500.0	1500.1-2500.0	2500.1-4000.0	>4000.0	0.06
Water hardness, mg-eq./dm³	≤4.0	4.1-8.0	8.1-12.0	12.1-16.0	>16.0	0.03
Oxidizability (permanganate), mg/dm³	≤1.0	1.1-10.0	10.1-25.0	25.1-35.0	>35.0	0.03
Dissolved oxygen in water, mg/dm³	>8.0	8.0-7.1	7.0-6.1	6.0-5.1	≤5.0	0.06
Overgrowth percentage, %	≤5.0	5.1-10.0	10.1-25.0	25.0-50.0	>50.0	0.03
Fish resources stocks, t	>30.1	30.0-20.1	20.0-10.1	10.0-1.1	≤1.0	0.03
Air temperature in summer, °C	19.9	-	19.8	-	19.7	0.03
Air temperature in daytime during summer, °C	-15.9 and below	-	-16.0	-	-16.1 and below	0.02
Water temperature, °C	>25.1	25.0-24.1	24.0-23.6	23.5-23.1	<23.0	0.08
Wind speed during warm period, m/s	2.6	2.7	2.8	2.9	>3.0	0.02
Wind speed during cold period, m/s	2.6-2.8	2.9-3.1	3.2-3.4	3.5-3.7	3.8-4.0	0.02
Nature of shallow (beach)	Wide gentle shallow: bottom gradually deepens to 1.5-2 m from shore, further to 2.5-3 m, sandy-silty soil, with sandy-loamy soil, vegetation development is well-expressed.	Gentle shallow: shore depth 1.5-3 m with gradual deepening at 0.5-2 m from shore, sandy bottom with soil; participation of underwater vegetation in coastal strip, rocky sites, developped plant groupings, coastal vegetation is well-expressed.	Moderate shallow: shore depth increases from 0.5-2 m to 10-15 m from shore; stony-sandy bottom; vegetation varies; shore and underwater vegetation development; coastal plants are rare.	Steep shallow: shore depth reaches 5-10 m at 5-10 m from shore, stony or rocky bottom without vegetation; bank vegetation; water entry is polluted.	Shallow absent: shore overgrown, immediately >10 m depth; solid (boulders, rocks), without bank or aquatic vegetation, shoreline plants on adjacent areas.	0.05

Shore character	Low gentle shore (≤0.3-1 m height) with uniform natural vegetation cover (grasses, reed); sandy-silty substratum, bereg, shore relatively flat, minimally dissected.	Moderately gentle shore (≤1-1.5 m) with herbaceous vegetation; alternating grassy and reed sections interspersed with gallery-forest sections and reed areas.	Moderate elevation (1.3-2 m): alternating marshy and elevated shoreline sections; coastal vegetation varies; vegetation traces visible to eroded soils; shoreline vegetation is rare.	Steep shore (2-3 m): elevated and reinforced sections of the coastline, signs of erosion; overgrown with stone, gravel, shrubs (willow, birch); shore deeply dissected erosion.	Very steep or artificially reinforced shore (>3 m): denuded or covered with retaining walls or riprap structures; no or sparse vegetation.	0.05
Water access	Free access: equipped path, no dense vegetation, soft silty entrance (sand/silt), safe access for person and equipment.	Moderately free: there is grassy path or soft grassy area, minor areas of difficult access in water up to soft ground, accessible in most areas, small natural obstacles.	Difficult access: path present, shore overgrown (reeds, cattails, rushes), limited access, water entry requires overcoming natural obstacles.	Very difficult: dense marshy or culturally overgrown shore (marshes, bushes, dense undergrowth), possible access along shore, steep descent only from narrow paths.	Absent: shore strongly degraded or absent, shore impassable (silty marshes, floodland, bog), physical or legal barriers (restrictions); practically no access to water.	0.10
Multi-plan landscape	High: pronounced multi-plane relief – foreground (coastal-shore vegetation by promenade, near plains with coastal edge), middle plane (open water surface or lake, water elements), and background plane (distant trees, shrubs). Viewpoints: diverse, abundant colorful natural textures and contrasts.	Moderate: two-three planes for example, near lake and distant shore, or near shore and lake background, less variety, landscape elements present (shrubs, rare trees, poles).	Medium: one-two planes – open lake and shore or coastal shore with lake, possibly one dominant element (solitary landmark, prominent tree, shrub area).	Low: one plane only – monotonous flat or swampy area, single or two perspective plane elements (distinctive landmark, plains in visible surrounding areas).	Absent: absolutely flat landscape – single plane, swampy or artificially dominated elements; no distinctive elements, excessive agricultural use; lack of recreational spatial dominant elements.	0.04
Transport accessibility, km	<1.0	1.1-10.0	10.1-20.0	20.1-30.0	>30.1	0.07
Anthropogenic load	Absence of human impact signs: natural condition, no buildings, roads or dumps; water is clean, minimally affected by eutrophication.	Weak impact: insignificant anthropogenic changes or rare dispersed campsites - infrequent activities, sporadic parking, small-scale grazing or hay making, infrequent waste accumulation or footpath, trash, minor traces of livestock grazing.	Moderate impact: proximity of fields, pastures or villages; visible logging and waste dumpsites; moderate shoreline overgrowth and presence of noticeable trash accumulation, slight colored plant-related trash.	Strong impact: directly adjacent farms or land use or industrial facilities or roads; regular discharge (waste, wastewater), significant amounts of trash and traces of mass tourism, regulated canals, colored water.	Critical load: presence of heavy industrial or acute facilities directly adjacent to water; significant water surface pollution (waste, chemical, oil spills, discharge eutrophication), shore transformed into dump, ecosystem extremely polluted.	0.09

Table 2. Scale for assessing the recreational potential of North Kazakhstan Region lakes (Source: developed by the authors)

R Value	Level of Recreational Potential
< 2.0	Low
2.0-2.5	Below average
2.5-3.0	Medium
3.0-3.5	Increased/Good
> 3.5	High, Very high

RESULTS AND INTERPRETATION

The highest assessment score is for Lake Peschanoye - 3.52, the lowest for Lake Stadnoe - 2.38. The average indicator was 2.87 points. The result of the assessment of the recreational potential of lakes showed that most of the water bodies under consideration have a sufficiently high recreational potential, are favorable for various types of recreation. Peschanoye is the only lake assigned to the group with very high recreational potential. Good prospects for recreation development on this lake are associated with a favorable combination of conditions for organized recreation (morphometric, fish resource reserves, transport accessibility, etc.). This lake is popular among "wild" tourists. Increased recreational potential (>3.0) is

possessed by 8 lakes (24%) (Belochubino, Galkirkol, Karykpandyk, Meshalkino, Slivnoe-Dubrovnoe, Ulkenkol, Musino, Gorkoe). These lakes are characterized by favorable morphometric and climatic parameters, convenient approach to water, pronounced landscape attractiveness and moderate anthropogenic load, high prospects for recreation development.

The majority of lakes (15 or 46%) belong to the "medium" class of recreational potential (2.5-3.0), which indicates the presence of reserves for improving the quality of the recreational environment and developing infrastructure (Suatkol, Bolshie Slivki, Bolshoe Krivoe, Maloe Beketskoye, Mully, Kamystykol, etc.).

Below average (2.0-2.5) received an assessment of 6 (18%) lakes (Strelbishche, Isnovskoye, Dolgovo, Mikhailovskoye, Suatkol-Shorokhovo, Kolshbay). Low recreational potential (<2.0) is characterized by 3 lakes (9%) (Solenoe Dalnee, Alykpash, Stadnoe). The main factors that determined insufficiently favorable conditions for recreational activity are: increased water hardness, inconvenient approach to water, high overgrowth, anthropogenic load, etc. (Figure 4).

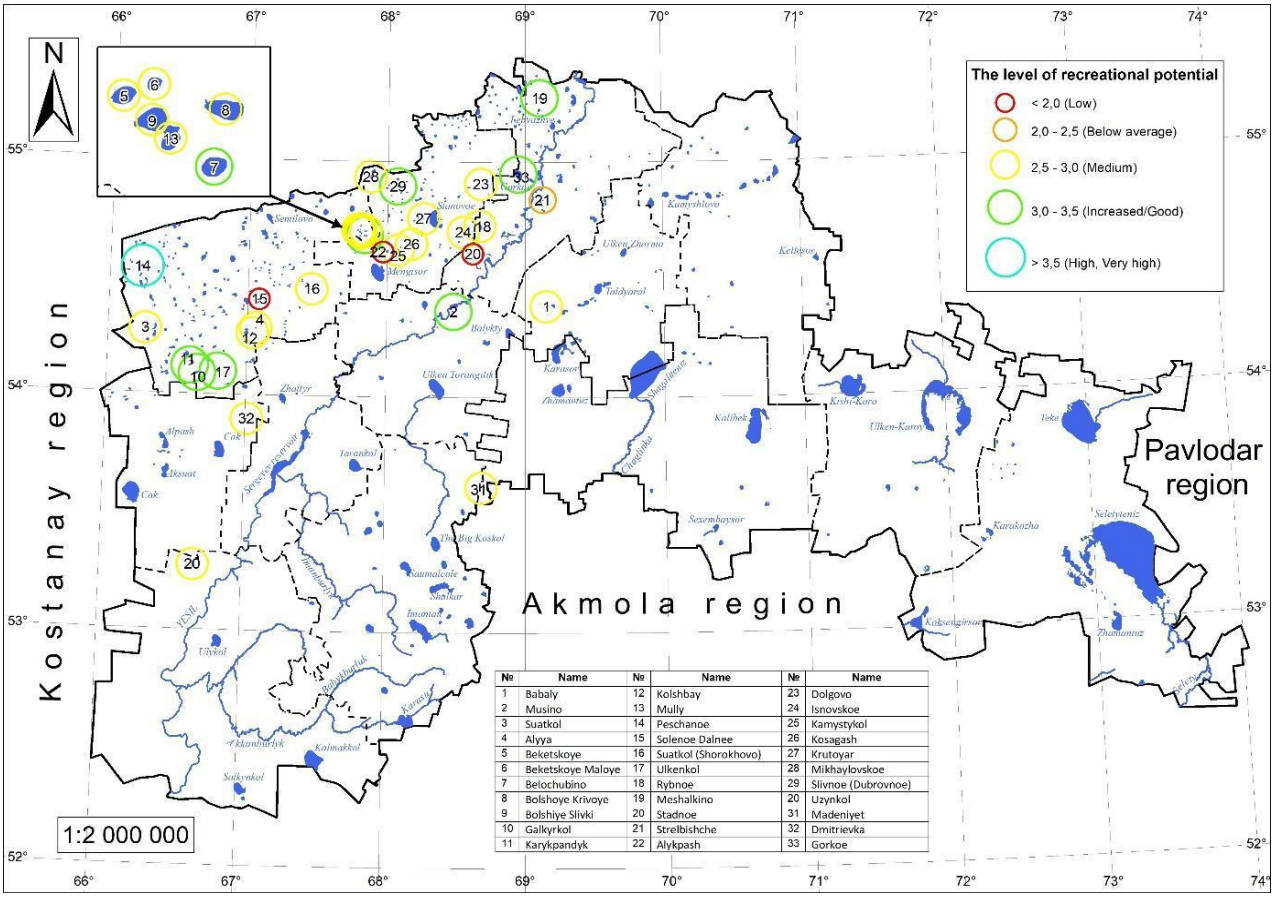

Figure 4. Map of assessment of recreational potential of North Kazakhstan Region lakes (Source: developed by the authors)

Recommended types of tourism activities

For lakes characterized by increased recreational potential, a list of recommended types of tourist and recreational activities and the most suitable season (period) for their organization and conduct were determined. For the summer period: beach-swimming, fishing, walking-excursion, boat riding, event tourism (Ivan Kupala, fisherman's day), ecological trails. For the winter period: ice fishing, walking-excursion, sledding, skating, skiing, winter swimming (walrus swimming), event tourism (Epiphany). According to hydrological parameters and fish reserves, the following can be included in the group of lakes for organizing recreation of local significance (fishing, swimming): Lake Musino, Lake Beketskoye, Lake Bolshie Slivki, Lake Galkirkol, Lake Karykpandyk, Lake Peschanoye, Lake Suatkol, Lake Suatkol (Shorokhovo), Lake Ulkenkol, Lake Meshalkino, Lake Karabul, Lake Dolgovo, Lake Isnovskoye, Lake Kosagash, Lake Mikhailovskoye, Lake Slivnoe (Dubrovnoe); Lake Stadnoe, Lake Dmitrievka (the last two lakes - swimming only).

For the organization of sport (amateur) fishing of local significance, Lake Madeniet (Shunkyrkol) can be recommended.

A number of lakes have relatively large fish reserves, which can contribute to the development of commercial tourism here. The following can be included in the group of fishery water bodies of local significance for commercial fishing: Lake Uzynkol, Lake Alya, Lake Beketskoye Maloe, Lake Belochubino, Lake Bolshoe Krivoe, Lake Kolshbay, Lake Strelbishche, Lake Alykpash, Lake Kamystykol and Lake Krutoyar. Lakes with increased mineralization can be used for local salt extraction, balneotherapy and treatment of skin diseases, joints (Lake Madeniet, Lake Kosagash, Lake Solenoe Dalnee). Small lakes in size can be used for recreation primarily by local residents living in nearby villages. Medium and large lakes have higher potential for the development of various types of health and sports recreation and are able to meet the demand for recreational services of residents not only of local residents, but from nearby districts and regions.

Lake Gorkoe should not be included in the list of water bodies for organizing recreational activities. This water body is part of the water supply and sewerage facilities of Petropavlovsk. It is a second-order storage pond for sewage treatment facilities of Limited Liability Partnership (LLP) "Kyzylzhar Su" Limiting factors. The following unfavorable (limiting) factors for the development of recreational activities on the lakes under consideration were identified: Most water bodies are located at an insignificant distance from settlements, experiencing anthropogenic impact. The catchments are heavily plowed, limited by the road network, which unfavorably affects the hydrological and hydrochemical regime.

Significant overgrowth of lake surfaces limits approach to water, acts as an unfavorable factor for organizing beach-swimming recreation, water walks, fishing, reduces visibility. On the other hand, aquatic plants protect coastal areas of lakes from wind well, reduce wave speed. In a number of the lakes under consideration, ichthyofauna was not detected (Lake Stadnoe, Lake Kosagash, Lake Dmitrievka), which excludes them from the list of water bodies for organizing such a type of recreation as fishing. A number of lakes are characterized by an unfavorable hydrological regime and cannot be recommended for use as recreation objects (Lake Babaly, Lake Mully, Lake Rybnoe). These water bodies can be used for recreation (fishing, swimming) only in case of restoration of a favorable hydrological regime.

CONCLUSION AND FINDINGS

An assessment of the recreational potential of lakes was carried out using a complex of criteria. Of the 33 lakes under consideration, 24 (73%) have sufficient potential for organizing recreational activities on them. On 6 lakes, anthropogenic impact and any types of nature management should be limited until their hydrological and other parameters improve. 3 lakes have low potential and are not recommended for inclusion in recreational nature management.

Based on the assessment results, measures for the development of recreation (tourism) on these lakes were proposed.

Recommendations

Infrastructure development: The reconstruction of existing and construction of new dirt roads and access roads to lakes is necessary. This work should be carried out by relevant services and regional administrations. Almost all water bodies need clearing of shores from reed and rush thickets. Hydrological restoration: On lakes: Lake Babaly, Lake Mully, Lake Rybnoe, restoration of the hydrological regime is required. This work should be carried out by relevant services.

Tourism infrastructure: For lakes characterized by sufficiently high recreational potential, it is necessary to: create safe swimming zones, equip convenient descents to water, install information stands, navigation. Organization of tourist infrastructure is required: light modular changing rooms, gazebos, canopies, benches, picnic areas, toilets, installation of trash bins, garbage tanks (containers) for waste, regular cleaning in the recreation zone. Ecological tourism: The development of ecological and educational tourism is promising: development of eco-trails around lakes with a description of natural features, observation of landscapes, local flora and fauna, creation of observation points with minimal interference with nature.

It is possible to include a number of lakes in tourist routes of the NKR, develop excursions "Lakes of the North Kazakhstan Region". Fishing tourism: On lakes that have potential for sport (amateur) fishing, it is necessary to create places for fishermen to stay, develop fishing routes. Monitoring and regulation: An important aspect of effective and ecologically balanced organization of recreational and tourist activities on lakes is its regulation taking into account the structure and features of their recreational potential, compliance of recreational infrastructure with the ecological capacity of aquatic and terrestrial natural-territorial complexes. A mandatory condition is periodic monitoring of overgrowth, the eutrophication process, oxygen regime of lakes, conducting periodic microbiological and toxicological studies. Educational use: Lakes with low recreational potential are inappropriate to consider as tourist objects of mass visitation. Possible use for ecological-educational purposes. Ecological-educational routes. School excursions on topics of hydrobiology, ecosystem processes, overgrowth of water bodies.

Abstract: Community-based ecotourism (CBET) has been increasingly promoted as a strategy to reconcile biodiversity conservation with livelihood improvement in protected areas, particularly in climate-vulnerable coastal wetlands. This study examines the potential of CBET as a driver of sustainable local livelihoods in Xuan Thuy National Park, Vietnam—a Ramsar-listed coastal wetland of international ecological importance. Using a mixed-methods approach, the study integrates household perception analysis with econometric modeling to assess community readiness for CBET development. Primary data were collected from a structured survey of 320 households in buffer-zone communes surrounding the park. A Sustainability Perception Index was constructed to capture community perceptions across environmental, socio-cultural, economic, and institutional dimensions, while a binary logistic regression model was employed to identify key determinants of household willingness to participate in CBET. The results reveal strong environmental and socio-cultural support for ecotourism, moderate economic expectations, and notably weak institutional confidence. Livelihood diversification emerges as the most robust determinant of participation willingness, followed by prior tourism experience, highlighting the importance of economic resilience and experiential capacity. In contrast, environmental awareness and institutional trust alone are insufficient to motivate participation. The findings underscore the need for livelihood-integrated, capacity-building, and governance-oriented CBET strategies to enhance community engagement and align conservation objectives with sustainable development in coastal wetland protected areas.

Keywords: community-based ecotourism, coastal wetlands, livelihood diversification, participation willingness, Ramsar site

INTRODUCTION

Ecotourism has increasingly been recognized as a development pathway capable of reconciling biodiversity conservation with socio-economic improvement, particularly in environmentally sensitive and protected areas. As a form of tourism that emphasizes minimal ecological impact, environmental education, and meaningful local participation, ecotourism has been widely documented to generate employment, diversify rural livelihoods, and contribute to conservation outcomes when appropriately designed and governed (Weaver & Lawton, 2007; Fennell, 2025; Buckley, 2012). Within this framework, community-based ecotourism (CBET) has emerged as a distinctive model that prioritizes local ownership, participatory decision-making, and equitable benefit-sharing, thereby aligning conservation objectives with community development goals (Scheyvens, 1999; Stronza & Gordillo, 2008).

In coastal wetland regions, ecotourism also serves as a potential climate adaptation strategy by reducing reliance on climate-sensitive livelihoods such as aquaculture, capture fisheries, and salt production. These livelihood systems are increasingly threatened by sea-level rise, saline intrusion, coastal erosion, and extreme weather events associated with climate change (Adger, 2000; IPCC, 2022). By promoting diversified income sources and conservation-compatible activities, CBET can enhance household resilience while simultaneously supporting ecosystem-based adaptation, particularly in mangrove-dominated landscapes that provide critical climate-regulating services, including coastal protection and carbon sequestration (Alongi, 2008; Barbier et al., 2011).

Vietnam hosts a dense and ecologically diverse network of protected areas, yet many remain weakly integrated into local development processes and livelihood strategies. Xuan Thuy National Park (XTNP), located in the Red River Delta of Nam Dinh Province, exemplifies this challenge. As Vietnam's first Ramsar site, XTNP supports internationally significant mangrove ecosystems and serves as a vital stopover for migratory waterbirds along the East Asian–Australasian Flyway. At the same time, communities in the surrounding buffer zone remain highly dependent on climate-sensitive and

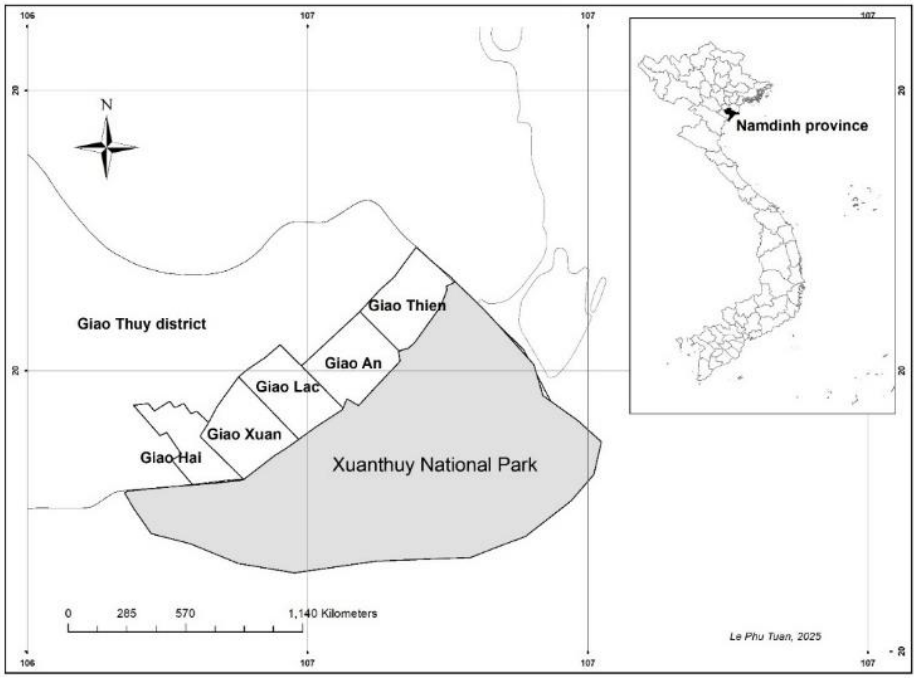
resource-based livelihoods, rendering them particularly vulnerable to environmental and economic shocks. This duality highlights the need for development approaches that simultaneously support biodiversity conservation and strengthen community resilience. Consistent with this need, Tuan et al. (2025) identified XTNP as having high potential for community-based ecotourism through an Analytic Hierarchy Process (AHP) assessment. However, their study focused on evaluating development potential and did not examine household willingness to participate or the socio-economic determinants of CBET participation, leaving these important issues largely unexplored.

In recent years, research on community-based ecotourism (CBET) has increasingly emphasized its role in linking biodiversity conservation with sustainable livelihood development in protected areas. Empirical studies across Asia and Africa indicate that CBET can generate local income, strengthen conservation incentives, and improve community resilience to environmental change (Benu et al., 2020; Khan et al., 2021; Jin et al., 2024; Gayo et al., 2025). However, the success of CBET initiatives varies widely depending on governance structures, community empowerment, and benefit-sharing mechanisms. For example, Luc et al. (2026) found that community participation significantly enhances tourism sustainability outcomes in rural Vietnam, while Stone & Stone (2022) highlight that weak institutional capacity and unequal benefit distribution remain major barriers to CBET success in protected areas. Similarly, Desalegn & Javed (2024) demonstrate that residents' empowerment and perceived economic benefits are key drivers of community support for tourism development. Despite these advances, recent reviews note that many CBET projects continue to struggle with governance fragmentation, limited financial sustainability, and inadequate integration of community perspectives into tourism planning (Botero et al., 2025; Casimiro et al., 2023; Paulus et al., 2023).

Recent scholarship increasingly emphasizes that the success of ecotourism initiatives depends not only on natural resource endowments or spatial suitability, but also on community perceptions, institutional readiness, and willingness to participate (Kiss, 2004; Nunkoo & Ramkissoon, 2011). Sustainable tourism theory conceptualizes tourism as a long-term process that must maintain ecological integrity while delivering enduring socio-economic benefits (Butler, 1999). Within CBET research, empowerment—across economic, social, psychological, and political dimensions—has been identified as a central criterion for evaluating success and sustainability (Scheyvens, 1999). Empirical studies consistently demonstrate that local support and participation are critical determinants of ecotourism outcomes, and that high environmental awareness alone is insufficient if communities lack trust in institutions or meaningful opportunities to influence governance and benefit-sharing arrangements (Stronza & Gordillo, 2008; Bennett & Dearden, 2014).

Several recent studies have examined community participation and livelihood outcomes associated with ecotourism in protected areas. In China, Xu & Hu (2021) demonstrated that community participation strengthens residents' support for tourism while encouraging environmentally responsible behavior. Qin et al. (2021) further showed that perceived economic benefits and positive tourism impacts are important determinants of residents' support for tourism development. In Nepal, Khatiwada (2022) found that community-based ecotourism enhances local participation, equitable benefit sharing, and rural livelihoods through homestay tourism. More recently, research from the Annapurna Sanctuary Trail indicated that ecotourism promotes livelihood diversification, social equity, and community participation, although challenges related to income inequality and governance remain (Tiwari & Nguyen, 2024). Nevertheless, empirical evidence from Ramsar wetland protected areas remains scarce, particularly in Vietnam, where the socioeconomic and governance contexts differ substantially from those reported in existing studies.

In developing-country contexts, CBET initiatives often face persistent challenges related to weak governance, externally driven project design, unequal benefit distribution, and limited inclusion of women and vulnerable groups (Kiss, 2004; Tosun, 2006). In Vietnam, CBET has expanded in both mountainous and coastal regions, yet implementation remains uneven due to institutional fragmentation and limited integration of community perspectives into tourism planning. In the case of Xuan Thuy National Park, existing research has largely focused on biodiversity conservation and climate vulnerability, with comparatively limited attention to community willingness, perceived benefits and concerns, and the institutional feasibility of CBET development.



Although the existing literature provides important insights into the relationship between ecotourism development and local livelihoods, several limitations remain. First, many studies focus primarily on environmental or economic outcomes while paying limited attention to the institutional conditions that influence community participation. Second, previous research frequently relies on qualitative case studies or descriptive approaches, which may limit the ability to quantitatively identify determinants of household participation in ecotourism activities. Third, relatively few studies examine CBET in coastal wetland protected areas, where communities face unique climate risks and livelihood vulnerabilities associated with sea-level rise, salinity intrusion, and extreme weather events. These gaps highlight the need for empirical studies that combine perception analysis with econometric modelling to better understand the socio-economic drivers of community participation in CBET initiatives.

Against this background, the primary objective of this study is to evaluate the potential of community-based ecotourism (CBET) to support sustainable local livelihoods in a coastal wetland protected area, using Xuan Thuy National Park in Vietnam as a case study. Specifically, the study aims to (1) assess community perceptions of ecotourism sustainability across environmental, socio-cultural, economic, and institutional dimensions; (2) examine perceived benefits and concerns related to CBET development; and (3) identify key socio-economic determinants influencing household willingness to participate in CBET using a binary logistic regression model. By integrating perception analysis with econometric modelling, the study contributes to the growing literature on sustainable tourism governance and provides policy-relevant insights for promoting inclusive ecotourism development in climate-vulnerable coastal wetland protected areas.

MATERIALS AND METHODS

Study Area

Xuan Thuy National Park, also known as the Xuan Thuy Ramsar Site, is in Nam Dinh province. It was the first wetland in Southeast Asia designated under the Ramsar Convention in 1989. In 2003, it was officially upgraded to a national park, and in 2004, UNESCO recognized it as the core zone of the Red River Delta Biosphere Reserve. Recently, the Ministry of Natural Resources and Environment proposed its nomination as an ASEAN Heritage Park, aiming to enhance protection and regional significance. Covering approximately 7,100 hectares, the park includes core protection areas, buffer zones, and transition zones. The ecosystem consists of estuarine mudflats, mangrove forests, tidal creeks, and coastal sandbars, providing habitat for over 200 bird species. Figure 1 illustrates the location of Xuan Thuy National Park together with representative landscapes of its mangrove ecosystems and intertidal wetlands that support numerous migratory waterbirds.Communities in the buffer zone rely primarily on aquaculture (clam and shrimp farming), capture fisheries, salt production, and small-scale agriculture. These livelihoods are highly exposed to climatic and market risks, creating strong incentives for diversification through non-extractive activities such as ecotourism.

Figure 1. Some pictures from the study area (a) Location of Xuan Thuy National Park (Tuan et al., 2025); (b) Mangrove ecosystems in Xuan Thuy National Park(c) Intertidal wetland habitat supporting migratory waterbirds in Xuan Thuy National Park

Household Survey

A structured household survey was conducted between August and October 2025 in the buffer-zone communes surrounding Xuan Thuy National Park. A total of 320 households were selected using a stratified random sampling approach to ensure adequate representation across communes and key socio-economic groups.

The questionnaire comprised three main components: (i) 20 Likert-scale items assessing household perceptions of ecotourism sustainability across multiple dimensions; (ii) binary and ordinal questions capturing household willingness to participate in community-based ecotourism (CBET); and (iii) a set of questions examining perceived benefits and concerns associated with ecotourism development.

Sustainability Perception Index

To quantify household perceptions of ecotourism sustainability, a Sustainability Perception Index (SPI) was constructed for each sustainability dimension following established practices in perception-based tourism and sustainability research (Likert, 1932; Nunkoo & Ramkissoon, 2011; Bennett & Dearden, 2014). For each dimension *d*, the index was calculated as the arithmetic mean of the corresponding perception items:

$$SPI_d \frac{1}{n_d} \sum_{i=1}^{n_d} x_i \qquad (1)$$

Where: SPI_d denotes the sustainability perception index for dimension *d*, x_i represents the score of item *i*, and n_d is the total number of items used to measure that dimension. All items were measured on a five-point Likert scale, with higher values indicating stronger agreement and more positive perceptions of ecotourism sustainability.

This aggregation approach allows for a standardized and comparable assessment of household perceptions across environmental, socio-cultural, economic, and institutional dimensions, and has been widely applied in studies examining residents' attitudes toward tourism development and protected area management (Butler, 1999; Stronza & Gordillo, 2008).

Binary Logistic Regression Analysis

To identify the determinants of household willingness to participate in community-based ecotourism (CBET), a binary logistic regression model was estimated. The dependent variable, Willingness to participate, was coded as 1 = willing and 0 = not willing or conditionally willing. Independent variables were selected based on the literature on community-based tourism and preliminary descriptive analysis and include gender, education, household income, livelihood diversification, environmental awareness, prior tourism experience, and institutional trust (Table 1).

The binary logistic regression model can be expressed in its basic form as (Hosmer et al., 2013):

$$Ln\left(\frac{P_i}{1-P_i}\right) = \beta_0 + \beta_1 Female_i + \beta_2 Education_i + \beta_3 Income_i + \beta_4 Diversified\_Livelihood_i + \beta_5 Envi\_Awareness_i + \beta_6 Tourism\_Experience_i + \beta_7 Instututional\_Trust_i \qquad (2)$$

where P_i is the probability that household *i* is willing to participate in CBET, β_0 is the intercept, and β_k (k=1,…,7) are the corresponding coefficients. Exponentiating the coefficients yields odds ratios (ORs), which indicate the change in the odds of women's leadership participation associated with a one-unit change in each predictor, holding other variables constant (Long & Freese, 2014).

Table 1. Definition and measurement of variables used in the binary logistic regression model

Variable name	Type	Definition	Measurement / Coding
Willingness to participate in CBET (willing_cbet)	Dependent	Household's expressed willingness to participate in community-based ecotourism activities (e.g., homestay, guiding, food services, conservation support)	Binary variable: 1 = willing to participate; 0 = not willing or conditionally willing
Female respondent (female)	Independent	Gender of the main survey respondent representing the household	Binary variable: 1 = female; 0 = male
Education (years) (education)	Independent	Human capital of the respondent measured by formal schooling	Continuous variable: number of completed years of education
Income (income)	Independent	Economic capacity of the household	Continuous variable: monthly household income (million VND)
Diversified livelihood (diversified_livelihood)	Independent	Whether the household engages in more than one income-generating activity (e.g., aquaculture + farming + services)	Binary variable: 1 = diversified livelihood; 0 = single livelihood
Environmental awareness index (environmental_awareness)	Independent	Household awareness of environmental values, conservation importance, and ecosystem services of XTNP	Composite index (Likert scale 1–5), calculated as the mean score of environmental awareness items
Prior tourism experience (tourism_experience)	Independent	Household's previous involvement in tourism-related activities	Binary variable: 1 = has tourism experience; 0 = no experience
Institutional trust index (institutional_trust)	Independent	Level of trust in local authorities, park management, and tourism-related institutions	Composite index (Likert scale 1–5), calculated as the mean score of institutional trust items

RESULTS

Community Perceptions of Ecotourism Sustainability

Figure 2 presents the mean scores of community perceptions of ecotourism sustainability across four key dimensions—environmental, socio-cultural, economic, and institutional—based on responses from 320 surveyed households. Among these dimensions, environmental sustainability received the highest mean score (4.28), indicating a strong level of environmental awareness and widespread recognition of the ecological importance of mangrove ecosystems and migratory

bird habitats within Xuan Thuy National Park. This finding reflects a high degree of local sensitivity to conservation values and the perceived role of ecotourism in supporting environmental protection. Socio-cultural sustainability also scored highly (mean = 4.01), suggesting strong social cohesion, well-established traditions of collective action, and a generally positive perception of community-based engagement in ecotourism activities. These social attributes constitute an important foundation for the successful implementation of community-based ecotourism initiatives. In contrast, perceptions of economic sustainability were more moderate (mean = 3.34). This indicates cautious expectations regarding income generation and livelihood benefits from ecotourism, possibly reflecting uncertainty about market access, revenue stability, or the distribution of economic gains among households. The institutional dimension recorded the lowest mean score (2.39), highlighting limited trust in governance structures, institutional support, and management effectiveness related to ecotourism development. This comparatively weak institutional confidence underscores a critical challenge for the long-term sustainability of ecotourism initiatives, as effective governance and transparent coordination mechanisms are essential for translating positive environmental and social perceptions into sustained economic outcomes. Overall, the results reveal a clear hierarchy of sustainability perceptions, with strong environmental and socio-cultural foundations, moderate economic expectations, and persistent institutional constraints shaping community views on ecotourism development.

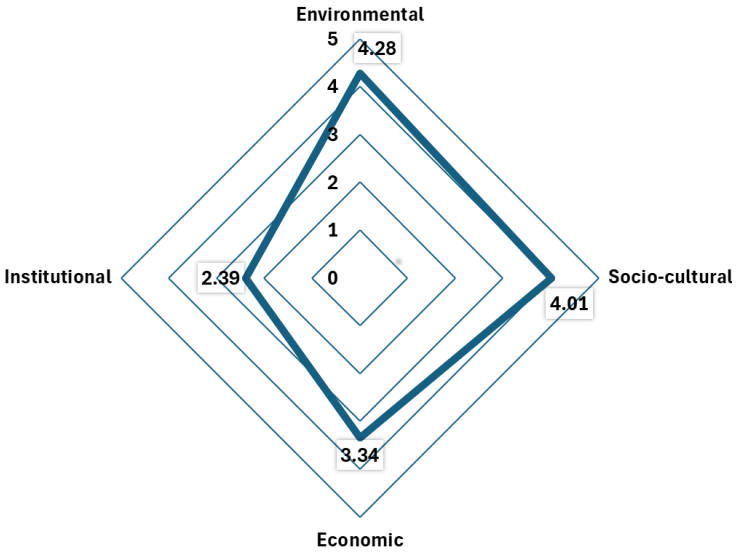

Figure 2. Sustainability perception scores across four dimensions

Perceived Benefits and Concerns Related to Ecotourism

Survey respondents identified a range of perceived benefits and concerns associated with the development of community-based ecotourism (CBET) in Xuan Thuy National Park. As shown in Figure 3, economic benefits were most frequently cited, with income diversification reported by 72.4% of households and local job creation by 64.8%.

These findings indicate strong expectations that ecotourism could contribute to livelihood enhancement and reduce dependence on climate-sensitive economic activities. Beyond economic considerations, a substantial proportion of respondents acknowledged environmental benefits, with 61.0% recognizing the role of ecotourism in supporting biodiversity conservation and ecosystem protection. Nearly half of the surveyed households (49.5%) also perceived cultural preservation as a potential benefit, suggesting that ecotourism is viewed not only as an economic opportunity but also as a means of sustaining local traditions and community identity. Despite these positive perceptions, significant concerns were also expressed, particularly with respect to equity and governance. Almost half of the respondents (46.2%) were concerned about the unequal distribution of benefits, reflecting apprehension that ecotourism revenues may be captured by a limited number of actors.

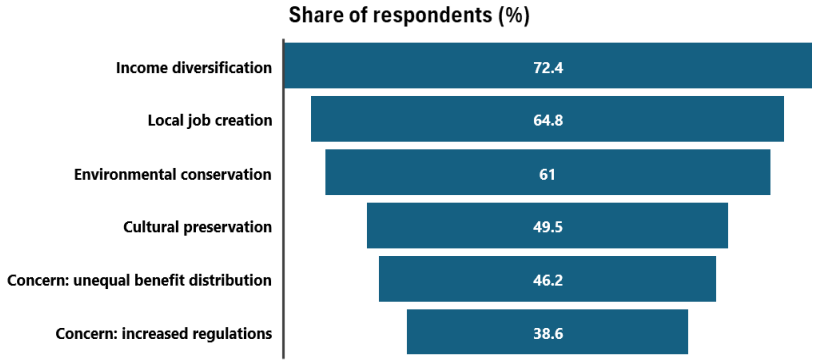

Figure 3. Perceived benefits and concerns of ecotourism development

Additionally, 38.6% of households expressed concern over increased regulations, which may impose constraints on traditional livelihood activities or exacerbate existing institutional burdens.

Overall, the results reveal a nuanced perception of ecotourism development: while communities recognize its potential economic, environmental, and cultural benefits, they remain cautious about governance arrangements and the fairness of benefit-sharing mechanisms. These concerns underscore the importance of inclusive planning, transparent management, and equitable distribution strategies in the design and implementation of CBET initiatives.

Determinants of Household Willingness to Participate in Community-Based Ecotourism

Table 2 reports the results of the binary logistic regression analysis examining the determinants of household willingness to participate in community-based ecotourism (CBET) in Xuan Thuy National Park. The overall model is statistically significant based on the likelihood ratio χ^2 test (Prob > χ^2 = 0.0050), indicating that the included explanatory variables jointly explain variations in household participation decisions. The McFadden Pseudo R^2 value is 0.1462, suggesting a modest yet acceptable level of explanatory power. In social and environmental studies, pseudo R^2 values in the range of 0.10–0.20 are commonly reported and reflect the complex nature of human behavior, particularly in household-level participation decisions shaped by multiple unobserved social and contextual factors (Menard, 2000).

Table 2. Binary logistic regression results for willingness to participate in CBET

Variable	B = ln(OR)	Odds Ratio	SE	p-value
(female)	0.784	2.191	1.162	0.139
(education)	0.108	1.114	0.097	0.217
(income)	0.189	1.208	0.171	0.180
(diversified_livelihood)	1.870	6.487	4.258	0.004
(environmental_awareness)	0.495	1.641	0.941	0.388
(tourism_experience)	1.242	3.462	2.306	0.062
(institutional_trust)	–0.072	0.931	0.428	0.875
Constant	–2.645	0.071	0.212	0.374
• Prob > chi2 = 0.0050 • Pseudo R^2 = 0.1462				

Among the explanatory variables, livelihood diversification emerges as the strongest and most robust determinant of willingness to participate in CBET. Households with diversified income sources are significantly more likely to express willingness to engage in ecotourism activities, with an odds ratio of 6.49 ($p < 0.01$). This finding suggests that households already engaged in multiple livelihood strategies perceive CBET as a complementary opportunity rather than a risky or uncertain economic shift. Tourism experience also exhibits a positive effect on participation willingness, with households possessing prior tourism-related experience being more than three times as likely to participate compared to those without such experience (OR = 3.46). Although this effect is only marginally significant ($p < 0.10$), it highlights the importance of experiential learning and familiarity with tourism operations in shaping engagement decisions.

The coefficients for female respondents, education, and household income are positive, indicating that gender and human and financial capital may facilitate participation in CBET. However, these effects are not statistically significant at conventional levels in the current model, suggesting that their influence may operate indirectly or in interaction with other socio-institutional factors. Similarly, environmental awareness shows a positive association with willingness to participate, implying that conservation values and ecological understanding may encourage engagement in ecotourism. Nevertheless, the effect is not statistically significant, indicating that pro-environmental attitudes alone are insufficient to translate into active participation without supportive economic and institutional conditions.

In contrast, institutional trust does not exhibit a meaningful effect on household willingness to participate in CBET, as reflected by its small and statistically insignificant coefficient. This result suggests that limited confidence in local institutions does not necessarily discourage initial participation, although it may have implications for the long-term sustainability and governance of CBET initiatives.

The estimated logistic regression model can be expressed as (Hosmer et al., 2013):

$$Ln\left(\frac{P_i}{1-P_i}\right) = -2.645 + 0.784Female_i + 0.108Education_i + 0.189Income_i + 1.870Diversified\_Livelihood_i + 0.495Envi\_Awareness_i + 1.242Tourism\_Experience_i - 0.072Instututional\_Trust_i \quad (3)$$

Overall, the results underscore the central role of economic resilience and prior tourism exposure in shaping household willingness to participate in community-based ecotourism, while highlighting the more limited direct influence of demographic and attitudinal factors in the study context.

DISCUSSION

This study provides a comprehensive assessment of community perceptions, perceived benefits and concerns, and econometric determinants of household willingness to participate in community-based ecotourism (CBET) in Xuan Thuy National Park. By integrating descriptive and inferential analyses, the results offer a nuanced understanding of both the opportunities and constraints shaping CBET development in a climate-vulnerable coastal wetland protected

area, while also illuminating how CBET may contribute to multiple Sustainable Development Goals (SDGs), particularly SDG 5 (Gender Equality), SDG 8 (Decent Work and Economic Growth), and SDG 13 (Climate Action).

The perception-based findings reveal a clear hierarchy across sustainability dimensions, with strong environmental and socio-cultural foundations, more cautious economic expectations, and persistently weak institutional confidence. High environmental sustainability scores reflect a widespread recognition of the ecological value of mangrove ecosystems and migratory bird habitats, indicating strong local alignment with conservation objectives.

From an SDG 13 perspective, this environmental awareness represents a critical enabling condition for climate action, as mangroves play a vital role in climate adaptation through coastal protection, carbon sequestration, and ecosystem resilience. Ecotourism, when properly designed, can reinforce these functions by creating incentives for conservation-oriented behavior and reducing pressure on climate-sensitive livelihoods.

Similarly, the high socio-cultural sustainability scores point to strong community cohesion, collective traditions, and social capital. These attributes are central to the participatory ethos of CBET and resonate with SDG 5, particularly in its emphasis on inclusive participation, empowerment, and social equity. Although gender does not emerge as a statistically significant determinant in the regression model, the positive coefficient suggests that women's participation may operate through indirect pathways, such as involvement in household decision-making, informal economic activities, and community networks—areas that are often undercaptured in quantitative models but critical to CBET implementation.

In contrast, perceptions of economic sustainability are more moderate, reflecting cautious expectations regarding income generation and livelihood security. This finding is reinforced by the perceived benefits and concerns analysis, where income diversification and job creation are widely acknowledged, yet concerns over unequal benefit distribution and increased regulatory burdens remain prominent. These patterns underscore the relevance of SDG 8, as they highlight both the potential of CBET to contribute to decent work and inclusive economic growth and the risks associated with poorly designed benefit-sharing mechanisms. Without transparent and equitable economic arrangements, CBET may fail to deliver on its promise of inclusive growth, thereby undermining community support.

The econometric results further refine these insights by identifying livelihood diversification as the most robust determinant of household willingness to participate in CBET. Households with diversified income sources are significantly more likely to engage in ecotourism, suggesting that economic resilience enables households to absorb risk and view CBET as a complementary livelihood strategy. This finding directly links CBET to SDG 8, as it emphasizes the role of diversified and resilient livelihood systems in fostering sustainable economic participation, particularly in environments exposed to climate and market uncertainties. Prior tourism experience also plays a positive role, highlighting the importance of skills, knowledge, and experiential learning in shaping participation decisions.

From a policy perspective, this suggests that targeted capacity-building and training programs could enhance CBET participation by lowering entry barriers, especially for households with limited prior exposure. Such interventions can simultaneously support SDG 8 by improving employment quality and SDG 5 by creating opportunities for women and marginalized groups to access tourism-related skills. While environmental awareness is positively associated with participation willingness, its lack of statistical significance indicates that conservation values alone are insufficient to motivate active engagement. This finding underscores a critical insight for SDG 13: climate awareness must be coupled with tangible livelihood benefits and supportive institutional arrangements to translate environmental concern into sustained climate action at the community level. The non-significant role of institutional trust is particularly revealing. Despite being the weakest sustainability dimension, low institutional confidence does not directly suppress willingness to participate in CBET. This suggests that communities may be willing to engage in ecotourism even in the absence of strong institutional support, creating a short-term opportunity for CBET development.

However, from a governance and equity perspective, this also signals a structural risk. Without improvements in participatory governance, transparency, and benefit-sharing, initial willingness may not lead to durable engagement or socially equitable outcomes—an outcome that would undermine progress toward all three SDGs. Taken together, the findings indicate that CBET readiness in Xuan Thuy National Park is primarily shaped by households' economic resilience and experiential capacity, rather than by demographic or attitudinal factors alone. The coexistence of strong environmental and socio-cultural support with weak institutional confidence creates both a strategic opportunity and a long-term challenge. On the one hand, there is clear potential to leverage CBET as an integrated pathway for advancing SDG 13 through conservation, SDG 8 through livelihood diversification, and SDG 5 through inclusive participation. On the other hand, failure to address governance and equity concerns may limit the sustainability and transformative potential of CBET initiatives. Overall, this study underscores the importance of livelihood-integrated, capacity-oriented, and institutionally strengthened CBET strategies. Policies that support livelihood diversification, provide targeted tourism training, and promote transparent and inclusive governance are more likely to align ecotourism development with the interconnected objectives of SDG 5, SDG 8, and SDG 13. In coastal wetland contexts such as Xuan Thuy National Park, aligning ecological conservation with socio-economic resilience is essential for translating community willingness into durable, equitable, and climate-resilient ecotourism outcomes.

CONCLUSION

This study examined the potential of community-based ecotourism (CBET) as a pathway for promoting sustainable local livelihoods in a climate-vulnerable coastal wetland protected area, using Xuan Thuy National Park, Vietnam, as a case study. By integrating community perception analysis with econometric modeling, the research provides a

comprehensive assessment of both the social readiness and structural conditions shaping CBET development in a Ramsar-listed ecosystem of high conservation value. The findings reveal strong environmental and socio-cultural support for ecotourism among local communities, reflecting high awareness of mangrove ecosystem services and a solid foundation of social cohesion and collective action. In contrast, perceptions of economic sustainability are more cautious, and institutional confidence remains notably weak. This imbalance underscores a critical challenge for CBET development: while communities recognize the ecological and social merits of ecotourism, concerns related to governance capacity, transparency, and equitable benefit-sharing persist. The binary logistic regression analysis further demonstrates that household willingness to participate in CBET is primarily driven by livelihood diversification and prior tourism experience, highlighting the importance of economic resilience and experiential capacity in shaping participation decisions. Demographic characteristics and environmental awareness alone are insufficient to motivate engagement, emphasizing that conservation-oriented attitudes must be complemented by tangible livelihood benefits and enabling institutional conditions. Although institutional trust does not emerge as a statistically significant determinant of initial willingness, its low perception scores signal potential risks to the long-term sustainability and equity of CBET initiatives.

From a policy perspective, the results suggest that CBET strategies in coastal wetland protected areas should prioritize livelihood-integrated approaches, targeted capacity-building, and governance strengthening. Supporting diversified livelihood portfolios, providing tourism-related training, and fostering inclusive and transparent institutional arrangements are essential for translating community willingness into sustained participation. More broadly, the study highlights CBET's potential to contribute simultaneously to climate adaptation, conservation, and inclusive development, aligning with the objectives of SDG 5 (Gender Equality), SDG 8 (Decent Work and Economic Growth), and SDG 13 (Climate Action).

Despite its contributions, this study is subject to certain limitations. The cross-sectional nature of the survey restricts causal inference, and future research could benefit from longitudinal designs to capture dynamic changes in perceptions and participation over time. In addition, qualitative approaches and gender-disaggregated analyses could further illuminate power relations, institutional dynamics, and intra-household decision-making processes that influence CBET outcomes.

Overall, this research underscores that the success of community-based ecotourism in coastal wetland protected areas depends not only on ecological assets or market potential, but fundamentally on the integration of livelihood resilience, experiential capacity, and inclusive governance. Addressing these dimensions is essential for ensuring that CBET evolves from a promising concept into a durable and equitable development pathway in Xuan Thuy National Park and similar protected areas. Despite its contributions, this study has several limitations.

First, the analysis is based on cross-sectional survey data collected at a single point in time, which limits the ability to capture dynamic changes in community perceptions and participation over time.

Second, the study focuses on households in the buffer-zone communes of Xuan Thuy National Park, and therefore the findings may not be fully generalizable to other protected areas with different socio-economic and ecological contexts.

Third, while the logistic regression model identifies key determinants of participation willingness, it does not fully capture complex institutional dynamics or power relations that may influence ecotourism governance. Future research could employ longitudinal data, comparative case studies, and mixed qualitative–quantitative approaches to better understand long-term community engagement and institutional effectiveness in CBET development.

A multi-level collaborative governance model for tourism ecosystem management: Evidence from a special economic zone in Indonesia. *Geojournal of Tourism and Geosites*, 67(3), 2162–2168. https://doi.org/10.30892/gtg.67329-1841

Abstract: Tourism ecosystem management increasingly faces governance challenges arising from institutional fragmentation, ecological vulnerability, and multi-actor complexity, particularly in developing country contexts. This study examines how multi-level collaborative governance operates in managing and restoring the tourism ecosystem of Tanjung Lesung, a tourism-based Special Economic Zone in Indonesia. The research aims to develop a conceptual model that explains how collaboration across policy, organisational, and operational levels shapes ecosystem restoration outcomes. Using a qualitative approach grounded in Soft Systems Methodology (SSM), the study draws on in-depth interviews, document analysis, and participatory observation involving government agencies, private sector actors, community groups, and academic institutions. The findings reveal that collaborative governance in Tanjung Lesung functions as an interconnected but uneven system. While collaboration exists at each governance level, weak vertical coordination, overlapping authority, and limited institutional learning constrain integration across levels. Community participation and knowledge co-production emerge as critical strengths at the operational level, yet their influence on higher-level decision-making remains limited. This study proposes a multi-level collaborative governance model that integrates policy direction, organisational coordination, and operational practice through communication, trust, coordination, and learning. The model contributes to collaborative governance theory by demonstrating that governance effectiveness depends on cross-level interaction rather than isolated partnerships. Practically, the findings offer insights for strengthening ecosystem-based tourism governance in special economic zones and similar multi-actor settings.

INTRODUCTION

Tourism governance increasingly operates within complex socio-ecological systems characterised by institutional fragmentation, ecological vulnerability, and multi-level authority dispersion. Such conditions resemble what public policy scholars define as wicked problems - issues that resist linear solutions due to interdependence, uncertainty, and contested values (Head & Alford, 2015). In tourism destinations, especially in developing countries, governance arrangements are frequently shaped by overlapping mandates, decentralised authority, and sectoral silos that weaken policy coherence and sustainability outcomes (Bramwell & Lane, 2011; Dredge, 2016).

Collaborative governance (CG) has emerged as a prominent response to these governance deficits. Defined as institutional arrangements in which public agencies engage non-state actors in consensus-oriented decision-making processes (Ansell & Gash, 2008), CG is widely promoted as a mechanism for managing cross-sectoral complexity (Bryson et al., 2015). Subsequent scholarship conceptualises collaborative governance regimes as dynamic systems shaped by principled engagement, shared motivation, and joint capacity for action (Emerson et al., 2012). More recent work emphasises the political and power-laden dimensions of collaboration, arguing that governance effectiveness depends on institutional design, power distribution, and meta-governance capacity (Ansell et al., 2025; Torfing et al., 2012).

Despite its normative appeal, collaborative governance frequently operates within fragmented multi-level governance systems where authority is distributed across national, regional, and local tiers (Hooghe & Marks, 2003). Such institutional

fragmentation often creates coordination challenges, overlapping policy responsibilities, and blurred accountability, making it more difficult to sustain effective collaboration across governance levels (Peters, 2015; Trein et al., 2019).

Previous studies have shown that tourism policy implementation is frequently constrained by weak vertical coordination between national policy formulation and local implementation, resulting in fragmented governance and inconsistent policy outcomes (Krutwaysho, & Bramwell, 2010; Wang & Ap, 2013). In tourism contexts, limited vertical integration between policy formulation and local implementation remains a persistent challenge (Provan & Kenis, 2008; Hall, 2011).

This study argues that collaborative governance cannot be adequately understood without accounting for its embeddedness in multi-level policy structures. Using Tanjung Lesung Special Economic Zone (SEZ) in Indonesia as an empirical case, this research examines how collaboration operates across policy, organisational, and operational levels in tourism ecosystem management (Sukran et al., 2025). By integrating collaborative governance theory, multi-level governance, and Soft Systems Methodology (SSM), the study develops a multi-level collaborative governance model that explains how cross-level interactions shape ecosystem restoration outcomes.

Conceptual and Theoretical Framework: Multi-Level Collaborative Governance

Collaborative governance has been widely conceptualised as a response to complex public problems that cannot be effectively addressed through hierarchical control or market mechanisms alone. Ansell & Gash (2008) define collaborative governance as a governing arrangement in which public agencies engage non-state stakeholders in a consensus-oriented decision-making process that is formal, deliberative, and collective. This perspective highlights key enabling conditions, such as trust, shared understanding, and facilitative leadership, as determinants of collaborative success. Emerson et al. (2012) further develop this framework by introducing the concept of collaborative governance regimes, which emphasises the dynamic interplay between principled engagement, shared motivation, and joint capacity for action.

Recent tourism governance studies have emphasised that sustainability challenges are deeply embedded in governance structures and power relations rather than technical management failures (Bramwell & Lane, 2011). Moreover, collaborative arrangements often struggle to deliver transformative outcomes when they are not supported by effective governance networks and cross-level coordination (Huxham & Vangen, 2005; Sørensen & Torfing, 2009).

While these frameworks provide a robust foundation for understanding collaboration, they often treat governance contexts as relatively flat institutional spaces. In practice, especially in decentralised or multi-tiered systems, collaboration unfolds across multiple levels of authority with distinct roles, resources, and power relations.

Multi-level governance theory addresses this complexity by focusing on the dispersion of authority across national, regional, and local levels, as well as the interactions between them (Allmendinger, 2017). Its shift from top-down regulation to networked decision-making requires conservation practitioners to adapt by engaging with diverse actors, integrating social equity into planning, and applying flexible, adaptive strategies across different scales to effectively manage ecological resilience (Armitage et al., 2012).

In tourism governance, this dispersion is particularly pronounced, as policy formulation, investment regulation, environmental management, and community engagement are frequently handled by different institutions operating at different scales. Integrating collaborative governance with a multi-level governance perspective provides a more comprehensive understanding of how coordination occurs simultaneously across vertical and horizontal institutional arrangements. Rather than functioning solely as a managerial mechanism, collaborative governance operates as a relational process in which trust, mutual understanding, interdependence, and shared motivation enable actors to coordinate collective action across institutional boundaries (Ansell & Gash, 2008; Emerson et al., 2012). This relational perspective is especially important in multi-level governance settings, where policy coherence depends on continuous interaction and feedback among actors operating at national, regional, and local levels. The effectiveness of collaborative governance therefore depends not only on stakeholder engagement at a single level, but also on the coherence and adaptive feedback mechanisms that connect policy formulation, organisational implementation, and operational practice.

In the context of tourism ecosystem management, this multi-level perspective is essential. Ecosystems are inherently complex and adaptive, requiring governance arrangements that can respond to uncertainty, ecological feedback, and social change. Ostrom (2010) argues that sustainable management of common-pool resources depends on polycentric governance systems, where multiple centres of decision-making operate autonomously, yet are coordinated through shared rules and norms. Applied to tourism, this implies that effective ecosystem restoration requires alignment between top-down policy frameworks and bottom-up community initiatives, mediated through organisational networks and learning processes.

To operationalise this complexity, this study adopts Soft Systems Methodology (SSM) as a complementary analytical framework. Developed by Checkland (1999) and further elaborated by Checkland & Poulter (2006), SSM is designed to address "messy" problem situations characterised by multiple actors, divergent worldviews (Weltanschauung), and ambiguous objectives. Rather than seeking optimal solutions, SSM facilitates learning by modelling human activity systems and comparing conceptual models with real-world practices.

Within this study, SSM serves not merely as a data collection method, but as a model-building approach that enables the integration of collaborative governance and multi-level governance perspectives. By combining collaborative governance theory, multi-level governance, and SSM, this research conceptualises tourism ecosystem management as a multi-level collaborative system. At the policy level, collaboration shapes strategic direction, legitimacy, and regulatory coherence. At the organisational level, it structures coordination mechanisms, partnerships, and resource mobilisation. At the operational level, collaboration is enacted through community participation, local knowledge, and day-to-day management practices. These levels are interconnected through continuous feedback, learning, and adaptation.

This conceptual framework provides the analytical foundation for examining the governance dynamics of Tanjung Lesung and for developing a transferable model of multi-level collaborative governance applicable to other tourism destinations facing similar ecological and institutional challenges.

RESEARCH METHODOLOGY

This study employed a mixed-method approach combining qualitative analysis with Soft Systems Methodology (SSM) to examine collaborative governance dynamics and develop a multilevel model for Tanjung Lesung tourism ecosystem management. Primary data were collected through 30 semi-structured interviews with government officials (n=15), private sector representatives from PT Banten West Java (n=5), and community actors including *Pokdarwis* leaders (a community-based tourism awareness organization established to support local tourism development), and Micro, Small, and Medium Enterprises (MSMEs) operators (n=10), supplemented by direct observation and informal discussions from August to November 2025. Secondary data comprised policy documents (RIPARNAS (National Tourism Development Master Plan), RPJMN (National Medium-Term Development Plan), Regional Medium-Term Development Plan (RPJMD), institutional records, and Special Economic Zone (SEZ) operational reports.

Data processing followed qualitative triangulation—transcription, filtering, SSM analysis, and validation through theoretical cross-checking—yielding the Multi-Level Collaborative Governance (MLCG) model through SSM's seven iterative stages. Data analysis followed the seven-stage SSM process, including problem structuring, CATWOE formulation, conceptual modelling, and real-world comparison. Thematic coding was guided by collaborative governance constructs (trust, coordination, shared motivation) and multi-level governance dimensions (vertical and horizontal integration). Triangulation and member checking enhanced credibility (Miles et al., 2014; Newman, 2021).

Soft Systems Methodology systematically derived the MLCG model through seven iterative stages applied to primary data: (1) unstructured problem situation (SEZ/PSN fragmentation); (2) rich picture (investment vs. resilience tensions); (3) root definitions (socio-ecological transformation); (4) conceptual modeling (co-planning / implementation / evaluation); (5) comparison with reality (administrative gaps); (6) feasible/desirable changes; and (7) action recommendations yielding the three-tier MLCG structure [Checkland, 1999].

The stages of the research especially data processing as follow the Figure 1 below.

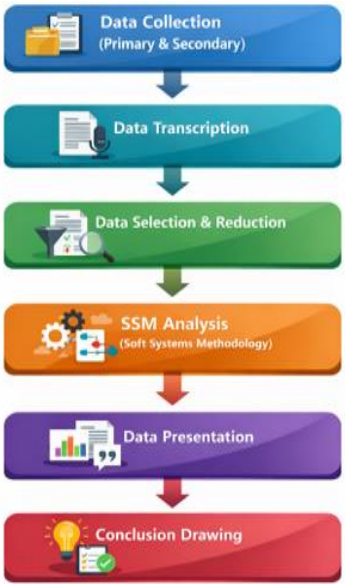

Figure 1. Stages of Data Processing

RESULTS

The multi-level collaborative governance in Tanjung Lesung demonstrates a vertically and horizontally integrated configuration spanning policy, organizational, and operational levels. At the policy level, central government agencies initiate SEZ development through regulatory frameworks and strategic infrastructure support, which provincial and district governments translate into local planning documents and derivative programs.

The organizational level features institutional structures involving district government, SEZ operator, PT. Banten West Java (PT. BWJ), local agencies, BUMDes (Village-Owned Enterprise), academic partners, and NGOs that coordinate planning, role division, and program oversight. Operationally, Pokdarwis, MSMeS groups, fisher collectives, youth organizations, and women's economic groups serve as frontline actors implementing economic recovery, ecotourism, environmental conservation, and disaster education initiatives.

Key Actors Across Governance Levels

Multi-level collaborative governance in Tanjung Lesung operates across policy, organizational, and operational domains, with vertical coordination from central SEZ/PSN mandates to local implementation.

Table 1. Multi-level actor configuration in Tanjung Lesung's collaborative governance model (Source : Author Analysis, 2025)

Governance Level	Key Actors	Primary Roles	Key Contributions
Policy (National)	Kemenparekraf (Ministry of Tourism and Creative Economy), PUPR (Ministry of Public Works and Housing), BKPM (Indonesia Investment Coordinating Board)	Policy framework, infrastructure investment	RIPARNAS (National Tourism Development Master Plan), RPJMN (National Medium-Term Development Plan), toll road, coastal protection
Policy (Provincial)	Banten Province (Regional Development Planning Agency (Bappeda), Tourism Office)	Policy mediation, program alignment	KEK (SEZ) prioritization in provincial tourism strategy
Policy (District)	Pandeglang Regency (Dispar, Investment and One-Stop Integrated Service Agency (DPMPTSP), Bappeda)	Local policy translation, capacity building	RPJMD (Regional Medium-Term Development Plan) integration, homestay training, MSMeS support
Organizational	PT BWJ, OPD (Regional Government Agencies), BUMDes	KEK management, investment facilitation	Events, hotels, marine, Islamic Center development
Operational (Community)	Pokdarwis, MSMeS, fishers, Karang Taruna (Village youth groups)	Implementation, local innovation	Homestays, mangrove ecotourism, tuna fishing festival, turtle conservation Bab-
Strategic Partners	UGM, UPI, President University, NGOs	Capacity enhancement, technical support	Digital marketing training, conservation education, disaster mitigation

At policy level, central-provincial-district alignment faces synchronization gaps : "National policies change rapidly... we often work with policy interpretations" [Provincial Official, I-P2, 2025]. Organizationally, PT BWJ, OPDs, and BUMDes synergize planning despite sectoral ego : "Sectoral egos still emerge over authority" [Bappeda Officer, I-O5, 2025]. Operationally, Pokdarwis and UMKM demonstrate co-production evolution : "From government programs to self-management... we feel ownership" [Pokdarwis Leader, I-C10, 2025].

These verbatim insights reveal MCG stages : preconception (cross-sector awareness: "We realized we can't do it alone" [Dispar Officer, I-P8, 2025], initiation (trust-building: "Initial suspicion gave way to understanding" [Community Rep, I-C3, 2025], formalization (MoUs/forums); operation (quick wins like digital promotion); and transformation (adaptive learning). Policy command-and-adjust patterns dominate higher levels, while operational joint capacity strengthens local resilience, confirming nested governance where lower-level innovations pressure upper-level reforms. Collaborative governance dynamics reveal interdependent yet unbalanced relationships between state, corporate SEZ operators, and local communities. Positive dynamics include intensified interactions through SEZ coordination forums, cross-institutional MoUs, CSR's tourism programs, joint training, and operational activities like homestay management, cultural festivals, and coastal conservation. These processes drive a shift from top-down approaches toward more participatory partnerships, evidenced by strengthened collective capacity, growing community ownership, and emerging inter-organizational routines. However, challenges persist in vertical coordination due to rapidly changing national policies outpacing local adaptation capacity, sectoral egos among organizations, and the absence of fully integrative decision-making platforms.

The emergent model constitutes an evolutionary Multilevel Collaborative Governance (MCG) framework operating through sequential stages—preconception, initiation, formalization, operation, and termination-transformation—interlinked across governance levels. The preconception stage reflects actors' recognition that post-tsunami recovery cannot be addressed sectorally, prioritizing collaboration in policy and institutional initiatives. Initiation involves negotiation and commitment-building, with district government mediating between PT BWJ and communities while cross-agency forums align visions. Formalization produces clearer governance structures through derivative regulations, SEZ coordination teams, and community institutions like tourism cooperatives. The operation stage manifests co-production practices where government, SEZ operators, and communities jointly implement infrastructure, economic empowerment, conservation, and digital promotion programs. Termination represents reflective transformation rather than cessation, yielding policy adjustments, partnership restructuring, and adaptive capacity strengthening for subsequent governance cycles.

This MCG configuration demonstrates that post-disaster collaborative governance constitutes an ongoing learning process that continuously renegotiates power relations, actor roles, and coordination mechanisms across governance levels.

DISCUSSION

Governance Fragmentation as a Systemic Problem

The empirical findings indicate that tourism ecosystem management in Tanjung Lesung is characterised by systemic fragmentation across governance levels. Rather than functioning as an integrated system, collaboration among actors tends to occur in silos, shaped by sectoral mandates and administrative boundaries. At the policy level, national, provincial, and regency authorities operate under overlapping regulatory frameworks that lack clear mechanisms for vertical coordination. While strategic documents consistently emphasise sustainable tourism and ecosystem preservation, these commitments are often diluted during implementation due to institutional discontinuity and shifting political priorities.

This condition reflects what Young (2009) describes as a governance gap, where policy aspirations are not matched by institutional capacity and coherence. Fragmentation is further reinforced by decentralisation dynamics, which distribute authority without necessarily strengthening coordination. In Tanjung Lesung, provincial government agencies

focus on macro-level development and investment facilitation, while local governments bear responsibility for environmental management and community engagement. The absence of a clearly mandated coordinating authority results in blurred accountability, particularly in ecosystem restoration initiatives that require sustained cross-sectoral collaboration (Bryson et al., 2015). Similar patterns have been observed in previous studies of tourism governance in Indonesia, where overlapping mandates and weak intergovernmental alignment undermine sustainability outcomes (Pujiyono et al., 2019; Kismartini & Pujiyono, 2020). From a systems perspective, this fragmentation represents a misalignment between governance structures and the ecological complexity of tourism ecosystems. Ecosystem restoration requires long-term commitment, adaptive management, and continuous feedback across governance levels. However, the findings reveal that policy instruments are often designed as static interventions, insufficiently responsive to local ecological dynamics and social realities. This condition reinforces the argument that conventional, hierarchical governance approaches are ill-suited for managing complex socio-ecological systems such as tourism destinations.

Multi-Level Collaborative Governance in Practice

Despite these structural limitations, the study identifies emerging forms of collaboration across policy, organisational, and operational levels that collectively shape tourism ecosystem management in Tanjung Lesung. These interactions illustrate how collaborative governance operates as a multi-level process rather than a single institutional arrangement.

In practice, Tanjung Lesung demonstrates how multilevel collaboration evolves through partially synchronised yet asymmetrical processes. Policy-level engagement remains largely procedural, with SEZ/PSN regulations providing formal mandates but limited mechanisms for incorporating local feedback or ecosystem-specific adaptations. Organisationally, coordination forums and MoUs between PT BWJ, district agencies, and BUMDes facilitate resource pooling and joint planning, though sectoral silos persist. Operational collaboration proves most dynamic, where Pokdarwis groups and MSMeS networks actively co-produce ecotourism innovations, homestay standards, and disaster resilience practices that gradually influence higher-level priorities (Sumarmi et al., 2026).

Findings confirm Ansell & Gash (2008) preconditions operate unevenly across levels, with operational collaboration strongest per Emerson et al. (2012). Policy proceduralism limits transformative potential (Hooghe & Marks, 2003)

A Proposed Model of Multi-Level Collaborative Governance

Synthesising the findings across governance levels, this study proposes a Multi-Level Collaborative Governance Model for tourism ecosystem management and restoration (Figure 2). This study proposes a multi-level collaborative governance model to explain how tourism ecosystem management is shaped through interactions across governance levels. The model conceptualises governance as a vertically interconnected system consisting of three analytical levels—policy, organisational, and operational—linked through core collaborative mechanisms that enable coordination, learning, and adaptive management.

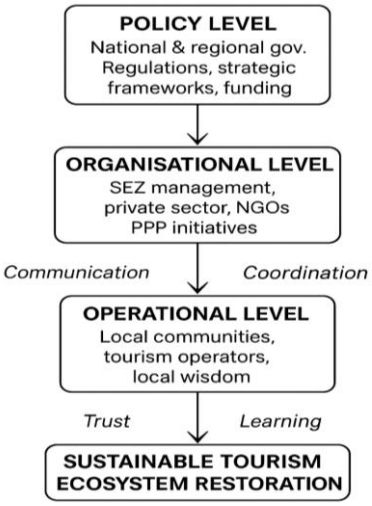

Figure 2. Conceptual Model of Multilevel Collaborative Governance in the Management of the Tanjung Lesung Tourism Ecosystem

At the policy level, national and regional governments provide strategic direction through regulations, development visions, and policy frameworks for tourism and ecosystem management. This level defines macro-level objectives and institutional mandates that guide tourism development within special economic zones. However, policy effectiveness depends on how these strategic directions are translated and operationalised at lower levels. The organisational level functions as a bridging arena between policy formulation and on-the-ground implementation. Key actors at this level include the special economic zone authority, sectoral agencies, and coordinating institutions responsible for aligning policy objectives with organisational capacities and resources. This level plays a critical role in facilitating cross-sector coordination, managing inter-institutional relationships, and translating policy goals into operational programmes.

At the operational level, collaboration occurs through direct engagement among local communities, private sector actors, non-governmental organisations, and academic institutions. This level is responsible for implementing ecosystem restoration initiatives, sustainable tourism practices, and community-based programmes (Sumarmi et al., 2026).

Operational actors also generate context-specific knowledge and practical insights that are essential for adaptive governance but are often weakly integrated into higher-level decision-making (Folke et al., 2005).

Across all governance levels, the model identifies four core collaborative mechanisms—communication, trust, coordination, and learning—that function as cross-cutting enablers of effective governance. Communication facilitates information exchange and mutual understanding, trust strengthens commitment and legitimacy, coordination aligns roles and resources, and learning enables feedback loops between practice and policy. The interaction of these mechanisms allows governance processes to evolve adaptively in response to ecological and institutional complexity.

The model suggests that effective tourism ecosystem management emerges not from isolated collaborative arrangements but from sustained interaction and feedback across governance levels. By emphasising vertical integration and institutional learning, the proposed model contributes to collaborative governance theory and offers practical insights for strengthening ecosystem-based tourism governance in special economic zones and similar multi-actor contexts.

CONCLUSION

This study demonstrates that tourism ecosystem management within Special Economic Zones should be understood not merely as an environmental or tourism governance issue, but as a broader challenge of development governance requiring sustained collaboration across multiple institutional levels. Using the Tanjung Lesung Special Economic Zone as an empirical case and employing Soft Systems Methodology (SSM), this research reveals that development outcomes are shaped by the quality of interactions among policy, organizational, and operational actors rather than by individual institutional performance. Although collaborative arrangements have emerged across these governance levels, fragmented authority, weak vertical coordination, overlapping mandates, and limited integration of local knowledge continue to constrain ecosystem restoration and sustainable regional development. Conversely, strong collaboration at the community level has fostered collective ownership, adaptive learning, local innovation, and resilience, demonstrating that participatory governance is an essential driver of long-term development.

The study contributes theoretically by proposing the Multi-Level Collaborative Governance (MLCG) Model as an integrated framework for development administration. Unlike conventional collaborative governance models that primarily emphasize inter-organizational partnerships, the MLCG model conceptualizes development governance as a dynamic process linking strategic policy direction, institutional coordination, and community-based implementation through continuous communication, trust, coordination, and institutional learning. The model therefore extends collaborative governance theory by positioning cross-level interaction as the principal mechanism through which complex socio-ecological development challenges can be addressed in decentralized governance systems.

From a practical perspective, the findings suggest that strengthening sustainable tourism development requires institutional reforms that enhance policy coherence, establish permanent cross-sector coordination mechanisms, empower local communities as co-producers of development, and integrate ecosystem restoration into regional development strategies. Beyond tourism, the proposed model provides a transferable governance framework for managing complex development programs in Special Economic Zones and other place-based development initiatives characterized by multiple stakeholders, ecological vulnerability, and institutional complexity.

Future research should validate the model across different regional development settings using comparative and longitudinal approaches to further examine its applicability and policy impact.

Limitation

This study presents three primary limitations. First, reliance on document analysis and cross-sectional interviews (n=30) limits longitudinal tracking of MLCG implementation dynamics. Second, single-case focus on Tanjung Lesung constrains generalizability despite contextual richness. Third, SSM's interpretive nature introduces researcher subjectivity despite triangulation. Future research should employ Social Network Analysis to quantify actor interactions, longitudinal designs to assess MLCG evolution, and comparative studies across Indonesian SEZs (Mandalika, Labuan Bajo) to test model transferability. Action research with SEZ practitioners would validate practical applicability.

Abstract: Restaurants increasingly rely on digital training; however, deaf and hard-of-hearing (DHH) employees still face barriers in noisy, fast-paced kitchens where spoken instruction is difficult to follow. This interpretive qualitative study examines how 30 restaurant managers in Egypt implement, adapt, and sustain accessible digital training for DHH employees under service pressure. Guided by the job demands-resources (JD-R) model and analyzed through reflexive thematic analysis, the study identifies four interconnected patterns. First, managers use visual and replayable tools, including captioned standard operating procedure videos, photo sequences, tablets, and workstation prompts, to reduce ambiguity and support self-paced rehearsal. Second, they engage in managerial bricolage by localizing corporate materials, improving Arabic captions, simplifying task steps, and distributing short refreshers through messaging applications. Third, caption errors, English-first interfaces, limited device access, and unstable connectivity can turn digital tools from job resources into additional operational demands. Fourth, peer mentoring, WhatsApp micro-coaching, and protected off-peak practice help convert digital content into confidence, task mastery, and psychologically safer learning. The findings extend hospitality disability employment research by shifting attention from hiring and inclusion climate to the day-to-day learning architecture through which inclusion is enacted in mainstream restaurants. They also extend JD-R by showing that inclusive digital training is a contingent job resource whose buffering value depends on localization and adaptation, access and quality management, and peer mentoring and coaching. Practically, the study shows how managers can convert mainstream videos, tablets, messaging applications, and AI-assisted captioning into workable inclusion practices for DHH employees in high-pressure restaurant operations.

Keywords: disability inclusion, digital training technologies, deaf and hard-of-hearing employees, restaurant management, job demands-resources, artificial intelligence

INTRODUCTION

Employees with disabilities represent an underutilized talent pool (Jamin et al., 2024). About one in six people worldwide live with a disability; however, hospitality organizations still struggle to provide equitable access to employment and career development (Ramukumba, 2024). In this labor-intensive industry, disability inclusion has shifted from being a peripheral social responsibility issue to a strategic priority linked to workforce resilience, service quality, and brand legitimacy (Manoharan et al., 2024; Lu et al., 2025).

However, studies show that people with disabilities are often concentrated in low-skill roles, face precarious contracts, and receive limited, non-individualized support at work (Manoharan et al., 2024; Scerri et al., 2026). According to Ramukumba (2024), disability research in hospitality and tourism has primarily focused on tourists with disabilities and accessible service design, while employment-related issues remain comparatively underexplored. Within the employment field, scholars have mainly concentrated on macro policies, employer attitudes, and guest responses to disability employment, rather than on the everyday practices through which managers enable employees with disabilities to learn complex service tasks and handle demanding frontline conditions (Manoharan et al., 2024; Lu et al., 2025). As a result, there are calls for context-sensitive studies of mainstream workplaces (Jamin et al., 2024; Scerri et al., 2026).

Globally, persons with disabilities represent about 15% of the population, and their labor force participation rate remains 30% lower than that of persons without disabilities, which highlights the continuing gap between inclusion commitments and actual work opportunities (Ramukumba, 2024). At the same time, hospitality learning systems are under pressure to do more with fewer resources. Recent industry evidence shows declining learning budgets and reduced time for ongoing training, even as operators prioritize speed, efficiency, and technology-enabled learning. In hospitality and restaurant operations, this pressure has accelerated investment in digital tools, including learning management systems, replayable microlearning, visual task guidance, and mobile messaging platforms (Tavitiyaman et al., 2024; Peng et al., 2024).

However, restaurants remain high-strain learning environments in which time pressure, communication load, space constraints, task complexity, task change, and infrastructure limitations shape what training can achieve, especially for DHH staff who cannot depend on spoken briefings in noisy kitchens. We selected the job demands-resources (JD-R) model as the guiding framework because the central issue in this study is not only whether training enhances ability, motivation, and opportunity, but whether managers can mobilize resources that buffer operational demands and prevent strain during service. In this context, an ability-motivation-opportunity AMO lens is useful for explaining performance-oriented human resource (HR) practices. Still, JD-R offers a stronger fit because it explains how accessible digital tools can operate as job resources, how those resources can fail under pressure, and how this balance shapes both learning and well-being in frontline restaurant work (Demerouti et al., 2001; Bakker & Demerouti, 2007; Bakker et al., 2023). In disability employment research, this distinction matters because prior hospitality studies explain why inclusion is important and which barriers persist. Still, they rarely show how managers build accessible training systems in everyday operations. To the best of our knowledge, AI- or digital-based training for employees with disabilities remains underexplored in hospitality, particularly in restaurant settings where communication barriers are amplified by speed and noise (Manoharan et al., 2024; Jamin et al., 2024; Lu et al., 2025). We therefore examine how restaurant managers in Egypt adapt digital training for DHH employees and show that inclusive digital training becomes valuable through three mechanisms: localization and adaptation, access and quality management, and peer mentoring and coaching. Accordingly, this study is guided by two research questions:

RQ1: How do restaurant managers implement and adapt digital training technologies to make onboarding and ongoing learning accessible for DHH employees?

RQ2: How do these technologies and managerial mechanisms operate as job resources that buffer job demands and shape both positive and negative outcomes for employees, teams, and service performance?

The study contributes to theory in three ways. First, it extends hospitality disability employment research from hiring and inclusion climate to the day-to-day learning architecture through which inclusion is enacted in mainstream restaurants. Second, it advances JD-R by showing that digital training is a contingent job resource rather than a generic organizational input; its buffering value depends on how managers localize content, secure usable access, and embed peer coaching under service pressure. Third, it explains managerial bricolage as a form of resource crafting through which managers repair misfits between corporate training systems and frontline realities. These contributions also offer a practice-ready explanation of how restaurants can convert digital training investment into substantive disability inclusion.

The rest of the paper is organized as follows. Section 2 reviews disability inclusion in hospitality employment and develops the JD-R foundation for technology-enabled training, alongside related work on accessibility and hospitality. Section 3 details the interpretivist, multi-site qualitative design, including sampling, interview procedures, and analytic approach. Section 4 reports the four themes and synthesizes them into the emerging JD-R framework of inclusive digital training for DHH employees. Section 5 interprets the findings by elaborating on the framework and propositions, then presents theoretical and managerial implications, and concludes with limitations and future research.

LITERATURE REVIEW

Theoretical foundation

JD-R explains how job demands consume employees' physical and psychological energy and, when sustained, can generate strain, whereas job resources support goal attainment, stimulate learning, and protect well-being (Demerouti et al., 2001; Bakker & Demerouti, 2007; Bakker et al., 2023). We use JD-R because restaurant training for DHH employees unfolds under intense operational pressure, where noise, speed, and communication complexity can quickly turn even well-designed tools into extra work. This makes the demand-resource balance central to the phenomenon under study.

An AMO lens can explain how practices enhance employees' ability, motivation, and opportunity to perform. Still, it is less able to show how accessible training tools buffer strain, fail under peak pressure, and redistribute workload across managers and peers. JD-R, therefore, offers the stronger theoretical fit for examining both the enabling and the burdensome sides of digital training in frontline restaurant settings.

Employees with disabilities and technology-enabled training in hospitality

Employees with disabilities encounter learning challenges in hospitality because training often relies on brief spoken instructions, informal coaching, and noise-sensitive cues. Technology-enabled training can improve accessibility by converting operational knowledge into multimodal, self-paced resources such as captioned task videos, annotated visuals, and replayable step sequences that employees can revisit during or after shifts (Berke et al., 2019; Alsalamah, 2020; Leung et al., 2022). However, the accessibility value of these tools depends on caption accuracy, interface usability, language fit, and the realities of service environments (Kuhn et al., 2024). Recent hospitality research also suggests that employees' digital capabilities shape whether technology contributes to inclusion, indicating that digital tools become meaningful only when workers can use them confidently and effectively in practice (Huang et al., 2026). To the best of our knowledge, hospitality research has not yet examined in depth how AI- or digital-enabled training is adapted for employees with disabilities in restaurant operations, particularly for DHH employees. Caution is advised when using automatic speech recognition (ASR)-based captions: performance varies across vendors and environments, and live or streaming modes can reduce accuracy. Organizations should test caption accuracy within their specific acoustic and language contexts before using ASR as an accommodation (Kuhn et al., 2024). Accessibility research also shows that DHH users' preferences for caption placement, segmentation, and readability influence usability during quick interactions, emphasizing user-informed design over standard defaults (Berke et al., 2019). Immersive approaches such as virtual reality

(VR) can enhance restaurant training outcomes (Leung et al., 2022). Still, research rarely examines accessibility for people with disabilities, leaving uncertainty about which features promote inclusion within real service flows.

Disability research in hospitality and tourism

Disability-at-work research contrasts medical perspectives (which view disability as an individual limitation) with social perspectives (which see disability as rooted in workplace barriers, routines, and systems). In hospitality, recent research increasingly aligns with the social model, urging firms to redesign HR systems and daily work practices to enable employees with disabilities to participate and advance on equal terms (Jamin et al., 2024; Manoharan et al., 2024). Early hospitality research on disability employment primarily examined whether firms hire and integrate employees with disabilities and why managers may hesitate to do so (Table 1). For example, HR-focused work in hotels has shown that gaps between policy and practice (e.g., limited accommodations, fragmented support, and uneven supervisory skills) hinder integration, even when organizations claim to promote inclusion (Gröschl, 2007).

Subsequent studies mapped employer concerns, recruitment approaches, and perceived barriers in the leisure and hospitality sector, emphasizing that many obstacles stem from managerial uncertainty and limited knowledge of inclusion, rather than job incompatibility (Houtenville & Kalargyrou, 2012; Jasper & Waldhart, 2013). Comparative data further indicated that service firms might express stronger intentions to hire people with disabilities but still worry about customer reactions and operational disruptions (Houtenville & Kalargyrou, 2015).

Table 1. Previous literature review of employees with disabilities in hospitality and tourism (Sources: Created by authors)

Study	Context and service	Method / data	Key constructs / theory	Main outcomes	Gap relative to this study
Gröschl (2007)	Hotels; integrating persons with disabilities	Empirical HR-focused study	HR policy/practice lens	Identifies policy/practice gaps in integrating employees with disabilities	Predates today's digital training stack; no focus on DHH accessibility, digital features, or AMO/JD-R pathways
Houtenville & Kalargyrou (2012)	Hospitality employers; disability hiring decisions	Employer-focused empirical study	Employer attitudes; business-case logics	Explains motivators and barriers shaping disability hiring	Front door focus (hiring) rather than how managers build accessible training ecosystems via digital tools
Jasper & Waldhart (2013)	Hospitality industry; disability employment perspectives	Empirical study	Employer/workplace inclusion issues	Evidence on perceptions and barriers in hospitality disability employment	Limited attention to day-to-day training /onboarding practices, digital accessibility, or DHH communication barriers
Houtenville & Kalargyrou (2015)	Hospitality employers; disability hiring perceptions/behavior	Empirical employer study	Attitudes/intentions; perceived barriers	Extends evidence on what drives/blocks inclusive hiring	Does not explain how inclusion is produced through training routines, especially tech-enabled and manager-adapted practices
Luu (2019)	Hotels employing workers with disabilities	Quantitative field data	Disability-inclusive HR; leadership resources	Links inclusive HR/leadership to improved employee outcomes	Does not specify which digital training features (captions, microlearning, messaging) drive AMO/JD-R mechanisms for DHH roles
Hui et al. (2021)	One international hotel; intellectual disability employment	Qualitative: interviews; focus groups	Supported employment; managerial practices	Identifies operational and social inclusion challenges; practical lessons	Not DHH; not restaurant/kitchen context; not focused on digital training affordances under constraints
Köseoglu et al. (2021)	Tourism/hospitality; disability hiring as CSR	Qualitative interviews (HR managers)	CSR; disability employment	Shows how CSR logics shape disability hiring narratives/practices	CSR lens rather than micro-level training design; little on digital accessibility features and AMO/JD-R pathways
Manoharan et al. (2024)	Hospitality disability employment research landscape	Systematic review	Thematic mapping; inclusion barriers/enablers	Notes employment stream is thinner; calls for workplace/process evidence	Review-level; does not unpack how digital training features affect AMO/JD-R for DHH staff in restaurants
Jamin et al. (2024)	Hospitality/tourism inclusion as an ecosystem	Integrative review; agenda	Ecosystem framing	Identifies multi-actor roles and major research gaps	Not empirical; doesn't show how managers adapt corporate digital tools (captions/language/device access) in daily training
Lu et al. (2025)	Tourism work; thriving with disability	Conceptual/empirical framing	Thriving / capabilities-oriented inclusion	Reorients inclusion toward thriving and meaningful work	Does not examine manager-level digital training adaptation/bricolage in restaurants or DHH-specific communication barriers
Huang et al. (2026)	Hotels; employees' digital skills and perceived inclusion	Cross-sectional survey of 607 hotel employees; PLS-SEM and set-theoretic mediation	Digital skills; psychological capital; perceived inclusion; social cognitive theory	Shows that employees' digital skills are positively associated with perceived inclusion, with psychological capital playing a mediating role	Not disability-specific; does not examine accessible training design, DHH communication barriers, restaurant operations, or manager adaptation of digital tools through JD-R processes
Scerri et al. (2026)	Hospitality employment; inclusive social innovation	Conceptual/typology-building	Social innovation; inclusive employment practices	Develops typologies/approaches to inclusion	Broad practice focus; limited detail on specific digital affordances shaping AMO/JD-R pathways for DHH frontline foodservice roles

A second stream shifted toward employee experiences and relational inclusion, showing that inclusive climates and leadership matter for well-being. Quantitative field evidence linked disability-inclusive leadership and climate to better outcomes for employees with disabilities (e.g., lower perceived discrimination and improved job attitudes), moving beyond hiring narratives toward the quality of everyday work life (Luu, 2019). Related hospitality research also shows that employees' day-to-day experiences are shaped by the distinctive features of specific service environments, reinforcing the need for context-sensitive analysis of workplace conditions and support systems (Marghany et al., 2025). More broadly, recent hotel research shows that employees' digital skills can strengthen perceived inclusion, suggesting that inclusion in hospitality is shaped not only by leadership and climate but also by workers' confidence in engaging with digital systems (Huang et al., 2026). Other studies documented gaps in perception between managers and frontline employees regarding disability employment and the practical tensions that emerge in team settings, reinforcing that inclusion is enacted in daily coordination, not only in HR policy statements (Hui et al., 2021).

Researchers also framed disability hiring through the lens of corporate social responsibility (CSR) logics. They identified structural barriers and stakeholder expectations; however, this line remains largely oriented toward organizational intentions and external legitimacy rather than toward micro-level training design (Köseoglu et al., 2021).

Qualitative work in foodservice examined moments of truth in customer interactions involving employees with disabilities, underscoring how frontline encounters can generate both dignity and vulnerability. However, it still leaves open the question of how managers prepare employees to handle these interactions through training systems. Across this literature, major reviews converge on a common limitation: hospitality research remains thin on process evidence of how inclusion is produced through day-to-day managerial practices, especially in operationally intense settings (Manoharan et al., 2024; Jamin et al., 2024). Complementary conceptual developments push the field from access to employment toward quality and thriving at work for workers with disabilities in tourism, thereby raising the bar for what inclusive systems must deliver (Lu et al., 2025).

Work on disability-inclusive social enterprises also highlights multi-actor pathways for sustaining inclusive employment. Still, it does not specify how mainstream hospitality managers translate corporate tools into accessible, role-specific learning in practice (Scerri et al., 2026). Digital training now sits at the center of this unresolved problem. Hospitality firms increasingly use apps, platforms, and mobile devices to standardize onboarding and performance support. Still, research on technology adoption and performance cautions that effects vary by context (including job level and cultural setting) and depend on how tools fit local work practices (Guo et al., 2023). However, disability employment studies rarely examine whether digital training is accessible, which digital features matter (e.g., caption accuracy, visual task sequencing, replayability, and quiet text-based coaching), and how managers adapt these features under real-world constraints (e.g., bandwidth, device access, language/localization). This gap is evident among DHH employees in restaurants, where noisy kitchens render spoken instruction unreliable and where training-as-talk can unintentionally reproduce exclusion. Therefore, prior research explains why inclusion matters and what barriers persist. However, it still under-specifies how managers build accessible training ecosystems that convert digital investments into AMO-enhancing resources while reducing communication-related job demands for employees with hearing disabilities.

MATERIALS AND METHODS

Research design

We used semi-structured interviews to examine how managers in Egyptian restaurants employ digital technologies to train and coach DHH employees. We focused on how managers select tools, adapt them to local constraints, and embed them in routine training tasks, such as onboarding, station sign-off, refresher coaching, and performance feedback.

Sampling and recruitment

We used purposive sampling to recruit managers who could provide recent, experience-based accounts of accessible training rather than general opinions. We required at least six months in a site-level role with training responsibilities because this threshold increased the likelihood that participants had completed full onboarding cycles, managed routine operational pressures, and worked with both corporate and local training systems. We also required at least one recent training episode with a disabled employee, usually a DHH employee, within the previous 12 months, so that the accounts reflected current tools, workflows, and specific incidents rather than distant recollections or hypothetical views. We excluded managers who did not meet these criteria because they could not speak directly to the phenomenon under study.

We recruited across Greater Cairo and Giza, Alexandria and Beheira, and Upper Egypt cities, including Minya, Luxor, and Assiut, to capture meaningful variation in restaurant density, infrastructure conditions, chain presence, and access to disability-support networks within Egypt. Greater Cairo and Giza offered large urban restaurant clusters and stronger access to corporate systems, Alexandria and Beheira added coastal and second-tier market conditions, and the Upper Egypt sites helped us examine how managers adapted training under relatively thinner institutional and digital support. Access was secured through three routes: corporate gatekeepers in multi-unit chains, professional contacts in independent restaurants, and nongovernmental organization (NGO) and interpreter networks that support disability-inclusive restaurant employment. This multi-channel strategy improved site access across cities and helped us reach managers who were actively involved in onboarding, coaching, and performance support for DHH employees.

We followed an information power logic to assess sample adequacy and stopped data collection when successive rounds no longer yielded new second-order concepts across outlet types and managerial levels. The final sample comprised 30 managers: 19 store managers, 5 assistant managers, 3 training supervisors, and 3 area managers. Twenty participants worked in Greater Cairo and Giza, seven in Alexandria and Beheira, and three in Upper Egypt.

Most participants worked in quick-service restaurants, followed by fast-casual outlets, cafés, and casual dining restaurants. The sample included 20 men and 10 women, which broadly reflected the male-dominated pattern of site-level operational management in the participating restaurant segments rather than a deliberate gender quota. All managers had experience training DHH employees, and 11 also supervised mixed-disability teams. Table 2 summarizes the respondent profile and the main training technologies discussed across the sample.

Table 2. Respondent profile (Source: Created by authors)

ID	Gender	Role	Outlet format	Location	Disability focus	Main training technologies discussed
R01	Woman	Store manager	quick-service restaurant (QSR)	Cairo	DHH only	Captioned standard operating procedure (SOP) videos; WhatsApp ASR
R02	Woman	Store manager	QSR	Cairo	DHH only	SOP videos; shared tablet microlearning
R03	Woman	Assistant manager	Fast-casual	Cairo	DHH; mobility	WhatsApp groups; checklists
R04	Woman	Store manager	Café	Cairo	DHH only	Tablet-based barista modules
R05	Woman	Store manager	QSR	Cairo	DHH only	Captioned fryer/assembly clips
R06	Woman	Training supervisor	QSR	Giza	Mixed (DHH, mobility)	Chain learning management system (LMS); WhatsApp
R07	Woman	Store manager	Fast-casual	Giza	DHH only	Tablet SOP; visual timers
R08	Woman	Assistant manager	QSR	Alexandria	DHH only	Captioned SOP playlist
R09	Woman	Store manager	Café	Alexandria	DHH; visual	Tablet; photo-based recipes
R10	Woman	Store manager	QSR	Upper Egypt (Minya)	DHH only	Offline videos on shared tablet
R11	Man	Store manager	QSR	Cairo	DHH only	WhatsApp ASR; captioned videos
R12	Man	Store manager	Fast-casual	Cairo	Mixed (DHH, mobility)	Chain LMS; WhatsApp groups
R13	Man	Assistant manager	QSR	Cairo	DHH only	Point of sale (POS) prompts; microlearning app
R14	Man	Store manager	Café	Giza	DHH only	Short barista clips; timers
R15	Man	Area manager	QSR	Cairo/Giza	DHH only	Group LMS oversight; store tablets
R16	Man	Store manager	Fast-casual	Giza	DHH; mobility	Captioned kitchen workflows
R17	Man	Store manager	QSR	Giza	DHH only	WhatsApp broadcasts; photos
R18	Man	Training supervisor	Casual dining	Cairo	Mixed (DHH, mobility, visual)	Central LMS; augmented reality (AR) trial
R19	Man	Store manager	QSR	Alexandria	DHH only	Video SOPs; haptic timers
R20	Man	Store manager	Fast-casual	Alexandria	DHH only	Tablet checklists; WhatsApp
R21	Man	Store manager	QSR	Alexandria	DHH only	Captioned assembly and service clips
R22	Man	Area manager	QSR	Alexandria/Beheira	Mixed (DHH, mobility)	Regional learning management system (LMS); audits
R23	Man	Store manager	Casual dining	Cairo	DHH; cognitive	Tablet menus; photo prompts
R24	Man	Assistant manager	QSR	Cairo	DHH only	Video-led onboarding flows
R25	Man	Store manager	QSR	Giza	DHH only	WhatsApp groups; peer videos
R26	Man	Store manager	Café	Upper Egypt (Luxor)	DHH only	Offline captioned clips
R27	Man	Store manager	Fast-casual	Upper Egypt (Assiut)	DHH; mobility	Tablet SOPs; messaging
R28	Man	Training supervisor	QSR	Cairo	Mixed (DHH, mobility, visual)	National LMS; microlearning
R29	Man	Area manager	QSR	Cairo/Alexandria	DHH only	Multi-site LMS; WhatsApp
R30	Man	Assistant manager	Casual dining	Giza	Mixed (DHH, visual)	Tablet menu training; videos

Interview guide and procedures

We developed a semi-structured interview guide. The guide opened with a brief profile module covering role, tenure, outlet type, branch size, disability mix, and current training technologies. We then moved through four blocks. First, we discussed inclusion and training practices, including the barriers managers aimed to reduce in their outlets. Second, we reconstructed recent onboarding and cross-training episodes step by step and asked managers to explain what they did, what the trainee did, and how understanding was assessed. Third, we created an inventory of technologies in use and discussed how each tool fitted into training. Examples included captioned standard operating procedure videos, microlearning or learning management systems, messaging apps, digital checklists, shared tablets, point-of-sale prompts, and visual or haptic timers. Fourth, we invited reflections on outcomes, barriers, and desired improvements. We used targeted probes to elicit critical incidents, such as miscommunication during peak periods, caption failures, device breakdowns, and instances in which a specific clip or message helped a trainee master a task. Interviews lasted 45 to 75 minutes and were scheduled during off-peak periods. Most interviews took place in a quiet office or a low-traffic corner within the restaurant; a minority were conducted via secure video calls with out-of-city managers. Participants chose Egyptian Arabic or English. Appendix A presents the main interview questions and illustrative probes used across the four interview blocks.

Ethics, transcription, and data management

We provided an information sheet and a brief ethics script explaining the study's purpose, procedures, voluntary participation, and the anonymization of brands and individuals. We obtained written consent before each interview for participation, audio recording, and use of anonymised quotations, and participants could skip any question without penalty.

With permission, we audio-recorded interviews using an encrypted application and took brief field notes on contextual details, without conducting systematic observation that would alter the interview design. We transcribed recordings verbatim in the source language. Bilingual research assistants translated key passages into English for analysis and reporting, and we back-checked 10-20% of the translations for accuracy. All files were stored on encrypted drives, with identifiers and consent forms kept separately, consistent with Consolidated Criteria for Reporting Qualitative Research (COREQ) aligned guidance for sensitive employment settings.

Data analysis and trustworthiness

We analyzed the data using reflexive thematic analysis (Braun & Clarke, 2006), combining inductive coding with JD-R-informed sensitizing concepts. Because our analysis moved iteratively between participants' accounts and theory, the process was abductive rather than purely inductive. First, both researchers familiarized themselves with the Arabic transcripts and field notes. Second, they generated initial codes that captured concrete actions, adaptations, barriers, and perceived outcomes. Third, the team compared codes and organized them into candidate themes related to demands, resources, and local workarounds. Fourth, we reviewed and refined the themes by returning to the transcripts, testing negative cases, and clarifying the boundaries between themes. Fifth, we defined and named the final themes and linked them back to the JD-R lens. To strengthen trustworthiness, we followed the practical criteria outlined by Nowell et al. (2017). We maintained an audit trail of coding decisions and theme revisions, used peer debriefing to challenge early interpretations, checked selected translations for accuracy, and sought brief member reflections from a small subset of participants. These steps supported credibility, dependability, confirmability, and transparency in the analysis.

RESULTS

Across 30 interviews, managers described a shared challenge: turning corporate training materials and disability policies into tools that genuinely help DHH staff master demanding restaurant work. They operated in noisy, space-constrained kitchens with high customer expectations while balancing efficiency and inclusion amid persistent job demands, including time pressure, communication load, task complexity, task change, and infrastructure limitations. Analysis generated four interrelated themes: (1) visual, replayable tools as bridges, (2) managerial bricolage and localization, (3) boundary conditions around language, design, and infrastructure, and (4) peer mentoring with micro-coaching and off-peak practice. These themes show how digital training underpins the emerging inclusion framework by positioning inclusive digital training technologies as job resources.

Visual, replayable tools as a bridge in noisy restaurants

Across formats, managers treated visual and replayable materials as the main entry point for training DHH staff. They contrasted earlier lecture-style briefings with practices centered on captioned SOP videos, stepwise photo sequences, and illustrated checklists. R3 summarized this shift: "Before, we talked, and they watched our lips; now the video shows every step, so they can follow without guessing." Visualization turned verbal instructions into concrete sequences that could be rehearsed, repeated, and refined at the workstation. Replayability emerged as equally crucial. Managers emphasized that many DHH trainees needed time to build confidence with sequencing, timing, and coordination under pressure. R11 commented: "If they forget a step, they rewind the clip, not the supervisor. That keeps dignity and saves time for everyone." Managers encouraged trainees to watch clips before and after shifts, treating microlearning modules as portable memory aids that reduced anxiety when menus changed or promotions introduced unfamiliar items. Several managers also noted that artificial intelligence (AI)-assisted captioning and translation enabled them to generate faster first drafts of subtitles, which they then reviewed to ensure accuracy for food terms and timing cues. Managers also highlighted the value of embedding visual prompts directly into the workflow. Tablets near fryers, dessert stations, or coffee machines allow staff to view short loops that show the correct sequence of actions. R7 explained: "During the rush, there is no time for big explanations; they just check the tablet and continue." These arrangements reduced dependence on spoken reminders and interpretation during peak periods and signalled that visual tools were a shared resource rather than a special accommodation. This theme shows that visual and replayable tools operate as immediate job resources because they reduce ambiguity, support self-paced rehearsal, and lower dependence on spoken instruction in noisy service settings. The finding extends accessibility and hospitality training research by showing that the value of captioned and replayable content lies not only in information delivery but also in its ability to buffer communication demands at the point of work (Alsalamah, 2020; Guo et al., 2023; Kuhn et al., 2024).

Managerial bricolage and localization of mainstream tools

The second theme examines how managers adapt mainstream technologies to address local constraints and disability-related needs. Corporate teams usually supply generic videos and PDFs, often in English. Store-level managers then cut, annotate, and re-order these materials to highlight critical steps and simplify language. R14 described: "Head office sends a long video; we trim it, slow some parts, add Arabic subtitles, and print key frames for the wall." Bricolage also shapes learning pathways, with DHH staff first assigned visually rich, tightly defined tasks before progressing to multi-step roles. Messaging applications, particularly WhatsApp, became informal learning platforms. Managers created groups that brought together supervisors, Deaf employees, and, at times, interpreters or NGO partners. They circulated short reminder videos, annotated photos, and emoji prompts before busy periods. R9 noted: "At night, I send a thirty-second clip about tomorrow's offer; in the morning, they already know the sequence." Physical and temporal bricolage complemented these practices, as managers negotiated off-peak micro-lab times and improvised mounts for phones when corporate tablets were

scarce, keeping the emerging framework workable in everyday restaurant conditions. This theme shows that digital inclusion is managerial and relational rather than purely technological. Managers created value through localization and adaptation, which supports recent hospitality evidence that technology improves practice only when it fits local workflows, service rhythms, and workforce realities (Guo et al., 2023; Tavitiyaman et al., 2024; Elmohandes et al., 2026).

Boundary conditions: Arabic user experience (UX), caption quality, and access gaps

The third theme surfaces boundary conditions that limit the inclusive potential of digital training. Managers repeatedly identified caption quality as the primary bottleneck. Automatically generated subtitles often distorted food terms or timing cues, creating errors when DHH staff followed them literally. R5 recalled: "The caption said 'sauce later' when it should be 'sauce first'; our Deaf colleague followed it exactly, and the burger was wrong." Where the head office invested in careful translation and proofreading, misunderstandings fell, and managers were more willing to delegate complex tasks. Language and interface design posed further challenges. Many tools defaulted to English menus, small fonts, or cluttered layouts designed for office workers rather than busy kitchens. To cope, managers produced simplified Arabic instructions in the form of laminated cards or infographics and placed them beside official devices. Infrastructure gaps compounded these issues: limited tablet availability, unreliable Wi-Fi, and power-outlet shortages meant that staff sometimes queued for devices or lost access during peak periods. R22 explained: "When the internet drops, the app is useless, so we fall back to gestures and memory." Partnerships with NGOs and interpreters were invaluable during recruitment and induction. However, they rarely provided funding for ongoing support, leaving store teams to shoulder day-to-day inclusion work with uneven digital scaffolding. This theme clarifies that inclusive digital training can also strain when content quality, language fit, or access to infrastructure breaks down. In JD-R terms, this is the point at which a putative resource stops buffering demands and begins to generate additional workload, uncertainty, and technostress (Tarafdar et al., 2007; Alfehaid et al., 2024; Ye & Chen, 2024).

Peer mentoring, WhatsApp micro-coaching, and off-peak practice

The final theme shows how digital tools enabled ongoing peer mentoring and micro-coaching that reinforced formal training. Many restaurants adopted buddy systems, pairing experienced DHH staff or supportive hearing colleagues with newcomers. Digital clips served as shared reference points during these interactions. R8 described: "We watch the video together once, then I stand next to him and repeat the moves; if he is unsure, we watch again." This combination of visual modelling and side-by-side practice created a safe environment for questioning, error correction, and gradual skill refinement. WhatsApp and similar platforms amplified these relationships outside scheduled sessions. Peers exchanged short reminders, photos of correctly assembled items, and encouraging messages after busy shifts. R19 noted: "When a new Deaf colleague nails the dessert order, we send a thumbs-up video in the group; he knows he is progressing." Managers deliberately protected off-peak times for structured practice with digital tools, scheduling short "micro-labs" during slow periods so staff could replay clips and rotate through stations. R27 summarized: "If we only train during the rush, they just survive; off-peak practice with videos is when they really learn." Over time, these routines turned digital tools from onboarding devices into embedded resources for continuous development and resilience.

This theme highlights the social side of digital training. Peer mentoring and micro-coaching translated digital content into confidence, error correction, and psychologically safer learning, which connects inclusive training to the broader literature on learning behaviour and retention in hospitality work (Edmondson, 1999).

Taken together, the four themes explain how inclusive digital training functions within the JD-R model and what new insight this study adds to that framework. In this setting, inclusive digital training technologies are visual, replayable, AI-assisted, and messaging-based tools that make task learning accessible to DHH employees. Localization and adaptation refer to managerial work that aligns corporate content with local language, task flow, and outlet routines. Access and quality management refer to maintaining caption accuracy, usable interfaces, device availability, and connectivity. Peer mentoring and coaching refer to the social practices through which coworkers and supervisors help one another convert digital content into skill mastery. The study extends JD-R by showing that digital training is a contingent resource whose buffering effect depends on these three mechanisms. When they are strong, training supports engagement, retention, service quality, customer value, and productivity. When they weaken, the same system intensifies strain, inconsistency, and supervisory burden.

DISCUSSION

Our results show that disability inclusion in restaurants depends less on hiring intentions and more on how managers make training usable in daily operations. This insight responds to recent calls to study disability employment as an enacted workplace process rather than a policy statement (Jamin et al., 2024; Manoharan et al., 2024). Managers described a persistent problem: they had corporate training assets and, in some cases, disability policies, but they still needed practical methods to help DHH staff learn high-risk tasks quickly in noisy, crowded kitchens. From a JD-R perspective, this setting entails multiple job demands, including time pressure, communication load, space constraints, task complexity, task change, and infrastructure limitations, which can undermine learning if managers do not provide compensatory resources (Demerouti et al., 2001; Bakker et al., 2023). This finding also aligns with hospitality technology research showing that digital investments improve performance only when managers integrate tools into local workflows (Guo et al., 2023; Helal et al., 2026).

Across restaurant formats, managers relied on inclusive digital training technologies as the most direct bridge to learning. They used captioned SOP videos, replayable microlearning loops, photo sequences, workstation prompts, and mobile and messaging-based platforms to reduce dependence on spoken coaching during peak periods. In JD-R terms, these technologies operate as job resources that buffer demanding conditions by reducing ambiguity, enabling self-paced

repetition, and supporting quiet coordination when noise and speed make verbal instruction unreliable (Bakker et al., 2023). Because task complexity and task change are constant in restaurant operations, replayable and updateable content becomes especially valuable for maintaining consistent execution during menu shifts and promotions.

However, technology did not work as a standalone solution. Managers repeatedly described localization and adaptation, in which they edited long corporate videos, strengthened Arabic captions, simplified steps, and distributed short refreshers via messaging to align with local language and operational constraints. They also engaged in access and quality management, addressing caption accuracy, interface readability, device shortages, and connectivity breakdowns that can turn resources into barriers (Kuhn et al., 2024). Peer mentoring and coaching then stabilised learning: buddy systems and micro-coaching helped trainees check understanding, correct errors quickly, and progress safely beyond survival mode. These practices build psychological safety for asking questions and learning from mistakes, which is critical when demands are high and errors are visible to coworkers and customers (Edmondson, 1999).

At the same time, managers highlighted boundary conditions that can turn digital tools into new burdens. Caption errors, English-first interfaces, device queues, and unstable connectivity disrupted learning and pushed teams back toward ad hoc methods. When job resources weaken, job demands dominate, producing negative outcomes such as work anxiety, emotional exhaustion, service inconsistency, and a heavier training-time burden for supervisors and peers. This demand-resource imbalance also increases the risk of technostress when tools require constant troubleshooting during service peaks (Tarafdar et al., 2007; Alfehaid et al., 2024). The four themes provide the empirical base for our framework, which explains when technology-enabled training produces substantive inclusion and operational gains, and when it remains symbolic.

Emerging framework

Our findings suggest that technology-enabled training can move disability inclusion from a policy aim to daily practice in restaurants when managers treat digital tools as inclusion resources rather than as generic training add-ons. Accordingly, we anchor the emerging framework in the JD-R model and specify how inclusive digital training technologies operate as job resources that help restaurants manage persistent job demands in DHH employment contexts.

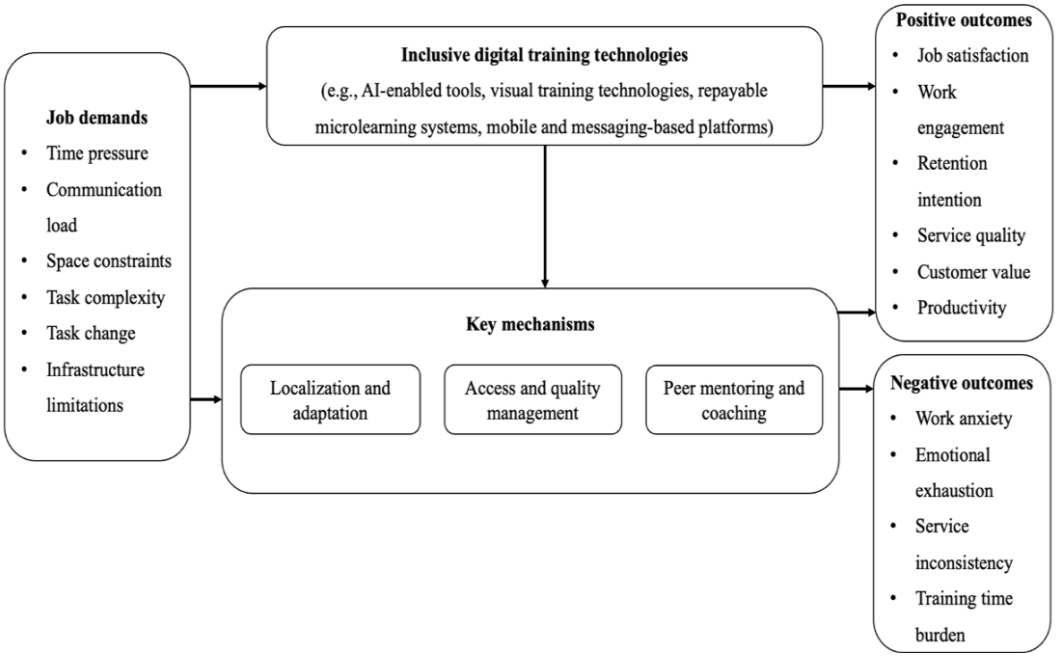

Figure 1. Conceptual framework

As shown in Figure 1, the left side of the model captures salient job demands that concentrate in restaurant operations: time pressure, communication load, space constraints, task complexity, task change, and infrastructure limitations. These demands intensify cognitive load and coordination costs, particularly in noisy kitchens where verbal instruction becomes unreliable, and service errors carry immediate customer-facing consequences. Consistent with the JD-R model, such demands can erode well-being and performance unless managers provide compensatory resources that enable learning and execution under pressure (Hassanin et al., 2023). The central element of the framework specifies inclusive digital training technologies as a bundle of job resources (rather than a single tool): AI-enabled tools, visual training technologies, replayable microlearning systems, and mobile and messaging-based platforms. Managers in our study relied on these technologies to translate verbal, time-sensitive routines into visual, replayable sequences that support self-paced rehearsal before, during, and after shifts, while reducing dependence on spoken reminders during rush periods. When embedded at the point of work (for example, station-based prompts or short task loops), these resources buffer communication demands and time pressure by reducing ambiguity, supporting quiet coordination, and stabilising task sequencing during menu changes and promotions.

Notably, the framework clarifies that technologies become effective through three key mechanisms that managers enact in situ. First, localization and adaptation capture managerial work to tailor corporate materials to local language and workflow

realities, including trimming videos, strengthening Arabic captions, simplifying steps, and converting content into wall-based or station-based visual prompts. Second, access and quality management reflect the operational governance required to keep resources usable in real kitchens, including ensuring caption accuracy, interface readability, device availability, connectivity continuity, and quick fallback options when systems fail. Third, peer mentoring and coaching explain how buddy systems and micro-coaching routines translate digital content into skill mastery through side-by-side practice, error correction, and confidence-building, especially during off-peak micro-labs. These mechanisms determine whether digital training functions as a stable job resource or becomes a fragile add-on that collapses under peak demand conditions.

The right side of the model specifies outcomes. When resources remain strong and mechanisms operate consistently, managers report positive outcomes, including job satisfaction, work engagement, retention intention, service quality, customer value, and productivity. However, when access breaks down, or content quality is unreliable (e.g., caption errors, English-first interfaces, device queues, unstable Wi-Fi), the same system can exacerbate strain, leading to negative outcomes such as work anxiety, emotional exhaustion, service inconsistency, and increased training time for supervisors and peers. In JD-R terms, these negative outcomes reflect a demand-resource imbalance, in which troubleshooting and compensating for tool failures add hidden work that intensifies strain during already demanding service periods (Tarafdar et al., 2007; Hassanin et al., 2023). Building on the emergent framework, we translate its pathways into propositions for future testing and practical application in restaurants that employ DHH staff. The propositions explicitly draw on the JD-R model, treating inclusive digital training technologies and supportive practices as job resources that buffer against high job demands and enable sustainable performance (Demerouti et al., 2001; Bakker & Demerouti, 2007; Bakker et al., 2023; Hassanin et al., 2023). Mechanism 1, localization and adaptation, explains how managers convert generic corporate content into usable training in specific restaurants. When managers trim and reorder procedures, strengthen local-language captions, and embed short, station-based learning materials into routines, DHH employees can rehearse steps with greater role clarity and lower ambiguity under real service conditions. Poor localization can recreate barriers, even when technology is available, by making content linguistically or operationally misaligned.

Proposition 1a: Localization and adaptation are positively associated with DHH task mastery.

Proposition 1b: Localization and adaptation mediate the relationship between inclusive digital training technologies and substantive training effectiveness.

Proposition 1c: Job demands weaken the positive effect of localization and adaptation on substantive training effectiveness.

Mechanism 2, access and quality management, captures how managers sustain resource reliability in busy kitchens. Accurate captions, readable interfaces, device availability, and stable connectivity determine whether digital tools function as resources or become friction. When access and quality break down, managers and peers absorb compensatory hidden work, increasing strain and undermining outcomes, consistent with technostress logic (Tarafdar et al., 2007).

Proposition 2a: Access and quality management are positively associated with substantive training effectiveness.

Proposition 2b: Access and quality management strengthen the relationship between inclusive digital training technologies and substantive training effectiveness.

Proposition 2c: Low access and quality management are positively associated with training time burden.

Mechanism 3, peer mentoring and coaching, explains how teams convert digital materials into capability through buddy systems, micro-coaching, and protected off-peak practice. These practices provide social support and rapid feedback, which can offset communication constraints during peak periods and reduce the likelihood that trainees merely survive the rush.

Proposition 3a: Peer mentoring and coaching are positively associated with the intention to retain DHH.

Proposition 3b: Peer mentoring and coaching mediate the relationship between the effectiveness of substantive training and service quality.

Proposition 3c: High job demands strengthen the positive effect of peer mentoring and coaching on DHH work engagement.

Theoretical implications

This study advances hospitality disability research by shifting attention from hiring intentions to the daily learning system that makes inclusion feasible in high-pressure restaurant work (Jamin et al., 2024; Manoharan et al., 2024). While prior work documents barriers and employer concerns, it provides limited process evidence of how managers develop training arrangements that remain workable during service peaks. Our findings address this gap by theorising inclusion as an operationally embedded training system in which restaurants must continuously translate policy and corporate content into accessible task execution.

Second, the study extends the JD-R model by treating inclusive digital training technologies as context-specific job resources rather than as a generic input (Demerouti et al., 2001; Bakker & Demerouti, 2007; Bakker et al., 2023). In restaurants, job demands are concentrated by high speed, noise, limited space, and frequent changes in menu routines, which can intensify strain for DHH staff when training relies on speech. We show how inclusive digital training technologies, including visual training technologies, replayable microlearning systems, and mobile and messaging-based platforms, buffer these demands by increasing role clarity and enabling self-paced rehearsal at the point of work. This articulation strengthens JD-R's explanatory power in hospitality by linking digital training directly to the buffering function that the theory assigns to resources.

Third, the framework clarifies how resources become effective through three mechanisms that managers enact in situ. Localization and adaptation convert generic content into locally usable routines; access and quality management protect

resource reliability; and peer mentoring and coaching sustain learning through guided practice and feedback. By specifying these mechanisms, we move beyond adoption narratives in hospitality technology research and explain why the same platforms yield uneven outcomes across outlets (Guo et al., 2023). We also demonstrate that inclusion is not only motivational but also infrastructural and procedural, requiring the ongoing maintenance of captions, interfaces, and device access (Kuhn et al., 2024).Finally, the study makes a theoretical contribution by integrating negative outcomes into the study of technology-enabled inclusion. When resources are poorly configured or unstable, they do not merely fail to help; they can increase strain and create additional work for managers and peers, consistent with technostress arguments (Tarafdar et al., 2007; Ye & Chen, 2024). This insight positions training time burden and service inconsistency as consequences of demand-resource imbalance rather than simple implementation errors. Conceptually, managerial bricolage functions as a form of resource crafting that repairs the misfit between corporate systems and frontline realities, extending JD-R discussions of how workers and managers actively shape resources to protect performance and wellbeing (Tims et al., 2013).

Managerial implications

Managers can use the framework to move from symbolic inclusion to daily, workable training for DHH staff by treating inclusive digital training technologies as core job resources that buffer restaurant job demands rather than as optional accommodations. The priority is to map the primary needs in each unit (time pressure, communication load, space constraints, task complexity, task change, and infrastructure limitations) and then embed visual, replayable training content at the point of work. Managers in our study relied on tablets, short clips, and workstation prompts to support learning during peak periods when spoken coaching is ineffective, particularly in noisy kitchens.

This approach aligns with evidence that digital tools improve frontline outcomes only when managers integrate them into local workflows (Guo et al., 2023) and with JD-R's claim that resources reduce ambiguity and protect performance under high demands (Demerouti et al., 2001; Bakker & Demerouti, 2007; Bakker et al., 2023). Second, restaurants should institutionalize localization and adaptation as routine managerial practices. Managers can trim long corporate videos, simplify step sequences, and upgrade local-language captions so DHH employees can rehearse tasks accurately during menu changes and promotions. Without this localization, available technology can still reproduce barriers through linguistic and operational misfit (Kuhn et al., 2024). Third, leaders should professionalize access and quality management. Managers should adopt a simple checklist to verify caption accuracy, interface readability, device availability, and offline backups when connectivity drops. These practices reduce the hidden work that emerges when staff must troubleshoot tools during service peaks, a pattern consistent with technostress research (Tarafdar et al., 2007; Hassanin et al., 2023).

Finally, managers should institutionalize peer mentoring and coaching through buddy systems, messaging-based micro-coaching, and protected off-peak micro-labs. These routines create faster feedback loops, support safe error correction, and build confidence beyond rush survival. Explicit messaging norms (brevity, visual prompts, and role clarity) also help prevent communication overload from turning coordination tools into additional demands. When managers align these resources with operational realities, restaurants are more likely to see higher engagement, retention intention, service quality, customer value, and productivity; when resources weaken, teams risk work anxiety, emotional exhaustion, service inconsistency, and increased training-time burden (Bakker et al., 2023; Habobati et al., 2023; Ye & Chen, 2024).

Limitations and future research

This study has several limitations. First, the sample was purposive and manager-centered, which means the findings reflect information-rich cases rather than statistical representation and may understate tensions that DHH employees themselves experience. Second, although the multi-city design improved contextual variation, the sample remained concentrated in urban and chain-dominated settings, with fewer cases from Upper Egypt and independent outlets. Future research should therefore test whether the framework travels across ownership forms, labor markets, and accessibility infrastructures. Third, the study relied on interview accounts rather than longitudinal performance records or sustained observation, so we cannot determine how digital training practices evolve or how they perform across repeated peak-service cycles. Future research should more explicitly examine contextual moderators, including outlet format, technology maturity, language localization, disability-support ecosystems, and infrastructure reliability. Mixed-method, longitudinal, and comparative designs could also test whether the three mechanisms identified here explain variation in task mastery, work engagement, retention intention, and service quality across settings.

CONCLUSIONS

This study examined how restaurant managers implement, adapt, and sustain digital training for DHH employees in demanding restaurant environments. The findings show that technology supports substantive inclusion only when embedded in everyday work practices. Visual and replayable resources, including captioned standard operating procedure videos, photo sequences, workstation prompts, and mobile microlearning, reduce dependence on spoken instruction and support self-paced learning. Managers also adapt corporate materials by improving Arabic captions, simplifying task sequences, and sharing short reminders through messaging applications. However, caption errors, English-first interfaces, limited device access, and unstable connectivity can turn digital tools into additional job demands.

Peer mentoring, micro-coaching, and protected off-peak practice are therefore essential for developing confidence, task mastery, and psychologically safer learning. The study extends the JD-R model by showing that inclusive digital training is a contingent job resource. Its value depends on three mechanisms: localization and adaptation, access and quality management, and peer mentoring and coaching. When these mechanisms are strong, digital training can improve

engagement, retention intention, service quality, customer value, and productivity. When they are weak, technology may increase anxiety, emotional exhaustion, service inconsistency, technostress, and training burden. For practice, restaurants should provide accurate local-language captions, readable interfaces, sufficient devices, offline alternatives, and short visual guides, supported by buddy systems and scheduled practice. Overall, inclusive digital training becomes effective when managers and coworkers continuously adapt, maintain, and socially embed it in frontline restaurant work.

Appendix A. Main interview questions

1. Please describe your role, your outlet, and your current responsibilities for training and supporting DHH employees.
2. How is training for DHH employees typically organized in your outlet, and what barriers are you aiming to reduce through these training practices?
3. Please tell us about a recent onboarding or cross-training episode involving a DHH employee, step by step, including what you did, what the employee did, and how you assessed understanding.
4. Which digital tools or training technologies were used in that process, and how did each one fit into training, coaching, or day-to-day task support?
5. How did you adapt the training content, language, pacing, or delivery to make it understandable and workable in daily restaurant operations?
6. What barriers, breakdowns, or misunderstandings occurred during training or service, and how did you respond to them?
7. What outcomes did you observe for the employee, the team, and service performance?
8. What improvements, resources, or changes would help make digital training more accessible and sustainable for DHH employees in your outlet?

Citation: Octaviany, V., Gusnadi, D., & Rafdinal, W. (2026). Fear of missing out (fomo) in generation z tourists: The role of content influencers and destination popularity. *Geojournal of Tourism and Geosites*, 67(3), 2181–2191. https://doi.org/10.30892/gtg.67331-1843

Abstract: The influence of influencer-generated content plays a significant role in shaping travel behavior, particularly among Generation Z. Influencer content depicts ideal travel experiences at popular destinations, creating a fear of missing out (FOMO) that encourages followers to visit those destinations to avoid missing out. This study aims to analyze the role of influencer content in shaping FOMO and destination popularity among Generation Z travelers. Specifically, this study analyzes how the originality, uniqueness, quality, and quantity of influencer content can create FOMO both directly and through destination popularity. To the authors' knowledge, this study is the first to apply the SOR model to analyze influencer content in influencing travel behavior, specifically from the perspective of destination popularity and FOMO in the tourism industry. The study involved 455 respondents who were Generation Z travelers, using structural equation modeling (SEM) to evaluate the relationship between influencer content, FOMO, and destination popularity. The results show that content uniqueness is proven to be a major factor triggering FOMO, even if the destination is not yet popular, while content quality has a significant influence on FOMO only through the mediation of increasing destination popularity. Furthermore, the more content available (quantity), the greater the psychological urge to always follow certain information or moments about trending or viral destinations, which in turn strengthens the feeling of FOMO among Generation Z travelers. Meanwhile, the originality of the content does not affect FOMO or destination popularity. The results of this study support the understanding that stimuli in the form of quality, quantity, and uniqueness of content created by influencers can encourage Gen Z travelers to develop curiosity about viral or trending destinations on social media, thereby creating a psychological response called FOMO, which ultimately encourages tourists to visit these popular tourist destinations. Tourist destination managers can utilize SOR theory to design more effective marketing strategies by focusing on stimulus elements that can trigger FOMO and increase the popularity of destinations among Generation Z audiences. Tourism destination managers can improve their marketing strategies by collaborating with influencers to create unique, high-quality, and consistent content. In this way, they can increase the popularity of their destinations and leverage the power of FOMO to attract more tourists.

Keywords: FOMO, destination popularity, content influencers, SOR, Generation Z

INTRODUCTION

Generation Z travelers are -highly engaged with social media, which influences their travel behavior and decisions (Thi Bich Dao & Do, 2024). This group is described as a generation that grew up with digital technology, relying heavily on content generated by fellow travelers in their travel planning and viewing it as a trusted source of information about destinations (Purwanegara et al., 2024). Generation Z often uses online reviews, social media posts, and influencer recommendations to make their travel choices (Daşkın & Tumati, 2024; Hammad, 2024). When planning a trip, Generation Z looks for information through online sources, not through travel agents or traditional brochures (Damanik et al., 2022). This shift from conventional methods marks a larger trend and opportunity in the tourism industry, where tourism providers must adapt to the new dynamics shaped by the influence of social media on Generation Z travelers (Vancia et al., 2023). In facing this opportunity, it is important for tourism destination managers to understand the behavior of Generation Z tourists in using social media for their travel planning, thus helping them create effective strategies in providing interesting information and in accordance with the preferences of Generation Z tourists. One of the characteristics of Generation Z travelers is their tendency to plan trips and choose destinations based on the appearance shown in social media posts and the level of trust in the influencers they follow (Chang et al., 2023; Viet Tran & Thanh Khoa, 2025). Influencers play a role in promoting tourist destinations through content deemed relevant and authentic, thus influencing the opinions and behavior of potential tourists (Ding et al., 2023; Kilipiri et al., 2023). Influencer content must be presented engagingly so that it can influence Generation Z tourists' decisions in choosing destinations (Fan et al., 2022; Warintarawej et al., 2024), creating

viral travel trends that encourage Generation Z travelers to visit the same destinations (Puiu et al., 2022). Previously little-known destinations become popular in a short time due to the domino effect of influencer content uploads (Barbe & Neuburger, 2021). The sudden surge in popularity of tourist destinations due to influencer content is often not matched by the destination's readiness in terms of management and environmental carrying capacity (Li et al., 2022). This creates a paradox, popularity is increasing rapidly, but the sustainability of the destination is actually threatened (Puiu et al., 2022). It is important to analyze factors that influence popularity, such as content shared by influencers on social media, so that stakeholders in the tourism sector (such as destination managers, travel agencies, and other related parties) can plan more appropriate marketing strategies, anticipate the surge in tourists, and adjust resources and infrastructure to the increasing demand (Firstianto et al., 2024). Therefore, a thorough understanding of the dynamics of destination popularity, as influenced by social media, is crucial for effective decision-making and tourism destination management.

In addition, the popularity of a destination is a benchmark for the level of interest and visits by tourists to a tourist destination (Lau & Koo, 2020), thus triggering feelings of Fear of Missing Out (FOMO) in Generation Z tourists (Szawłoga et al., 2024). The feeling of FOMO makes Generation Z tourists feel the need to visit popular destinations to stay on top of trends. (Pettersen-Sobczyk, 2023; Tan et al., 2023; Przybylski et al., 2013). However, Generation Z, driven by FOMO, visits destinations only because of temporary trends, not based on authentic tourism experiences. This creates a spatial pattern of quickly moving from one hotspot to another following content trends (Szawłoga et al., 2024). As a result, tourist arrivals become unstable. Newly popular destinations often experience a sudden surge in visitors, followed by a decline as the trend shifts to other destinations. This phenomenon leads to rapid changes in travel routes and a redistribution of tourists between regions. Visitation patterns become volatile and shift easily, making destination popularity vulnerable and unstable. Therefore, influencer-based marketing strategies need to be tested for their long-term effectiveness (Wibowo et al., 2021). The need to understand how influencer content can create FOMO through destination popularity can be crucial so that digital promotion strategies not only produce a momentary surge but also create sustainable popularity (Hammad, 2024). Therefore, this research helps destination managers formulate strategies that align social media trends with the destination's carrying capacity. Without proper understanding, popularity can lead to negative impacts such as overtourism, environmental damage, and a decline in the quality of the tourist experience.

The Stimulus–Organism–Response (SOR) model developed by Mehrabian & Russell (1974) is used in this study to provide a conceptual framework for understanding how external factors can influence consumer behavior (Jeong et al., 2022). The SOR model serves as a basic framework for understanding consumer behavior, integrating how environmental stimuli interact with an individual's internal processes to produce behavioral responses (Dheawara Zemafi & Tulus, 2024). Previous research shows that this model is recognized in various fields, reflecting its ability to explain consumer dynamics related to sustainability, technology adoption, marketing strategies, and tourists' emotional engagement with destinations (Kim et al., 2018). The SOR theory is used to understand the influence of influencer content on FOMO (Fear of Missing Out) through the popularity of tourist destinations. In this study, content produced by influencers functions as a stimulus (S) consisting of various dimensions, namely uniqueness, originality, quality, and quantity of content. Unique content that attracts attention, originality that differentiates it from others, attractive visual quality, and consistent content quantity can influence the audience psychologically. The audience (Generation Z), as an Organism (O), responds to this stimulus based on their psychological characteristics, namely curiosity and the desire to connect with trends that are viral or popular on social media (Koç et al., 2023). In this case, FOMO is a psychological response (R) that arises because the audience is afraid of being left behind or not following current developments related to popular tourist destinations (De Souza et al., 2025). Audience response is evident in the increased interest in visiting the tourist destinations promoted by influencers, thus increasing the popularity of those destinations. Thus, the SOR theory describes how stimuli provided by influencers can trigger an emotional response (FOMO) in audiences, which then leads to a decision to visit the destination.

Previous research findings revealed that influencer content characteristics such as informativeness, credibility, and relevance to followers' needs significantly influence travel intention (Kılıçarslan & Caber, 2026), and the protagonist's perspective (the view presented by the influencer) is also effective in increasing visit intention because the audience feels like they are experiencing the experience- (Ran et al., 2026). Influencer-created content also presents experiences in a unique, original, and high-quality manner (Ong et al., 2022). Other research indicates that uniqueness, quantity, and quality are the most important content characteristics for social media users in stimulating interaction and increasing their desire to follow influencer advice (Rodrigues et al., 2024). There is a research gap in these studies, which only focus on influencer perspectives and their influence on visit intention, while ignoring their influence on FOMO and destination popularity. Other studies have shown that destination trends or popularity are measured by directly classifying reviews from various platforms into sentiment polarities (i.e., positive, negative, and neutral ratings) (Liu et al., 2026), while FOMO is an important predictor in triggering travel motivation and visits to trending tourist destinations (Tan & Wu, 2025). However, these studies did not comprehensively analyze the factors influencing destination popularity that can trigger FOMO. Therefore, this study fills a research gap that has not been conducted by previous researchers, namely by comprehensively analyzing influencer content (dimensions of uniqueness, originality, quality, and quantity) in creating feelings of FOMO through destination popularity by applying the SOR model for Generation Z tourists.

MATERIALS AND METHODS

Hypothesis Development

Original content on social media, especially that created by influencers, can increase FOMO and drive consumer purchase intent (Raafat et al., 2023). Individuals who actively follow influencers tend to experience FOMO due to the urge

to emulate the lifestyle and interesting experiences displayed in the influencer's content (Dinh & Lee, 2021). The level of FOMO individuals feel toward original content varies depending on their personality (Lin & Jian, 2022). Therefore, the hypothesis of this research is depicted in Figure 1 below:

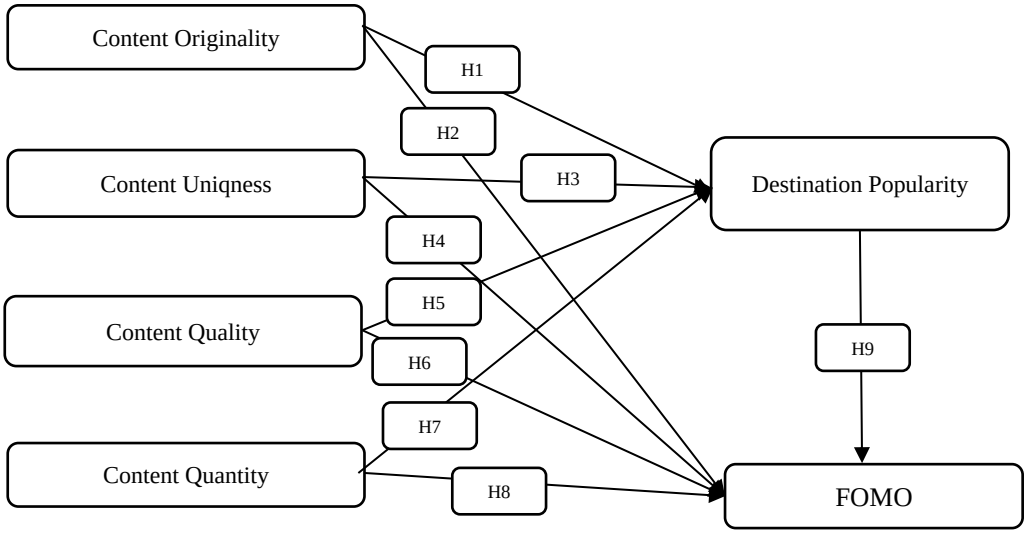

Figure 1. Research Hypothesis Diagram

Figure 1 shows that the research hypothesis is:

H1. There is a significant influence of content originality on FOMO.

Engaging and original content on social media increases audience engagement and drives interest in visiting a destination, supporting the notion that originality plays a crucial role in shaping destination popularity (Omeish et al., 2024). Authentic narratives that highlight a destination's uniqueness can build an attractive image for potential tourists. This originality increases audience attention and makes the destination more recognizable, even during a crisis (Antunes et al., 2022).

H2. There is a significant influence of content originality on destination popularity.

Influencer content typically features personal storytelling and clear visuals, creating a compelling narrative that encourages audiences to engage and experience the experience being shared (Saini et al., 2025). This phenomenon is particularly evident in the travel context, where idealized experiences portrayed by influencers trigger FOMO, prompting audiences to immediately plan trips. The authenticity and uniqueness of the content reinforce FOMO, prompting audiences to engage in similar experiences to stay in tune with their social circles (Vo et al., 2023).

H3. There is a significant influence of content uniqueness on FOMO.

Unique content contributes to the formation of a strong and positive destination image among young audiences (Saulīte & Ščeulovs, 2022). This is in line with Tandon, who emphasized that FOMO is related to an individual's psychological state and is triggered by interactions with unique content on social media (Tandon et al., 2021).

H4. There is a significant influence of content uniqueness on destination popularity.

In particular, quality, informative, credible, and well-produced content strengthens the destination image and can increase FOMO (Fear of Missing Out) by signaling exclusivity, novelty, and timely opportunities, thereby accelerating the decision-making process of Gen Z travelers who are constantly curating experiences through social media platforms (Sakulsom, 2026).

H5. There is a significant influence of content quality on FOMO.

When content demonstrates informativeness, source credibility, and social proof through authentic narratives and high production values, it enhances perceived destination image and social influence, which in turn drives intention and exploratory interest toward the destination, contributing to popularity metrics such as visit likelihood, sharing, and recommendations (Xue et al., 2024)

H6. There is a significant influence of content quality on destination popularity.

Content on platforms like TikTok and Instagram frequently appears and dominates Gen Z feeds, where trending sounds, fast-paced storytelling, and visually cinematic scenes create a strong destination image and a sense of urgency to visit before missing out (Fong et al., 2024).

H7. There is a significant influence of content quantity on destination popularity.

The perception formed through unique content can be in the form of an interesting and emotional narrative, popularity, and experiences that are more relevant to Generation Z, so this content is more effective than traditional marketing strategies (Bejoc et al., 2025). Unique content created and shared by social media users builds credibility and attracts the attention of potential visitors, making the destination more popular thanks to its visual appeal and the experiences it offers (Liu et al., 2021).

H8. There is a significant influence of content quality and quantity on FOMO and destination popularity

Continuously viewing a variety of quality content on social media can increase FOMO, encouraging social media users to share in popular experiences and trends (Manthiou et al., 2024). High-frequency, high-quality content can increase anxiety, as social media users often compare their experiences and opinions with what others post online. The implication is that influencers or content managers need to focus not only on creating high-quality content but also on maintaining consistent posting frequency

and engagement to keep the content engaging and relevant to their audience. Content frequency and quality create a mutually reinforcing effect, so feelings of FOMO continue to increase, leading to increased popularity (Bejoc et al., 2025).

H9. There is a significant influence of destination popularity on FOMO

Relevant content on social media has a significant influence on Generation Z's travel behavior, with 73% of users stating that such content influences the popularity of a destination (Das, 2025). Content on social media not only drives the rapid spread of travel trends but also increases Generation Z's attention and interest in certain destinations, even influencing their intention to visit them (Bejoc et al., 2025; Das, 2025).

The population in this study was all tourists who had visited destinations in Bandung Regency, aged 19–26. Bandung Regency, located in West Java Province, Indonesia, has various niche tourism destinations, including nature, culture and history, culinary, religious, educational, water tourism, and adventure (Darwis et al., 2024; Lusianingrum & Pertiwi, 2023; Widodo & Octaviany, 2019). A study shows that the use of social media can increase visibility, such as through the Instagram account @disbudpar.kabbdg (Culture and Tourism Office of Bandung Regency), which actively promotes tourism in Bandung Regency by using technology such as videos, images, and hashtags to increase the popularity of niche tourism in Bandung Regency (Wahyuni et al., 2021). In addition, previous research also shows that content created by influencers can shape tourist behavior, so it is important to involve influencers in marketing campaigns and make destinations in Bandung Regency famous (Salamah et al., 2022). To obtain a representative sample, a purposive sampling technique was used with a nonprobability sampling method (Dodgson, 2017). A total of 455 Gen Z travelers were sampled in this study.

This sample size was selected based on general SEM guidelines, which recommend a minimum of 200 respondents to achieve valid and reliable results (Sarstedt et al., 2020).

Data collection was conducted using a Likert-scale questionnaire (1-5) and distributed online and offline. The collected questionnaires were then verified to ensure completeness and accuracy of the data before further analysis. The following are the measurement items used in this study, as shown in Table 1:

Table 1. Measurement Items

Constructs		Indicators	Source
Content Originality	**CO1**	The authenticity of content created by influencers about tourist destinations is not a copy of each other.	(Ong et al., 2022)
	CO2	The authenticity of content created by influencers about tourist destinations is based on social media trends.	(Rodrigues et al., 2024)
	CO3	The authenticity of content created by influencers makes me interested in visiting the destination.	(Ong et al., 2022)
Content Uniqueness	**CU1**	Content created by influencers about tourist destinations has its own unique characteristics.	(Rodrigues et al., 2024)
	CU2	Content about tourist destinations created by influencers is different from other content.	
	CU3	Content created by influencers about tourist destinations is highly creative.	(Rodrigues et al., 2024)
Content Quality	**CQL1**	Influencers' content about tourist destinations provides important information.	(Ong et al., 2022)
	CQL2	Influencers' content about tourist destinations has good and attractive image quality.	
	CQL3	Influencers' content about tourist destinations often appears on social media.	(Ong et al., 2022)
Content Quantity	**CQT1**	Content about tourist destinations is often created by influencers.	
	CQT2		
Destination Popularity	**PD1**	Tourist destinations go viral on social media because of content created by influencers.	(Koç et al., 2023)
	PD2	The more often information about tourist destinations appears, the more interested I am and want to visit them.	
	PD3	The more often information about tourist destinations goes viral on social media, the more interested I am and want to visit them.	
FOMO	**F1**	The influencers' content about travel destinations makes me feel like I have to visit there soon.	(De Souza et al., 2025)
	F2	I don't want to miss out on information about tourist destinations that are going viral on social media.	
	F3	I was disappointed when I couldn't visit a tourist destination that was going viral on social media.	
	F4	When I visit a tourist destination, I feel like other people should know by uploading my content on social media.	

Data Analysis

After data collection, analysis was conducted using the SEM method, which involves several stages, starting with the measurement model, which is the analysis stage used to test how well the indicators or measurement variables describe the construct or latent variable to be measured. This stage aims to ensure the validity and reliability of each indicator used in the study. Reliability testing uses the Cronbach's Alpha coefficient, with values above 0.70 considered reliable.

The results of this validity and reliability test determine whether the research instrument can be used in the overall SEM analysis (Hair et al., 2023). For the measurement model, convergent and discriminant validity tests were also conducted. The analysis continued with structural model testing to identify causal relationships between variables.

SmartPLS 4 statistical software was used to process the data and produce relevant outputs, such as parameter estimation, model fit, and hypothesis testing (Moreno-Manzo et al., 2024).

RESULTS AND DISCUSSION

Respondent Profile

Based on the survey results of 455 respondents as shown in Figure 2, the gender composition shows that the majority of respondents are women, namely 285 people (63%), while men numbered 170 people (37%). In terms of occupation, most respondents are students, 358 people (79%), and the rest are employees, 97 people (21%). Regarding social media use, TikTok is the most frequently used platform among respondents, at 45% (205 people), followed by Instagram at 43% (200 people). Meanwhile, Facebook is used by 40 people (9%), and Twitter is in last place with the fewest number of users, namely 10 people (2%). This data shows that the majority of respondents are women of productive age in the student and college categories and actively use visual and short-video-based social media, such as TikTok and Instagram, as sources of information and entertainment.

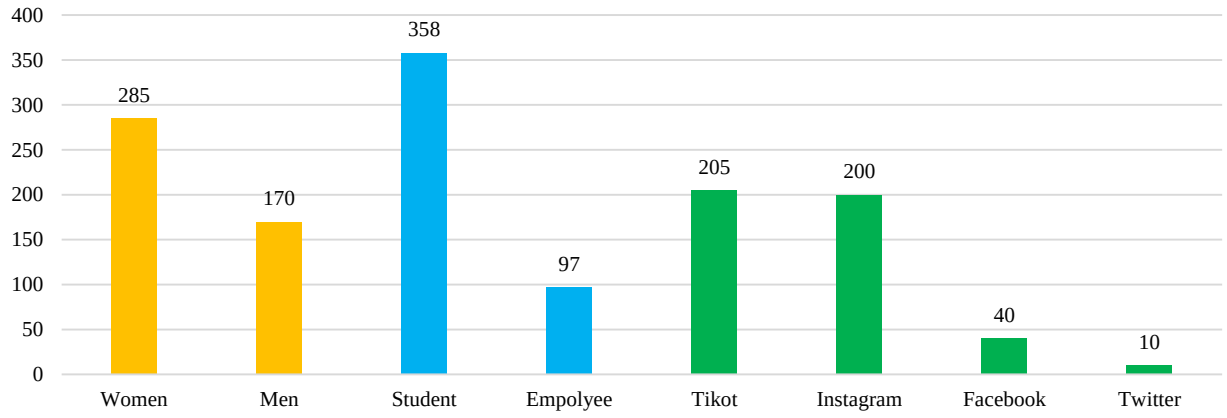

Figure 2. Respondent Profile

There are two stages in testing this research model: the outer model and the inner model, or structural model. The outer model is used to test the validity and reliability of indicators used to measure latent variables, namely convergent validity and discriminant validity. Meanwhile, the inner model, or structural model, focuses on the relationships between variables, testing the strength and significance of these relationships using R^2, path coefficients, and path significance.

Outer Model

The initial step in the research was to conduct reliability and validity tests to ensure that the indicators consistently and accurately reflect their respective latent constructs (Hair et al., 2022). The following are the results of the measurement model in this study. Table 2 shows that all constructs in this study meet the criteria for good reliability and convergent validity. The outer loading values for all indicators in this study are above 0.70, indicating that these indicators are valid in representing the latent constructs (Hair et al., 2023). Additionally, the Cronbach's Alpha and Composite Reliability (CR) values for each construct exceed the threshold of 0.70, indicating good internal consistency, meaning the indicators used can be trusted to measure the construct. Furthermore, the Average Variance Extracted (AVE) value for all constructs is greater than 0.50, meeting the requirements for convergent validity, indicating that more than 50 percent of the variance in the indicators is explained by the latent construct.

Table 2. Measurement model evaluation

Latent Variables	Indicators	Loadings	Cronbach's Alpha	CR	AVE
Content Originality	CO1	0.865	0.761	0.731	0.647
	CO2	0.796			
	CO3	0.826			
Content Uniqueness	CU1	0.806	0.815	0.891	0.560
	CU2	0.851			
	CU3	0.838			
Content Quality	CQL1	0.849	0.792	0.788	0.535
	CQL2	0.906			
	CQL3	0.808			
Content Quantity	CQT1	0.703	0.778	0.871	0.654
	CQT2	0.902			
Destination Popularity	PD1	0.785	0.748	0.758	0.731
	PD2	0.826			
	PD3	0.879			
FOMO	F1	0.774	0.799	0.766	0.692
	F2	0.709			
	F3	0.723			
	F4	0.852			

This confirms that the relationship between indicators and constructs in this study is valid and reliable. The measurement model assessment in this study uses the heterotrait-monotrait ratio (HTMT) to evaluate discriminant validity. HTMT is used to measure the correlation between two constructs that are measured reflectively, namely constructs that cannot be measured directly but are represented by certain indicators. If the HTMT value exceeds 0.90, it indicates low discriminant validity, meaning the constructs are not clearly distinct from each other, and the indicators used do not exclusively represent the construct (Hair et al., 2023).

Table 3 in this study shows the HTMT value for each construct, and overall, the HTMT value obtained is below the threshold of 0.90, which confirms that the discriminant validity in this study has been achieved satisfactorily. Namely, the constructs measured have clear differences, and the indicators used exclusively represent the construct.

Table 3. Heterotrait-monotrait (HTMT)

Latent variables	Content Originality	Content Quality	Content Quantity	Content Uniqueness	FOMO	Destination Popularity
Content Originality						
Content Quality	0.701					
Content Quantity	0.678	0.650				
Content Uniqueness	0.700	0.695	0.508			
Destination Popularity	0.402	0.649	0.580	0.660		
FOMO	0.372	0.163	0.464	0.188	0.412	

Structural Model

Evaluation of the structural model yielded positive findings. First, the Variance Inflation Factor (VIF) values ranged from 1.016 to 2.263, indicating no significant multicollinearity, as they were all below the threshold of 5 (Hair et al., 2019). Second, the Q^2 results between 0.081 and 0.309 indicate predictive relevance, with values above zero, confirming the model's ability to predict endogenous constructs (Hair & Alamer, 2022). Third, the analysis results obtained an R-square value of 0.575 for the FOMO variable and 0.511 for the destination popularity variable.

This can be interpreted as meaning that the content influencer variable, consisting of content originality, content uniqueness, content quality, and content quantity, can influence the FOMO variable by 57.5%, while the remaining 42.5% is influenced by other variables outside the research model. In addition, the content influencer variables in the form of content originality, content uniqueness, content quality, and content quantity also have an influence on destination popularity by 51.1%, while the remaining 48.9% is influenced by other variables outside the research model. The overall model structure in this study can be seen in Figure 3 below:

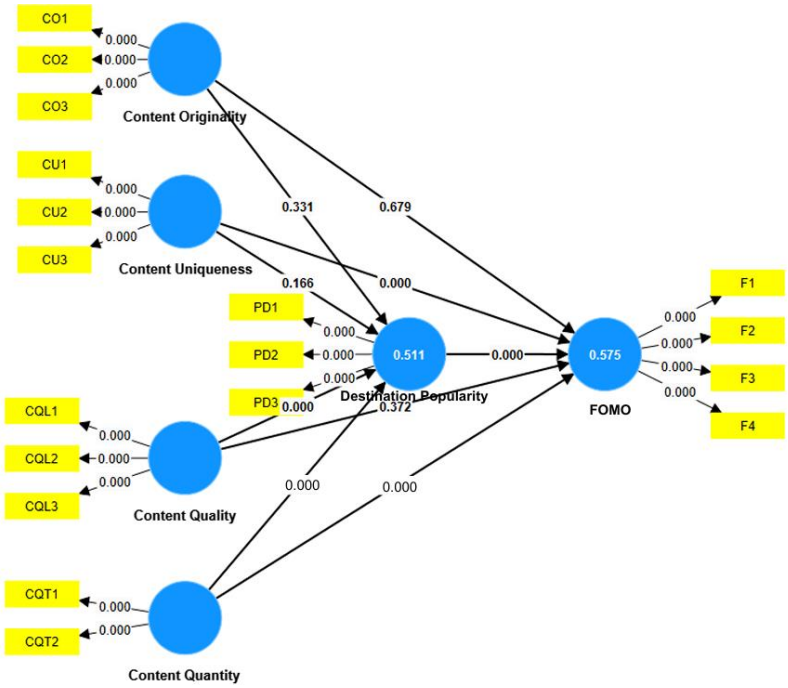

Figure 3. Result Model

Significance Test

The significance test in SEM PLS is conducted to determine whether the relationship between latent variables in the model can be considered statistically significant. This process uses bootstrapping, where data is resampled to calculate the path coefficient and its standard error. The results are reported as a t-statistic or p-value. A relationship is considered significant if the p-value is smaller than the predetermined significance level. A significant path coefficient indicates that

the relationship between the latent independent and dependent variables has strong statistical support; thus, the proposed hypothesis can be accepted. The following are the bootstrapping results of this research model:

Table 4. Results of Bootstrapping Test of Research Model

Effect	Original sample (O)	Sample means (M)	Standard deviation (STDEV)	T statistics (|O/STDEV|)	P values
Content Originality -> FOMO	-0.033	-0.025	0.079	0.414	0.679
Content Originality -> Destination Popularity	0.088	0.087	0.090	0.972	0.331
Content Uniqueness -> FOMO	0.396	0.389	0.111	3.581	0.000
Content Uniqueness -> Destination Popularity	0.134	0.139	0.097	1.387	0.166
Content Quality -> FOMO	-0.088	-0.094	0.099	0.893	0.372
Content Quality -> Destination Popularity	0.501	0.497	0.090	5.563	0.000
Content Quantity -> FOMO	0.324	0.359	0.103	3.221	0.000
Content Quantity -> Destination Popularity	0.331	0.394	0.098	3.132	0.000
Destination Popularity -> FOMO	0.492	0.497	0.083	5.921	0.000

Hypothesis testing used the bootstrapping method with a 95% confidence level and a t-value greater than 1.96 (Hair et al., 2022). The results, as shown in Table 4, indicate that the relationship between Content Originality and FOMO has a t-statistic of 0.414 and a p-value of 0.679, thus rejecting the hypothesis. The relationship between Content Originality and Destination Popularity also has a t-statistic value of 0.972 and a p-value of 0.33, so the hypothesis is rejected. Then the relationship between Content Uniqueness and Destination Popularity has a t-statistic value of 1.387 and a p-value of 0.166, which also experienced a rejection of the hypothesis. Similarly, the relationship between Content Quality and FOMO has a t-statistic value of 0.893 and a p-value of 0.372, so the hypothesis is rejected.

Furthermore, the relationship between Content Uniqueness and FOMO, with a statistical t-value of 3.581 and a very low p-value (0.000) indicates that this relationship is significant, so the hypothesis is accepted. The relationship between Content Quality and Destination Popularity shows a statistical t-value of 5.563 and a p-value of 0.000, which is very significant, so the hypothesis is accepted. Then, the relationship between Content Quantity and FOMO also has a statistical t-value of 3.221 and a significant p-value (0.000), which means the hypothesis is accepted. The relationship between Content Quantity and Destination Popularity also shows a statistical t-value of 3.132 and a very significant p-value (0.000), so this hypothesis is accepted. The last relationship, namely between Destination Popularity and FOMO, also has a statistical t-value of 5.921 and a p-value of 0.000, which is very significant, so the hypothesis is accepted.

This study also examines the indirect relationship between content influencer variables (content originality, content uniqueness, content quality, and content quantity) and FOMO through destination popularity, with the following results:

Table 5. Results of Indirect Effects

Effect	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	T statistics (|O/STDEV|)	P values
Content Originality -> Destination Popularity -> FOMO	0.043	0.041	0.044	0.976	0.329
Content Uniqueness -> Destination Popularity -> FOMO	0.066	0.072	0.055	1.213	0.225
Content Quality -> Destination Popularity -> FOMO	0.247	0.247	0.063	3.932	0.000
Content Quantity -> Destination Popularity -> FOMO	0.253	0.268	0.072	2.940	0.000

The indirect effect analysis used the bootstrapping method with a 95% confidence level and a t-value greater than 1.96 (Hair et al., 2022). Table 5 is the result of the study, which shows that Content Originality does not have a significant influence on FOMO, either directly (t-statistic = 0.414, p-value = 0.679, see Table 4) or indirectly through Destination Popularity (t-statistic = 0.976, p-value = 0.329, see Table 5). Meanwhile, the relationship between Content Uniqueness and FOMO was found to be significant directly (t-statistic = 3.581, p-value = 0.000, see Table 4), but not significant indirectly through Destination Popularity (t-statistic = 1.213, p-value = 0.225, see Table 5). Then, the relationship between Content Quality and FOMO has an insignificant direct relationship (t-statistic = 0.893 and p-value = 0.372, see Table 4) but is significant indirectly through Destination Popularity (t-statistic = 3.932 and p-value = 0.000, see Table 5). Meanwhile, the relationship between Content Quantity and FOMO has proven to be significant both directly (t-statistic = 3.221 and p-value = 0.000, see Table 4) and indirectly through Destination Popularity (t-statistic = 2.940 and p-value = 0.000, see Table 5).

This research makes an important contribution to the understanding of tourist behavior, particularly regarding the influence of influencer content on feelings of FOMO and destination popularity. The results of this study indicate that not all elements of influencer-created content have a significant influence on these two factors.

Specifically, the uniqueness of influencer-created content proved to be a key factor in eliciting feelings of FOMO in Generation Z tourists, even if the destination was not previously popular. This phenomenon demonstrates Generation Z's tendency to seek authentic, exclusive, and distinctive experiences, suggesting that unique content can trigger FOMO without necessarily relying on destination popularity. This is supported by previous research that found that unique

digital content can significantly influence FOMO, as individuals seek to avoid feelings of isolation from the experiences depicted in the content (Maar et al., 2023). Furthermore, content quality was shown to have a significant influence on destination popularity, indicating that content presented in a professional, informative, and visually appealing manner can increase destination popularity. However, this study found that content quality does not directly influence FOMO, but rather through the mediation of destination popularity. In other words, while high-quality content can increase destination attractiveness, its effect on FOMO is only apparent if the destination becomes more popular.

These findings suggest that perceived destination popularity significantly influences FOMO among Generation Z travelers. This result is consistent with previous studies by Kim & Kim (2024) and Oan-Oon & Choibamroong (2025), which demonstrate that destination popularity plays an important role in shaping travel decisions.

This study also shows that content quantity has a significant influence on FOMO and destination popularity. The more content available, the higher the FOMO felt by Generation Z travelers. Abundant content creates a psychological urge to stay on top of certain information or moments. Furthermore, greater content availability can also increase destination popularity, indicating that the presence of consistent and abundant content can increase destination visibility, create a greater desire to visit, and make it more well-known, as found by Bermúdez et al. (2023) and Viet Tran & Thanh Khoa (2025). This finding is consistent with the characteristics of Generation Z, who are responsive to high volumes of information on social media and often make impulse-based decisions due to repeated exposure. On the other hand, the results of this study found that content originality had no significant influence on FOMO or destination popularity. This suggests that Generation Z travelers are more responsive to content with a familiar visual or narrative style. Content that is similar to content that has already gone viral or follows trending visual aesthetics tends to be more accepted and trusted by audiences, even if the content is not entirely original. This finding supports the results of the study by Ulucan (2024), which shows that content that aligns with visual trends is more likely to go viral and increase destination popularity. Therefore, while authentic content can increase influencer credibility, its impact on FOMO and destination popularity is not as strong as content that follows existing visual trends.

This study also contributes to a deeper theoretical understanding of FOMO and destination popularity. Previous research conducted by Rajput & Gandhi (2025) showed that the popularity of trending destinations can create FOMO, which plays a significant role in determining travel decisions, especially among Generation Z, who are heavily influenced by social media. This finding is reinforced by the results of this study, which show that the higher the popularity of a destination, the stronger its influence on FOMO among Generation Z tourists.

This phenomenon indicates that destinations experiencing high popularity through social media will attract more tourists to visit. This illustrates the curious characteristics of Generation Z, where destinations that are widely informed on social media provide a strong incentive to visit those destinations.

If they cannot experience the experiences offered by the destination, they will feel disappointed. Therefore, tourism destination managers must design more effective marketing strategies by utilizing the uniqueness, quality, and quantity of content to increase destination popularity and create FOMO among the audience.

This study also uses the Stimulus Organism and Response (SOR) theory, where the results of the study show that the Stimulus (S), which refers to influencer content published through social media, includes visual quality, originality, quantity, and uniqueness of the content displayed (Ong et al., 2022; Rodrigues et al., 2024), does not always give rise to a sense of curiosity and a desire to connect with trending tourist destinations that are viral or popular on social media (Koç et al., 2023), and creates a psychological response (R) that appears in the form of feeling afraid of being left behind or not following existing developments, related to popular tourist destinations (De Souza et al., 2025).

The results of this study indicate that the stimulus in the form of original content created by influencers on social media is unable to provide a boost of curiosity about destinations that are currently viral or popular, so it cannot create a fear of missing out (FOMO) if you do not visit the popular destination. Therefore, destination managers can utilize marketing through influencer content shared through social media by focusing on paying attention to the uniqueness, quality, and quantity of content rather than considering the originality of the content in increasing the popularity of tourist destinations, which ultimately can create FOMO among Generation Z tourists.

CONCLUSION

This study provides in-depth insights into the influence of influencer content on FOMO feelings and destination popularity, particularly among Generation Z travelers. Based on the Stimulus-Organism-Response (SOR) theory, the findings of this study indicate that influencer content published through social media, which includes elements such as uniqueness, quality, and quantity, acts as a stimulus that influences the organism (Generation Z tourist) to respond with FOMO feelings and increased interest in the destination. The uniqueness of the content is the main factor that triggers FOMO, even if the destination is not yet popular, while the quality of the content significantly influences FOMO by mediating the increase in destination popularity. In addition, a greater amount of content creates a greater psychological urge to stay up to date on certain information or moments about trending or viral destinations, which in turn strengthens FOMO feelings among Generation Z travelers. In contrast, the originality of the content does not significantly influence FOMO or destination popularity, indicating that Generation Z is more responsive to content that follows popular visual trends.

The results of this study support the understanding that stimuli in the form of quality, quantity, and uniqueness of influencer content can encourage Gen Z tourists to have curiosity about destinations that are currently viral or trending, thus creating a psychological response in the form of FOMO, which ultimately encourages tourists to visit these popular tourist destinations. Therefore, tourist destination managers can utilize SOR theory to design more effective marketing strategies by

focusing on stimulus elements that can trigger FOMO and increase the popularity of destinations among Generation Z audiences. Overall, this study emphasizes the importance of tourism destination managers and influencers working together to create high-quality, engaging, and consistent content. An effective marketing strategy should involve the use of engaging visual content, increased posting frequency, and content selection that aligns with emerging trends.

Therefore, destination managers should consider the popularity of a destination as a crucial element in building FOMO, which can increase tourists' interest in visiting. Furthermore, it is important to understand that the FOMO effect created must be carefully managed, given the potential negative impacts of overtourism or environmental damage.

Therefore, destination managers need to plan marketing strategies that not only aim to increase short-term popularity but also ensure the sustainability of the destination and provide a quality tourism experience for tourists.

Research Limitations

This study has some limitations that should be considered. Firstly, it used a cross-sectional approach, which limits the understanding of how tourist motivations and experiences develop over time. Future research could use a longitudinal approach to explore changes in tourist behavior over time, particularly in relation to the impact of FOMO and destination popularity. Secondly, this study relied solely on a questionnaire for data collection, which could lead to perceptual bias. Future studies could incorporate mixed methods to reduce this bias and offer more detailed insights into tourist experiences. Thirdly, this study did not distinguish between the influence of different social media platforms, despite the fact that each platform has its own unique characteristics in terms of content and user interaction. Future research should examine the differences in how various social media platforms influence the promotion of tourist destinations.

The impact of integrated management systems on environmental responsibility and complaint elimination in the hotel sector of the Visegrad Four countries. *Geojournal of Tourism and Geosites*, 67(3), 2192–2198. https://doi.org/10.30892/gtg.67332-1844

Abstract: This article examines the relationships between the implementation complexity of integrated management systems, environmental responsibility, and operational efficiency in hotels within the V4 countries. The aim was to analyse the impact of procedural complexity on the willingness to adopt environmental standards and to evaluate whether integrated quality management systems contribute to reducing customer complaints. The research was conducted in 2025 on a sample of 312 hotels in Slovakia, the Czech Republic, Poland, and Hungary using the Computer-Assisted Web Interviewing (CAWI) method, achieving a response rate of 65.27%. Spearman's rank correlation coefficient and the Independent Samples t-test were applied to verify the proposed hypotheses. The statistical analysis confirmed a strong negative correlation ($\rho = -0.742$; $p < 0.001$) between implementation complexity and the level of environmental activity, indicating that administrative burden represents a major barrier to the adoption of sustainable management practices. At the same time, hotels with an established quality management system recorded significantly fewer customer complaints (1.82 per 100 guests) than non-certified hotels (4.18 per 100 guests). The findings demonstrate that integrating quality and environmental management systems generates measurable operational and reputational benefits while highlighting the importance of simplifying implementation procedures. The study contributes to the literature on Green Quality Management in the Central European hospitality sector and provides practical recommendations for hotel managers seeking to improve service quality, strengthen environmental responsibility, and enhance long-term competitiveness through integrated management approaches. The findings also provide empirical evidence supporting the wider adoption of integrated management systems as a strategic tool for sustainable hotel development in the V4 region.

Keywords: destination loyalty, environmental practices, service quality, sustainable tourism, visitor satisfaction

INTRODUCTION

The current global accommodation services sector has been undergoing a period of radical paradigmatic transformation over the last five years. Traditional management models, which historically focused exclusively on volume maximization and immediate profit, are currently being replaced by sophisticated models built on digital agility, an ethical approach, and environmental integrity (Buhalis, 2020). In the specific socio-economic space of the Visegrad Group (V4) countries, this process is amplified not only by post-pandemic recovery and the energy crisis but primarily by increasing legislative pressure from the European Union in the areas of ESG (Environmental, Social, and Governance) reporting and taxonomy requirements for sustainability (Bani-Melhem et al., 2022). Today, 3* to 5* category hotels in this region face competition not only in price or location but, above all, in the ability to demonstrate systemic quality linked to authentic environmental responsibility, which is becoming a key determinant of the modern traveller's purchasing behaviour. Despite the proclaimed support for green innovations and digital transformation, the practice of Central European hospitality exhibits a phenomenon defined by the academic community as "implementation paralysis" or resistance to systemic change. Hotel management in the V4 region often perceives the introduction of certified management systems (such as ISO 9001 or ISO 14001) not as a strategic investment in efficiency, but as a bureaucratic burden and an administrative barrier that consumes critical personnel and financial resources (Yeh et al., 2017; Vargová & Matušíková, 2025). This study, therefore, responds to the existing scientific gap in understanding the causal relationship between the perceived procedural complexity of these systems and the actual willingness of enterprises to implement environmental standards. In an era of online reviews and user-generated content, guest feedback has become a critical source of information for improving service quality and maintaining hotel competitiveness (Xiang et al., 2015). At the same time, digital transformation and smart tourism technologies enable hotels to respond more effectively to customer expectations and continuously improve service quality (Buhalis, 2020). Consequently, the ability to

eliminate operational deficiencies and customer complaints through rigorous systemic management has become a decisive factor for the long-term competitiveness and reputation of hotel facilities in the Central European region.

THEORETICAL BACKGROUND

Integrated Management Systems (IMS) and Process Synergy

The traditional concept of Total Quality Management (TQM) has gradually evolved into Integrated Management Systems (IMS), which combine several international management standards into a single coherent framework. The core of these systems is typically the ISO 9001 standard (quality management), which is commonly integrated with ISO 14001 (environmental management) and ISO 45001 (occupational health and safety), enabling organisations to improve process efficiency, reduce duplication, and strengthen overall organisational performance (Zeng et al., 2007).

According to Zeng et al. (2007), the successful implementation of integrated management systems reduces process duplication and improves organisational coordination. However, their effectiveness depends largely on top management commitment, organisational capabilities and the successful integration of management practices into everyday organisational processes. Innovation in the hospitality industry depends not only on the implementation of formal management systems but also on organisational conditions that support employees' intrinsic motivation, empowerment and innovative behaviour. Hotels that foster these organisational capabilities are better positioned to implement new managerial practices and improve their competitiveness (Khalifa et al., 2023).

Green Quality Management (GQM) and Barriers in the V4 Countries

The concept of "Green Quality Management" (GQM) currently represents the most advanced approach to managing hotel services, where quality control tools are directly linked to environmental sustainability goals (Buhalis et al., 2023). Despite clear benefits in terms of energy optimisation, waste reduction and customer loyalty, the implementation of GQM still faces significant organisational and economic barriers. Early evidence by Mensah (2006) showed that although many hotels recognise the importance of environmental management, the adoption of structured environmental practices varies considerably according to hotel characteristics and available organisational resources. Garay & Font (2012) demonstrated that the successful implementation of environmental initiatives in accommodation enterprises depends largely on managerial commitment and the effective integration of sustainability practices into everyday business operations. Similarly, Vargová & Matušíková (2025) found that tourism enterprises perceive environmental innovations as beneficial for competitiveness, but their implementation is constrained by high implementation costs, technical requirements and the need for specialised knowledge. Consistent with these findings, Yeh et al. (2017) argue that hotels often hesitate to adopt green management practices because managers perceive substantial organisational and economic barriers and because the benefits of environmental initiatives are not always immediately reflected in customer perceptions or short-term business performance. Robinot & Giannelloni (2010) additionally demonstrated that customers do not always recognise or value environmental initiatives unless these are effectively communicated and integrated into the overall service experience.

Psychological Factors: Authenticity versus Greenwashing

Current academic discourse increasingly emphasizes the distinction between genuine, systemic implementation of sustainable solutions and their superficial marketing presentation. Hotels that implement environmental initiatives only superficially risk being perceived as engaging in greenwashing, which may undermine customer trust and reduce the credibility of sustainability claims (Garay & Font, 2012). Authentic sustainability practices have become an increasingly important factor influencing guests' perceptions and service evaluation. Beresecká et al. (2024) further demonstrated that the labelling and communication of accommodation services significantly influence guests' emotional perceptions and the overall evaluation of hospitality services, highlighting the importance of transparent and credible communication.

In the Central European context, Lőrincz et al. (2022) also highlight the growing importance of sustainability-related attributes in shaping customer perceptions of hospitality services. Olya et al. (2021) demonstrated that hotels' sustainability practices positively influence guests' satisfaction and loyalty, particularly when guests are familiar with these environmental initiatives. Similarly, Thai & Nguyen (2022) found that green hotel practices enhance customer satisfaction and strengthen the hotel's green image, which subsequently encourages positive customer behaviours and greater engagement with the hotel. Therefore, integrating quality management with environmental management systems enables hotels to communicate sustainability initiatives as an authentic part of their value proposition, thereby increasing the perceived value of the service.

Complaint Elimination via Standard Operating Procedures (SOPs)

Customer complaints in the hospitality industry represent an important source of information for improving service quality and maintaining customer satisfaction. They provide managers with valuable feedback regarding operational deficiencies, service inconsistencies, and unmet customer expectations, enabling continuous quality improvement. According to Kandampully et al. (2015), an effective quality management system serves as a preventive and stabilising mechanism that minimises operational errors through clearly defined Standard Operating Procedures (SOPs), thereby supporting consistent service quality despite operational challenges. Standardised operating procedures reduce service variability, facilitate employee training, and ensure that critical service processes are performed consistently regardless of staff turnover. In the digital environment, customer complaints expressed through online reviews have become an increasingly important indicator of service quality and organisational performance, significantly influencing hotels' reputation and competitiveness (Xiang et al., 2015). Consequently, the systematic collection, analysis, and elimination

of recurring complaints should be regarded as an integral component of integrated quality management. By combining standardised operational procedures with continuous customer feedback, hotels can reduce service failures, improve guest satisfaction, and strengthen their long-term competitive position.

Regional Trends and Digital Transformation in the Hospitality Industry

Within Poland, the ISO 14001 standard is becoming a key differentiation tool for competitiveness in the international market (Fonseca & Domingues, 2018). In Hungary, increasing attention has been devoted to integrating sustainability attributes into hotel services, as guests increasingly value environmentally responsible accommodation and holistic sustainability practices (Ásványi & Chaker, 2023). Recent studies indicate that the implementation of smart technologies and digital solutions supports more efficient destination and tourism management by simplifying operational processes and improving decision-making (Gajdošík, 2019). Previous research indicates that investments in environmental sustainability and systematic quality management can strengthen hotels' long-term competitiveness and organisational performance (Singjai et al., 2018; Kandampully et al., 2015).

Zeng et al. (2007) demonstrated that the successful implementation of integrated management systems depends largely on top management commitment, organisational capabilities and the effective integration of management practices into everyday organisational processes. Based on the synthesis of the aforementioned literature, we formulated two primary hypotheses that address the identified research gaps.

Hypothesis 1 (H1), is grounded in the findings of Khalifa et al. (2023), Yeh et al. (2017), and Vargová & Matušíková (2025), who identify administrative and organisational barriers as key inhibitors of environmental innovation and the implementation of management systems.

Hypothesis 2 (H2), which assumes that quality management leads to a reduction in customer complaints and environmental deficiencies, stems from the theoretical framework of Kandampully et al. (2015) regarding the stabilising role of Standard Operating Procedures (SOPs) in service quality. In this context, the development of a methodological model for the digital passportization of tourism in Slovakia appears to be a critical step. Such a system would enable the standardized digital recording of hotel attributes, including their environmental and quality certifications, thereby facilitating more efficient management and benchmarking within the sector.

For this reason, the aim of the study was to find out through the following research questions:

RQ1: To what extent does the perceived administrative and procedural complexity of integrated management systems act as a barrier to the implementation of environmental responsibility standards in hotels within the V4 region?

RQ2: Is there a statistically significant difference in the frequency of customer complaints between hotels that have implemented a quality management system and those that operate without such a system?

MATERIALS AND METHODS

The aim of the research was to analyse the relationships between the complexity of management system implementation, environmental responsibility, and operational efficiency expressed through the complaint rate in the hotel sector of the V4 countries. Based on the theoretical framework and anticipated barriers in the service sector, the following hypotheses were established:

Hypothesis 1 (H1): We assume that the complexity of implementing integrated quality management systems significantly influences the rate of adoption of environmental standards within the management of hotel facilities.

Hypothesis 2 (H2): We assume that the implementation of quality management positively affects the elimination of deficiencies in environmental responsibility, leading to an overall reduction in the number of customer complaints.

The survey was conducted in 2025 to obtain a representative perspective of the Central European hotel market. Out of a total of 478 contacted hotels, 312 entities participated in the research. To ensure high data quality, the sample was categorized by hotel standard (stars) across all V4 countries:

Poland (PL): 115 hotels in total, consisting of 54 (3*), 48 (4*), and 13 (5*) facilities.

Czech Republic (CZ): 85 hotels in total, consisting of 42 (3*), 33 (4*), and 10 (5*) facilities.

Hungary (HU): 62 hotels in total, consisting of 31 (3*), 24 (4*), and 7 (5*) facilities.

Slovakia (SK): 50 hotels in total, consisting of 25 (3*), 19 (4*), and 6 (5*) facilities.

In summary, the final sample (n = 312) comprised 152 three-star hotels (3), 124 four-star hotels (4), and 36 five-star hotels (5)*. The distribution of the sample by country and their share in the total research is presented in the following Table 1.

Table 1. Research sample distribution and response rate by country (Source: own processing)

Country	Number of Contacted Hotels	Number of Returned Questionnaires (n)	Response Rate within Country	Share of Total Sample
Poland (PL)	180	115	63.89 %	36.86 %
Czech Republic (CZ)	130	85	65.38 %	27.24 %
Hungary (HU)	90	62	68.89 %	19.87 %
Slovakia (SK)	78	50	64.10 %	16.03 %
TOTAL	478	312	65.27 %	100.00 %

Data were collected using a structured questionnaire (CAWI), which was distributed to hotel managers. The variables were quantified as follows:

1. Perceived Complexity: Measured using a 5-point Likert scale (1 – minimum complexity, 5 – high complexity), encompassing financial, temporal, and personnel aspects.
2. Environmental Activity: An index score based on the presence of green certifications (e.g., ISO 14001, EU Ecolabel) and internal eco-policies.
3. Management Quality: Binary classification (certified quality management system vs. informal management).
4. Customer Feedback: The average number of official complaints recorded per 100 guests during the monitored period.

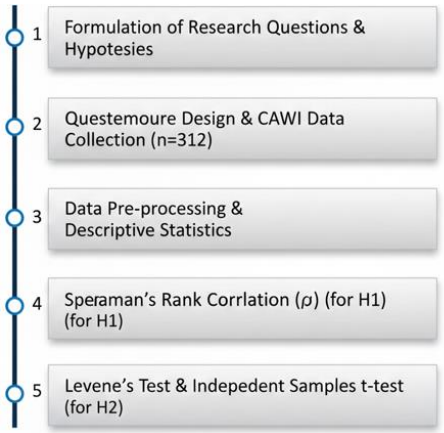

Figure 1. Display of methodological progression (Source: own processing)

The primary data obtained were subjected to statistical analysis using IBM SPSS Statistics software. The analytical procedures were selected based on the nature of the variables and the distributional characteristics of the dataset:

For Hypothesis 1 (H1): Spearman's rank correlation coefficient (ρ) was employed to test the relationship between implementation complexity and environmental activity. This non-parametric test was chosen because the data regarding perceived complexity are ordinal in nature (5-point Likert scale) and do not meet the assumption of a normal distribution.

For Hypothesis 2 (H2): An Independent Samples t-test was used to compare the means of two independent groups (hotels with a certified management system vs. those without). Prior to the t-test, Levene's Test for Equality of Variances was performed to verify homoscedasticity, ensuring the reliability of the comparison between the groups.

The methodological progression of this study, as illustrated in Figure 1, follows a structured multi-stage framework designed to ensure high internal validity1. The process began with the identification of specific research gaps within the V4 hotel sector, leading to the formulation of two research questions and corresponding hypotheses.

Data collection was executed through a targeted CAWI survey of 312 hotels, ensuring a representative sample across all V4 countries. For data analysis, we employed a combination of non-parametric tests (Spearman's ρ) to evaluate implementation barriers (H1) and parametric tests (Independent Samples t-test) to quantify operational efficiency gains (H2), following rigorous checks for homoscedasticity via Levene's test.

RESULTS AND DISCUSSION

In this chapter, we present the statistical evaluation of the primary data obtained from the research conducted in the V4 countries. The analysis focuses on the verification of two established scientific hypotheses using a sample of n=312 hotel facilities in the 3–5 categories

The objective of testing H1 was to identify the degree of dependence between the perceived complexity of implementing integrated management systems (independent variable) and the level of adoption of environmental standards (dependent variable). Given the ordinal nature of the data, Spearman's rank correlation coefficient (ρ) was applied.

Table 2. Correlation analysis of environmental activity dependence on procedural complexity (Source: own processing)

Statistical Indicator	Value (V4 total)	Interpretation of Result
Spearman's Coefficient (ρ)	-0.742	Strong negative correlation
Coefficient of Determination (R2)	0.551	High degree of influence (55.1%)
Significance Level (p-value)	< 0.001	Statistically highly significant
Standard Deviation	0.48	High degree of respondent consensus

The results in Table 2 confirm a strong indirect linear dependence. The coefficient of determination $R^2 = 0.551$ suggests that the perceived complexity of processes explains more than half of the variability in the rate of adopting environmental innovations. Based on $p < 0.001$, we can conclude that hypothesis H1 is confirmed. For hotel management in the V4 region, the administrative and temporal complexity of certification represents a barrier that significantly inhibits pro-environmental behavior. Within H2, we examined the effectiveness of quality management systems in eliminating operational deficiencies. We compared the average incidence of complaints per 100 guests between hotels with an implemented system and those without. Regarding the sample structure, it is important to note that certified management systems predominated especially in the 5-star category (all 36 facilities) and 4-star hotels (98 facilities), while informal

management prevailed in the 3-star hotel segment. The statistical analysis in Tables 3 and 4 demonstrated that hotels with an implemented quality management system achieve, on average, 2.36 fewer complaints per 100 guests compared to hotels without a system. This 56.5% difference in the error rate confirms the high operational efficiency of process management. This phenomenon is most prominent in the 4-star and 5-star segments, where standard operating procedures (SOPs) are more deeply integrated into daily operations. Given the significance level of $p < 0.001$, we accept hypothesis H2.

Table 3. Descriptive statistics of complaints by the presence of a management system (Source: own processing)

Hotel Group	Number (n)	Mean Complaints	Standard Deviation
With a quality management system	177	1.82	0.65
Without a quality management system	135	4.18	1.24

Note: The group with a system consists primarily of higher-standard hotels (4* and 5*), suggesting a correlation between hotel category and procedural discipline.

Table 4. Independent samples t-test parameters (H2) (Source: own processing)

Parameter	Value	Interpretation
t-statistic	-11.84	Significant difference in means
Degrees of freedom (df)	310	Corresponds to the research sample size
Significance level (p)	< 0.001	The difference is statistically certain

The results provide clear evidence of the economic and reputational value of management systems. While H1 identifies bureaucracy as the primary obstacle to sustainability, H2 demonstrates that overcoming this barrier—particularly in the higher-standard segment (4* and 5*) - leads to significant cost savings associated with guest compensation and strengthens brand reputation in the saturated V4 market.

It appears that although the administrative burden is perceived negatively, its systemic mastery directly correlates with higher operational integrity. The results obtained reveal a specific pattern of managerial behaviour within the hotel segment of the V4 countries. We observe a critical clash between the effort to modernize services and persistent structural barriers defined by the subjective perception of procedural complexity.

The "Administrative Brake" Phenomenon in Environmental Management

The confirmation of hypothesis H1 uncovers problematic areas of current managerial practice in the Central European region. The identified strong negative correlation ($\rho = -0.742$) suggests that environmental responsibility in V4 hotels is not yet perceived as an inherent part of quality management, but rather as an external administrative burden. In the context of the studied region, this phenomenon can be attributed to a certain "historical debt" in the culture of process management. While in Western Europe, standards such as ISO 14001 are accepted as effective tools for optimizing operating costs and resources, managers in the V4 region primarily interpret them through the prism of bureaucracy. The coefficient of determination ($R^2 = 0.551$) clearly indicates that up to 55% of the variability in the implementation of environmental standards is conditioned by the perceived complexity of processes.

This phenomenon is particularly significant in the 3-star hotel segment, which represents 48.7% of our sample (n=152) and often lacks dedicated personnel for the ESG (Environmental, Social, and Governance) area.

Consequently, the key to accelerating sustainable tourism is not merely tightening regulations, but radically simplifying implementation frameworks. A promising solution to this 'administrative brake' is the implementation of digital passportization systems. By modeling tourism data digitally, the administrative burden associated with certification and reporting could be significantly reduced, allowing hotel managers to focus on the actual implementation of sustainable practices rather than on manual documentation.

Quality as an Economic Shield Against Increasing Complaints

The verification of hypothesis H2 provides a fundamental counterargument to concerns regarding implementation complexity. Although the introduction of Quality Management Systems (QMS) is perceived as complex, its impact on operational stability is demonstrable. The profound difference in the average number of complaints (1.82 for certified hotels vs. 4.18 for non-certified) confirms that investment in systemic management represents a highly effective form of risk management in the V4 context. We explain this significant difference by the high degree of standardization.

Our analysis showed that while 5-star hotels in the V4 region utilize the benefits of certification extensively, clearly defined Standard Operating Procedures (SOPs) are absent in lower categories.

At a time when the V4 labour market faces acute fluctuation, SOPs serve as a key stabilizing element. The modern guest in the 3-star to 5-star hotel segment demands a consistent level of service; our data confirm that process-driven hotels can eliminate human factor failures, which are the primary source of complaints in the hospitality industry.

Synergy of Quality and Ecology: An Integrated Approach as the Way Forward

A surprising, yet logically following finding is that hotels that successfully overcame the complexity barrier (H1) automatically achieve the best results in guest satisfaction (H2). The modern customer in the V4 region is undergoing a knowledge transformation; they no longer complain only about primary deficiencies (e.g., a "cold dinner") but have become highly sensitive to environmental lapses, such as the excessive use of single-use plastics. This finding is consistent

with Ülkü (2025), who demonstrated that hotel managers still prioritize service quality over sustainability objectives, although the long-term competitiveness of hotels depends on achieving an appropriate balance between these two dimensions. An Integrated Management System (IMS) thus protects the hotel from two critical risks simultaneously: operational error rates and reputational damage in the area of greenwashing. The future success of hotel facilities in the V4—from family-owned 3-star pensions in the Tatra Mountains to luxury Warsaw hotels—will depend on the ability of managers to perceive ecology not as isolated "extra work," but as an integral part of the overall promise of quality.

CONCLUSIONS

The aim of this study was to examine the relationships between the implementation of management systems, the perceived complexity of processes, and their impact on environmental responsibility and guest satisfaction within the hotel sector of the V4 countries. The empirical analysis of the sample of 312 hotels yielded key insights that advance both theoretical understanding and managerial practice within the hospitality industry. The research confirmed both established hypotheses. First, a high perceived complexity of implementation acts as a significant barrier preventing hotels from transitioning to sustainable business models (H1). This reveals that administrative paralysis remains a primary obstacle to green innovation in Central Europe, as complex documentation requirements distract hotel operators from adopting functional ecological initiatives. Second, it was demonstrated that hotels that overcame this resistance and implemented a formal quality management system exhibit a 56.5% lower rate of customer complaints (H2). This substantial reduction in operational errors underscores that process standardization acts as a stabilizing mechanism for service quality.

This synergistic effect proves that quality and ecology are not in conflict but form a common foundation for increasing competitiveness in the region. From a practical perspective, these findings yield several critical managerial implications. Hotel executives must focus on the reduction of administrative burden by prioritizing process digitalization, which can effectively lower perceived system complexity and free up operational capacity for environmental measures.

In this context, hotel managers are encouraged to actively participate in emerging systems of digital passportization. Adopting these methodological frameworks for the digital evidence of service quality enhances procedural transparency and offers a distinct competitive advantage in the V4 digital marketplace. Furthermore, standardization of operating procedures (SOPs) serves as a vital cost-saving tool, ensuring service stability even amidst the high employee turnover typical of the Central European hospitality sector. To maximize operational efficiency, ecological measures should be integrated directly into daily quality checklists, ensuring that sustainable behavior becomes a routine operational habit rather than an additional administrative burden. Ultimately, this study contributes to the development of Green Quality Management theory within the specific context of the transitioning economies of Central Europe. By illustrating how quality standards directly mitigate operational risks while fostering environmental responsibility, the research provides a holistic framework for regional hospitality management. To build upon these findings, future research should focus on the longitudinal monitoring of hotels over extended periods (5 years or more) to systematically measure the long-term return on investment (ROI) of environmentally oriented quality management systems and evaluate the sustained durability of these integrated processes.

Limitations of the study

Despite the robustness of the data obtained and the high statistical significance of the results, it is essential to consider certain methodological limitations when interpreting the findings:

- Self-reporting Bias: The primary data were generated through surveys administered to hotel managers. As noted by Podsakoff et al. (2003), self-reported survey data are susceptible to common method bias and social desirability bias, potentially leading respondents to overstate socially desirable behaviours, including their commitment to environmental responsibility. Similarly, Kandampully et al. (2015) warn that managers might underreport the incidence of complaints to protect the enterprise's reputation.
- Abstraction of Cost Indicators: The variable "implementation complexity" was operationalized as a subjective managerial attitude. This study encounters a limitation defined by Vargová & Matušíková (2025)—the absence of objective financial data (e.g., actual audit costs in EUR), which prevents a precise quantification of the investment's break-even point.
- Heterogeneity of the V4 Legislative Environment: Although the V4 countries share a common geopolitical space, differences in national regulatory frameworks and institutional support mechanisms may influence hotels' willingness to adopt environmental standards beyond the legal minimum (Vargová & Matušíková, 2025). These external factors were not explicitly incorporated into our analytical model and may therefore have affected the observed relationships.
- Sectoral Constraints: The research focused on the 3-star to 5-star hotel segment (with a significant representation of 3 and 4 categories, comprising 88.5% of the sample). According to Gajdošík (2019), these categories exhibit a higher degree of procedural discipline; therefore, the results cannot be automatically generalized to the budget accommodation or pension segments.
- Cross-sectional Nature of the Data: This study is based on a cross-sectional research design, which does not allow the long-term effects of integrated management systems on organisational performance to be assessed. Future longitudinal studies are therefore needed to evaluate the sustainability of these effects over time.

Trends and patterns in social media and ecotourism research: A bibliometric analysis. *Geojournal of Tourism and Geosites*, 67(3), 2199–2212. https://doi.org/10.30892/gtg.67333-1845

Abstract: The main aim of this study to conduct a bibliometric analysis and to identify the publication trends, major contributions, thematic structures and future directions in field of social media and ecotourism. Between 2011 and 2025, 301 publications were gathered from Scopus database on social media and ecotourism have been identified.The VOSviewer and the R softwares were utilised for all the analyses. According to the results, the number of studies in this domain has grown over the previous few years. Also, the results co-occurrences analysis revealed that social media and its impact on ecotourism have continued to be the primary areas of study. This study may create a base for the emerging topic of social media and ecotourism by evaluating pertinent articles, allowing future scholars to analyse the usage and advantages of social media in ecotourism. This study will help the academicians and researchers to understand the gaps in the existing literature and prospective study paths, which would help them perform future investigations. The analysis results add to a comprehensive knowledge of social media and ecotourism research development. The findings further indicate that Sustainability (Switzerland), the Journal of Sustainable Tourism and the Journal of Outdoor Recreation and Tourism are the leading outlets in this domain, while China, Australia and the United States emerge as the most productive contributing countries. Bibliographic coupling, citation and co-citation analyses further map the intellectual foundations of the field and identify the authors, countries and sources that anchor its scholarly conversation. The thematic map distinguishes motor, basic, niche and emerging themes, with tourist behaviour, sustainable tourism development and the tourism industry emerging as the most promising directions for future enquiry.

Keywords: social media, ecotourism, tourism, bibliometric analysis, VOSviewer, bibliometrix, rstudio, thematic maps

INTRODUCTION

Social media (SM) has grown into an integral component of our everyday life. Individuals utilise it for different reasons, including gathering or sharing information, awareness about any commodity, location, incident, or business. It allows users to communicate with other people worldwide (Williams et al., 2012).

It can be termed as a collection of internet-based applications building on ideological and technical platforms of Web 2.0, and enable the development and sharing of user generated content (Kaplan & Haenlein, 2010). Individuals generate, distribute, and exploit a wide scope of online sources of data, particularly, social media, to inform other people about the things, services, and brands present in the market (Murugesan, 2007). Examples of social media platforms are contemporary social networking sites such as Facebook, photo and video sharing sites such as Flickr and YouTube, and professional networking sites such as LinkedIn, micro-blogging sites such as Twitter and many others.

The utilisation of SM is one of the most prevalent internet activities. Worldwide, there were around 4.26 billion users of social media in 2021 (Dixon, 2023). Recent advances in information and communication technology (ICT) have boosted the appeal of SNSs. This spike has had a significant influence on consumer behaviour and decision-making, notably in the areas of trip planning and purchasing travel-related items and services (Buhalis, 1998). Furthermore, ecotourism is visiting relatively intact natural places to appreciate the beauty of natural landscapes, learn about animals,

and experience unique local cultures while ensuring the preservation of the environment in those locations (Lee & Jan, 2019). With an increasing awareness of the need of sustainable tourism growth, ecotourism serves as a panacea for mitigating negative consequences and a crusader for eco-friendly activities (Li et al., 2021). This type of tourism is distinguished by its responsible approach, which contributes significantly to the global tourist sector while minimising its influence on socio-cultural factors and natural resources (Walsh & George, 2019; Sharma & Arora, 2024). Nowadays, ecotourism is regarded as among the fastest expanding market categories in the travel industry, with a promising future, especially in light of rising visitor demand for the ideal natural experience throughout the world.Web2.0 has been used to demonstrate ICT applications in ecotourism. Planeta.com is a good example of Web2.0 in ecotourism since it uses User Generated Content (UGC) to encourage interaction, cooperation, and information exchange among users who have a common purpose that aligns with the core values of ecotourism (Chai, 2008).

Social media and the internet have revolutionised all aspects of social life, including relationships, use, interactions, and economy. Integrating these technologies remains a huge challenge for individuals, notably enterprises, and, in the tourist industry, destinations (Özdemir & Çelebi, 2015). Due to the rapid advancement of technology and its extensive incorporation into the global network, destination management organisations (DMOs) must adapt and integrate tools and methods to improve the efficiency and efficacy of destination marketing. This is critical in addressing the issues given by the competitive landscape of the modern tourist business (Soteriades, 2012; Sharma et al., 2024).

There were significant changes in the diffusion of information about tourism products, and the introduction of SNSs has influenced traveller planning and consumption habits (Buhalis & Law, 2008). The information available on these websites is usually used to plan the trips by tourists. They visit the internet to research destinations, seek information about their trips, and they plan sufficiently. Social media platforms are regarded as the most successful marketing instruments used by operators of ecotourism to boost visitor awareness and to promote ecotourism (Sarkar & Lecturer, 2016; Sharma & Arora, 2025). Both the internet and social media have effectively impacted the nature and extent of the ecotourism sector. Not only ecotourism service providers, but also ecotourism travellers, utilise various social sites based on their demands. They choose different social media channels for different goals.

Bibliometric studies have been utilized regularly in academia to investigate the evolution, progress, and significance of numerous academic topics (Apriliyanti & Alon, 2017). As ecotourism has risen as a prominent field of study during the last two decades, the increase in study on ecotourism has prompted a reassessment of what is now known about this domain. Existing studies on ecotourism and social media have been conducted in different contexts like social media's role in the development of ecotourism (Bindu et al., 2018; Gaffar et al., 2022), social media and ecotourism destinations' intentions(Chi, 2021; Sharma et al., 2023), ecotourism promotion through social media (Clark et al., 2022; Chen et al., 2021; Alaflak et al., 2025; Sharma, Khatri, Khan, et al., 2023). Also, numerous studies conducted bibliometric analysis linking social media with tourism (Nusair et al., 2019), social enterprise (Ali et al., 2022), psychology (Zyoud et al., 2018) and many more. Furthermore, there are many studies like Khanra et al. (2021); Liu & Li (2020); Nordin & Jamal (2020); Hasana et al. (2022); Esparza-Huamanchumo et al. (2024); Kropinova et al. (2023) which have been conducted on ecotourism bibliometrics. However, the research that highlights the evolution and present scenario of ecotourism and social media study is still at its nascent stage. Also, this is the first attempt to provide the science mapping, performance and network analyses of the social media and ecotourism research. So, to fill these research gaps this study addressed the below listed research questions.

Q1- What is the current publication trend in the field of social media and ecotourism?

Q2- Who are the key contributors in the domain of social media and ecotourism?

Q3- What are the mature and emerging themes in the domain of social media and ecotourism?

The rest of the article is divided into seven parts: Section 2 will cover the methodology that the authors chose to include in order to explore the phenomenon, Section 3 will include the results, Section 4 will cover the discussion of the results, Section 5 will cover the conclusion, Section 6 will cover the implications of the research, and finally Section 7 will cover the limitations of the research.

RESEARCH METHODOLOGY

Data Collection

The current research utilised the Scopus that provides a wide range of academic literature. The database is especially applicable and also helpful in targeted studies like bibliometric research. The terminology utilized in this study was a blend of two cross-disciplinary components: social media and ecotourism. To make sure that all aspects of social media and ecotourism were addressed in this study, the keywords linked with each domain were included.

The search string "Ecotourism" OR "Nature-based tourism" OR "eco-tourism" OR "Sustainable tourism" AND "Social media" OR "Social media networking" OR "Social media platforms" OR "Facebook" OR "Instagram" OR "YouTube" OR "SNSs" OR "Social networking sites" OR "Twitter" was finalized.159 published publications were revealed by this search string in the subjects of "Business, management and accounting, Environmental science, Arts and Humanities, Multidisciplinary, Economics, Econometrics and Finance and Social sciences" from journals as well as conference proceedings. Our data retrieval procedure and search approach is summarised in Figure 1. Furthermore, any search engine, including Scopus, is susceptible to providing inaccurate bibliometric and bibliographic data due to the quoting of the original articles in later manuscripts (Baker et al., 2021). Thus, processing such data directly without data cleansing poses the risk of producing inaccurate analysis. As a consequence, we had to go through several steps to clean and organize the data. As indicated by Donthu et al. (2021), we searched for "bibliographic and bibliometric data, as well as visualization and

interpretation of the results". We removed a total of four records that lacked author and title names. An overview of the complete research design followed in this study, from database selection to the reporting of results, is presented in Figure 2.

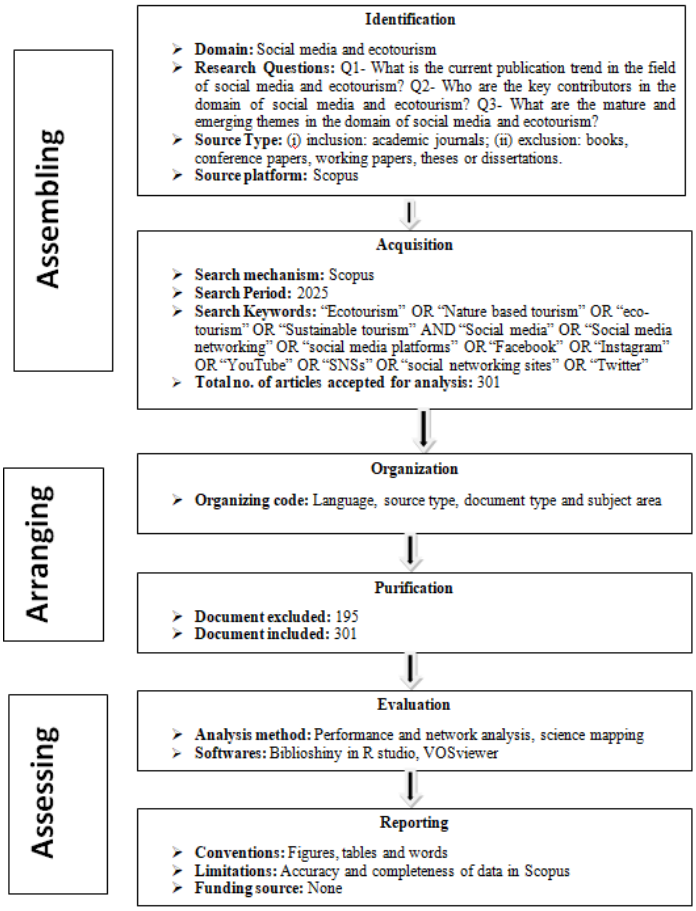

Figure 1. SPAR-4-SLR Protocol adapted from Paul et al. (2021) (Source: Authors' Own)

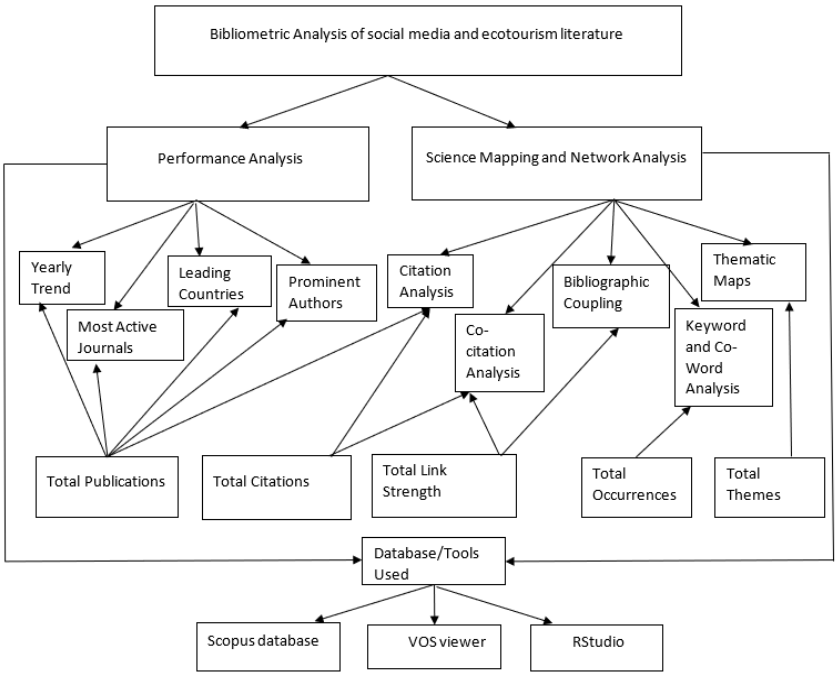

Figure 2. Overview of the study (Source: Author's Own)

Analysis Techniques

The data was analysed using "VOSviewer software and Bibliometrix package from R software". VOSviewer is utilized to create maps of authors or journals on the basis of the co-citation information, or maps of keywords on the basis of co-

occurrence information. It is a bibliometric network generation and visualisation tool. These networks all can be established through the use of citation, bibliographic coupling, co-citation, or co-authorship relationship and may be made out of journals, researchers, or single articles. VOSviewer displays a bibliometric map in a variety of ways, each highlighting a distinct facet of the map (van Eck & Waltman, 2010).Furthermore, "Bibliometrix is a package for the R statistical programming language for quantitative research in scientometrics and bibliometrics" (Pritchard, 1969). Bibliometrix includes a variety of analytical techniques that are appropriate for practitioners via Biblioshiny. It primarily works with data from "WoS, Scopus, and Dimensions". So, the VOSviewer and Bibliometrix were appropriate for data analysis for the current study.

RESULTS

Q1: Current publication trend

The publication trend in the domain of social media and ecotourism reveals a dynamic and rapidly growing research area, as evidenced by the bibliometric data extracted from the Scopus. This section elaborates on no. of publications, top publishing countries, the journals with the greatest no. of publications, and authorial dimensions of publication trends to provide a comprehensive understanding of the research evolution. A consolidated summary of these four dimensions is presented in Table 1.

Table 1. Current trends

Year Analysis		Source Analysis		Authors Analysis		Countries Analysis	
Year	**Documents**	**Source**	**Documents**	**Authors**	**Documents**	**Countries**	**Documents**
2025	62	Sustainability Switzerland	52	Pickering, C.M.	5	China	46

2012	1	-	-	-	-	-	-
2011	3	-	-	-	-	-	-

Distribution of publication year

The latest trends in the social media and ecotourism field have been discussed by taking into consideration the amount of exploratory articles and longer periods of publication between 2011 and 2025.

The comparison of yearly production of publications since 2011 to 2025 shows that the trend is distinctively rising, indicating the growing academic concern on the role of social media in ecotourism. Publications on the subject are still very few, with 3 papers in 2011, as this is a fledgling interdisciplinary area. Nevertheless, the publications have been increased significantly, with 67 publications in 2024 and 62 publications in 2025, which points to the continuous growth and developmental motion of this research field. This tendency implies that the impact of social media on the ecotourism industry is a new priority in the academic discussion, and it is predetermined by the general tendencies in digital communication and sustainable tourism activities. The results are depicted in Figure 3.

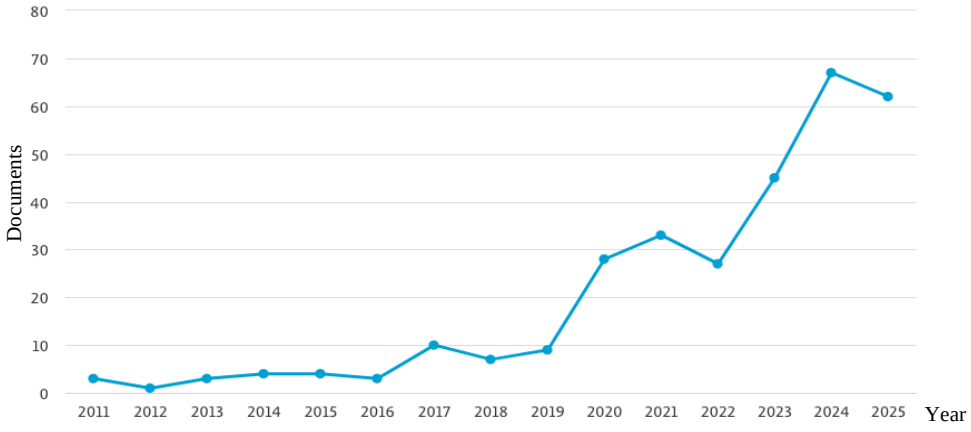

Figure 3. Documents by year (Source: Authors' own elaboration based on Scopus data)

Coverage of research regions

The geographical distribution of research input is in 57 countries, which proves the international sense of social media in ecotourism research. Asia-Pacific and North America China has the highest number of 46 publications, Australia (36) and the United States (34) come next, and this indicates excellent research on the subject. This distribution represents the strategic significance of the ecotourism and social media utilization in these areas, which could be explained by their wide range of ecotourism attraction sites and well-developed digital infrastructure. The participation of such countries as Indonesia, the United Kingdom, Malaysia, and South Korea only stresses the international interest and multidisciplinary cooperation that shaping the field. The results are depicted in Figure 4. Country-level bibliometric mapping of this kind has been shown to be an effective way of profiling the international structure of a research field (Merigó et al., 2016).

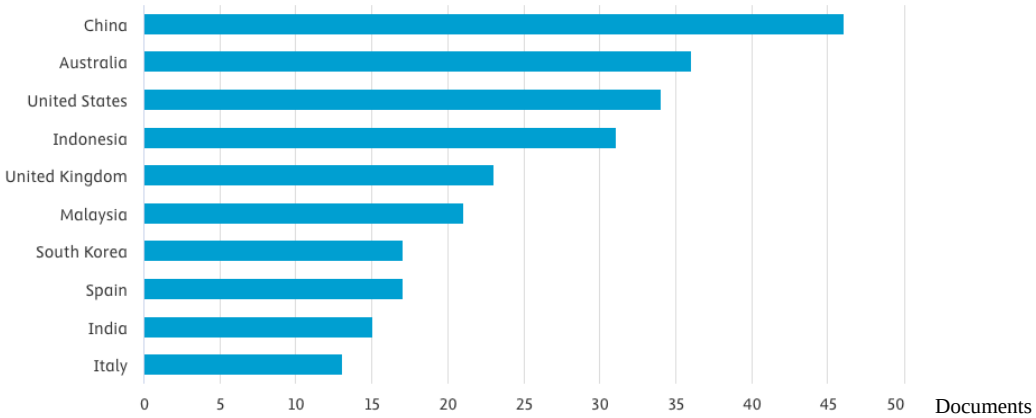

Figure 4. Documents by country (Source: Authors' own elaboration based on Scopus data)

Distribution of publication sources

The sharing of the research findings is focused on major academic journals, and the number of published articles is 301 in 76 journals. Sustainability Switzerland presents the highest number of publications (52 papers), then there is the Journal of Sustainable Tourism (20 papers), and the Journal of Outdoor Recreation and Tourism (14 papers). This concentration indicates that the scholars give preference to the journals that are related to the sustainability and tourism management as they are closer to the themes of the importance of social media on ecotourism. The popularity of these journals also shows that they are the most important sources of knowledge development and the promotion of discussions in this niche. The results are depicted in Figure 5.

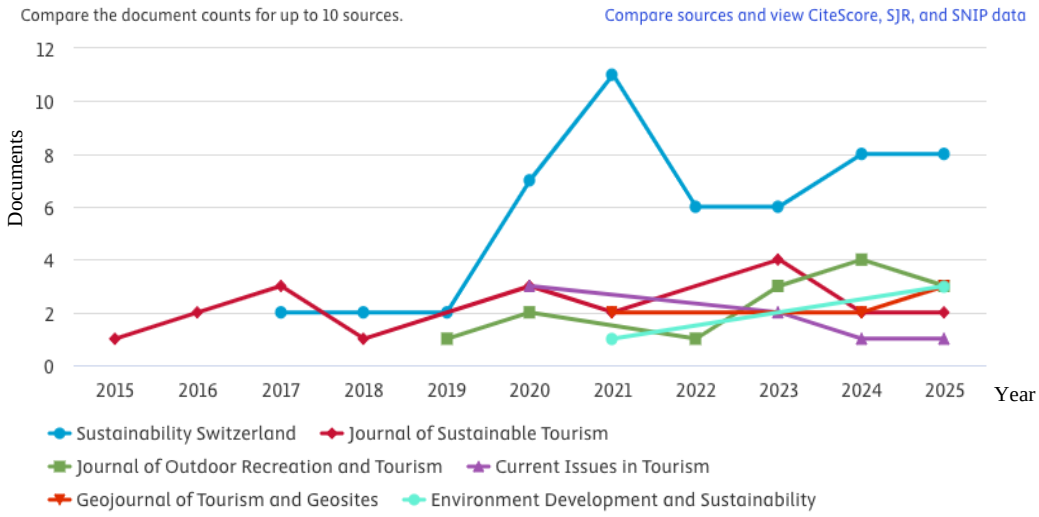

Figure 5. Documents by source (Source: Authors' own elaboration based on Scopus data)

Distribution by authors' contribution

The discipline is informed by a set of powerful authors of this genre, whose contribution has been of great importance to the literature surrounding social media and ecotourism. Pickering, C.M. is the leader of 5 publications, Gretzel, U. and Nam, Y. are the leaders of 4 publications each. Their repeated contributions can be attributed to their long-term involvement and leadership of thoughts in the field by these authors. Han, W., Mangachena, J.R., Wang, Y., Wood, S.A., and Zada, M. (Mangachena & Pickering, 2021) are also other prominent contributors with each having their fair share to add to the developing discourse. The presence of these dominating writers points to a cooperative academic network that facilitates research innovation. The results are depicted in Figure 6.

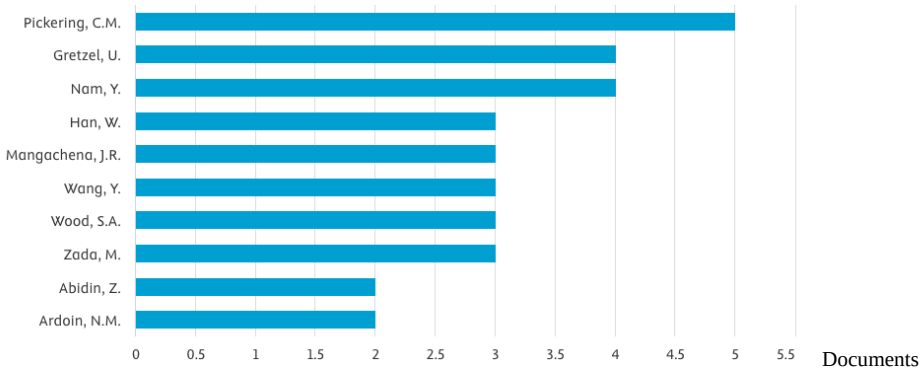

Figure 6. Top 10 prominent authors contributing to social media and ecotourism domain retrieved from Scopus
(Source: Authors' own elaboration based on Scopus data)

Q2- The key contributors in the domain of social media and ecotourism

The identification of key contributors in the social media and ecotourism domain provides insight into the intellectual structure and collaborative networks that drive research in this field.

Using bibliographic coupling, citation analysis, keyword co-occurrence, and co-citation methods, this section elaborates on the influential authors, countries, and journals shaping the discourse.

Bibliographic Coupling

It is also used to match two publications referring to the same document as similar references suggest that the two publications have much in common in terms of intellectual capital (Shin & Perdue, 2019). This is applied to two publications that cite the same document as one similar reference implies that the publications share a large portion of intellectual capital.This analysis is better implemented over a specific period of time and is oriented towards a classification of articles into thematic groups based on shared references. The bibliographic coupling analysis can be used to determine the interrelatedness of the research through the identification of bi-directional publications that share common references, meaning that the publications share common intellectual foundations. Among the authors in the period under investigation, Nam Y. stands out as the most influential, with a link strength of 450, and the next author, Hysa B., Karasek A., and Zdonek I. (Hysa et al., 2021) all have a link strength of 406. This implies that these authors make significant contributions to the literature foundations and are the focus of thematic groupings in the subject. At the country level, the United States shows the highest link strength (2375) meaning that it produces and has a high level of intellectual output and influence, then it is followed by Australia (2308) and United Kingdom (2153). These nations are centers of academic life, which promote research partnerships and theme building. Sustainability (Switzerland) has the highest level of influence with a link strength of 491 which shows that the journal is one of the main dissemination tools of the influential research articles. The complete bibliographic coupling results for authors, countries and sources are reported in Table 2.

Table 2. Bibliographic coupling

Authors	Link Strength	Countries	Link Strength	Sources	Link Strength
Nam Y.	450	United States	2375	Sustainability (Switzerland)	491
Hysa B.	406	Australia	2308	Journal of Sustainable Tourism	360
Karasek A.	406	United Kingdom	2153	Journal of Outdoor Recreation and Tourism	234
Zdonek I.	406	China	1622	Tourism Geographies	114
Joo Y.	327	Denmark	1138	Tourism Management	110
Seok H.	327	South Africa	943	Current Issues in Tourism	85
Chung H.C.	231	France	596	Land	85
Chung N.	231	South Korea	536	Journal of Cleaner Production	52
Wood S.A.	193	New Zealand	531	ISPRS International Journal of Geo-Information	43
Fisher D.M.	191	Italy	498	Journal Of Hospitality and Tourism Technology	42

Citation analysis

References and citation allow us to establish intellectual relationships (Appio et al., 2014). In the citation analysis method, the number of citations of a published document is a measure of that document that has gained recognition in the academic field. Citation analysis measures the academic standpoint and acknowledgement of both authors and nations by counting the regularity of reference. Wood S.A. is the most influential writer with 748 references in 4 sources which proves a great acknowledgement and influence in the social media and ecotourism studies. Once again, the United States is first among the countries with the highest number of 1382 citations of 26 publications, emphasizing its prevalence in the creation of the most widely acknowledged research. Wang M., Pickering C. and Kang M. are other influential authors with citation counts of 94-101 and this indicates the contribution they have made to the field of knowledge. The patterns of citation display a cluster of influential research in certain areas and in a group of scholars that influences the academic discourse and determines the research priorities. The detailed citation counts for the leading authors and countries are presented in Table 3.

Table 3. Citations Analysis

Authors	TP	TC	Countries	TP	TC
Wood S.A.	4	748	United States	26	1382
Wang M.	2	101	United Kingdom	15	521
Pickering C.	2	94	Australia	25	448
Kang M.	2	11	Italy	10	419
Papafitsoros K.	2	10	China	20	287
Schofield G.	2	10	South Korea	11	145
Han W.	3	6	Spain	9	117
Wang Y.	3	6	South Africa	5	77
Pickering C.M.	3	2	Greece	5	14

Co-occurrence of keywords

Co-word analysis is based on the frequency of co-occurrence of keywords i.e. the number of articles that two keywords co-occur in (Whittaker, 1989). This analysis was developed to address such an analytical dilemma because it finds and visualises associations of two keywords based on the strength of the association between them (Callon et al., 1991). It is often applied to analyse the idea network of the research topics and the trends within a particular field as the keywords are the expressions, which describe the nature of a research work (Callon et al., 1991; Ding et al., 2001). However, due to term changes throughout time, co-word analysis has a shortcoming in terms of stability.

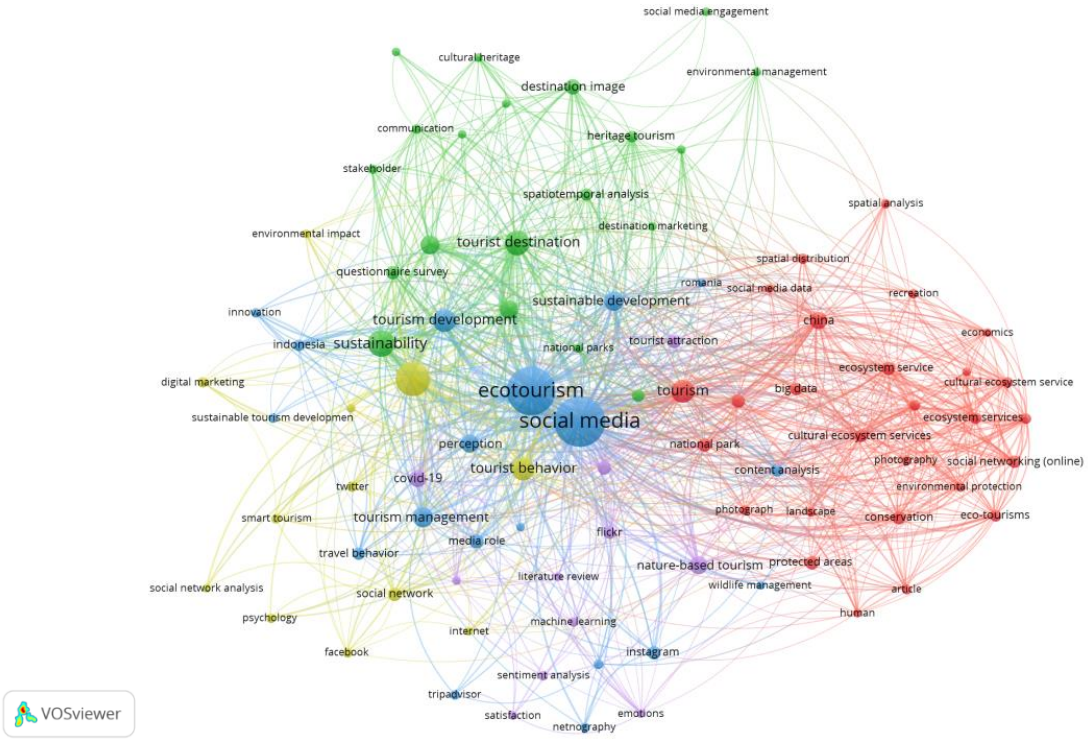

Figure 7. Co-Occurrences of words (Note: Minimum occurrences of keyword 5)

In Figure 7, the keywords appearing in the field of social media and ecotourism are co-occurrence. Other common terms in the field that are not related to the area of study include sustainable tourism, sustainability, tourist destination, sustainable development, tourism management, tourist behavior, etc, as it can be seen in Table 4.

Table 4. Co- Occurrences of words

Keywords	Occurrences
Social Media	86
Ecotourism	74
Sustainable Tourism	40
Tourism	24
Sustainability	23
Tourist Destination	21
Sustainable Development	18
Tourism Management	17
Tourist Behavior	17
Marketing	15

Co-occurrence analysis of keywords will identify the commonly used terms when paired together in publications, and this analysis will show how the field is thematically structured and research-focused. The most frequently used keywords are social media (86 times), ecotourism (74), and sustainable tourism (40), which show that the authors prioritize the topic of combining online tools and sustainability in tourism settings.
